Inspect the eyelids. Eyelids should be the colour of the person's facial skin, without redness, discharge or drooping. *The sclera should not be visible.*	■ Unusual redness or discharge may indicate an inflammatory state due to trauma, allergies or infection. ■ Drooping of one eyelid, called **ptosis**, may be the result of a stroke, indicate a neuromuscular disorder or be congenital (see Figure 44.9).

Technique/normal findings	Abnormal findings
	■ Unusual widening of the lids may be due to exophthalmos (protrusion of the eyeball). Exophthalmos is often associated with hyperthyroid conditions (see Chapter 18). ■ Yellow plaques noted on or near the lid margins are referred to as xanthelasma and may indicate high lipid levels. ■ An acute localised inflammation of a hair follicle is known as a *hordeolum* (sty) and is generally caused by staphylococcal organisms. ■ A *chalazion* is an infection or retention cyst of the meibomian glands.
Inspect the puncta. *The puncta should be free of redness or discharge.*	■ Unusual redness or discharge from the puncta may indicate an inflammation due to trauma, infection or allergies.
Inspect the bulbar and palpebral conjunctiva. *The conjunctiva should be clear, moist and smooth. The upper and lower palpebral conjunctiva should be clear, without redness or swelling.*	■ Increased erythema or the presence of exudate may indicate acute conjunctivitis. ■ A cobblestone appearance is often associated with allergies. ■ A fold in the conjunctiva, called a *pterygium*, may be seen as a clouded area that extends over the cornea. This is an abnormal growth of the bulbar conjunctiva, usually seen on the nasal side of the cornea. It may interfere with vision if it covers the pupil.
Inspect the sclera. *The sclera is white in Caucasians; people with darker skin normally have yellow sclera.*	■ Unusual redness may indicate an inflammatory state as a result of trauma, allergies or infection. ■ Yellow discolouration of the sclera in people with fair skin may be seen in conditions involving the liver, such as hepatitis. ■ Bright red areas in the sclera are often subconjunctival haemorrhages and may indicate trauma or bleeding disorders. They may also occur spontaneously.
Inspect the cornea. *The cornea is normally transparent.*	■ Dullness, opacities or irregularities of the cornea may be abnormal. ■ *Corneal arcus* is a thin, greyish-white arc seen towards the edge of the cornea. It is normal in older adults.
Assess corneal sensitivity. Lightly touch a wisp of cotton to the person's cornea. *This action should cause a corneal reflex (blinking the eye).*	■ Failure of the corneal reflex may indicate a neurological disorder.
Inspect the iris. *The iris is normally round, flat and evenly coloured.*	■ Lack of clarity of the iris may indicate a cloudiness of the cornea. ■ Constriction of the pupil accompanied by pain and circumcorneal redness indicates acute iritis.
Internal eye	
Assess internal structures of the eye by using the ophthalmoscope, an instrument that allows visualisation of the lens, the vitreous humour and the retina. Box 44.1 provides guidelines for using the ophthalmoscope.	
Inspect for the red reflex. *The red reflex should be clearly visible.*	■ Absence of a red reflex often indicates improper position of the ophthalmoscope, but also may indicate total opacity of the pupil by a cataract or a haemorrhage into the vitreous humour.
Inspect the lens and vitreous body. *The lens should be clear.*	■ A cataract is an opacity of the lens, often seen as a dark shadow on ophthalmoscopic examination. It may be due to ageing, trauma, diabetes or a congenital defect.

FIGURE 44.9 ■ Ptosis

Source: © Medical-on-Line/Alamy.

Technique/normal findings	Abnormal findings
Inspect the retina. *There should be no visible haemorrhages, exudate or white patches.*	■ Areas of haemorrhage, exudate and white patches may be a result of diabetes or long-standing hypertension.
Inspect the optic disc. *The optic disc should be round to oval in shape with clear, well-defined borders.*	■ Loss of definition of the optic disc, as well as an increase in the size of the physiological cup, is seen in papilloedema from increased intracranial pressure.
Inspect the blood vessels of the retina. *The retinal blood vessels should be distinct.*	■ Glaucoma often results in displacement of blood vessels from the centre of the optic disc due to increased intraocular pressure. ■ Hypertension may cause a narrowing of the vein where an arteriole crosses over. ■ Engorged veins may occur with diabetes, atherosclerosis and blood disorders.
Inspect the retinal background. *The retina should be a consistent red-orange colour, becoming lighter around the optic disc.*	■ Variations in colour or a pale colour overall may indicate disease.
Inspect the macula. *The macula should be visible on the temporal side of the optic disc.*	■ Absence of the fovea centralis is common in older adults. It may indicate macular degeneration, a cause of loss of central vision.
Palpate over the lacrimal glands, puncta and nasolacrimal duct. *There should be no tenderness, drainage or excessive tearing.*	■ Tenderness over any of these areas or drainage from the puncta may indicate an infectious process. (Wear gloves if you see any drainage.) ■ Excessive tearing may indicate a blockage of the nasolacrimal duct.

BOX 44.1 Guidelines for using the ophthalmoscope

The ophthalmoscope has a head and a handle (see figure). The head contains a focus wheel (also called a lens selector dial) located on the side, lenses of varying magnification and an opening through which the eye structures are visualised. The focus wheel adjusts the lens refraction, which is measured in diopters. The diopter measurements range from 0 to +40 when the lens is rotated clockwise and from 0 to –25 when the lens is rotated anticlockwise. By moving the focus wheel, the examiner can converge or diverge light rays to visualise the retina. The handle usually contains batteries that can be recharged.

Before the examination, explain the procedure to the person. Assemble the ophthalmoscope. Wash hands and wear disposable gloves if the person has any drainage from the eyes. Darken the room (to allow the pupils of the person to dilate) and ask the person to look straight ahead, focusing on a fixed point such as an object on the wall. Hold the ophthalmoscope in one hand, resting the index finger on the focus wheel (see the figure below left).

1. Turn on the ophthalmoscope light and set focus wheel to 0 diopters. Hold the ophthalmoscope in your right hand with your index finger on the focus wheel. Standing in front of the person, position yourself at a 15-degree angle to the person's line of vision.
2. Hold the opening of the ophthalmoscope up to your right eye and direct the light towards the person's right eye from a distance of about 30 cm.
3. As the beam of light falls on the person's pupil, observe for the red reflex which appears as a sharply outlined orange glow from within the pupil. This glow is the reflection of the light from the retina.

An ophthalmoscope

4. Move closer to the person, turning the focus wheel clockwise towards the positive numbers as needed to maintain clear focus.
5. Examine the lens and the vitreous body; both should be clear.
6. Gradually rotate the focus wheel anticlockwise towards the negative numbers as needed, focusing on a structure of the retina (such as the disc or a blood vessel). Turn the focus wheel until the image is clear. Examine the structures of the retina as follows:
   a. The optic disc (see the figure below right). Assess for size, shape, colour, distinct margins and the physiological cup. The disc is round to slightly oval and about 1.5 mm in diameter. It has a yellow to pink colour that is lighter than the retina itself. The margins should be sharp and clear. The physiological cup is a small depression that occupies about one-third of the optic disc, lying temporal to the centre of the disc.

(continued)

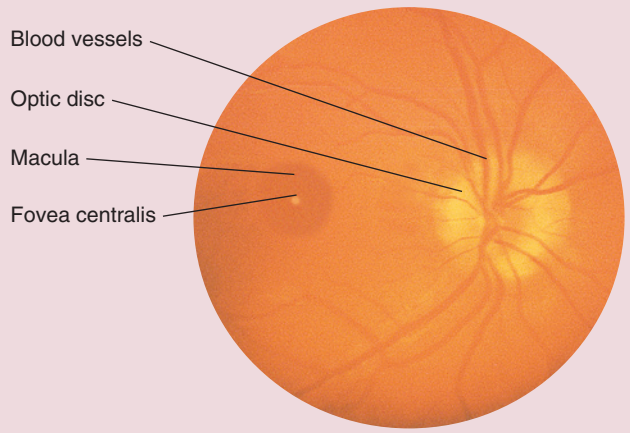
BOX 44.1 Guidelines for using the ophthalmoscope (continued)

b. The vessels of the retina. Assess for colour, arteriolar light reflex, ratio of arterioles to veins and arteriovenous crossings. The arterioles are red, brighter than the veins and about one-fourth smaller. The arterioles normally have a narrow light reflex from the centre of each vessel; veins do not have this light reflex. The ratio of arterioles to veins is usually 2:3 or 4:5. The vessels normally cross and become smaller towards the periphery.

Technique for holding an ophthalmoscope

c. The retinal background. Assess colour and changes in colour. The retina is normally reddish orange and regular in colour.
d. The macula. Assess size and colour. To assess the macula, ask the person to look directly into the ophthalmoscope light. The macula is temporal to the optic disc, appears slightly darker than the retina and has no visible vessels. The fovea centralis may be seen as a bright spot of light. Because looking directly into the light causes some discomfort, conduct this portion of the examination last. The macula is often difficult to visualise.

7. Using the same technique, examine the left eye.



The optic disc as seen through an ophthalmoscope

ANATOMY, PHYSIOLOGY AND FUNCTIONS OF THE EARS

As a sensory organ, the ears have two primary functions: hearing and maintaining equilibrium. Anatomically, each ear is divided into three areas: the external ear, the middle ear and the inner ear (see Figure 44.10). Although each area has a unique function, all three are involved in hearing, but only the inner ear is involved in equilibrium.

THE EXTERNAL EAR

The external ear consists of the auricle (or pinna), the external auditory canal and the tympanic membrane.

The auricles are elastic cartilage covered with thin skin. They contain sebaceous and sweat glands and sometimes hair. Each auricle has a rim (the helix) and a lobe that serves to direct sound waves into the ear.

The external auditory canal, which is about 2.5 cm long, extends from the auricle to the tympanic membrane. The canal is lined with skin that contains hair, sebaceous and ceruminous glands. The external auditory canal serves as a resonator for the range of sound waves typical of human speech and increases the pressure that sound waves in this frequency range place on the tympanic membrane. The canal's ceruminous glands (modified apocrine glands) secrete a yellow to brown waxy substance called **cerumen** (earwax). Cerumen traps foreign bodies; it also has bacteriostatic properties, protecting the tympanic membrane and the middle ear from infections.

The tympanic membrane lies between the external ear and the middle ear. It is a thin, semitransparent, fibrous

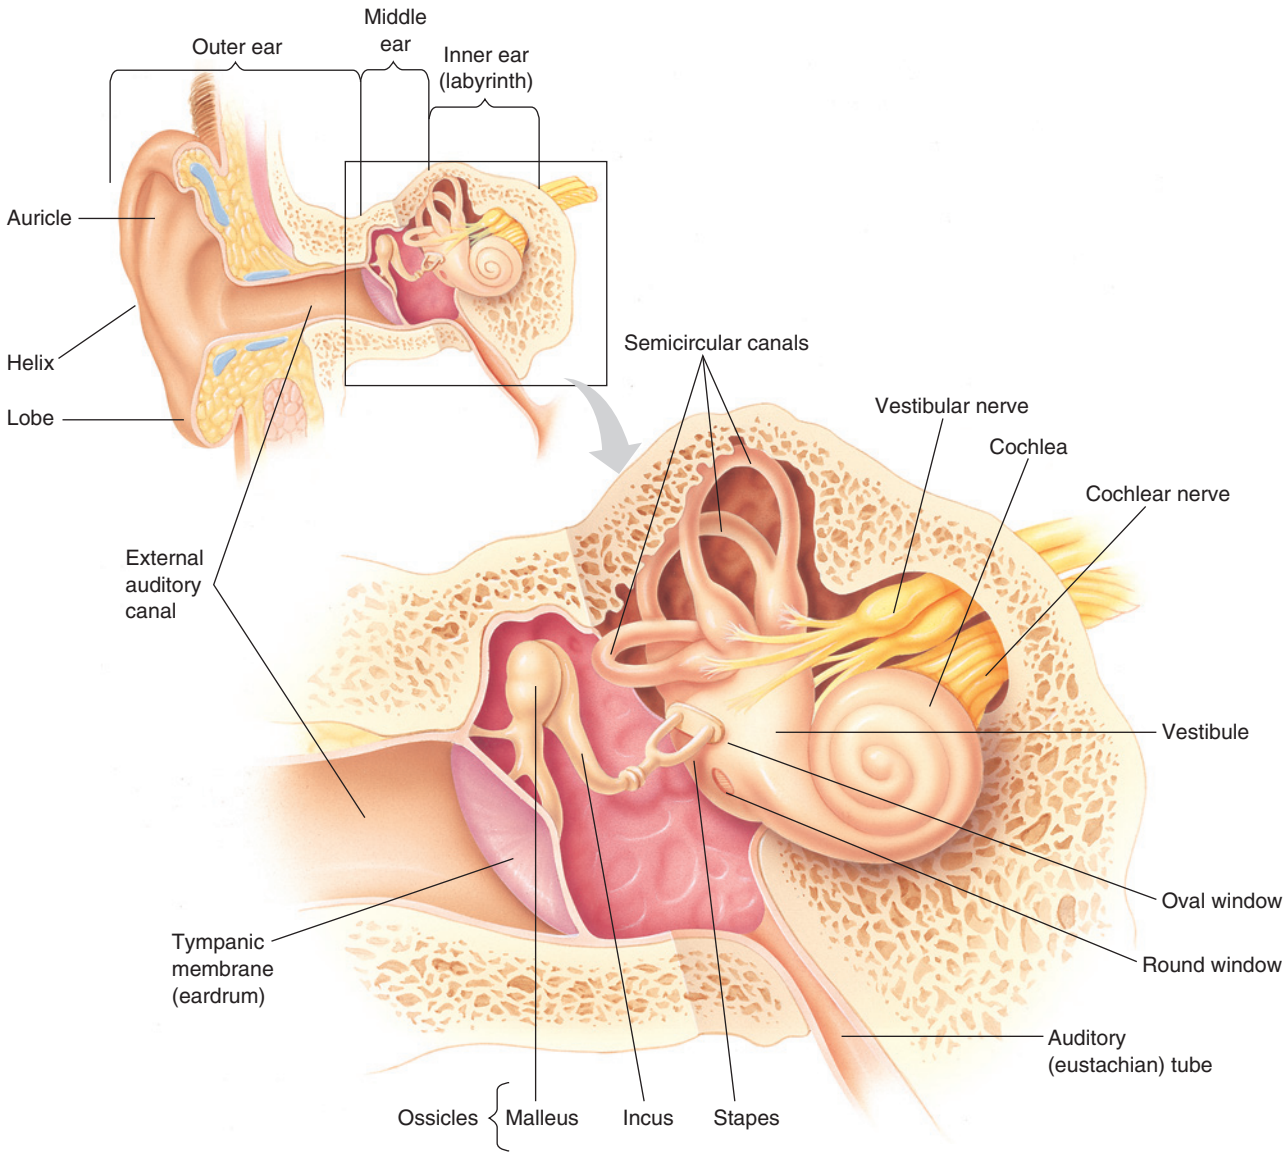

FIGURE 44.10 ■ Structures of the external ear, middle ear and inner ear

Source: ©Todd Buck, Pearson Education.

structure covered with skin on the external side and mucosa on the inner side. The membrane vibrates as sound waves strike it; these vibrations are transferred as sound waves to the middle ear.

THE MIDDLE EAR

The middle ear is an air-filled cavity in the temporal bone and contains three auditory ossicles: the malleus, the incus and the stapes. These bones extend across the middle ear. The medial side of the middle ear is a bony wall containing two membrane-covered openings: the oval window and the round window. The posterior wall of the middle ear contains the mastoid antrum. This cavity communicates with the mastoid sinuses, which help the middle ear adjust to changes in pressure. It also opens into the eustachian tube, which connects with the nasopharynx. The eustachian tube helps to equalise the air pressure in the middle ear by opening briefly in response to differences between the pressure in the middle ear and atmospheric pressure. This action also ensures that vibrations of the tympanic membrane remain adequate. The mucous membrane lining the middle ear is continuous with the mucous membranes lining the throat.

The malleus attaches to the tympanic membrane and articulates with the incus, which in turn articulates with the stapes. The stapes fits into the oval window. When the tympanic membrane vibrates, the vibrations are conducted across the middle ear to the oval window by the ossicles. The vibrations then set in motion the fluids of the inner ear, which in turn stimulate the hearing receptors. Two small muscles

attached to the ossicles contract reflexively in response to sudden loud noises, decreasing the vibrations and protecting the inner ear.

THE INNER EAR

The inner ear, also called the labyrinth, is a maze of bony chambers located deep within the temporal bone, just behind the eye socket. The labyrinth is further divided into two parts: the bony labyrinth, a system of open channels that houses the second part, the membranous labyrinth. The bony labyrinth is filled with a fluid (similar to cerebrospinal fluid) called perilymph, which bathes the membranous labyrinth. Within the chambers of the membranous labyrinth is a fluid called endolymph.

The bony labyrinth has three regions: the vestibule, the semicircular canals and the cochlea. The vestibule is the central portion of the inner ear, one side of which is a bony wall containing the oval window. Two sacs within the vestibule (the saccule and the utricle) join the vestibule with the cochlea and the semicircular canals. The saccule and the utricle contain receptors for equilibrium that respond to changes in gravity and changes in position of the head. The three semicircular canals each project into a different plane (anterior, posterior and lateral). Each canal contains a semicircular duct that communicates with the utricle of the vestibule. Each duct has an enlarged area at one end containing an equilibrium receptor that responds to angular movements of the head.

The cochlea is a tiny bony chamber that houses the organ of Corti, the receptor organ for hearing. The organ of Corti is a series of sensory hair cells, arranged in a single row of inner hair cells and three rows of outer hair cells. The hair cells are innervated by sensory fibres from the VIII (acoustic) cranial nerve. The organ of Corti is supported in the cochlea by the flexible basilar membrane, which has fibres of varying lengths that respond to different sound wave frequencies.

Sound conduction

Hearing is the perception and interpretation of sound. Sound is produced when the molecules of a medium are compressed, resulting in a pressure disturbance evidenced as a sound wave. The intensity or loudness of sound is determined by the amplitude (height) of the sound wave, with greater amplitudes causing louder sounds. The frequency of the sound wave in vibrations per second determines the pitch or tone of the sound, with higher frequencies resulting in higher sounds. The human ear is most sensitive to sound waves with frequencies of between 1000 and 4000 cycles per second; however, it can detect sound waves with frequencies of between 20 and 20 000 cycles per second.

Sound waves enter the external auditory canal and cause the tympanic membrane to vibrate at the same frequency. The ossicles not only transmit the motion of the tympanic membrane to the oval window, but also amplify the energy of the sound wave. As the stapes moves against the oval window, the perilymph in the vestibule is set in motion. The increased pressure of the perilymph is transmitted to fibres of the basilar membrane and then to the organ of Corti (directly above the basilar membrane). The up-and-down movements of the fibres of the basilar membrane pull the hair cells in the organ of Corti, which in turn generates action potentials that are transmitted to the VIII (acoustic) cranial nerve and then to the brain for interpretation.

Several brainstem auditory nuclei transmit impulses to the cerebral cortex. Fibres from each ear cross, with each auditory cortex receiving impulses from both ears. Auditory processing is so finely tuned that a wide variety of sounds of different pitch and loudness can be heard at any one time. In addition, the source of the sound can be localised.

Equilibrium

The inner ear also provides information about the position of the head. This information is used to coordinate body movements so that equilibrium and balance are maintained. The types of equilibrium are static balance (affected by changes in the position of the head) and dynamic balance (affected by the movement of the head).

Receptors called maculae in the utricle and the saccule of the vestibule detect changes in the position of the head. Maculae are groups of hair cells that have protrusions covered with a gelatinous substance. Embedded in this gelatinous substance are tiny particles of calcium carbonate called otoliths (ear stones), which make the gelatin heavier than the endolymph that fills the membranous labyrinth. As a result, when the head is in the upright position, gravity causes the gelatinous substance to bear down on the hair cells. When the head changes position, the force on the hair cells alters, bending them and changing the pattern of stimulation of the neurons. Thus, a different pattern of nerve impulses is transmitted to the brain, where stimulation of the motor centres initiates actions that coordinate various body movements according to the position of the head.

The receptor for dynamic equilibrium is in the crista, a crest in the membrane lining the ampulla of each semicircular canal. The cristae are stimulated by rotatory head movement (acceleration and deceleration) as a result of changes in the flow of endolymph and of movement of hair cells in the maculae. The direction of endolymph and hair cell movement is always opposite to the motion of the body.

ASSESSING THE EARS

The structure and functions of the ears are assessed through findings from a health assessment interview to collect subjective data, a physical assessment to collect objective data and diagnostic tests (see below for sample documentation).

Health assessment interview

To determine problems with the ear, a health assessment interview may be conducted during a health screening. It may focus on a chief complaint, such as hearing problems or pain in the ear. If the person has a problem involving one or both ears, analyse its onset, characteristics and course, severity, precipitating and relieving factors, and any associated symptoms,

SAMPLE DOCUMENTATION

Assessment of the ear

25/9/2016
NURS
0930 hrs

22-year-old male complaining of 'having some problems hearing these days'. States he often listens to music in his car 'as loud as it will go' and uses ear phones at home so as not to bother other family members. Ears are placed bilaterally; skin smooth without lesions. Small amount of dark brown cerumen present in both ear canals. Tympanic membranes grey and shiny. No bulging or retraction noted. Whisper test: unable to repeat back words spoken by examiner. Weber's test: sound lateralised to left ear. Rinne test: BC ≥ AC. No tenderness noted when mastoids palpated. Referred to ear clinic for further evaluation.

RN Fehon
O. FEHON RN

noting the timing and circumstances. For example, the following questions may be asked:

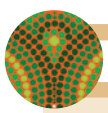
- Have you noticed any difficulty hearing high-pitched sounds, low-pitched sounds, or both?
- When did you first notice the ringing in your ears?
- Is your workplace very noisy? If so, do you wear protective ear equipment at work?

Throughout the examination, be alert to non-verbal behaviours, such as inappropriate answers or requests to repeat statements that may suggest problems with ear function. Explore changes in hearing, ringing in the ears (*tinnitus*), ear pain, drainage from the ears or the use of hearing aids. When taking a medical history, ask about trauma, surgery or infections of the ear, as well as the date of the last ear examination. In addition, ask the person about a history of infectious diseases, such as meningitis or mumps, as well as the use of medications that may affect hearing. Because ear problems tend to run in families, ask about a family history of hearing loss, ear problems or diseases. If the person has a hearing aid, ascertain the type and assess measures for its care.

Interview questions categorised by functional health patterns are found in the 'Functional health pattern interview' table below.

Physical assessment of the ears and hearing

Physical assessment of the ears and hearing may be performed as part of a total health assessment or separately for people with known or suspected problems with the ears. The ears and hearing are assessed primarily through inspection of external structures through palpation, the external auditory canal and



FUNCTIONAL HEALTH PATTERN INTERVIEW The ear

FUNCTIONAL HEALTH PATTERN	INTERVIEW QUESTIONS AND LEADING STATEMENTS
Health perception–Health management	■ Describe your hearing. Rate it on a scale of 1 to 10, with 10 being excellent hearing. Is it the same in both ears? If not, which ear is better? ■ Describe any current hearing problems. How have these been treated? ■ Do you use ear medications? What type, dosage and how often? ■ Have you ever had ear surgery? Provide details. ■ Describe the type of hearing aid that you use. Are you satisfied with this appliance? How do you care for it? ■ Describe how you care for your ears each day. ■ Have you ever had your hearing tested? When was your last ear examination? ■ Do you listen to loud music? Do you use ear phones when you listen to loud music?
Nutritional–Metabolic	■ Do you have any swelling or tenderness in the ears or drainage from the ears?
Activity–Exercise	■ Does your hearing problem interfere with your usual activities of daily living? Provide details. ■ Do you wear protective earplugs when you take part in activities that increase the risk of injury to your ears (such as at work or when operating machinery)?
Sleep–Rest	■ Does your ear problem interfere with your ability to rest or sleep (e.g. pain)? If so, what do you do?
Cognitive–Perceptual	■ Do you have pain in or around your ears? Have you ever had ringing in your ears? If so, describe its location, intensity, what makes it worse and how long it lasts. How do you treat it? ■ Do you have difficulty hearing conversations, either in person or on the telephone? Do you have trouble hearing the television? Do you have difficulty hearing when you are in crowds or there is background noise?

(continued)

FUNCTIONAL HEALTH PATTERN INTERVIEW The ear (continued)

	■ Have you noticed your hearing is different in each ear? ■ Do you have buzzing, ringing or crackling noises in one or both ears? Provide details. ■ Do you ever feel dizzy?
Self-perception–Self-concept	■ Has this problem with your ears affected how you feel about yourself?
Role–Relationships	■ How has having this condition affected your relationships with others? ■ Has having this condition interfered with your ability to work? Provide details. ■ Has anyone in your family had problems with ear disease? Provide details.
Sexuality–Reproductive	■ Has this condition interfered with your usual sexual activity?
Coping–Stress–Tolerance	■ Has having this condition created stress for you? If so, does your health problem seem to be more difficult when you are stressed? ■ Have you experienced any kind of stress that makes the condition worse? Provide details. ■ Describe what you do when you feel stressed.
Value–Belief	■ Describe how specific relationships or activities help you cope with this problem. ■ Describe specific cultural beliefs or practices that affect how you care for and feel about this problem. ■ Are there any specific treatments that you would not use to treat this problem?

the tympanic membrane. Disorders of the middle ear may be identified with tympanometry and hearing acuity is assessed by voice and tuning fork tests. Normal age-related findings for the older adult are summarised in Table 44.2.

Prior to the assessment, collect all necessary equipment and explain the techniques to the person to decrease anxiety. During the assessment, the person should be sitting and the examiner's head should be level with the head of the person. The auditory canal and tympanic membrane are inspected with the otoscope. Guidelines for use of the otoscope are listed in Box 44.2.

Diagnostic tests

The results of diagnostic tests of the structure and functions of the ears are used to support the diagnosis of a specific injury, disease or hearing problem; provide information to identify and/or modify the appropriate medications or assistive devices used to treat the disease or problem; and help nurses monitor the person's responses to treatment and nursing care interventions. Diagnostic tests of the ear, especially for hearing, are most often conducted in a healthcare provider's office. Diagnostic tests to assess the structure and functions of the ears are described in the 'Diagnostic tests' table below

TABLE 44.2 Age-related changes in the ear

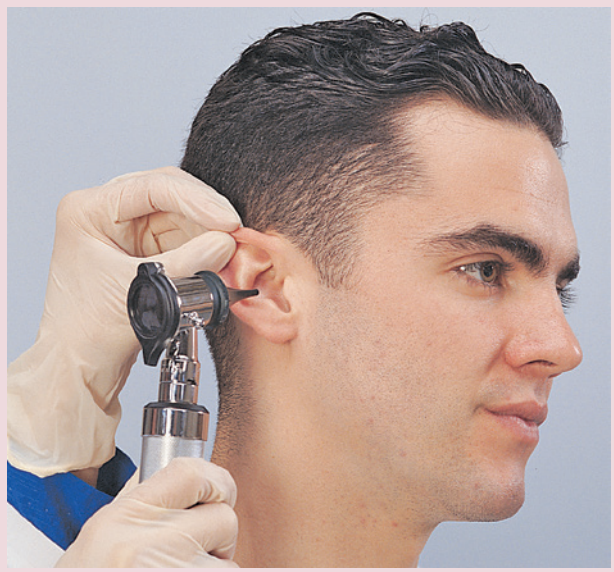
AGE-RELATED CHANGE	SIGNIFICANCE
The inner ear:	
• Loss of hair cells, ↓ blood supply, less flexible basilar membrane, degeneration of spiral ganglion cells and ↓ production of endolymph result in progressive hearing loss with age (presbycusis). • High-frequency sounds are lost; middle- and low-frequency sounds may also be lost or decreased. • Vestibular structures degenerate, organ of Corti and cochlea atrophy.	Older adults may require hearing aids to hear well. With loss of high-frequency sounds, speech may be distorted, contributing to a risk of problems with communication. Degeneration and atrophy of inner ear structures concerned with balance and equilibrium increase the risk of falls.
The middle ear:	
• Muscles and ligaments weaken and stiffen, decreasing the acoustic reflex.	Own speech and sounds are louder and may further interfere with hearing, speech and communications.
The external ear:	
• Increased cerumen in the ear canal is due to its high keratin content.	Accumulated cerumen may impair hearing.

BOX 44.2 Guidelines for using the otoscope

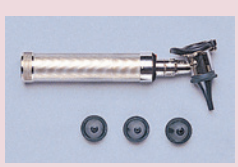
The otoscope has a handle that contains batteries for the light and various specula that fit on to the handle (see the accompanying figure). It is used to inspect the auditory canal and the tympanic membrane. A pneumatic otoscope is used to determine the mobility of the tympanic membrane. It has an attached rubber bulb that can be squeezed to inject air into the auditory canal, causing a normal tympanic membrane to move in and out.

Before the examination, explain the procedure. Assemble the otoscope using the largest speculum that will fit into the person's auditory canal without discomfort. Wash your hands; wear disposable gloves if the person has any drainage from the ears. Turn on the otoscope light. Ask the person to tip the head slightly towards the shoulder opposite the ear being examined. When they are in this position, the auditory canal is aligned with the speculum.

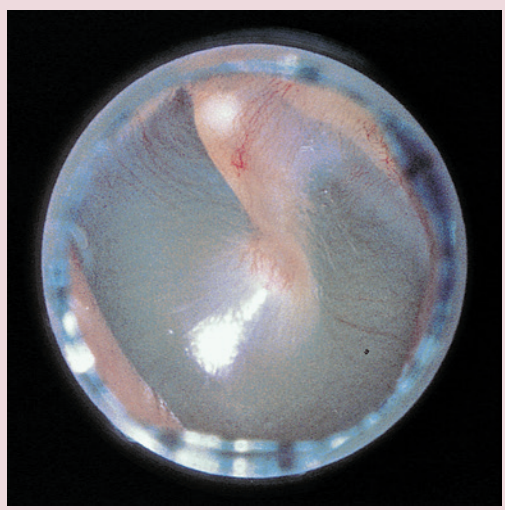
1. Hold the handle of the otoscope in your dominant hand. If the person is restless, hold the otoscope handle upward, resting the hand against the person's head. If the person is cooperative, hold the handle downward.
2. For adults, grasp the superior portion of the auricle and pull up, out and back to straighten the auditory canal (see the figure above right).
3. Insert the speculum into the ear and advance it gently. Assess the walls of the auditory canal while advancing the speculum, inspecting for colour, obstructions, hair growth and cerumen. Old cerumen is very dark and may obstruct visualisation of part or all of the tympanic membrane.
4. Move the otoscope so that you can see the tympanic membrane. You may need to realign the auditory canal by gently continuing to pull up and back on the auricle. A normal membrane is semitransparent, allowing visualisation of a portion of the auditory ossicles. The concave nature of the tympanic membrane and its oblique position in the auditory canal account for the triangular light reflex (cone of light) seen on otoscopic examination.
5. Note the colour and surface of the membrane. The normal tympanic membrane is pearly grey, shiny and semitransparent. The surface should be continuous, intact and either flat or concave.
6. Identify the landmarks on the tympanic membrane (see the figure below right):
   a. the cone of light, located over the anteroinferior quadrant
   b. the malleus, pars tensa, annulus, pars flaccida and malleolar folds.
7. Assess movement of the tympanic membrane. If the auditory tube is patent, the membrane moves in and out when air is injected or when the person performs the Valsalva manoeuvre.
8. Gently withdraw the speculum. If the speculum is soiled with drainage or cerumen, use a clean speculum for the other ear.
9. Using the same technique, examine the other ear.



Technique for using an otoscope



An otoscope



The tympanic membrane as it appears through the otoscope

and summarised in the following list. More information is included in the discussion of specific injuries or diseases in Chapter 45.

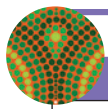
- Audiometry is used to evaluate and diagnose conductive and sensorineural hearing loss.
- Electrical activity of the auditory nerve may be evaluated by using an auditory evoked potential (AEP) or an auditory brainstem response (ABR).
- Vestibular system function is evaluated with a caloric test. If no nystagmus occurs during the test, further testing for brain lesions is conducted.

Regardless of the type of diagnostic test, the nurse may be responsible for explaining the procedure and any special preparation needed, assessing for any medication use that might affect the outcome of the tests, supporting the person during the examination as necessary, documenting the procedures as appropriate and monitoring the results of the tests.

Genetic considerations

When conducting a health assessment interview and a physical assessment, it is important for the nurse to consider genetic influences on the health of the adult as several diseases of the ears have a genetic component. During the health assessment interview, ask about a family history of congenital deafness or deafness associated with a thyroid goitre or with tumours of the auditory nerve.

During the physical assessment, assess for any manifestations that might indicate a genetic disorder (see 'Genetic considerations' box below). If data are found to indicate genetic risk factors or alterations, ask about genetic testing and refer for appropriate genetic counselling and evaluation. Chapter 7 provides further information about genetics in medical–surgical nursing.



GENETIC CONSIDERATIONS
Ear disorders

- Deafness (hearing loss) is a common disorder that is seen from newborns to those of old age. About 1 in 1000 infants have a profound hearing loss, with about half being genetic in origin (National Center for Biotechnology Information (NCBI) (US), 1998). Early diagnosis is important to facilitate language and social skill development in adults.
- Penred syndrome is an inherited disorder that accounts for as much as 10% of hereditary deafness. The deafness is usually accompanied by a thyroid goitre.
- Neurofibromatosis, a rare inherited disorder, is characterised by the development of acoustic neuromas (benign tumours of the auditory nerve) and malignant central nervous system tumours.

DIAGNOSTIC TESTS Ear disorders

NAME OF TEST Audiometry

PURPOSE AND DESCRIPTION Used to evaluate and diagnose conductive and sensorineural hearing loss. Person sits in soundproof room and responds by raising a hand or pressing a button when sounds are heard.

RELATED NURSING CARE No special preparation is needed.

NAME OF TEST Auditory evoked potential (AEP)

PURPOSE AND DESCRIPTION Used to identify electrical activity of the auditory nerve. Electrodes are placed on various areas of the ear and on the forehead, and a graphic recording is made.

RELATED NURSING CARE No special preparation is needed.

NAME OF TEST Auditory brainstem response (ABR)

PURPOSE AND DESCRIPTION Measures electrical activity of the auditory pathway from inner ear to brain to diagnose brainstem pathology, stroke and acoustic neuroma.

RELATED NURSING CARE No special preparation is needed.

NAME OF TEST Caloric test

PURPOSE AND DESCRIPTION Used to assess vestibular system function. Cold or warm water is used to irrigate the ear canals one at a time and the person is observed for nystagmus (repeated abnormal movements of the eyes). Normally, the nystagmus occurs in the eye opposite to the ear being irrigated. If no nystagmus occurs, the person needs further testing for brain lesions.

RELATED NURSING CARE Assess person for use of alcohol, central nervous system depressants and barbiturates. These chemicals may alter the test results.

EAR AND HEARING ASSESSMENTS

Hearing assessment

Tuning forks are used to determine whether hearing loss is conductive or perceptive (sensorineural). Hold the tuning fork at the base and make it ring softly by stroking the prongs or by lightly tapping them on the heel of the opposite hand. The vibrating tuning fork emits sound waves of a particular frequency, measured in hertz (Hz). Tuning forks with a frequency of 512 to 1024 Hz are preferred for auditory evaluation because that range corresponds to the range of normal speech.

Technique/normal findings	Abnormal findings
Perform the Weber test. Place the base of a vibrating tuning fork on the midline vertex of the person's head (see Figure 44.11). Ask whether the person hears the sound equally in both ears or better in one than the other. *Sound is normally heard equally in both ears.*	■ Sound heard in, or lateralised to, one ear indicates either a conductive loss in that ear or a sensorineural loss in the other ear. The sound will be louder on the impaired side with conductive hearing loss. Conductive losses may be due to a build up of cerumen, an infection such as otitis media or perforation of the eardrum. The sound will be softer on the impaired side, suggesting sensorineural hearing loss.
Perform the Rinne test. Place the base of a vibrating tuning fork on the person's mastoid bone. Ask the person to indicate when the sound is no longer heard. When the person does so, quickly reposition the tuning fork in front of the person's ear close to the ear canal. Ask whether the person can hear the sound. If the person says yes, ask the person to indicate when the sound is no longer heard. Repeat over the opposite mastoid bone (see Figure 44.12). *The person with no conductive hearing loss will hear the sound twice as long by air conduction as by bone conduction.*	■ Bone conduction is greater than air conduction in the ear with a conductive loss. The normal pattern is air conduction greater than bone conduction (AC > BC).

FIGURE 44.11 ■ Performing the Weber test with a tuning fork

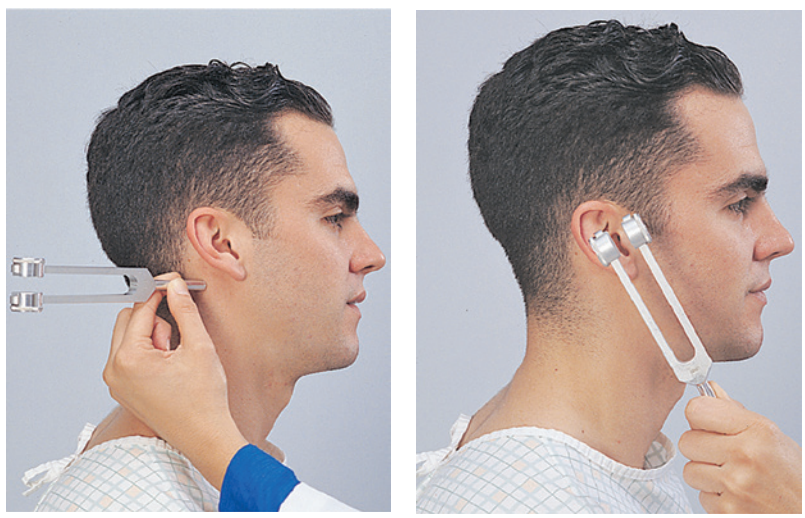


FIGURE 44.12 ■ Performing the Rinne test with a tuning fork

Technique/normal findings	Abnormal findings
Perform the whisper test. Ask the person to occlude one ear with a finger. Stand 30–60 cm away from the person, on the side of the opposite ear. Softly whisper numbers and ask the person to repeat them. Repeat the procedure, having the person occlude the other ear. Note whether you need to raise your voice or to stand closer to make the person hear you.	■ This test provides a rough estimate of hearing loss.
Use a tympanogram to measure the pressure of the middle ear and observe the tympanic membrane's response to waves of pressure. Insert the device into the ear canal. Ask the person not to speak, move, swallow or jump when hearing a sound. Tell the person they will hear a loud tone as the measurements are taken. The normal pressure inside the middle ear is a 100 daPa (a very small amount). Repeat for the other ear.	■ Abnormal findings may include fluid in the middle ear, a perforated eardrum, impacted earwax or a tumour of the middle ear.
External ear	
Inspect the auricle. *External ears are normally bilaterally equal in size, of equal colour with the person's face, and without redness or lesions.*	■ Unusual redness or drainage may indicate an inflammatory response to infection or trauma. ■ Scales or skin lesions around the rim of the auricle may indicate skin cancer. ■ Small, raised lesions on the rim of the ear are known as tophi and indicate gout.
Inspect the external auditory canal with the otoscope. *Canal walls should be pink and smooth without lesions. Cerumen is normally present in small, odourless amounts.*	■ Unusual redness, lesions or purulent drainage may indicate an infection. ■ Cerumen varies in colour and texture, but hardened, dry or foul-smelling cerumen may indicate an infection or an impaction of cerumen that requires removal. People with darker skin tend to have darker cerumen.
Inspect the tympanic membrane. *The tympanic membrane should be pearly grey, shiny and translucent without bulging or retraction.*	■ White, opaque areas on the tympanic membrane are often scars from previous perforations (see Figure 44.13). ■ Inconsistent texture and colour may be due to scarring from previous perforations caused by infection, allergies or trauma. ■ Bulging membranes are indicated by a loss of bony landmarks and a distorted light reflex. Such bulges may be the result of otitis media or malfunctioning auditory tubes. ■ Retracted tympanic membranes are indicated by accentuated bony landmarks and a distorted light reflex. Such retraction is often due to an obstructed auditory tube.
Palpate the auricles and over each mastoid process. *There should be no pain or swelling on palpation.*	■ Tenderness, swelling or nodules may indicate inflammation of the external auditory canal or mastoiditis.

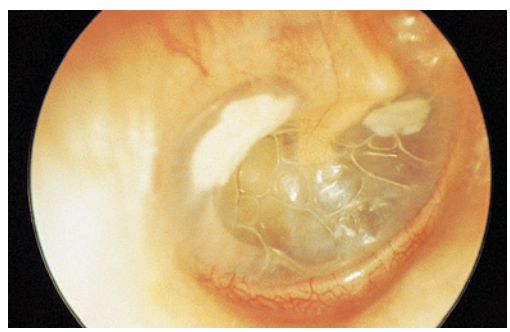

FIGURE 44.13 ■ Scarring of the tympanic membrane

CONCEPT CHECK

1 During an eye assessment, you touch the part of the eye covering the iris and pupil. What normal response would you expect?
1 excess tearing
2 blinking of eyelids
3 bilateral nystagmus
4 pupil dilates

2 Which of the following statements would indicate a person has presbyopia?
1 'I am having so much trouble hearing music.'
2 'I can't seem to remember anything these days.'
3 'I think I have a lot of earwax in my ears.'
4 'My arms don't seem long enough for reading.'

3 What equipment would be necessary to test sound conduction during an assessment of the ear?
1 ophthalmoscope
2 tuning fork
3 otoscope
4 penlight

4 What occurs when light enters the lens of the eye?
1 accommodation
2 convergence
3 pupillary reflex
4 hyperopia

5 What would you tell a person before a test of refraction is done?
1 'This test is uncomfortable, but it doesn't take long.'
2 'You will be blindfolded during the test.'
3 'Are you allergic to seafood?'
4 'Your pupils will be dilated for several hours.'

6 Which function, in addition to hearing, is provided by the inner ear?
1 Coordinates visual pathways.
2 Integrates efferent neuron messages.
3 Provides information about head position.
4 Maintains middle ear structure and function.

7 Why is the Snellen eye chart used during vision assessment?
1 to test distant vision
2 to test near vision
3 to determine visual fields
4 to examine convergence

8 Of the following ear assessments, which one is a rough estimate of the ability to hear?
1 whisper test
2 Rinne test
3 Weber test
4 audiometry

9 What is a high-priority risk for the older adult with age-related changes in the vestibular structures of the ear?
1 infection
2 falls
3 medication errors
4 food intolerance

10 Which criterion is important to accurately assess visual fields?
1 Person must wear corrective lenses.
2 Person must have no less than 6/9 vision.
3 Examiner must not wear glasses.
4 Examiner must have normal visual field.

CHAPTER 45

NURSING CARE OF PEOPLE WITH EYE AND EAR DISORDERS

KAMAREE BERRY

KEY TERMS

LEARNING OUTCOMES

- Relate knowledge of normal anatomy, physiology and sensory functions of the eye and ear to the effects of disorders of these organs on the cognitive/perceptual functional health pattern.
- Describe the pathophysiology of commonly occurring disorders of the eyes and ears, relating their manifestations to the pathophysiological process.
- Explain the risk factors for selected disorders of the eyes and ears, identifying the nursing implications for these risk factors.
- Identify diagnostic tests used for specific eye and ear disorders.
- Discuss the effects of and nursing implications for medications prescribed to treat eye and ear disorders.
- Describe surgical and other invasive procedures used to treat eye and ear disorders, identifying their implications for nursing care.
- Discuss the nurse's role in caring for a person with impaired vision or hearing loss.

CLINICAL COMPETENCIES

- Assess vision, hearing and functional health of people with eye and ear disorders.
- Using assessed data, determine priority nursing interventions and care for people with eye and ear disorders.
- Collaborate with other members of the healthcare team to provide effective care for people with eye and ear disorders.
- Plan and implement appropriate and individualised evidence-based nursing interventions and education for the person with an eye or ear disorder.
- Safely and effectively administer eye and ear medications and prescribed treatments.
- Provide appropriate care and education for the person having eye or ear surgery.
- Evaluate the effectiveness of nursing care provided for people with eye and ear disorders and revise the plan of care as indicated.

Vision and hearing provide the primary means of input for much of what we know about the world. The ability to receive and organise information orients us to our surroundings. These senses allow us to communicate easily, gain access to information and derive pleasure from the sights and sounds of the world around us.

This chapter discusses conditions affecting vision and hearing as the result of eye and ear disorders. Nursing care focuses on people with vision and hearing deficits that can result from the disorders presented.

EYE DISORDERS

Any portion of the eye and its protective structures may be affected by an acute or a chronic condition. While many disorders of the eye are minor and have little or no effect on vision, others can and often do result in permanent vision impairment. Disorders and diseases of the outer, visible portion of the eye often cause discomfort and may have cosmetic effects. Vision impairment can often be prevented or reversed with appropriate treatment.

Disorders affecting the internal structures or the function of the eye are more likely to have adverse effects on vision (e.g. disorders of the cornea present the greatest risk to vision in this group) and are more likely to affect adults over the age of 40 and the older adult. The person who has had eye surgery or minor trauma may experience either temporary or permanent visual impairment.

Although disorders that commonly affect vision cannot often be prevented or cured, some can be controlled with vision corrected to normal or near normal. Regardless of the real threat a disorder poses to vision, the person may experience anxiety related to a perceived threat. The box below discusses major causes of significantly impaired vision and nursing care for the person who is blind. These principles of nursing care may apply to people with many of the disorders discussed in this chapter.

THE PERSON WITH CONJUNCTIVITIS

The conjunctiva—the thin, transparent membrane that covers the anterior surface of the eye and lines the inner surfaces of the eyelids—is vulnerable to inflammation and infection because of its constant exposure to the environment. **Conjunctivitis**, inflammation of the conjunctiva, is the most common eye disease caused by a bacterial or viral infection. These infections can be transmitted to the eye by direct contact (e.g. hands, tissues, towels). Allergens, chemical irritants and exposure to radiant energy such as ultraviolet light from the sun or tanning devices can also lead to this common condition. Its severity can range from mild irritation with redness and tearing to conjunctival oedema, haemorrhage or a severe necrotising process with tissue destruction.

Pathophysiology and manifestations

Acute conjunctivitis

Infectious conjunctivitis may be bacterial, viral or fungal in origin. Bacterial conjunctivitis, also known as 'pink eye', is highly contagious and often is caused by *Staphylococcus* and *Haemophilus*. Adenovirus infection is the leading cause of conjunctivitis in adults. Systemic infections that may affect the eyes include herpes simplex and other viral infections. Contact with genital secretions infected with *Gonococcus* can cause gonococcal conjunctivitis, a medical emergency that can lead to corneal perforation.

Redness and itching of the affected eye are common manifestations of acute conjunctivitis (see Figure 45.1). The person may also complain of a scratchy, burning or gritty sensation. Pain is not common; however, photophobia may occur. Tearing and discharge accompany the inflammatory process. The discharge may be watery, purulent or mucoid, depending on the cause of conjunctivitis. The person may have associated manifestations such as pharyngitis, fever, malaise and swollen pre-auricular lymph nodes.

Trachoma

Trachoma, a chronic conjunctivitis caused by *Chlamydia trachomatis*, is a significant preventable cause of blindness worldwide. Trachoma is endemic in sub-Saharan Africa, the Middle East and parts of Asia. Australia is the only

FAST FACTS

- In 2007–2008, 11 million (52%) Australians had a least one long-term vision disorder (Australian Institute of Health and Welfare (AIHW), 2012).
- The economic impact of visual impairment in Australia has been estimated at $9.85 billion. Vision disorder direct spending costs are more than the combined costs associated with stroke, arthritis and depression.
- The most common, presbyopia, affected 26% of the population; myopia affected 23%. Glaucoma, cataracts and macular degeneration affected 3% of the population. Other conditions included:
  - diabetic retinopathy: 2%
  - neuro-ophthalmic conditions: 2%
  - other retinal conditions: 7%
- Over the past 4 years, the Australian Government has committed $58 billion to deal with chronic ear and eye conditions in Indigenous Australians. The prevalence of eye disease is nearly 10 times higher in Indigenous Australians than in the general population.

Sources: Eye Research Australia (2004). *Clear insight: The economic impact and cost of vision loss in Australia—An overview of the report*; Australian Bureau of Statistics (2006). *Australian demographic statistics as at 30 June 2005 (Table 7) (Report 3101.0)*, provides the individual state and territory statistics; Vision 2020 Australia (2009); AIHW (2012).

NURSING CARE OF THE PERSON who is blind

Visual impairment exists on a continuum from blindness to decreased visual acuity that can be corrected with refractive lenses, to normal or near normal vision. *Visual impairment* is defined as 6/12 vision in the better eye, even with corrective lenses. The legal definition of *blindness* is visual acuity no better than 6/60 in the better eye with optimal correction or a visual field of less than 20 degrees in diameter (compared to the normal of 180 degrees) (Prevent Blindness America, 2008). Total blindness usually indicates that the person has no light perception at all. In practical terms, a person with a visual deficit sufficient to need assistive devices or aid from other people for normal activities of daily living is considered blind.

According to the World Health Organization (2014), there are 285 million people worldwide with visual impairment. Although blindness often can be prevented or cured, it remains a significant problem worldwide because of lack of access to care, fear of surgery or treatment, poor sanitation and nutrition, and ignorance of need. In Australia, cataracts, age-related macular degeneration, glaucoma and diabetic retinopathy remain significant causes of blindness in adults.

NURSING CARE

Blind people need to cope not only with the loss of a major sense but often also with societal attitudes that may make them feel inferior, helpless and inadequate. The idea of losing the ability to see is uniformly feared, leaving sighted people often unable to understand the magnitude and impact of the loss in those who have experienced it. Because of this fear and confusion, sighted people are unsure of what the blind expect from them.

The adjustment of the person who is born blind and raised to become an independent member of society differs from that of the person who has been sighted and becomes blind. The person who has been blind from birth has developed numerous adaptive strategies that the newly blind person has yet to learn.

Although adaptation may be easier for the person who experiences a gradual loss of vision than for someone with an abrupt loss, both grieve the lost sense. The blind person needs to grieve the lost body part as well as the loss of mobility, self-sufficiency, perhaps economic security and, to a certain extent, contact with reality as it has previously been perceived. The person's self-concept and self-esteem are threatened. Anger, denial, remorse and self-pity are not uncommon in the initial period following loss of sight. Interpersonal relationships and roles are affected and communication patterns change with the loss of the ability to perceive many non-verbal cues. In addition, expressions of sexuality may be impaired.

Acceptance of the change from sighted to blind is characterised by releasing the hope that vision will be regained. Self-esteem increases as the person attempts and masters activities of self-sufficiency such as completing ADLs, cooking and becoming mobile outside the known home environment.

Health professionals often confuse the blind person with someone helpless, dependent and lacking in personal identity and control. Although nurses need to take blindness into account in planning care and maintaining the person's safety, it is vital to give the blind person the same respect and decision-making control and power that all people deserve. Nurses who have dealt with their own emotions and responses to vision loss are better prepared to help the person adapt.

Nurses can foster independence in the hospitalised person with a significant vision deficit by carrying out the following:

- Orientation to the environment verbally and physically. Describe the room using a central point such as the bed, then lead the person around the room, identifying chairs, sink, bathroom and other landmarks. Be sure that objects such as chairs, personal items and clothing remain in the same place unless moved by the person. Leave doors either fully open or closed as the person requests, but preserve safety by not leaving doors partially open. Keep the room and hallways free of clutter.
- Use verbal communication freely. Introduce yourself as you enter the room and let the person know when you are leaving, and describe activities going on around the person.
- Provide other sensory stimuli such as radio and television, as desired by the person.
- Orient to food trays by using the face of a clock to describe the position of food items on the plate and tray (unless the person has always been blind and cannot visualise a clock face).
- When assisting with ambulation, allow the person to hold your arm as you walk slightly ahead. Do not hold the person's arm. Verbally describe the environment; for example: 'There will be two steps up 1.5 metres ahead.'
- Do not hesitate to ask what assistance the person desires.

For the person with a new loss of sight, refer to available services. Counselling can help the person cope with and eventually adapt to the loss of sight. People who are blind can receive mobility training, assistance with relearning self-care activities, education in the use of Braille to communicate and vocational and other forms of rehabilitation. Local, state and national agencies such as the Association for the Blind, state and territory guide dog associations, Seeing Eye Dogs Australia, Australian Braille Authority, Vision Australia, Blind Welfare Association and Blind Citizens Australia coordinate services for the blind. They provide many assistive devices, including guide dogs, computer services, talking books and tape players, and low-vision aids.

developed country with endemic trachoma, with extremely high incidence in the Indigenous population. Trachoma is contagious, transmitted primarily by close personal contact (eye to eye, hand to eye) or by fomites such as towels, handkerchiefs and flies (Gaydos & Quinn, 2012). Certain forms of trachoma are transmitted during delivery when the newborn is exposed to contaminated genital secretions of the mother (Gaydos & Quinn, 2012).

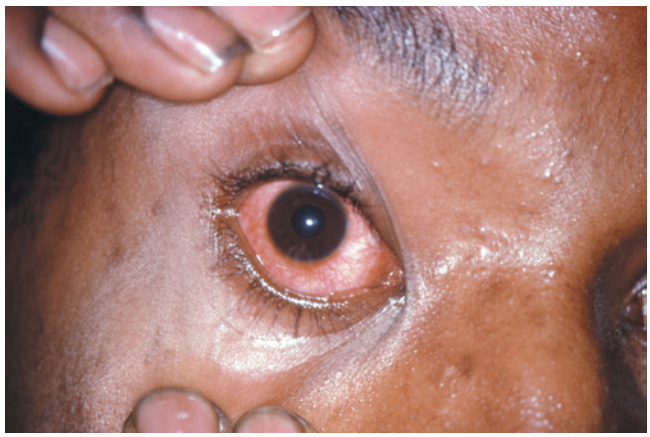

FIGURE 45.1 ■ The appearance of an eye with conjunctivitis

Source: CDC/Joe Miller.

Early manifestations of trachoma include redness, eyelid oedema, tearing and photophobia. Small conjunctival follicles develop on the upper lids. The inflammation also causes superficial corneal vascularisation and infiltration with granulation tissue. Scarring of the conjunctival lining of the lid causes entropion (see Figure 45.2). The lashes then abrade the cornea, eventually causing ulceration and scarring. The scarred cornea is opaque, resulting in loss of vision.

INTERPROFESSIONAL CARE

Management of the person with conjunctivitis focuses on establishing an accurate diagnosis and prompt treatment.

Diagnosis

Diagnosis is especially important because of other potentially vision-threatening conditions, such as acute uveitis or acute angle-closure glaucoma, that can also cause acute red eye (see Table 45.1). Diagnostic procedures may include:

- *culture and sensitivity* of exudates to determine presence of an infection and identify the infecting organism

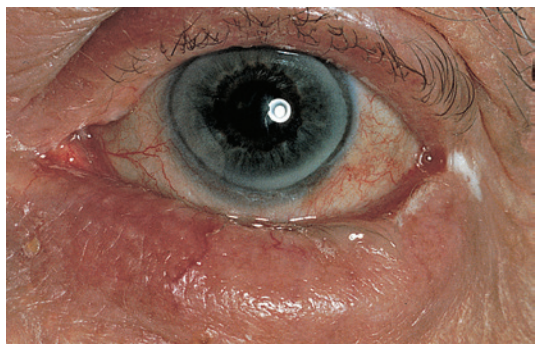

FIGURE 45.2 ■ Entropion

Source: © Science Photo Library/Science Source.

- *fluorescein stain* with slit-lamp examination to identify possible corneal ulcerations or abrasions, which appear green with staining
- *conjunctival scrapings* that are examined microscopically or cultured to identify the organisms.

Additional laboratory testing such as blood counts or antibody titres may be used to identify underlying infectious or autoimmune processes.

Medications

Conjunctivitis is treated with antibiotic, antiviral or anti-inflammatory drugs as appropriate. Topical antibiotic eye drops or ointments are usually prescribed with severe cases of conjunctivitis. Trachoma is usually treated with a single dose of oral azithromycin (Bryant & Knights, 2014). Antihistamines are used to minimise symptoms of conjunctivitis when an allergic response underlies the inflammatory process.

Complementary therapies

Frequent eye irrigations may be ordered to remove the copious purulent discharge associated with conjunctivitis. Soaking the lids with warm saline compresses prior to cleansing promotes comfort and facilitates the removal of crusts and exudate in conjunctivitis.

TABLE 45.1 Possible causes of acute red eye

	ACUTE CONJUNCTIVITIS	CORNEAL TRAUMA OR INFECTION	ACUTE UVEITIS	ACUTE ANGLE-CLOSURE GLAUCOMA
Incidence	Very common	Common	Common	Rare
Pain	Mild	Moderate to severe	Moderate	Severe
Vision	Normal	Blurred	Blurred	Markedly blurred
Discharge	May be copious	Watery, may be purulent	None	None
Conjunctival erythema	Diffuse	Primarily around cornea	Primarily around cornea	Primarily around cornea
Cornea	Clear	Depends on cause	Usually clear	Cloudy
Pupils	Normal size, response to light	Normal size, response to light	Small, minimal response to light	Moderately dilated, fixed

Nursing care

The nursing role in treating conjunctivitis is primarily one of education to prevent the disorder and its spread when it does occur.

Health promotion

Education is a vital strategy for preventing conjunctivitis. Teach all people about proper eye care, including the importance of not sharing towels, make-up or contact lenses, and avoiding rubbing or scratching the eyes. Instruct to avoid using old eye make-up, which can cause eye infections. Educate contact lens users about appropriate care (see Box 45.1). Emphasise the need to follow precise cleaning instructions to avoid bacterial contamination of lenses. If the eyes become red, irritated or develop discharge, instruct the person to avoid wearing contact lenses until the inflammatory process has cleared.

Assessment

- *Health history:* presence of redness, discomfort, tearing, photophobia and drainage; symptom onset; care measures; use of contact lenses; exposure to 'pink eye' or recent travel; allergies; previous history of conjunctivitis; presence of any chronic diseases.
- *Physical assessment:* visual acuity; inspect eyelids, conjunctiva, sclera and cornea; vital signs (temperature, heart rate, respirations, blood pressure).

Nursing diagnoses and interventions

Nursing care focuses primarily on preventing complications from the disorder. The priority nursing diagnoses include risk of infection and altered vision.

Risk of infection

Acute conjunctivitis is highly contagious. While most people experience discomfort from the disease, the infection carries a risk of scarring and damage to the delicate cornea. Preventing the spread of this infection is a vital nursing role.

BOX 45.1 Contact lens care

- Wash hands thoroughly before handling contact lenses.
- Keep storage case clean.
- Remove lenses before sleep, cleaning and storing as recommended by the manufacturer, or dispose of if single-use only.
- Use cleaning and wetting solutions recommended by the eye care professional or lens manufacturer. Do not use water or home-made solutions for wetting or cleaning lenses.
- If eye redness, tearing, vision loss or pain occurs, remove lenses and contact eye care professional as soon as possible.
- Do not share contact lenses with another person.

- Educate to wash hands thoroughly before instilling eye medications. Instruct to avoid touching or rubbing the eyes. Advise to use a new, clean cotton-tipped swab or cotton ball for cleaning each eye. *Handwashing is the single most important measure to prevent transmission of infection to the eye. Touching or rubbing the eyes increases the risk of infection and corneal trauma. Using a new swab or cotton ball prevents cross-contamination between eyes.*
- Educate person to instil prescribed eye drops as ordered. *Prescribed medications reduce inflammation and eliminate infection.*
- Discuss the importance of avoiding contact lens use until the infectious process has cleared, and of completing the prescribed treatment. *Use of contact lenses in the inflamed eyes can lead to further damage and impair healing.*

Risk of disturbed visual perception

Conjunctivitis can potentially disrupt the integrity or clarity of the cornea. Because of its vital role in focusing light on the retina, corneal damage can impair visual acuity.

- Assess vision with and without corrective lenses. *Assessment provides a baseline to evaluate possible changes in vision resulting from the infection.*
- Instruct to avoid activities requiring high visual acuity until the infection has cleared. *The inflammatory process, oedema of the conjunctiva and local antibiotic applications can decrease visual acuity and cloud vision.*
- Instruct to use dark sunglasses with appropriate UV protection when outdoors, even on cloudy days. *Photophobia, a common manifestation of conjunctivitis, causes eye pain with increased light intensity.*

Community-based care

People with conjunctivitis are typically managed in the community, reinforcing the need for effective education for home care. Emphasise to the individual and family ways to prevent transmission of infection. If the person is unable to administer eye medications, involve and educate the family in the following:

- safety and medical asepsis when cleansing the eye
- instillation of prescribed eye drops and ointments
- comfort measures such as reducing lighting intensity and wearing sunglasses
- avoiding activities such as excessive reading while the eye is inflamed.

THE PERSON WITH A CORNEAL DISORDER

The clear cornea allows light rays to enter the eye and transmits images onto the retina. It helps to focus light on the retina and protects the internal eye structures. The cornea can be affected by a variety of disorders, including infection and

trauma. While the cornea heals quickly after minor injuries or abrasions, injury to its deeper layers can delay healing or result in scarring.

Physiology review

The cornea has three main layers: the outermost epithelium, which consists of five or six layers of cells that are constantly being renewed; the stroma, which makes up 90% of corneal tissue; and the single-cell-thickness endothelium adjacent to the aqueous humour of the anterior chamber. The cornea is avascular tissue; the central cornea is dependent on atmospheric oxygen to meet its metabolic needs. Because there is no blood supply, immune defences have difficulty fending off infections of the cornea.

Pathophysiology and manifestations

When light enters the eye through the normally clear curved cornea, it is bent or *refracted* onto the lens, which then focuses the light on the sensory cells of the retina. A change in the curvature of the cornea or in its clarity affects the ability of the eye to clearly focus; as a result, vision is distorted or blurred. Refractive errors such as myopia, hyperopia and astigmatism are common. Corneal scarring or ulceration are two main causes of blindness worldwide.

Refractive errors

Refractive errors are the most common problems affecting visual acuity; they result from an abnormal curvature of the cornea or an altered shape of the eyeball. People with *emmetropia* (normal vision) can see near and far objects clearly because light rays focus directly on the retina. In myopia (nearsightedness) the curvature of the cornea is excessive or the eyeball is elongated, causing the image to focus in front of the retina instead of on it. Objects in close range are seen clearly and those at a distance are blurred. The eyeball is too short in **hyperopia** (farsightedness), causing the image to focus behind the retina. People with this condition see objects at a distance more clearly than they see those close to them.

Astigmatism develops due to an irregular or abnormal curvature of the cornea. Instead of the round, even curvature, it curves more in one direction than the other, resembling the back of a spoon. As a result, light rays focus on more than one area of the retina, distorting both near and distance vision.

Keratitis

Keratitis is inflammation of the cornea. (When the inflammatory process involves both the conjunctiva and the cornea, the term *keratoconjunctivitis* may be used.) Keratitis may be caused by infection, hypersensitivity reactions, ischaemia, tearing defects, trauma and impaired innervation of the cornea. Scarring that occurs as a result of keratitis is a leading cause of blindness worldwide (Porth & Matfin, 2014).

Keratitis is described as either non-ulcerative or ulcerative. In *non-ulcerative keratitis*, all layers of corneal epithelium are affected, but remain intact. Viral infections, tuberculosis and autoimmune disorders such as lupus erythematosus may cause non-ulcerative keratitis. *Ulcerative keratitis*, in contrast, affects the epithelium and stroma of the cornea, leading to tissue destruction and ulceration. Bacterial conjunctivitis (e.g. *Staphylococcus*, *S. pneumoniae*, *Chlamydia*) may lead to ulcerative keratitis.

Keratitis commonly causes tearing, discomfort ranging from a gritty sensation in the eye to severe pain, decreased visual acuity and *blepharospasm* (spasm of the eyelid and inability to open the eye). A discharge may be present, especially if the conjunctiva is also inflamed. Corneal ulceration may be visible on direct examination.

Corneal ulcer

A **corneal ulcer**, local necrosis of the cornea, may be caused by infection, exposure trauma or the misuse/overuse of contact lenses. Herpes viruses (e.g. herpes simplex and herpes zoster) are a leading cause of ulcerative corneal disease. Corneal ulcers may also complicate bacterial conjunctivitis, trachoma, gonorrhoea and other acute infections. People who are immunosuppressed because of disease or drug therapy are at particular risk of developing corneal ulcers due to infection.

In corneal ulceration, a portion of the epithelium and/or stroma is destroyed. Ulcers may be superficial or deep, penetrating underlying layers and posing a risk of perforation. Fibrous tissue may form during healing, resulting in scarring and opacity of the cornea. Perforation can lead to infection of deeper eye structures or extrusion of eye contents. Partial or total vision loss may result.

Corneal dystrophies

A corneal dystrophy is accumulation of cloudy material in part or parts of the normally clear cornea, potentially affecting visual acuity. Corneal dystrophies are typically inherited disorders that progress gradually and affect both eyes. *Keratoconus*, progressive thinning of the cornea, is the most common corneal dystrophy. It typically affects teenagers and young adults. In keratoconus, the centre of the cornea thins and bulges outwards, affecting its shape and ability to focus light on the lens of the eye. In most cases, the thinning stabilises over time. In Australia, there is a 98.1% success rate in reconstructive surgery for this condition in which corneal transplantation and the sclera are used.

INTERPROFESSIONAL CARE

Management of the person with a disorder of the cornea focuses on establishing an accurate diagnosis and prompt treatment to reduce the risk of permanent vision deficit. The person's history and physical assessment are key in diagnosing these disorders.

Although many eye disorders can be treated in the community, the person with a severe corneal infection or ulcer may require hospitalisation. Corneal ulcers are medical emergencies that require prompt referral to an ophthalmologist for treatment. Pressure dressings may be applied to both eyes for comfort in order to reduce the risk of perforation and possible loss of eye contents.

Diagnosis

Visual acuity is tested on all people presenting with refractory or corneal disorders. See Chapter 44 for more information about

testing visual acuity. The following tests may be ordered to identify the cause and extent of eye infections or inflammations:

- *Fluorescein stain* with slit-lamp examination allows visualisation of any corneal ulcerations or abrasions, which appear green with staining.
- *Conjunctival* or *ulcer scrapings* are examined microscopically or cultured to identify the organisms.

Additional laboratory testing such as blood counts or antibody titres may be used to identify any underlying infectious or autoimmune disease processes.

Medication

Infectious processes are treated with antibiotic or antiviral therapy as appropriate. The only topical antiviral available in Australia is aciclovir (Bryant & Knights, 2014). Corticosteroids may be prescribed for keratitis related to systemic inflammatory disorders or trauma; however, it is important to avoid their use with local infections to avoid suppressing the immune and inflammatory responses.

Corrective lenses

Corrective lenses, either in the form of eyeglasses or contact lenses, generally are prescribed to restore visual acuity for people with refractive errors such as myopia, hyperopia and astigmatism. Specially fitted contact lenses to reduce vision distortion are ordered for people with keratoconus. Because contact lenses are a risk factor for corneal infection and ulcers, providing appropriate education regarding lens care is vital (see Box 45.1).

Surgery

LASER EYE SURGERY Laser eye surgery is commonly performed to correct refractive errors such as myopia, hyperopia and astigmatism. A laser is used to permanently change the shape of the cornea, and in most cases the need to use corrective lenses is reduced or eliminated. Several surgical procedures are now available:

- laser in situ keratomileusis (LASIK)
- photorefractive keratectomy (PRK)
- laser epithelial keratomileusis (LASEK)
- laser thermokeratoplasty (LTK).

These procedures reshape the cornea using laser technology to remove a thin layer of epithelial cells or to shrink and reshape the cornea. Candidates for laser vision-correction surgery should be in good health and must have adequate corneal thickness to ensure that the risk of perforation does not occur.

Following surgery, people may experience a temporary loss of contrast sharpness (images do not appear crisp as with corrective lenses), over- or under-correction of visual acuity, dry eyes or temporarily decreased night vision with halos, glare and starbursts. Diffuse lamellar keratitis (DLK) is a rare complication of surgery that, while treatable, can lead to vision impairment if not identified and treated early.

Phototherapeutic keratectomy (PTK) provides an alternative to corneal transplant in treating corneal dystrophies, scars and some infections. In this procedure, diseased corneal tissue is vaporised and surface irregularities are corrected with little trauma to surrounding tissue; healing occurs rapidly.

CORNEAL TRANSPLANT Once the cornea has become scarred and opaque, no treatment can restore its clarity. The first successful corneal transplant (*keratoplasty*), replacement of diseased cornea by healthy corneal tissue from a donor, was performed in 1906. Current corneal transplant procedures have a success rate of approximately 90% in Australia. Data collected from the Australian Corneal Graft Registry (2012), one of the world's largest registries, show that 91.2% of such transplants in Australia survive for approximately 1 year.

Corneas are harvested from the cadavers of uninfected adults who were under the age of 65 and who died as a result of acute trauma or illness. After harvesting, the cornea can be stored in a tissue-culture medium for up to 4 weeks before being used as a graft. Corneal transplantation is usually an elective surgery, although emergency transplantation may be required for perforation of the cornea.

Corneal transplant may be either lamellar or penetrating. In a lamellar keratoplasty, the superficial layer of cornea is removed and replaced with a graft. The anterior chamber remains intact. In a penetrating keratoplasty, a button or full thickness of cornea is removed and replaced by donor tissue (see Figure 45.3). The graft is then sutured in place using suture finer than human hair and a continuous or interrupted stitch. Because the cornea is avascular, these sutures remain in place for up to a year to ensure healing.

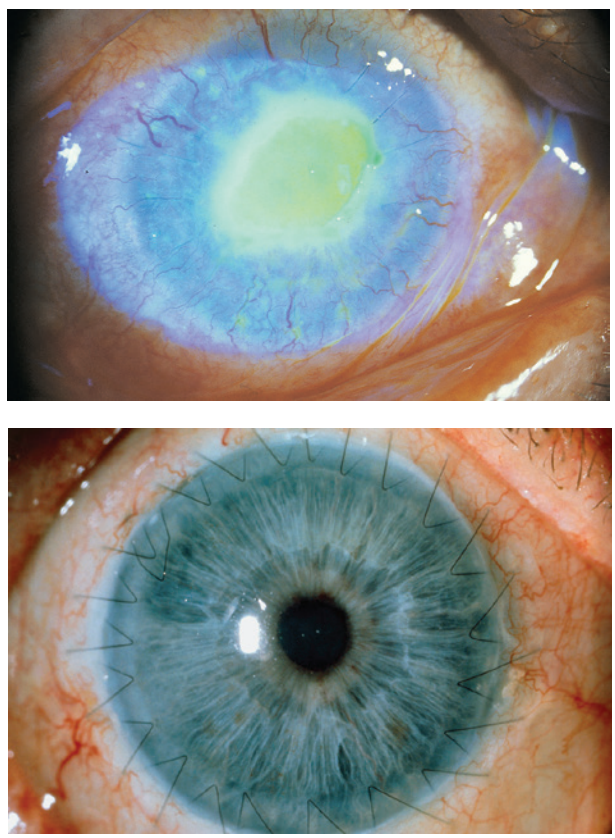

FIGURE 45.3 ■ Corneal transplant. *A*, The diseased, opaque cornea. *B*, The diseased cornea is removed and a corneal graft is sutured in place using material finer than a human hair

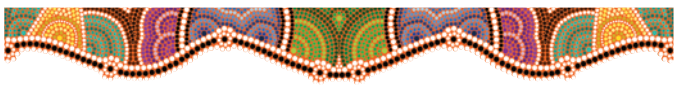
Source: Custom Medical Stock Photo.

Most corneal transplants do not require hospitalisation. The eye is patched for 24 hours following surgery. Narcotic analgesia may be required initially because the cornea is extremely sensitive. Corticosteroid eye drops are ordered to reduce the inflammatory response and prevent oedema of the graft, and antibiotic drops may be prescribed to prevent infection.

The risk of transplant rejection is low as the cornea is avascular and there is little exposure of the transplanted corneal tissue to the host's immune defences (Grossman & Porth, 2014). Research suggests that matching of blood type (not tissue type, as is required for major organ transplants) between the donor and the transplant recipient may reduce the risk of transplant rejection (Dana, 2011). When rejection does occur, it occurs within 3 weeks of the transplant, beginning with inflammation at the edge of the grafted tissue and spreading to involve the entire graft. In many cases, rejection can be successfully treated using corticosteroid therapy, preserving the graft. (See the accompanying box for nursing care of the person undergoing eye surgery.)



Nursing care

Nurses working in clinics and outpatient surgical settings care for people undergoing corneal transplant and surgeries to correct refractive errors. The nursing role in caring for people with corneal disorders may involve direct care; however, the focus is on prevention and education.

Health promotion

Education is a vital strategy for preventing many corneal disorders. Educate all involved about proper eye care, including the importance of not sharing towels and make-up, and avoiding rubbing or scratching the eyes, as well as preventing trauma and infection. Teach contact lens users appropriate care and cleaning techniques. Stress the importance of periodic removal of lenses, even extended-wear or single-use lenses. In general, lenses should be removed at night, even though manufacturers may claim it is safe to wear them while sleeping. Emphasise the need to follow cleaning instructions (as per the manufacturer's instructions) to avoid bacterial contamination of lenses and possible corneal infection. If the person experiences a corneal abrasion or keratitis, instruct the person to avoid wearing contact lenses until the cornea has healed completely.

Assessment

Collect the following data through a health history and physical examination (see Chapter 44). Additional focused assessments are described with the interventions below:

- *Health history:* risk factors; presence of redness, discomfort, tearing, photophobia, oedema and drainage; symptom onset; presence of pain, effect on vision.
- *Physical assessment:* visual acuity; inspect external eye, including conjunctiva, sclera and cornea; extraocular movements.

Nursing diagnoses and interventions

Nursing care focuses primarily on preventing complications and promoting healing. The priority nursing diagnosis for people with corneal disorders includes risk of altered vision, pain and injury.

Risk of disturbed visual perception

Disorders affecting the cornea may disrupt its integrity and/or clarity as the cornea plays a vital role in focusing light on the retina. Any corneal damage can affect vision, impairing visual acuity and even causing legal blindness.

- Assess vision with and without corrective lenses. *Assessment provides a baseline to evaluate possible vision changes resulting from the disorder and/or treatment.*
- Educate the person about thorough handwashing before inserting or removing contact lenses or instilling any eye medications, and about avoiding touching or rubbing the eyes. Instruct to use a new, clean cotton-tipped swab or cotton ball for cleaning each eye. *Handwashing is the single most important measure to prevent transmission of infection to the eye. Touching or rubbing the eyes increases the risk of infection and possible corneal trauma. Using a new swab or cotton ball prevents cross-contamination between eyes.*
- Emphasise the importance of proper care of contact lenses specific to the type of lens used. *People who wear hard contact lenses must remove them daily, as the central cornea requires exposure to atmospheric oxygen. Although soft and extended-wear lenses allow the cornea to 'breathe', improper cleaning carries a major risk of infection.*
- Emphasise the importance of using eye protection when engaging in potentially dangerous activities. *Trauma can increase the risk of infection and scarring of the cornea.*
- If corneal perforation is suspected, place the person in the supine position, close the eye and cover it with a dry, sterile dressing. Notify the doctor immediately. *Corneal perforation may occur without warning in people with corneal ulcers. It places the person at risk of loss of eye contents. Emergency measures are taken to reduce intraocular pressure and maintain eye integrity to preserve vision.*

CONSIDERATION FOR PRACTICE

Suspect corneal perforation with complaints of sudden, severe eye pain and photophobia.

Acute pain

The cornea of the eye is extremely sensitive; therefore, corneal disorders frequently cause significant pain. This in turn increases the stress response and interferes with rest, potentially impairing healing.

- Assess pain, using verbal and non-verbal cues. *Pain is a subjective experience and can be evaluated only by the person's response and in terms of its effect on the person.*

- Administer prescribed analgesia routinely in the first 12 to 24 hours after corneal surgery. *Routine administration of analgesics prevents pain from reaching a level of severity at which it becomes difficult to relieve.*
- Patch both eyes if necessary. *Patching both eyes reduces eye movement and irritation of the affected eye.*
- Instruct to apply warm compresses to reduce inflammation and pain. *Warm compresses for 15 minutes, three to four times a day, promote comfort for people with keratitis or corneal injury.*
- Instruct to use dark sunglasses with appropriate UV protection when outdoors, even on cloudy days. *True photophobia, often associated with corneal disorders, causes eye pain with increased light intensity.*

NURSING CARE OF THE PERSON having eye surgery

PREOPERATIVE CARE

- Review Chapter 3 for routine preoperative care.
- Assess visual acuity of the affected eye prior to surgery. *The person with limited vision in the affected eye may need additional attention and ADL assistance postoperatively to ensure safety.*
- Assess the person's support systems and the possible effect of impaired vision on lifestyle and ability to perform ADLs in the postoperative period. *Safety measures such as installing handrails and removing throw rugs from the home can help promote mobility and safety, especially if the person has limited vision in the unaffected eye.*
- Educate the person regarding measures to prevent eye injury postoperatively, such as avoiding possible vomiting, straining with stool movement, coughing, sneezing, lifting more than 2 kg and bending over at the waist. *These activities can temporarily increase intraocular pressure and may lead to postoperative complications.*
- Remove all eye make-up and contact lenses or glasses prior to surgery. Store corrective lenses and eyeglasses in a safe place and make them readily available to the person on return from surgery. *Maintaining visual acuity in the unaffected eye helps reduce fear and maintains safety.*
- Administer preoperative medications and eye drops and/or ointments as prescribed. *Mydriatic (pupil-dilating) or cycloplegic (ciliary-paralytic) drops, and/or drops to lower intraocular pressure, may be prescribed preoperatively.*

POSTOPERATIVE CARE

- Review Chapter 3 for routine postoperative care.
- Assess eye dressing for bleeding and/or drainage following surgery *as it may indicate a surgical complication.*
- Maintain the eye patch or shield in place *to prevent inadvertent injury to the operative site.*
- Place in semi-Fowler's or Fowler's position on the unaffected side. *Elevating the head of the bed and lying on the unaffected side reduces intraocular pressure in the affected eye.*
- Remind the person to avoid coughing, sneezing and/or straining, *as these activities can increase intraocular pressure.*
- Assess and medicate as necessary for complaints of pain, aching and/or a scratchy sensation in affected eye. *Complaints of sudden sharp eye pain must be reported to the doctor immediately. An abrupt increase in or onset of eye pain may indicate haemorrhage or other ocular emergency requiring immediate intervention to preserve sight.*
- Assess for potential complications:
  a. pain and/or drainage from the affected eye
  b. haemorrhage with blood in the anterior chamber of the eye
  c. indications of retinal detachment, including flashes of light, floaters or the sensation of a curtain being drawn over the eye; cloudy appearance to the cornea (corneal oedema).

  Early intervention is often necessary to preserve sight.
- Approach the person on the unaffected side *as this facilitates eye contact and communication.*
- Place personal articles and the call bell within easy reach *to prevent the person stretching and/or straining.*
- Administer antibiotics, anti-inflammatory and/or other systemic and/or topical eye medications as prescribed. *Medications are prescribed to prevent infection and/or inflammation of the operative site, maintain pupil constriction and control intraocular pressure.*
- Administer anti-emetic medication as required. *It is important to prevent vomiting, in order to maintain normal intraocular pressures.*

HEALTH EDUCATION FOR THE PERSON AND FAMILY

- Educate the person and family about home care:
  a. how to instil eye drops
  b. the name, dosage, schedule, duration, purpose and side effects of medications
  c. how and when to use the eye patch and eye shield
  d. the importance of avoiding scratching, rubbing, touching or squeezing the affected eye
  e. measures to avoid constipation and straining
  f. activity limitations, if ordered
  g. reporting of symptoms including eye pain or pressure, redness or cloudiness, drainage, decreased vision, floaters, or flashes of light or halos around bright objects
  h. the need to wear sunglasses with side shields when outdoors to reduce photophobia
- Remind the person that vision may not stabilise for several weeks following eye surgery. If new corrective lenses are required they will not be prescribed until vision has stabilised. *A person may be alarmed that vision seems worse after surgery and need reassurance that visual acuity usually improves with time and healing of the affected eye.*
- Emphasise the importance of keeping follow-up appointments. Provide referral to a community service for assistance with home care after discharge as required.

- Instruct how to instil prescribed eye drops/ointment as ordered. *Prescribed medications may reduce inflammation and eliminate infection, reducing discomfort.*

Risk of injury

The person who has undergone corneal transplantation has an increased risk of injury for several reasons. The eye on which surgery was performed is patched for 24 hours after surgery, changing depth perception and increasing the risk of falls. Increased intraocular pressure or trauma to the eye may damage the graft, resulting in graft rejection.

- Instruct to call for help before getting up or ambulating after surgery. Ensure access to the call bell. It may take time for the person to adjust to changes in depth perception caused by the eye patch. *Assistance helps prevent falls that may not only injure the person but also traumatise the operative site.*
- Encourage deep breathing and use the incentive spirometer to promote lung expansion. *These important postoperative measures help prevent pulmonary complications. Coughing is avoided because it increases intraocular pressure.*
- Educate the person on how to apply an eye shield at night after the eye patch is removed. *An eye shield may be recommended at night to prevent inadvertent rubbing or trauma to the eye during sleep.*
- Encourage the person not to rub or scratch the eye. *Rubbing or scratching may disrupt suture lines or damage the grafted tissue.*
- Reinforce the importance of using eye protection during hazardous activities. *Following a corneal transplant, the person has the same risk of eye injury as other people who perform hazardous activities.*

CONSIDERATION FOR PRACTICE

Administer prescribed anti-emetics and stool softeners postoperatively to prevent vomiting and straining at stool—activities that increase intraocular pressure and can damage suture lines.

Community-based care

Following treatment, educate the person to manage these conditions at home. Emphasise to the person and family ways to prevent transmission of infection. If the person is unable to administer eye medications or to perform other eye care required, involve the family in the education session. The following topics should be included:

- safety and medical asepsis when cleansing the eye
- instillation of prescribed eye drops and ointments
- application of an eye patch/shield and where to obtain supplies
- avoidance of activities such as excessive reading while eye is inflamed
- follow-up appointments after corneal transplant surgery
- signs and symptoms of graft rejection
- avoidance of activities that increase intraocular pressure, such as straining, coughing, sneezing, bending over, lifting heavy objects
- helpful resources:
  - Lions Eye Institute: www.lei.org.au
  - state organ and tissue agencies.

DISORDERS AFFECTING THE EYELIDS

The eyelids and eyelashes are constantly exposed to the environment as they protect the eye from damage. When these structures are inflamed, deformed or their function is impaired, this affects both appearance and their protective functions.

Pathophysiology and manifestations

The most common disorder affecting the eyelids is *marginal blepharitis*, an inflammation of the glands and lash follicles on the margins of the eyelids. This inflammatory disorder can be caused by a staphylococcal infection, or it may be seborrhoeic in origin; commonly, both types are present. Seborrhoeic blepharitis is usually associated with seborrhoea (dandruff) of the scalp or eyebrows. Irritation, burning and itching of eyelid margins are common manifestations of blepharitis. The eye appears red rimmed with mucus discharge and there is crusting or scaling of lid margins. Lid margins may ulcerate, resulting in a loss of eyelashes.

Infection of one or more of the sebaceous glands of the eyelid may cause a **hordeolum (sty)**. Hordeolum is a staphylococcal abscess that may occur on either the external or internal margin of the lid (see Figure 45.4). An external hordeolum is characterised initially by acute pain at the lid margin with redness, and a small tender raised area is visible. The person may also experience

FIGURE 45.4 ■ Hordeolum

Source: © Francoise Sauze/Science Source.

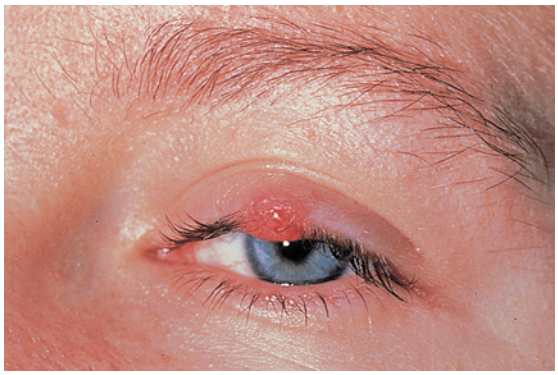


FIGURE 45.5 ■ Chalazion

Source: © SPL/Custom Medical Stock Photo.

photophobia, tearing and the sensation of a foreign body in the affected eye. Internal hordeola are seen on the conjunctival side of the lid and may have more severe manifestations.

Chronic inflammation of a meibomian gland may lead to formation of a **chalazion**, a granulomatous cyst or nodule of the lid (see Figure 45.5). It presents as a hard swelling on the lid, and the surrounding conjunctival tissue is red and inflamed. Chalazion may also follow a hordeolum that was inadequately treated. Unlike a hordeolum, a chalazion is painless; however, it may slowly increase in size and eventually require removal, although most resolve within several months.

Entropion, the inversion of the lid margin (see Figure 45.2), may be associated with the normal ageing process (senile entropion) or result from an infectious process such as trachoma. Entropion can lead to corneal irritation and, potentially, scarring as the lashes rub on the conjunctiva and cornea during blinking and sleep. *Ectropion*, or eversion of the lid margin, occurs primarily as an effect of ageing (see Figure 45.6). Other conditions may also lead to ectropion, including facial nerve paralysis or palsy (Bell's palsy), scarring or infection. Here the eye does not close effectively, increasing the risk of drying and damage to the conjunctival membrane and cornea. Both entropion and ectropion have cosmetic effects as they alter the appearance of the eyes and face.

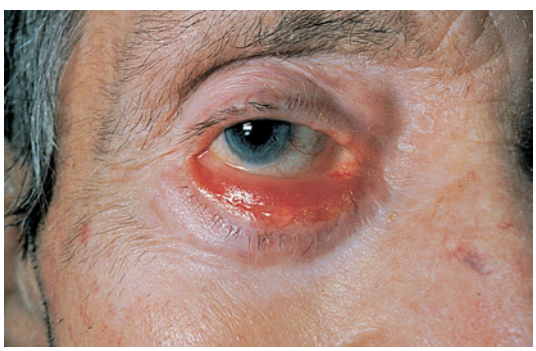

FIGURE 45.6 ■ Ectropion

INTERPROFESSIONAL CARE

Disorders affecting the eyelids typically are managed in the community. Diagnosis is typically made through the person's history and physical examination. Diagnostic tests are rarely required except to identify corneal or conjunctival damage resulting from the condition.

Topical antibiotics (eye drops or ointments) may be prescribed for the person with hordeolum and to treat infection resulting from irritation of the eye by a deformed lid. Careful cleansing of the lid margins using a 'no-tears' baby shampoo is often recommended for marginal blepharitis. Soaking the lids with warm saline compresses prior to cleansing facilitates the removal of crusts and exudate in blepharitis. Local heat applications may be used to treat hordeolum or chalazion; excision and drainage may be required if this is not effective. In entropion or ectropion, surgery may be performed to correct the defect, reduce the risk of damage to the eye and improve cosmetic appearance.

Nursing care

The nursing role focuses on education and comfort measures. Educate people about appropriate eye care, including avoiding rubbing or scratching the eyes. Discuss the importance of not using old eye make-up, which can cause lid infections. Instruct to wash hands well before cleansing the eyelids or instilling any eye medications. Instruct to use a new, clean cotton-tipped swab or cotton ball for cleaning each eye. Instruct to instil prescribed eye drops and apply ointments as ordered. If the person is unable to administer eye medications, involve the family. Instruct to apply warm compresses to reduce inflammation and discomfort.

THE PERSON WITH EYE TRAUMA

Most eye injuries are minor but, without timely and appropriate intervention, even a minor injury can threaten a person's vision. Therefore, all eye injuries should be considered medical emergencies requiring immediate evaluation and intervention.

Pathophysiology and manifestations

Any part of the eye, especially the exposed parts, may be affected by trauma. Foreign bodies, abrasions and lacerations are the most common types of eye injury, along with traumatic injuries such as burns, penetrating objects and/or blunt force.

Corneal abrasion

Corneal abrasion is the disruption of the superficial epithelium of the cornea. Objects commonly causing corneal abrasion include contact lenses, eyelashes, small foreign bodies (dust, dirt and fingernails), drying of the eye surface and chemical irritants.

Superficial abrasions of the cornea are extremely painful but generally heal rapidly without complications or scarring. Photophobia and tearing are commonly present. When the stroma is damaged by a deep abrasion or laceration, there is an increased risk of infection, healing is slowed and scar formation occurs.

Burns

The outer surface of the eye may be subjected to burns caused by heat, radiation or explosion; however, chemical burns are the most common. Acid or alkaline substances may burn the eye. Ammonia, products that contain lye (such as oven and drain cleaners) and acids from car batteries or other sources are often implicated in eye injuries. Burns caused by alkaline substances are particularly serious as tiny particles of the chemical may remain in the conjunctival sac, causing progressive damage. Acid causes rapid damage to the eye; however, in general it causes less serious burns than alkaline substances.

Explosions and flash burn injuries pose the greatest risk of thermal burns of the eye. UV rays can also cause corneal damage ranging from mild to extensive. Depending on the source of the ultraviolet light, these burns may be known by various names such as snow blindness, welder's arc burn or flash burn.

In addition to giving a history of the face and eye contact with a caustic substance or other burning agent, the person complains of eye pain and decreased vision, and eyelids are often swollen. Burns may also affect the face or lids, and the appearance of the eye may vary, depending on the type of burn. The conjunctiva is reddened and oedematous; sloughing may be seen, particularly with chemical burns. The cornea often appears cloudy or hazy, and ulcerations may be evident.

Penetrating trauma

Perforation of the eye occurs from a variety of causes including metal flakes or other particles produced by high-speed drilling or grinding, glass shards or other substances. In a *perforating* injury, the layers of the eye do not spontaneously reapproximate, resulting in rupture of the globe and potential loss of ocular contents.

In a *penetrating* injury, the layers of the eye spontaneously reapproximate after entry of a sharp-pointed object or small missile into the globe (e.g. knives, arrows and gunshot). These injuries may not be readily apparent through inspection of the eye. Penetrating injuries may be hidden or missed due to tissue swelling or when the person has other significant injuries that command attention. When the eyelid is lacerated or has a puncture wound, inspection of the underlying eye tissue for possible damage is vital. Eye perforations/penetrations cause pain, partial or complete loss of vision, and possible bleeding or extrusion of eye contents.

Blunt trauma

Sports injuries are a common cause of blunt trauma to the eye; for example, being struck with a ball or injured in contact sports. Other causes include injury from a motor vehicle accident, falls and physical assault.

Blunt trauma may lead to a minor eye injury such as lid ecchymosis (black eye) or subconjunctival haemorrhage caused by rupture of a blood vessel in the conjunctiva. A well-defined bright area of erythema appears under the conjunctiva; however, no pain or discomfort is associated with the haemorrhage and no treatment is necessary. The blood typically reabsorbs within 2 to 3 weeks.

Hyphaema, bleeding into the anterior chamber of the eye, is a potential result of blunt eye trauma. When the highly vascular uveal tract of the eye is disrupted by blunt force, haemorrhage may result, filling the anterior chamber. The person complains of eye pain, decreased visual acuity and seeing a reddish tint. Blood is visible in the anterior chamber.

An orbital blowout fracture is another potential result of blunt eye trauma. Although any part of the eye orbit may be fractured, the ethmoid bone on the orbital floor is the most likely site. Orbital contents, including fat, muscles and the eye itself, may herniate through the fracture into the underlying maxillary sinus. The person complains of diplopia (double vision), pain with upward movement of the affected eye and decreased sensation on the affected cheek. The eye appears sunken (**enophthalmos**) and has limited movement on examination.

INTERPROFESSIONAL CARE

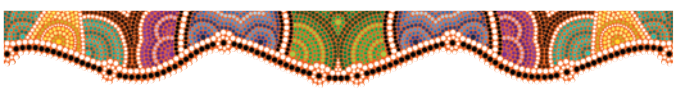
When trauma to the eye is known or suspected, a thorough examination is conducted to determine the type and extent of the injury. Unless immediate treatment is indicated, as with a chemical burn, vision is evaluated initially. If the person normally wears corrective lenses, vision assessment is performed while glasses are worn. Eye movement is evaluated unless a penetrating object is present and the lid and eye are inspected for lacerations. Inspection is performed using strong light and magnification with a headband loupe or slit lamp. Topical anaesthesia may be used prior to inspection if eye pain and photophobia make eye opening difficult. Fluorescein staining can help identify foreign bodies and abrasions. Any conjunctival or anterior chamber haemorrhage is noted, as is the presence or absence of the red reflex. Ophthalmoscopic examination is used to detect haemorrhage or trauma to the interior chamber. Facial x-rays and computed tomography (CT) scans are used to identify orbital fractures or foreign bodies within the globe. Ultrasonography may be employed to detect a detached retina or vitreous haemorrhage.

Foreign bodies are removed using irrigation, a sterile cotton-tipped applicator or a sterile needle or other instrument. Antibiotic ointments can be applied once objects have been removed. In a person with corneal abrasion and large foreign bodies, an eye patch is applied firmly after the antibiotic application to keep the eye closed for approximately 24 hours.

The immediate priority of care for people with chemical burns is flushing the affected eye with copious amounts of fluid. Normal saline is preferred; however, water may be used if saline is not available. A special contact lens irrigating unit (Morgan lens), normal saline eye bath or bag of irrigation with intravenous tubing held to flush all eye surfaces may be useful. The eyelid is everted to identify and remove material from the conjunctival sac. A topical anaesthetic helps relieve pain, making inspection and irrigation easier. During irrigation, fluid is directed from the inner canthus of the eye to the outer. Tipping the person's head slightly to the affected side prevents contamination of the unaffected eye. Irrigation is continued until the pH of the eye is normal (in the range 7.2 to 7.4). Following irrigation, a topical antibiotic ointment may be applied.

Penetrating wounds of the eye generally require surgical intervention by an ophthalmic surgeon. Immediate care focuses on relieving pain and protecting the eye from further injury. To prevent loss of intraocular contents, pressure should not be placed directly on the eye, but gently cover with a sterile gauze or an eye pad. If a foreign body is embedded in or sticking out of the eye, no attempt should be made to remove it. The object should be immobilised and the eye protected with a metal eye shield until the surgeon can review the person. A paper cup or other protective device may be used if the object is too large to use an eye shield. Patching the unaffected eye decreases ocular movement. Pain is managed using narcotic analgesics such as morphine. The person may also require sedation (e.g. diazepam), anti-emetic medications to prevent vomiting and antibiotics to prevent infection.

Interventions for the person with blunt trauma to the eye include placing the person on bed rest in semi-Fowler's position and protecting the eye from further injury with an eye shield. The unaffected eye is also patched to minimise eye movement. A carbonic anhydrase inhibitor may be prescribed to reduce intraocular pressure.



Nursing care

The nursing role involves educating people about prevention and providing direct care regarding eye injuries.

Health promotion

Educating individuals and groups about how to prevent eye injuries, the use of protective devices and first aid measures is an important nursing role, especially for people involved in hazardous occupations and high-risk sports. Emphasise the importance of using seat belts and air bags to prevent eye injury in motor vehicle accidents. Instruct people to immediately flush the eye with copious amounts of water if a chemical splash occurs. Loose, visible foreign bodies can be removed using a clean, moistened cotton-tipped swab. If an abrasion, penetrating or blunt injury is suspected, the eye should be covered loosely with sterile gauze and medical attention sought immediately; people should not try to remove objects.

Nursing diagnoses and interventions

Ocular injuries require immediate interventions simultaneously with assessment and accurate history collection, including pre-existing visual problems. The time, type and extent of injury, and the circumstances under which it occurred, must be determined.

Impaired ocular tissue integrity

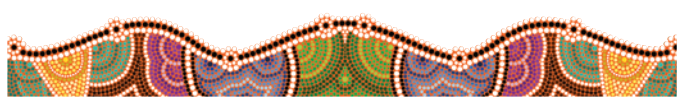
All types of eye trauma pose the risk of violating the integrity of the eye and threatening vision. The goals of nursing care are to preserve vision and the integrity of the eye, and prevent further damage.

- Assess vision in each eye followed by both eyes together, with and without corrective lenses, on entry into the emergency department or primary care setting. *An initial assessment provides valuable information about the effect of the injury on the person's vision and a baseline for future comparisons.*
- Inspect eye(s) carefully for evidence of foreign bodies, burns, penetrating injury or blunt trauma. Note if lacerations, burns or other trauma are evident in tissues surrounding the eye. *Eye trauma may be hidden by other injuries and, as a result, remain untreated.*
- If a burn or foreign body is present, anaesthetic drops may be instilled and the eye irrigated either before or after the doctor evaluates the person. *Blepharism and eye pain may impair assessment of the injured eye. Irrigation to remove the chemical is of higher priority than assessment of the eye.*
- Loose foreign bodies may be removed using a moist, sterile cotton-tipped applicator. *Prompt removal of foreign bodies may prevent corneal abrasion.*
- For a severe or penetrating injury, promote rest and stabilise the injured eye by applying an eye pad or gauze dressing loosely over both the affected and unaffected eye. Stabilise any penetrating object if possible. *These measures reduce eye movement and can help preserve the person's vision.*
- Following treatment, apply eye drops or ointment as prescribed and apply an eye pad or shield as required. *An eye pad is applied to the affected eye to reduce pain and photophobia and to promote healing.*

Community-based care

Following an injury, discuss the following topics with the person and family:

- prescribed medications and possible adverse effects
- strategies to prevent further trauma
- application of the eye pad or shield
- avoidance of activities that increase intraocular pressure
- importance of restricting activities.



THE PERSON WITH UVEITIS

The middle vascular layer of the eye, including the choroid, the ciliary body and the iris, is known as the uvea and uveal tract. *Uveitis* is inflammation of all or part of this vascular layer; *iritis*, inflammation of the iris, occurs more commonly than uveitis.

Uveitis is a disease limited to the eye; it may be idiopathic or caused by an autoimmune process, infection, parasitic disease or trauma. Many cases can be linked to a systemic disease, often an arthritic or autoimmune disorder such as ankylosing spondylitis, Reiter's syndrome, rheumatoid arthritis or sarcoidosis (see Chapter 39). Uveitis has also been linked with tuberculosis and syphilis. Manifestations of uveitis include pupillary constriction and erythema around the limbus, severe eye pain and photophobia and blurred vision.

Immunosuppressive therapy may be used to suppress the inflammatory response in people with severe uveitis. Atropine may also be prescribed for associated inflammation of the iris. The person may require analgesics for pain management. Nursing care is supportive, focusing on promotion of comfort and education regarding the disorder and its management.

THE PERSON WITH CATARACTS

A **cataract** is an opacification (clouding) of the lens of the eye which can significantly interfere with light transmission to the retina and the ability to perceive images clearly.

Incidence and risk factors

Age is the greatest single risk factor for cataract; however, genetics may contribute to the risk, although the link is unclear. Environmental and lifestyle factors also play a role, such as long-term exposure to sunlight (UVB rays); cigarette smoking and heavy alcohol consumption are associated with earlier cataract development. Although senile cataracts are by far the most common, cataracts may also be congenital or acquired in origin. Eye trauma, including injury to the lens capsule by a foreign body, blunt trauma or exposure to heat or radiation, can precipitate cataract formation. Diabetes mellitus is associated with earlier development of cataracts, especially when the blood glucose level is not carefully controlled at or near normal levels. Certain drugs such as systemic or inhaled corticosteroids also prompt the formation of cataracts.

Pathophysiology

The majority of cataracts are known as senile and are formed as a result of the ageing process. As the lens ages, its fibres and proteins change and degenerate. In addition, the proteins clump, clouding the lens and reducing light transmission to the retina. This process generally begins at the periphery of the lens, gradually spreading to involve the central portion. As the cataract continues to develop, the entire lens may become opaque. An immature cataract occurs when only a portion of the lens is affected; however, a mature cataract affects the entire lens. In addition to clouding, the lens may discolour over time, affecting the ability to accurately discriminate colours.

FIGURE 45.7 ■ A scene as viewed by a person with cataracts

Source: Courtesy of National Eye Institute, National Institutes of Health (NEI/NIH).

Manifestations

Cataracts tend to occur bilaterally unless they are related to eye trauma. Fortunately, they tend to develop at different rates and one cataract generally matures more rapidly than the other. As a cataract interferes with light transmission through the lens, visual acuity decreases, affecting both close and distance vision (see Figure 45.7). Light rays are scattered as they pass through the lens, causing complaints of glare, which affects the ability to adjust between light and dark environments. Colour discrimination is impaired, particularly in the blue to purple range. When the cataract is mature, the pupil may appear cloudy grey or white, rather than black.

INTERPROFESSIONAL CARE

The diagnosis of a cataract is made based on the person's history and eye examination. Ophthalmoscopic examination confirms the diagnosis by identifying the location and extent of a cataract. As the cataract matures, ophthalmoscopy reveals a dark area instead of the red reflex.

Surgery

Surgical removal is the only treatment used for cataracts, as no medical treatment is available to prevent or treat them. If the person presents with bilateral cataracts, surgery is performed on one eye at a time. If an intraocular lens (an artificial lens to replace the diseased lens of the eye) is to be implanted during surgery, the corneal curvature and anteroposterior diameter of the eye are measured prior to surgery to determine the lens power needed for the intraocular lens implant.

Surgical removal of the cataract and lens is indicated when the cataract has developed to the point that vision and ADLs

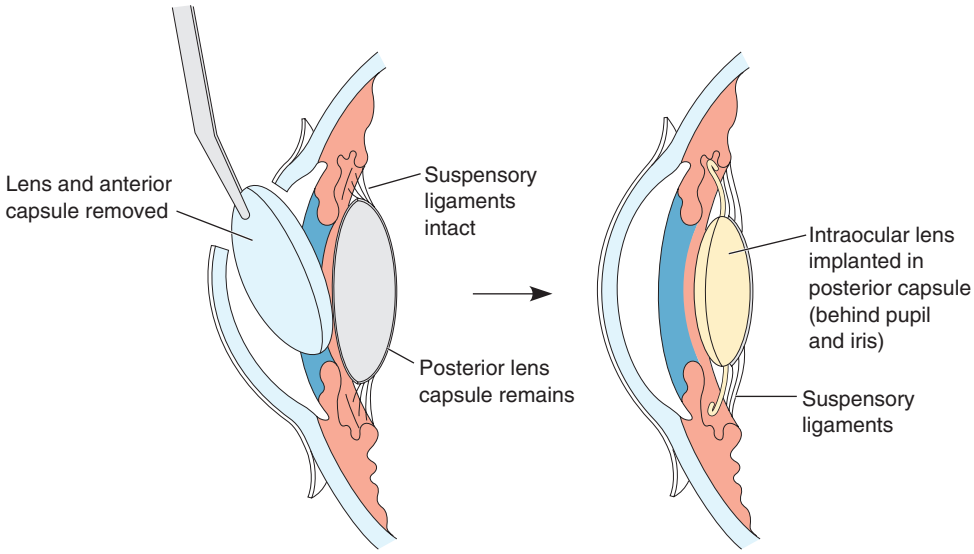


FIGURE 45.8 ■ Extracapsular cataract extraction with removal of the lens and anterior capsule, leaving the posterior capsule intact. The intraocular lens is implanted within the posterior capsule

are affected. A mature cataract may also be removed when it causes a secondary condition such as glaucoma or uveitis.

Cataract surgery is usually done on a day surgery basis, using local anaesthesia. If general anaesthesia and/or sedation is required, the person may be hospitalised overnight. Extracapsular extraction, in which the anterior capsule, nucleus and cortex of the lens are removed, leaving the posterior capsule intact, is the procedure of choice (see Figure 45.8). Using an operating microscope, the surgeon makes a small incision at the edge of the cornea and extracts the lens intact or via emulsification and aspiration. In the latter technique, ultrasound vibrations are used to break the lens material into fragments (phacoemulsification), which are then suctioned out of the eye. The remaining capsule supports the lens implant and protects the retina.

After removal of the lens, the eye can no longer focus light on the retina and vision is seriously affected. Usually a polymethylmethacrylate (PMMA or Plexiglas) intraocular lens is implanted at the time of surgery. This implant rapidly restores binocular vision and depth perception. Following extracapsular lens removal, the intraocular lens is positioned in the posterior capsule behind the iris (see Figure 45.8).

If an intraocular lens cannot be implanted, convex corrective glasses or contact lenses may be used to correct vision after cataract removal. Although contact lenses can provide excellent vision correction following cataract surgery, they may be difficult for some people to adapt to or manipulate. The person with a pre-existing refractive error may continue to require corrective lenses and often needs a prescriptive change even after surgery.

Complications of cataract surgery are unusual and occur in less than 1% of the surgeries. Loss of vitreous humour, corneal oedema, increased intraocular pressure, haemorrhage, inflammation or infection, retinal detachment and displacement of the implanted lens are considered potential complications. Up to 35% of people who undergo extracapsular extraction may develop opacification of the remaining posterior capsule. Vision can be restored using laser capsulotomy (creating an opening for light to pass through the opacified capsule) or surgical incision into the posterior capsule to allow light to reach the retina (Rothrock, 2011).

Nursing care

Health promotion

Advise all people about the importance of protecting the eyes from UVB rays by wearing eye protection during activities such as welding and when outdoors. Discuss the link between heavy smoking and cataract development, and provide necessary education and resources to young people regarding the additional effects of smoking.

Assessment

- *Health history:* effect of vision changes on lifestyle and activities (e.g. ability to read, watch television, participate in work and recreational activities); history of smoking, diabetes, use of prescription drugs associated with increased risk of cataract.
- *Physical examination:* general health; visual acuity (using corrective lenses and Snellen chart) in each eye; presence of red reflex.

Nursing diagnoses and interventions

The person with cataracts has few physical care nursing requirements. Patient advocacy, psychological and emotional

support, and education are typically of higher priority for these people. (See 'Nursing care of the person having eye surgery' in the earlier box.)

Decisional conflict: cataract removal

With the initial diagnosis of a cataract, the nurse often becomes an important information resource for the person.

- Explain the non-emergent nature of the condition and help the person determine the extent to which the cataract is affecting daily life. *Providing information about cataracts and their surgical removal assists with decision making and helps the person decide whether to proceed with the surgery.*
- Attend to verbalised concerns about surgery and its outcome. Address questions factually and completely. Fear of blindness is second only to fear of cancer for many people. *Careful listening, education and a caring, understanding attitude can help the person deal with possible fear prior to surgery.*

Risk of ineffective therapeutic regimen management

- Assess for factors that may interfere with the person's ability to be self-caring in the postoperative phase. *A chronic condition such as arthritis may affect the ability to administer eye drops and may indicate the need to include the education and support of a family member.*
- Assess for additional care needs that may be necessitated by vision changes in the early postoperative period. *Additional needs, such as insulin injections, may suggest the requirement for additional home or nursing care postoperatively.*

Community-based care

Following the initial diagnosis, the focus is on education, indications for surgery and vision restoration following cataract removal. Provide adaptive strategies to deal with effects of the cataract on vision and depth perception. When surgery is scheduled, provide pre- and postoperative education and include a significant other in the sessions. Reinforce the following information with written instructions:

- limitations such as avoiding reading, lifting, strenuous activity and sleeping on operative side
- importance of not disturbing the eye dressing
- importance of not rubbing or scratching the eye
- prescribed medications and side effects
- importance of follow-up appointments
- manifestations of postoperative complications such as eye pain, decreased visual acuity or other change in vision, headache, nausea or itching and redness of the affected eye
- instillation of eye drops and application of eye patch or shield
- care, insertion and removal of contact lenses as appropriate
- visual changes associated with thick-lensed eyeglasses as appropriate.

THE PERSON WITH GLAUCOMA

Glaucoma is a condition characterised by optic neuropathy with gradual loss of peripheral vision and, usually, increased intraocular pressure. Glaucoma is a silent thief of vision in that the person typically experiences no manifestations other than narrowing of the visual field, which occurs so gradually that it often goes unnoticed until late in the disease process.

Incidence and risk factors

Glaucoma affects over 300 000 Australians aged over 60 and is the leading cause of blindness worldwide. The limited data available to date highlight the prevalence of glaucoma in the older generation of Indigenous Australians.

Glaucoma is usually a primary condition without an identified cause. Primary glaucoma is most common in adults over the age of 60; however, it may be a congenital condition in infants and children. Secondary glaucoma can develop as a result of infection or inflammation of the eye, cataract, tumour, haemorrhage or eye trauma.

Pathophysiology

The aqueous humour occupies both the anterior and posterior chambers of the eye. The normal intraocular pressure of approximately 10 to 20 mmHg is maintained by a balance between the production of aqueous humour in the ciliary body, its flow through the pupil from the posterior to the anterior chamber of the eye and its outflow or absorption through the trabecular meshwork and canal of Schlemm (see Figure 44.3). If the balance is disrupted, due to a decrease in the outflow or absorption of aqueous humour, the intraocular pressure increases. Although the exact relationship is unclear, it appears that increased intraocular pressure injures the optic nerve. Axons in the periphery of the optic disc are damaged first. As optic fibres are destroyed, the rim of the optic disc shrinks and the normal depression in its centre (the *optic cup*) becomes larger and deeper (called optic 'cupping'). These changes to the optic disc are visible before visual field changes can be detected. As the disease progresses, there is a painless, progressive narrowing of the visual field (see Figure 45.9) and eventual blindness. Vision loss is often significant before the person seeks treatment and glaucoma is diagnosed.

Primary glaucoma in adults has two main forms: open-angle and angle-closure glaucoma. Both terms refer to the angle formed at the point where the iris meets the cornea in the eye's anterior chamber (see Figure 45.10). Forms of primary glaucoma are compared in Table 45.2.

Open-angle glaucoma

Open-angle glaucoma, often called chronic simple glaucoma, is the most common form of glaucoma in adults, accounting for approximately 90% of all glaucoma. Its cause is unknown; it is thought to have a hereditary component, but no clear inheritance pattern can be identified.

In open-angle glaucoma, the anterior chamber angle between the iris and cornea is normal (see Figure 45.10A);

FIGURE 45.9 ■ Narrowing of visual fields typical of untreated glaucoma

Source: Courtesy of National Eye Institute, National Institutes of Health (NEI/NIH).

hence the term *open angle*. However, the flow of aqueous humour through the trabecular meshwork and into the scleral venous sinus is relatively obstructed: the cause of this obstruction is unknown. Restricted outflow leads to an increased amount of fluid in the eye and increased intraocular pressure. Open-angle glaucoma tends to be a chronic, gradually progressive disease. The trabecular meshwork increasingly inhibits the outflow of aqueous humour and the intraocular pressure gradually increases. The result is neuronal ischaemia and optic nerve degeneration, leading to gradual loss of vision.

Open-angle glaucoma typically affects both eyes, although the pressures and progression may not be symmetrical.

MANIFESTATIONS Open-angle glaucoma is painless, with gradual loss of visual fields. The loss of peripheral vision generally is so gradual that the person is often unaware of it until it is detected through a comprehensive vision examination. Intraocular pressure is usually, but not always, elevated (Horton, 2012).

Angle-closure glaucoma

Acute angle-closure (also called narrow-angle or closed-angle) glaucoma is a less common form of primary glaucoma in adults. It accounts for approximately 5–10% of all cases of glaucoma (Grossman & Porth, 2014). Approximately 1% of people over the age of 40 have narrowed anterior chamber angles; the incidence is higher in older adults and in people of Far Eastern, Asian or Inuit ancestry (Riordan-Eva, 2012).

Narrowing of the anterior chamber angle (see Figure 45.10A for an illustration of the normal anterior chamber angle) occurs because of corneal flattening or bulging of the iris into the anterior chamber. When the lens thickens during accommodation, or the iris thickens during pupil dilation, this angle can close completely. Closure of the angle blocks the outflow of aqueous humour through the trabecular meshwork and scleral venous sinus, and the intraocular pressure rises abruptly (see Figure 45.10B). This abrupt increase in intraocular pressure damages the neurons of the retina and the optic nerve, leading to a rapid and permanent loss of vision if not treated promptly.

Episodes of angle-closure glaucoma are typically unilateral. However, a history of angle-closure glaucoma of one eye increases the risk that it will occur in the other eye.

Because of the effect of pupil dilation on aqueous outflow in angle-closure glaucoma, episodes often occur in association with darkness, emotional upset/stress or other factors that cause the pupil to dilate. People may have intermittent episodes

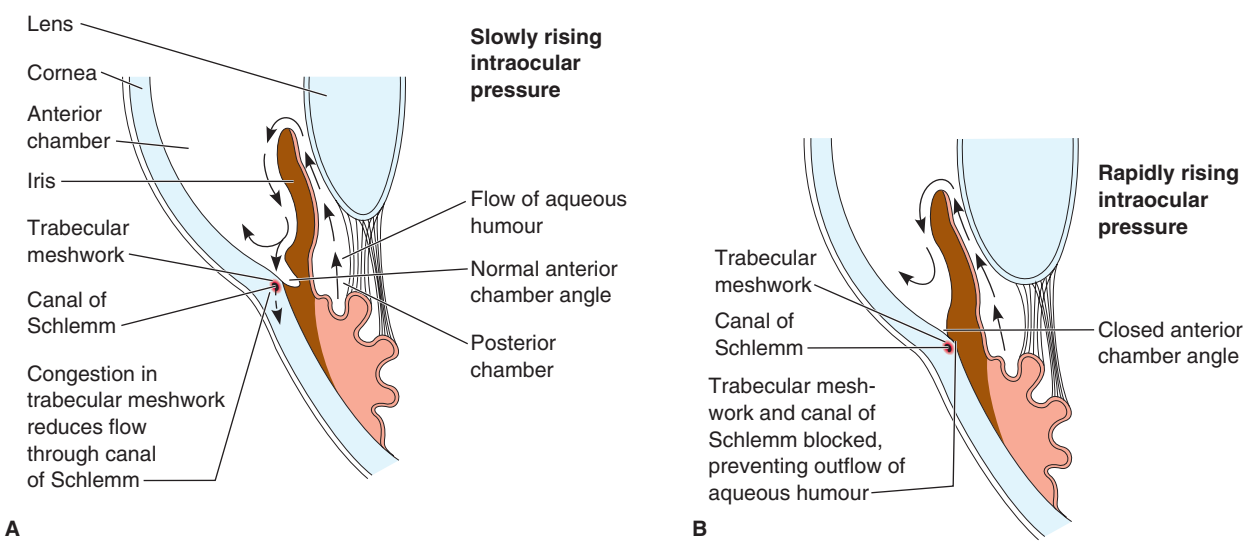

FIGURE 45.10 ■ Forms of primary adult glaucoma. *A*, In chronic open-angle glaucoma, the anterior chamber angle remains open, but drainage of aqueous humour through the canal of Schlemm is impaired. *B*, In acute angle-closure glaucoma, the angle of the iris and anterior chamber narrows, obstructing the outflow of aqueous humour

TABLE 45.2 A comparison of open-angle and angle-closure glaucoma

	OPEN-ANGLE GLAUCOMA	ANGLE-CLOSURE GLAUCOMA
Incidence	• Common • Accounts for 90% of all cases of glaucoma	• Uncommon
Risk factors	• Over age 40 • Genetic link	• Narrow anterior chamber angle • Ageing • Asian ancestry
Pathophysiology	• Impaired aqueous outflow through the scleral venous sinus • Damage to axons of retinal ganglion cells with optic nerve atrophy • Gradual, consistent increase in intraocular pressure • Usually bilateral	• Pupil dilation or lens accommodation causes already narrowed angle to close, blocking aqueous outflow • Rapid rise in intraocular pressure • Usually unilateral
Manifestations	• No initial manifestations • Frequent lens changes in glasses • Impaired dark adaptation • Halos around lights • Gradual reduction of visual fields with preservation of central vision until late in the disease • Mild to severe increased intraocular pressure	• Abrupt onset of eye pain, headache • Decreased visual acuity • Nausea and vomiting • Reddened conjunctiva • Cloudy cornea • Fixed pupil • Rapid, significant increase in intraocular pressure
Management	• Topical medications such as miotics, beta-blockers, prostaglandin analogues • Carbonic anhydrase inhibitors • Laser trabeculoplasty, trabeculectomy	• Topical miotics or beta-blockers • Systemic osmotic agents, carbonic anhydrase inhibitors • Laser iridotomy or peripheral iridectomy

lasting several hours before having a more typically prolonged attack of angle-closure glaucoma. For people with a history of the condition, it is vital to avoid medications such as atropine and other anticholinergics, which have a mydriatic or pupil-dilating effect.

MANIFESTATIONS Symptoms such as severe eye and face pain, general malaise, nausea and vomiting, seeing coloured halos around lights and an abrupt decrease in visual acuity are associated with acute episodes of angle-closure glaucoma. The conjunctiva of the affected eye may be reddened and the cornea clouded with corneal oedema, and the pupil may be fixed (non-reactive to light) at midpoint. Some people may experience periodic mild attacks, usually in the evening, with eye discomfort, impaired vision and coloured rings around lights.

INTERPROFESSIONAL CARE

Although glaucoma cannot be predicted, prevented or cured, in most cases it can be controlled and vision can be preserved if diagnosed early. Because open-angle glaucoma, the most prevalent type of glaucoma, has few symptoms, routine eye examinations are recommended for early detection. Measurement of intraocular pressure, fundoscopy to assess the optic disc and visual field testing are used for diagnosis and monitoring of treatment effectiveness.

Diagnosis

The following diagnostic studies are used to detect and evaluate for the presence, severity, type and effects of glaucoma:

- *Tonometry* indirectly measures intraocular pressure (see Figure 45.11). Contact or non-contact tonometry may be used. Routine tonometry screening is recommended for all people over the age of 60. A single elevated pressure reading does not warrant a diagnosis of glaucoma; variations in intraocular pressure occur throughout the day. See Chapter 44 for more information about tonometry.
- *Fundoscopy* (visual inspection of the optic fundus using an ophthalmoscope) identifies pallor and an increase in the size and depth of the optic cup on the optic disc. These changes are significant for diagnosing glaucoma.
- *Gonioscopy* uses a gonioscope to measure the depth of the anterior chamber. This test differentiates open-angle from angle-closure glaucoma.
- *Visual field testing* (see Figure 45.12) identifies the degree of central visual field narrowing and peripheral vision loss. The person with glaucoma may retain 6/6 central vision even though there is severe peripheral vision loss.

Medications

Although medications cannot cure glaucoma, many people with open-angle glaucoma can control intraocular pressure and preserve vision indefinitely with medications. Medications are used alone or in combination, with the timing and

FIGURE 45.11 ■ An eye professional uses a tonometer to indirectly measure the intraocular pressure of a person's eye

Source: Courtesy of National Eye Institute, National Institutes of Health (NEI/NIH).

FIGURE 45.12 ■ Visual field testing. Peripheral vision or visual fields are assessed by testing the person's ability to detect an object brought into the line of vision from the periphery. The person's peripheral vision is compared to the nurse examiner's. Each eye is tested separately

dosage individually determined by pressure measurements. The primary pharmacological agents used to treat glaucoma are topical beta-adrenergic blocking agents, adrenergics (mydriatics), prostaglandin analogues or carbonic anhydrase inhibitors. An oral carbonic anhydrase inhibitor also may be used.

Topical beta-adrenergic blocking agents decrease the production of aqueous humour in the ciliary body. Beta-adrenergic blockers can be used once or twice a day, depending on the drug and dosage form. When administering beta-blockers or teaching about their use, it is important to remember that ophthalmic preparations can produce systemic effects, including bronchospasm, bradycardia and heart failure.

Prostaglandin analogues are a newer class of ophthalmics prescribed to increase aqueous outflow. They are similar to beta-blockers in their longer duration of action, thus requiring only a daily dose. Although they have fewer systemic effects, these drugs may cause conjunctival hyperaemia and permanent changes in the colour of the iris and eyebrows.

An adrenergic agonist may be prescribed along with a beta-blocker, or, if beta-blockers are contraindicated (e.g. in a person with heart failure, asthma or chronic obstructive pulmonary disease (COPD)), another adrenergic agonist may be prescribed when other drugs do not sufficiently reduce intraocular pressure, but adverse effects make it inappropriate for long-term use (Riordan-Eva, 2012).

A carbonic anhydrase inhibitor decreases the production of aqueous humour and reduces intraocular pressure. It is used with other drugs to control pressures and in people for whom beta-blockers are contraindicated because of heart failure or reactive airway disease. A systemic carbonic anhydrase inhibitor also may be used for some people.

Nursing implications for the medications used to control chronic glaucoma are outlined in the 'Medication administration' box below.

In acute angle-closure glaucoma, diuretics may be administered intravenously to achieve a rapid decrease in intraocular pressure prior to surgical intervention. Carbonic anhydrase inhibitors and osmotic diuretics are used. Fast-acting miotic drops, such as acetylcholine, are also administered to constrict the pupil and draw the iris away from the angle and the scleral venous sinus.

Surgery

Surgical intervention is indicated for people with acute angle-closure and chronic open-angle glaucoma that is not effectively controlled by medication.

Surgical management of chronic open-angle glaucoma involves improving the drainage of the aqueous humour from the anterior chamber of the eye. Trabeculoplasty and trabeculectomy filtration surgery are the most commonly used procedures.

In a *laser trabeculoplasty*, an argon laser is aimed through a gonioscope to create multiple laser burns spaced evenly around the trabecular meshwork. As the burns heal, the scars they create cause tension, stretching and opening the meshwork. This non-invasive technique is the treatment of choice because it requires no incision and can be performed as an outpatient procedure.

Trabeculectomy is a type of filtration surgery in which a permanent fistula is created to drain aqueous humour from the anterior chamber of the eye. A portion of trabecular meshwork is removed and a flap of sclera is left unsutured to create a channel or fistula between the anterior chamber and the subconjunctival space. Aqueous humour is able to drain into the space under the conjunctiva, where it can be absorbed into the systemic circulation. A trabeculectomy is usually performed under general anaesthesia and requires hospitalisation.

MEDICATION ADMINISTRATION The person with glaucoma

ADRENERGIC AGONISTS (MYDRIATICS)

Brimonidine
Apraclonidine

Adrenergic agonists dilate the pupil, reduce the production of aqueous humour and increase its absorption, effectively reducing intraocular pressure in open-angle glaucoma.

Nursing responsibilities

- Assess the person for contraindications and adverse reactions to adrenergic agonists, including acute angle-closure glaucoma, hypertension, cardiac arrhythmias and coronary heart disease.
- Assess for central nervous system side effects of anxiety, nervousness and muscle tremors. If these side effects are severe, notify the doctor.
- Assess for a hypersensitivity reaction, including itching, lid oedema and discharge from the eyes. Notify the doctor if you notice these signs.

Health education for the person and family

- Report any change in visual acuity or eye pain. (Eye pain may indicate an attack of angle-closure glaucoma and must be reported to the doctor immediately.)
- Avoid over-the-counter sinus and cold medications containing pseudoephedrine and phenylephrine, as they may accentuate the side effects of this drug.

BETA-ADRENERGIC BLOCKERS

Betaxolol
Carteolol
Levobunolol
Metipranolol
Timolol

Selected beta-adrenergic blockers reduce intraocular pressure by decreasing the production of aqueous humour. Because beta-blockers do not affect pupil size and lens accommodation, they do not have the adverse effects on visual acuity that adrenergic agonists do. Their systemic effects, however, may limit their usefulness for certain people.

Nursing responsibilities

- Assess the person for allergies or contraindications to beta-blocker therapy, including asthma, COPD, heart block and heart failure.
- Maintain pressure over the lacrimal sac after administration to prevent systemic absorption.
- Assess for side effects such as bradycardia, hypotension and depression.
- Educate about the drug, its dose, administration and desired and side effects.

Health education for the person and family

- After instilling the eye drops, put pressure on the lacrimal sac, at the corner of the eye near the bridge of the nose, to keep the drug from entering your system.
- Your vision may be blurred during the initial period of therapy, but it will improve as you continue to use the drug.
- Report adverse effects, including worsening vision, difficulty breathing, reduced exercise tolerance and sweating or flushing, to the doctor.

CARBONIC ANHYDRASE INHIBITORS

Dorzolamide
Brinzolamide
Acetazolamide (most common)

The carbonic anhydrate inhibitors lower intraocular pressure and are used primarily as adjunctive therapy. Dorzolamide and brinzolamide are administered as eye drops; acetazolamide may be given PO, IM or IV in glaucoma emergencies.

Nursing responsibilities

- Assess for allergies or other contraindications to the use of carbonic anhydrase inhibitors, including known allergy to sulfur or severe kidney or hepatic disease.
- Monitor for increased drug interactions of amphetamines, procainamide, quinidine, tricyclic antidepressants, and ephedrine and pseudoephedrine.
- Assess daily weight, intake and output, serum electrolytes and vital signs in people taking oral or parenteral carbonic anhydrase inhibitors.
- Administer PO in the morning to prevent sleep disruption because of the diuretic effect.
- If used with another topical ophthalmic, administer 10 minutes apart.
- Educate the person about the drug, its dose, administration and desired and side effects.

Health education for the person and family

- For oral medications, maintain a fluid intake of 2 to 3 L per day and rise slowly from lying or sitting positions because you may feel dizzy when you first stand (orthostatic hypotension).
- For topical medications, notify the doctor if you have prolonged eye irritation.

PROSTAGLANDIN ANALOGUES

Bimatoprost
Latanoprost
Travoprost

The prostaglandin analogue drugs relax the ciliary muscle, improving the outflow of aqueous humour and reducing intraocular pressure. These drugs have the advantage of requiring only a single daily dose; however, they do have some adverse effects such as blurred vision and stinging and, when used long term, cause permanent darkening of the iris of the eye and eyebrows, increased growth of eyelashes and conjunctival hyperaemia (redness).

Nursing responsibilities

- Assess and note eye colour, presence of inflammation, exudates or pain.
- Note vital signs and most recent liver function test results because these may be altered by the drug.

Health education for the person and family

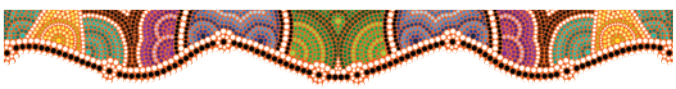
- Use once daily at bedtime as directed. This drug may blur vision; use at bedtime minimises associated safety risks.
- Remove contact lenses before administering this drug.
- Minor eye discomfort, including burning and tearing, may occur with this drug. Notify your doctor if adverse effects are severe or intolerable.
- This drug may cause darkening of your iris, the skin around the eyes and the eyebrows, as well as increased growth of the eyelashes. These colour changes are permanent and will not progress if the drug is discontinued by your doctor.

If these procedures are not fully effective, either photocoagulation using an argon laser (heat) or cyclocryotherapy using a probe to freeze tissue may be employed to destroy portions of the ciliary body. This tissue destruction reduces the production of aqueous humour, subsequently reducing intraocular pressure. Another surgical procedure involves insertion of a glaucoma drainage device that regulates the outflow of aqueous humour.

Surgical procedures used in the treatment of acute angle-closure glaucoma include gonioplasty, laser iridotomy and peripheral iridectomy. Because of the high risk of a future attack of angle-closure glaucoma in the unaffected eye, these procedures are often performed prophylactically.

In *gonioplasty*, the healing and scarring of microscopic lesions created at the periphery of the iris draws the iris away from the cornea, widening the anterior chamber, increases the angle and opens drainage channels for the aqueous humour.

Laser iridotomy is a non-invasive procedure using a laser to create multiple small perforations in the iris of the eye. These perforations allow aqueous humour to drain from the posterior chamber to the anterior chamber, and out through the trabecular meshwork and the scleral venous sinus. During an *iridectomy*, a small segment of the iris is removed to facilitate the flow of aqueous humour between the posterior and anterior chambers and to open the anterior chamber angle.



Nursing care

When planning and providing nursing care for the person with glaucoma, both the specific form of the disease and its actual or potential effects on the person's vision, lifestyle, safety and psychosocial wellbeing must be considered. In the hospitalised person, glaucoma is typically a concurrent diagnosis rather than the primary reason for seeking care, unless the diagnosis is acute angle-closure glaucoma. For additional nursing activities for the person with glaucoma, see the accompanying nursing care plan.

Health promotion

Although glaucoma cannot be prevented, its severity and potentially deleterious permanent effects can be limited with early visual screening. The nurse assumes an important role in educating the public about the risk factors for glaucoma, such as increased age and the higher incidence in certain cultures. All people over the age of 40 are encouraged to receive an eye examination every 2 to 4 years, including tonometry screening. Those with a predominant family history should be evaluated more frequently, every 1 to 2 years. After the age of 65, yearly ophthalmological examinations are recommended.

Assessment

Collect the following data through a health history and physical examination (see Chapter 44).

- *Health history:* family history; presence of altered vision, halos and excessive tearing; sudden, severe eye pain; use of corrective lenses; most recent eye examination.
- *Physical examination:* distant and near vision, peripheral fields and retina for optic nerve cupping.

Nursing diagnoses and interventions

Nursing care planning focuses on problems associated with the temporary or permanent visual impairment, the resultant increased risk of injury and the psychosocial problems of anxiety and coping.

Disturbed visual perception

Whether glaucoma and resulting impaired vision is the person's primary problem or a pre-existing condition in a person with another disorder, it must be a primary consideration in nursing care planning.

- Establish rapport with the person. Orient to time, place, person and situation as indicated. State the purpose of your visit. *The person with impaired vision must rely on input from the other senses. A lack of visual cues increases the importance of verbal ones. For example, the person with impaired vision cannot see the nurse checking an intravenous infusion and needs a verbal explanation of who is in the room and why. When the person's normal daily routine is disrupted by illness or hospitalisation, additional sensory input such as a radio or television, and explanations of the routine and activities, are useful to maintain the person's orientation.*
- Provide any visual aids that are routinely used. Keep them close, making sure that the person knows where they are and can reach them easily. *Easy access encourages the person to use these items and enhances the ability to provide self-care.*
- Orientate the person to the environment. Explain the location of the call bell, personal items and the furniture in the room. If able, tour the person's room, including the bathroom and sink. *People with visual impairments are usually very capable of providing self-care in a known environment.*
- Provide other tools or items that can help compensate for diminished vision:
  a. bright, non-glare lighting
  b. books, magazines and instructions in large print
  c. books on tape, CD or MP3 player
  d. telephones with oversized pushbuttons
  e. a clock with numbers and hands that can be felt.
- Assist with meals by:
  a. reading menu selections and marking choices
  b. describing the position of foods on a meal tray according to the clock system—for example, 'On the plate, the peas are at 9 o'clock, the mashed potatoes at 1 o'clock and the chicken breast at 6 o'clock. The water glass is at 2 o'clock on the tray above the plate and coffee is at 11 o'clock'
  c. placing the utensils in a readily accessible position
  d. removing lids from containers, buttering bread and cutting meat, as needed
  e. if the visual impairment is new or temporary, the person may need feeding or continued assistance during the meal.

NURSING CARE PLAN A person with glaucoma and cataracts

Lila Rainey is an 80-year-old widow who lives alone in the house she and her late husband built 50 years ago. She has worn glasses for myopia since she was a young girl and now wears bifocals to correct her near vision as well. She was diagnosed 4 years ago with chronic open-angle glaucoma, for which she takes timolol maleate 0.5%—one drop in each eye twice a day. Recently she has noticed difficulty reading and watching television despite a new lens prescription. She has stopped driving at night because the glare of oncoming headlights makes it difficult for her to see. Mrs Rainey's ophthalmologist has told her that she has cataracts but that they do not need to come out until they bother her. Although her glaucoma is still controlled by the medication, her intraocular pressure measurements have been gradually increasing. Mrs Rainey has taken 325 mg of aspirin daily since a transient ischaemic attack 8 years ago. She is being admitted to the outpatient surgery unit for a cataract removal and intraocular lens implant in her right eye.

ASSESSMENT

Mrs Rainey is admitted to the eye surgery unit by Susan Schafer, RN. In her assessment, Ms Schafer finds Mrs Rainey to be alert and oriented, though apprehensive about her upcoming surgery. Assessment findings include BP 134/72, P 86 and R 18. Mrs Rainey's neurological, respiratory, cardiovascular and abdominal assessments are essentially normal. Her pupils are round, equal and react briskly to light and accommodation. Her conjunctiva are pink; sclera and corneas, clear. Using the ophthalmoscope, Ms Schafer notes that the red reflex in Mrs Rainey's right eye is diminished. Ophthalmic examination shows visual acuity of 6/45 OD (right eye) and 6/15 OS (left eye) with corrective lenses. Her intraocular pressures are 21 mmHg OD and 17 mmHg OS. On fundoscopic exam, no disease of the blood vessels, retina, macula or disc is found. Ms Schafer reviews the operative procedure with Mrs Rainey, answering her questions and advising what to expect after surgery. Following preoperative protocols, Mrs Rainey is prepared and transported to surgery.

NURSING DIAGNOSIS

- *Risk of disturbed visual perception* related to myopia and lens extraction.
- *Risk of anxiety* related to anticipated surgery.
- *Risk of knowledge deficit* related to lack of information regarding postoperative care.
- *Risk of impaired home maintenance* related to activity restrictions and impaired vision.

PLANNING

- Provide a safe environment, placing the call bell and personal care items within easy reach.
- Encourage Mrs Rainey to express her fears about surgery and its potential effect on vision.
- Explain all procedures related to surgery and recovery.

Expected outcomes

- To regain sufficient visual acuity to maintain ADLs, including reading and watching television for enjoyment.
- Demonstrate the procedure for instilling eye drops postoperatively.
- Demonstrate knowledge of the home care she will require after surgery, signs of complications and actions to take if complications occur.
- Use appropriate resources to assist with home maintenance until vision stabilises and activity restrictions are lifted.
- Demonstrate a reduced level of anxiety.

IMPLEMENTATION

- Instruct her to avoid shutting her eyelids tightly, sneezing, coughing, laughing, bending over, lifting or straining to have a bowel movement. Educate her to wear glasses during the day and an eye shield at night to prevent injury to the surgical site.
- Explain and demonstrate the procedure for administering eye drops.
- Provide verbal and written instructions about postoperative care, including a schedule of follow-up examinations, potential complications and actions to take in response.
- Refer Mrs Rainey to a discharge planner or social worker to help establish a plan for home maintenance as required.

EVALUATION

Mrs Rainey is discharged the morning after her surgery. She is visibly relieved when the eye patch is removed because her vision in the operated eye is better than before surgery, even without her glasses. She is able to relate the recommended activity restrictions. Mrs Rainey administers her own eye drops before discharge and relates an understanding of the prescribed postoperative care and safety precautions. Mrs Rainey's daughter plans to visit her mother two to three times a week to help with laundry and vacuuming until she is able to resume all her household activities. Mrs Rainey says that she will not 'be so scared when I need my other eye done'. She understands the chronic nature of her glaucoma and states that her vision is too important for her to neglect her timolol drops and routine eye exams.

CRITICAL THINKING IN THE NURSING PROCESS

1. Why did it become more difficult to control Mrs Rainey's intraocular pressure as her cataract matured?
2. Identify medications that are commonly prescribed following cataract surgery. What are the risks of interactions between these medications and Mrs Rainey's timolol drops?
3. Develop a care plan for the nursing diagnosis *Self-care deficit: dressing/grooming*, related to visual impairment and restricted bending.

REFLECTION ON THE NURSING PROCESS

1. Outline what you have learned from the case study and how this applies to your future practice.
2. What communication strategies could you use when caring for a person experiencing issues with their vision?

Providing assistance during meals is important to maintain the person's nutritional status. The person may be ashamed of needing help or embarrassed to request it, and may respond by not eating or by claiming not to be hungry.

- Assist with mobility and ambulation as needed:
  a. Have the person hold your arm or elbow and walk slightly ahead as a guide. Do not hold the person's arm or elbow.
  b. Describe the surroundings and progress as you proceed. Warn in advance of potential hazards, turns and steps.
  c. Educate on how to feel the chair, bed or commode with the hands and the back of the legs before sitting.

  These measures help ensure the person's safety while providing for mobility and helping prevent complications associated with immobility.
- If the vision loss is unilateral and recent, provide instructions related to this loss and change in depth perception:
  a. Caution about the loss of depth perception and educate about safety precautions, such as reaching slowly for objects and using visual cues for distance, especially when driving.
  b. Educate the person to scan their environment, turning the head fully towards the affected side to identify potential hazards and looking up and down to compensate for the loss of depth perception.

  The person with a unilateral vision loss is often unaware of its effects on peripheral vision and depth perception.

Risk of injury

Whether the person is experiencing a sudden loss of vision due to acute angle-closure glaucoma or significant visual impairment due to inadequately managed chronic glaucoma, both are at an increased risk of injury. People who have had surgical interventions for glaucoma are at even greater risk.

- Assess ability to perform ADLs. People may be reluctant to request assistance, believing that they should be able to perform these familiar tasks. *Careful assessment and provision of needed assistance help prevent injury and maintain the person's self-esteem and confidence.*
- Notify all staff and place a sign on the person's door to alert all personnel not to change the arrangement of the person's room. *The person with impaired vision is at high risk of falling when in an unfamiliar environment. It is important to maintain a safe, familiar room when the person is hospitalised.*
- Raise the person's side rails on their bed. *Raised rails remind people to ask for assistance before ambulating in an unfamiliar environment.*
- Discuss possible adaptations in the home to help the person remain as independent as possible and prevent falls or other injuries. *Often minor changes in the home environment, such as removing scatter rugs and small items of furniture, allow the person to navigate safely in this already familiar environment.*

CONSIDERATION FOR PRACTICE

Keep traffic areas free of clutter to reduce the risk of injury in people with impaired vision.

Anxiety

The actual or potential loss of sight threatens the person's self-concept, role functioning, patterns of interaction and, potentially, environment. The person with impaired vision who functions well in a familiar environment will feel anxious in the unfamiliar setting of a hospital or care facility.

- Assess for verbal and non-verbal indications of anxiety levels and for normal coping mechanisms. Repeated expressions of concern or denial that the vision change will affect the person's life indicate anxiety. Non-verbal indicators include tension, difficulty concentrating or thinking, restlessness, poor eye contact and changes in vocalisation (rapid speech, voice quivering). Physical indicators include tachycardia, dilated pupils, cool and clammy skin, and tremors. *The person may not recognise this feeling as anxiety. Identifying and acknowledging the anxiety state can help the person recognise and deal with it.*
- Encourage to verbalise fears, anger and feelings of anxiety. *Verbalising helps externalise the anxiety and allows fears to be addressed.*
- Discuss perception of the eye condition and its effects on lifestyle and roles. *Discussion provides an opportunity to correct misperceptions and introduce alternative activities and assistive devices for people with visual impairments.*
- Establish rapport with the person by explaining all procedures fully before and as they are being performed, and use touch to convey proximity and caring. *The person with impaired vision must rely on the other senses to make up for the loss of sight. Because the person cannot see what you are doing, complete explanations of even simple tasks such as refilling a water glass help to relieve anxiety.*
- Identify coping strategies that have been useful in the past and adapt these strategies to the present situation. *Previously successful coping strategies may be employed to increase the person's sense of control.*

Community-based care

People with glaucoma require education about lifetime strategies for managing the disease at home. They need to understand the importance of lifetime therapy to control the disease and prevent blindness. If a permanent visual impairment has resulted, the person needs information on achieving the maximum possible independence while maintaining safety. The following topics should be discussed with the person and family:

- prescribed medications, including proper way to instil eye drops
- importance of not taking certain prescription and over-the-counter medications without consulting a doctor
- periodic eye examinations with intraocular pressure measurement

- risks, warning signs and management of acute angle-closure glaucoma
- possible surgical options
- available state and territory community resources.

THE PERSON WITH AGE-RELATED MACULAR DEGENERATION

In Australia, age-related **macular degeneration** (AMD) is the second most common eye disease that causes visual impairment after cataracts.

FAST FACTS

The total cost of vision loss associated with AMD in Australia was estimated at $5 billion in 2010. In 2010, there were approximately 1 million Australians with AMD, equivalent to one in seven people over the age of 50. This could reach almost 2 million by 2030 (Deloitte Access Economics & Macular Degeneration Foundation, 2011).

Although the exact cause of AMD is unknown, factors associated with it include ageing, smoking, race and, possibly, genetic factors and cultural background. The destructive changes in the macula occur most often as a response to the ageing process. AMD affects males and females equally. Recent evidence suggests that inflammation plays a role in the development of AMD (Horton, 2012) as does the interaction of certain genes with the immune system (NEI, 2012c). Evidence suggests that the risk of developing AMD may be reduced by consumption of omega-3 fatty acids in fish, and vegetables high in lutein and zeaxanthin (carotenoids found in vegetables such as spinach, kale and broccoli).

Pathophysiology

The macula is the area of the retina that provides sharp central vision, receiving light from the centre of the visual field. Two forms of AMD identified are non-exudative (dry) and exudative (wet). Although both are progressive disorders, their manifestations and management differ.

Non-exudative or *dry macular degeneration* is the more common form of AMD. It is a gradual process that begins with accumulation of deposits called *drusen* beneath the pigment epithelium of the retina. Over time, these deposits enlarge and become more numerous. The pigment epithelium detaches in small areas and becomes atrophic, interfering with sensory function of the macula. Vision loss typically is not significant and the disorder progresses slowly. There is, however, a risk that the disorder will progress to the exudative stage of the disease.

Exudative macular degeneration is characterised by the formation of new, weak blood vessels in the potential space between the choroid (vascular layer of the eye) and the retina (neurosensory layer). These new vessels are prone to leak, elevating the retina from the choroid and distorting vision. Although exudative macular degeneration typically is a gradual process, bleeding can lead to acute vision loss in some cases. With significant or repeated bleeding episodes, scar tissue forms and central vision is permanently lost (Horton, 2012).

Manifestations

When the macula is damaged, central vision becomes blurred and distorted, but peripheral vision remains intact. Distortion of vision in one eye is a common initial manifestation; straight lines appear wavy or distorted. With the loss of central vision, activities that require close central vision, such as reading and sewing, are particularly affected (see Figure 45.13).

INTERPROFESSIONAL CARE

Age-related macular degeneration is diagnosed through vision and retinal examination. The Amsler grid (see Figure 44.5) may be used to identify distortion of central vision caused by AMD. If treatment for wet AMD is planned, a *fluorescein angiogram* may be done. Pictures are taken as the dye passes through the blood vessels of the retina, allowing detection of leaks.

In its early or intermediate stages, the progress of dry AMD can be slowed through the use of high-dose antioxidants and zinc. Research demonstrated a benefit when vitamins C and E, beta-carotene (vitamin A), zinc and copper were administered daily.

Wet AMD is treated with laser surgery or photodynamic therapy. Although these treatments do not cure the disease, they may slow the rate of vision loss. In laser surgery, fragile blood vessels are destroyed, preventing bleeding. There is a risk, however, of damage to surrounding healthy tissue, some vision loss and continued growth of new vessels. In photodynamic therapy, verteporfin, a drug that tends to adhere to the surface of new blood vessels, is injected systemically. Light is

FIGURE 45.13 ■ Loss of central vision with advanced age-related macular degeneration

Source: Courtesy of National Eye Institute, National Institutes of Health (NEI/NIH).

then shined into the affected eye, activating the drug and destroying new blood vessels. This treatment is relatively fast and painless, but does require avoidance of exposure to direct sunlight or bright indoor light for 5 days following treatment (NEI, 2013a).

Large-print books and magazines, the use of a magnifying glass and high-intensity lighting can help the person to cope with the reduced vision of macular degeneration.

Nursing care

Nurses should be alert for people demonstrating new and rapid onset manifestations of macular degeneration and promptly refer these people for ophthalmological evaluation. Early intervention may preserve a greater degree of vision and slow the progress of the disease. For people with slowly progressive manifestations, the nursing focus is on helping the person and family members adapt to the gradual decline in vision by recommending visual aids and other coping strategies. Person education materials should be in a large-print format. See also the accompanying 'Translation to practice' box.

THE PERSON WITH DIABETIC RETINOPATHY

Diabetic retinopathy is a vascular disorder affecting the capillaries of the retina. The capillaries become sclerotic and lose their ability to transport sufficient oxygen and nutrients to the retina.

The risk of developing diabetic retinopathy is related to the duration of the diabetes and the degree of glycaemic control. Hypertension also is a risk factor (Powers, 2012). Retinopathy is seen in both type 1 and type 2 diabetes. Nursing care of the person with diabetes is discussed in Chapter 19.

FAST FACTS

- In Australia, diabetic retinopathy is the third most common eye disease that causes visual impairment after cataracts and age-related macular degeneration.
- People with diabetes are 25 times more likely to become legally blind than people unaffected by the disease (Powers, 2012).

Pathophysiology and manifestations

Diabetic retinopathy progresses through four stages: (1) mild *non-proliferative* or background retinopathy, (2) moderate non-proliferative retinopathy, (3) severe non-proliferative retinopathy, and (4) *proliferative* retinopathy (NEI, 2013b). Non-proliferative retinopathy is typically the initial form seen. The venous capillaries of the eye dilate and develop microaneurysms that may then leak,

TRANSLATION TO PRACTICE Evidence-based practice: the person with impaired vision

Age-related macular degeneration is the leading cause of significant visual impairment among older adults. However, little research has been done to study the effect of visual impairment on the lives of older adults. Moore and Miller (2003) studied the lived experience of severe visual impairment for a group of older, community-dwelling men with AMD. While the lives of the men in the study tended to be somewhat defined by what they could and could not do, these men tended to express hope and optimism, focusing on remaining abilities and developing strategies to cope with vision loss. However, in contrast to the results of a similar study of older women with AMD, the men in this study expressed scepticism about their disorder and its prognosis, critically questioning treatment and consistency of the care received.

IMPLICATIONS FOR NURSING

Older adults with significant vision deficit continue to cherish their independence and focus on their remaining abilities (as opposed to their disabilities). While it is important to present clear, accurate and realistic information to people with irreversible vision impairment, maintenance of hope and optimism also is important to the older adult. Many people faced with impaired vision make conscious choices to maintain a positive attitude and lifestyle, developing strategies that allow them to continue with activities that are important to them or provide pleasure. The nurse can help support and encourage these choices and selection of positive behaviours to maintain independence and self-worth.

CRITICAL THINKING IN PERSON-CENTRED CARE

1. The men in this study cherished their freedom and found many ways to maintain it despite impaired vision. Discuss ideas to suggest for a person with impaired vision to continue to engage in activities such as shopping, attending cultural events and playing golf or participating in other sports.
2. The men participating in this study expressed more scepticism about their diagnosis and prognosis and criticism of their treatment than did older women with AMD who had participated in an earlier study. What factors might account for this difference? What implications could this difference have for nursing assessment and care?
3. Develop a teaching plan for a person with newly diagnosed AMD using the nursing diagnosis of *Deficient diversional activity* related to recent change in visual acuity.

causing retinal oedema; or they may rupture, causing small haemorrhages into the retina. On ophthalmoscopic examination, yellow exudates, cotton-wool patches indicative of retinal ischaemia and red-dot haemorrhages are observed (see Figure 45.14). When the peripheral retina is involved, the person may experience few symptoms other than light glare. Oedema of the macula or a large haemorrhage may cause vision loss.

Diabetic retinopathy may progress to the proliferative form. This disease is marked by large areas of retinal ischaemia and the formation of new blood vessels (neovascularisation) spreading over the inner surface of the retina and into the vitreous body. These vessels are fine and fragile, making them permeable and easily ruptured. Blood and blood protein leakage contribute to retinal oedema, and haemorrhage into the vitreous body may occur. The vessels gradually become fibrous and firmly attached to the vitreous body, increasing the risk of retinal detachment.

INTERPROFESSIONAL CARE

People with diabetes should be examined yearly by an ophthalmologist. The development of any new visual manifestations is an additional indication for prompt ophthalmological examination and possibly retinal angiography.

Laser photocoagulation is used to treat both the nonproliferative and proliferative forms of diabetic retinopathy. Leaking microaneurysms are sealed and proliferating vessels destroyed, reducing the risk of haemorrhage, retinal oedema and retinal detachment. This treatment also slows the progress of aneurysms and new vessel formation; however, it does not cure the disorder. People with severe proliferative retinopathy may undergo vitrectomy to remove vitreous haemorrhage or treat associated retinal detachments (Papadakis & McPhee, 2015). Although conclusive research is lacking, the diabetic person with retinopathy may be advised to avoid physical activity associated with the Valsalva manoeuvre (e.g. weight training) (Longo et al., 2012).

Nursing care

As with many other eye disorders, the nursing care focus for diabetic retinopathy is primarily educational. The newly diagnosed diabetic person needs to understand the importance of regular eye examinations, beginning approximately 5 years after the onset of type 1 diabetes and at the time of onset of type 2 diabetes. Changes of diabetic retinopathy may already be present when type 2 diabetes is diagnosed.

Educate the person to report promptly any new visual manifestation, including blurred vision; black spots (floaters), cobwebs or flashing lights in the visual field; or a sudden loss of vision in one or both eyes. Emphasise to the person that careful blood glucose control may help prevent diabetic retinopathy from developing; it may also slow its progress. The person's blood pressure should also be maintained within normal limits to prevent further damage to retinal vessels. Although diabetic retinopathy cannot be halted or cured, its progress can be slowed with aggressive management. Much of the burden for this management falls on the person, increasing the importance of good teaching.

THE PERSON WITH A RETINAL DETACHMENT

The retina contains the photoreceptors of the eye, which allow the perception of light and initial processing of images and stimuli for transmission to the optic centre of the brain. Disruption of this neural layer of the eye by trauma or disease interferes with light perception and image transmission, potentially resulting in blindness.

Both primary eye conditions and systemic diseases can affect the retina and interfere with vision.

Pathophysiology and manifestations

Separation of the retina or sensory portion of the eye from the choroid, the pigmented vascular layer, is known as a **retinal detachment**. Although retinal detachment may be precipitated by trauma, it usually occurs spontaneously. The vitreous humour normally adheres to the retina at the optic disc, the macula and the periphery of the eye. With ageing, the vitreous humour shrinks and may pull the retina away from the choroid. Ageing therefore is a common risk factor, as are myopia and aphakia—absence of the lens (e.g. following lens removal for cataracts) (Porth & Matfin, 2014; Papadakis & McPhee, 2015).

The retina may actually tear and fold back on itself, or may remain intact but no longer adhere to the choroid. A break or tear in the retina allows fluid from the vitreous cavity to enter the defect. This, along with fluid that escapes from choroid

vessels, the pull of gravity and traction exerted by the vitreous humor, separates the retina from the choroid. The detached area may rapidly increase in size, increasing loss of vision. Unless contact between the retina and choroid is re-established, the neurons of the retina become ischaemic and die, causing permanent vision loss. For this reason, retinal detachment is a true medical emergency, requiring prompt ophthalmological referral and treatment.

The person experiences floaters, 'spots', lines or flashes in the visual field when the retina detaches. Often the person describes the sensation of having a curtain drawn across the vision, much like a curtain being drawn over a window. The area of the visual field affected is directly related to the area of detachment. For example, because light rays cross as they pass through the lens, a retinal tear in the superior portion of the eye results in a deficit in the lower part of the visual field. The person feels no pain and the eye appears normal to visual inspection. Common manifestations of retinal detachment are listed in the box below.

MANIFESTATIONS Retinal detachment

- Floaters: irregular dark lines or spots in the field of vision.
- Flashes of light.
- Blurred vision.
- Progressive deterioration of vision.
- Sensation of a curtain or veil being drawn across the field of vision.
- If the macula is involved, loss of central vision.

INTERPROFESSIONAL CARE

Retinal detachment is a medical emergency; prompt treatment is necessary to preserve vision. The manifestations and examination of the ocular fundus by ophthalmoscopy establish the diagnosis of retinal detachment, as early diagnosis and intervention are vital. If the condition is left untreated, the detached portion will become necrotic because of separation from the vascular supply of the choroid. The result is permanent blindness in that portion of the eye. If an ophthalmologist is not readily available, the person's head is positioned so that gravity pulls the detached portion of the retina into closer contact with the choroid.

Interventions are directed towards bringing the retina and choroid back into contact and re-establishing the blood and nutrient supply to the retina. Either cryotherapy, using a supercooled probe, or laser photocoagulation may be used to create an area of inflammation and adhesion to 'weld' the layers together.

A surgical procedure called *scleral buckling* also may be used. In this procedure, an indentation or fold is created in the sclera, bringing the choroid into contact with the retina. Contact is maintained with a local implant on the sclera or an encircling strap or 'buckle'. Air may also be injected into the vitreous cavity, a procedure called pneumatic retinopexy. The person is positioned so that the air bubble pushes the detached portion of the retina into contact with the choroid.

With a retinal tear, it may be necessary to use surgical instruments to manipulate the detached section of retina into place. Air or a liquid is then injected into the vitreous to maintain retinal contact with the choroid or laser therapy is used to create a bond.

Nursing care

The nursing focus for the person with a detached retina is on early identification and treatment. Because early intervention is vital to preserve the person's sight, nurses must recognise early manifestations of retinal detachment and intervene appropriately to obtain definitive treatment for the person. Retinal detachment can be successfully treated on an outpatient basis, often in an ophthalmologist's office. For these people, the nursing focus is on education.

Ineffective retinal tissue perfusion

Restoring contact between the retina and choroid is a priority of nursing and medical care for the person with retinal detachment. Vitreous humour may leak through a retinal tear and fluid exudate may collect behind the tear, causing further detachment. If the macula is detached, central vision is lost and the prognosis for full vision restoration is poorer.

CONSIDERATION FOR PRACTICE

Carefully assess anyone who complains of a sudden rapid loss of vision because this often signals a medical emergency.

- Assess for other manifestations of eye disease. Retinal detachment is painless and has no outward manifestations. *The person with a red eye or cloudy cornea may be experiencing acute angle-closure glaucoma rather than retinal detachment.*
- Notify the doctor and ophthalmologist immediately. *Immediate medical intervention is required in people with retinal detachment to preserve vision.*
- Position so the area of detachment is inferior. For instance, for a superior temporal retinal detachment of the right eye (with corresponding vision loss in the inferior medial visual field of that eye), place supine with the head turned to the right. *Correct positioning allows the contents of the posterior portion of the eye to place pressure on the detached area, bringing the retina in closer contact with the choroid.*

Anxiety

Retinal detachment causes a rapid decline in vision in the affected eye, often occurring spontaneously and without pain. Unless previous episodes have occurred, the person usually does not know what is causing the problem. Anxiety and fear of complete vision loss are common, expected reactions.

- Maintain a calm, confident attitude while carrying out priority interventions. *Administering care in a calm, although urgent, manner helps reassure the person that the problem is treatable and that appropriate measures are being taken.*
- Reassure that most retinal detachments are successfully treated, usually on an outpatient basis. *Reassurance can help allay the person's fear of permanent vision loss.*
- For spontaneous detachments, assure the person that they did not cause the detachment to occur. *The person may believe that the detachment is related to a specific activity and feel guilty for 'causing' this loss of vision.*
- Explain all procedures fully, including the reason for positioning. *Explanations facilitate understanding and help relieve anxiety in unfamiliar settings.*
- Allow supportive family members or friends to remain with the person as much as possible. *Additional support helps lower the person's anxiety level.*

Community-based care

Teaching for the person undergoing surgical repair of retinal detachment is similar to that for people experiencing other types of eye surgery. If the retina remains detached, provide instructions about the change in peripheral vision or other visual fields, and changes in depth perception.

Discuss the following topics with the person and family to prepare for home care:

- limitations on positioning the head before or following repair
- activity restrictions such as no bending or straining at stool movement
- use of eye shield
- early manifestations and the importance of seeking immediate treatment
- follow-up treatment with the ophthalmologist.

THE PERSON WITH RETINITIS PIGMENTOSA

Retinitis pigmentosa is a hereditary degenerative disease characterised by retinal atrophy and loss of retinal function progressing from the periphery to the central region of the retina. It is inherited as an autosomal dominant, autosomal recessive or X-linked trait, and may be associated with other genetic defects (Longo et al., 2012; Porth & Matfin, 2014).

In retinitis pigmentosa, the genetic defect appears to cause production of an unstable form of rhodopsin, the receptor protein of rod cells in the retina. Rod cells degenerate, initially at the periphery of the retina. The areas of degeneration and cell death slowly expand, causing vision to narrow. Central vision is finally lost as well.

The initial manifestation of retinitis pigmentosa, difficulty with night vision, is often noted during childhood. As the disease progresses, there is slow loss of visual fields, photophobia and disrupted colour vision. The progression to tunnel vision and blindness is gradual; the person may be totally blind by age 40.

Currently, there is no effective treatment for retinitis pigmentosa. Research into defective rhodopsin holds future promise for the development of therapy that may at least slow its progress.

People with retinitis pigmentosa may benefit from low-vision aids, much like those for the person with macular degeneration. Additionally, information about the disease and its progress is vital so the person can plan for the eventual total loss of sight. People should be referred for genetic counselling prior to starting a family to determine the risk of transmitting the disease to their children.

THE PERSON WITH HIV INFECTION

More than 50% of people infected with the human immunodeficiency virus (HIV) develop an infectious or non-infectious ocular condition, generally as a late manifestation of the disease (Longo et al., 2012).

HIV retinopathy, seen as cotton-wool spots around the optic nerve, is the most common non-infectious ophthalmic lesion in AIDS. Cotton-wool spots indicate areas of retinal ischaemia. Microaneurysms and dot-, blot- or flame-shaped haemorrhages may also be seen in HIV retinopathy.

Neoplasms common in the person with AIDS can also affect the eye. Kaposi's sarcoma may affect the external surface or anterior segment of the eye or the eyelids. Kaposi's lesions vary in colour (red, brown or purple) and in size, shape and location. Conjunctival lesions resemble a benign subconjunctival haemorrhage. Kaposi's lesions of the lid may cause ptosis (drooping of the lid) and abnormal lid function. Vision or eye position and movement may be affected by the tumour or by the effect of increased intracranial pressure on the cranial nerves.

The most serious and frequent opportunistic eye infection associated with HIV infection is cytomegalovirus (CMV) retinitis. CMV retinitis generally develops when CD4 cell counts drop below 50 mL. Initially unilateral, CMV retinitis commonly progresses to become bilateral because of the systemic nature of the infection. CMV invades the retina of the eye directly, producing exudate and cotton-wool spots, haemorrhage, cell death and necrosis. Visual field deficits develop and can progress to eventual blindness.

Corneal ulcers from opportunistic bacterial, fungal, protozoal or viral infections are also associated with HIV infection. Toxoplasmic and fungal retinal infections may occur.

The person with an HIV-associated eye disorder may complain of a change in visual acuity, blurring, floaters or gaps in the field of vision. Extensive retinal damage may cause retinal detachment and symptoms of flashing lights, multiple floaters and a loss of vision. Because the observed changes in the retina are non-specific, it is important for the examining healthcare provider to know that the person is HIV positive in order to make an accurate diagnosis.

In addition to the general treatment of HIV infection with retroviral medications, specific therapies may be directed towards the ocular manifestations of the disease. CMV retinitis is commonly treated with the antivirals ganciclovir and foscarnet sodium.

Although treatment of ocular Kaposi's sarcoma is usually not indicated, conjunctival lesions may be excised for comfort or cosmetic reasons. Lid lesions may be treated with radiation or intralesional chemotherapy.

THE PERSON WITH AN ENUCLEATION

Occasionally, surgical removal of an eye is necessary because of trauma, infection, glaucoma, intractable pain or malignancy. This procedure is known as **enucleation**.

Enucleation is performed under local or general anaesthesia. After the globe is removed, the conjunctiva and eye muscles are sutured to a round implant inserted into the orbit to maintain its shape. A pressure dressing is left in place for 24 to 48 hours. The person is permitted out of bed on the day of surgery. Haemorrhage and infection are the most commonly seen complications.

Postoperative nursing care includes education, psychological support and observation for potential complications. The person may be instructed to apply warm compresses and instil antibiotic ointment or drops postoperatively.

Within 1 week, a temporary prosthesis called a conformer is fitted into the empty socket. The permanent prosthesis is individually designed to closely resemble the person's other eye. The prosthesis can be fitted 1 to 2 months after surgery. Often it is difficult to discern which eye is functional and which is the prosthesis. Procedure 45.1 outlines the proper way to remove and reinsert an eye prosthesis when the person is unable to do so.

PROCEDURE 45.1 Removing and reinserting a prosthetic eye

GATHER SUPPLIES

- Gloves
- Clean basin or plastic denture cup
- Sterile normal saline or soap and water for cleaning the prosthesis
- Gauze squares or cotton cloth for cleaning the socket
- A bulb syringe for irrigation if necessary

BEFORE THE PROCEDURE

Most people who have an artificial eye provide self-care and require little assistance. However, it may be necessary for the nurse to remove an eye prosthesis from the unconscious or debilitated person. If the person is conscious, explain the procedure and provide for privacy.

PROCEDURE

- Follow standard precautions.
- Wash the hands and put on clean exam gloves.
- To remove the prosthesis, do one of the following:
  - Pull down the lower lid and gently exert outward and upward pressure on the lower edge of the prosthesis. This pressure usually causes the prosthesis to slip out.
  - Pull down the lower lid and apply a moistened suction cup to the prosthesis by squeezing the device. Twist gently to remove the prosthesis from the socket.
- Wash the prosthesis using mild soap and water or normal saline. Rinse thoroughly. Do not use abrasives or chemicals for cleaning.
- If the prosthesis is not immediately replaced in the eye socket, store it in a clearly labelled plastic container lined with a soft cloth or gauze squares. Avoid scratching or damaging the prosthesis. Store it in a safe place to prevent loss.
- If irrigation of the eye socket is ordered, have the person lean over a sink or basin if possible or position on the affected side with a clean emesis basin to hold the irrigant as it flows out of the socket. Gently hold the lids open and irrigate the socket using a bulb syringe and clean warm water.
- Reinsert the prosthesis.
  a. Moisten the prosthesis with warm normal saline or water.
  b. Gently hold the lids open. Insert the upper edge of the prosthesis under the upper lid first, then the lower edge under the lower lid using slight pressure.
  c. If a suction device is used, attach it to the cleaned prosthesis over the pupil. Holding the lids open, insert the prosthesis using the above procedure, then remove the suction cup by squeezing it gently and exerting slight pressure on the edge of the cup with the lower lid.

AFTER THE PROCEDURE

- Ensure that the person is comfortable. Chart the procedure and any abnormal findings, such as drainage or inflammation.

EAR DISORDERS

For a person to hear, sound waves must enter the external auditory meatus and travel through the ear canal to vibrate the tympanic membrane and bony structures of the middle ear, which in turn activate the receptors of the cochlea. Trauma or disease involving any portion of this pathway can affect hearing. **Tinnitus**, the perception of sound such as ringing, buzzing or roaring in the ears, is another potential result of problems affecting the auditory system.

Disorders of the external ear, including the auricle, auditory meatus and ear canal, can affect the conduction of sound waves and hearing. Obstruction of the external auditory canal or damage to the tympanic membrane, which separates the outer from the middle ear, may lead to conductive hearing loss. Infection or inflammation, trauma and obstruction of the ear canal with cerumen (wax) or a foreign body are the most common conditions affecting the external ear.

Disorders of the middle ear may be either acute or chronic. Unless these disorders are treated promptly and effectively, damage and scarring of middle ear structures can result in a permanent conductive hearing loss. Infectious or inflammatory disorders such as otitis media and mastoiditis are the most common conditions affecting the middle ear. Otosclerosis, a genetic condition, may also affect the structures of the middle ear.

THE PERSON WITH OTITIS EXTERNA

Otitis externa is inflammation of the ear canal. Commonly known as *swimmer's ear*, it is most prevalent in people who spend significant time in the water. Competitive athletes, including swimmers, divers and surfers, are particularly prone to otitis externa. Wearing a hearing aid or ear plugs, which hold moisture in the ear canal, is an additional risk factor. Although *Pseudomonas aeruginosa* or other bacterial infection is the most common cause, external otitis may also be due to fungal infection, mechanical trauma (such as cleaning the ear with a toothpick) or a local hypersensitivity reaction.

Pathophysiology and manifestations

Disruption of the normal environment within the external auditory canal typically precedes the inflammatory process. Retained moisture, cleaning or drying of the ear canal removes the protective layer of cerumen, an acidic, water-repellent substance with antimicrobial properties. Its removal leaves the skin of the ear canal vulnerable to invasion and infection. For surfers, the presence of *exostoses*, bony growths in the ear canals resulting from prolonged exposure to cold, predisposes to impaction and retained moisture within the canal.

The person with otitis externa often complains of a feeling of fullness in the ear. Ear pain typically is present and may be severe. The pain of otitis externa can be differentiated from that associated with otitis media by manipulation of the auricle. In external otitis, this manoeuvre increases the pain, whereas the person with otitis media experiences no change in pain perception. Odourless watery or purulent drainage may be present. The ear canal appears inflamed and oedematous on examination.

INTERPROFESSIONAL CARE

Management of the person with an external ear disorder focuses on restoring the normal balance of the external ear and canal and teaching the person how to prevent future problems.

For otitis externa, the following steps are recommended in treatment:

- thorough cleansing of the ear canal, particularly if drainage or debris is present
- treatment of the infection with local antibiotics; if cellulitis is present, systemic antibiotics may be necessary
- medication to relieve the pain and itching
- education on the prevention of future episodes of swimmer's ear.

Topical antimicrobials used to treat otitis externa include chloramphenicol, framycetin, neomycin, gramicidin, ciprofloxacin and bacitracin. Nystatin, an antifungal agent, is also used (Bryant & Knights, 2014).

A topical antibiotic is often prescribed for the treatment of otitis externa. A topical corticosteroid may be ordered in combination with the antibiotic to provide immediate relief of the pain, swelling and itching. Chloramphenicol ear drops (broad-spectrum antibiotic) are effective against *Pseudomonas*, *Staphylococcus aureus* and *Enterobacter*. Other ear drop preparations include aminoglycoside antibiotics (framycetin and neomycin); however, it is important to identify known sensitivity to any of the drugs in this preparation prior to initiating therapy. People who are sensitive to neomycin may develop dermatitis, in which case the drug must be stopped.

Nursing care

External otitis can cause severe pain and discomfort. Although the disorder is rarely serious enough to require hospitalisation, the nurse teaches the person about the disorder, comfort measures and prevention of future episodes.

Nursing diagnoses and interventions

Impaired tissue integrity

External otitis may result from attempts to clean the ear canal with a toothpick, cotton-tipped applicator or other implement that damages the skin, allowing an infectious organism to invade the tissue. Even if the canal is not damaged by attempts

to clean it, the cleaning process often interrupts normal mechanisms, causing cerumen and debris to collect in the canal. The collected debris, in turn, tends to trap water within the canal, causing maceration of the skin.

- Inform that ear canals rarely need cleansing beyond washing of the external meatus with soap and water. Educate people of all ages not to clean ear canals with any implement. '*Cleaning' increases the risk of tissue damage and impairs the normal mechanism that clears the canal of accumulated cerumen and debris.*
- Educate person (and, if necessary, a family member) about how to instil prescribed ear drops:
  a. Wash hands.
  b. Warm the medication briefly by holding the container in the hand or placing it in a pocket for approximately 5 minutes before instilling the drops. *Warming the medication promotes comfort.*
  c. Lie on the unaffected side; if sitting, tilt the head towards the unaffected side. *This position allows gravity to assist in moving the medication to the inner portion of the ear canal.*
  d. Partially fill the ear dropper with medication.
  e. Using the non-dominant hand, straighten the ear canal by pulling the pinna of the ear up and back. *Straightening helps the medication travel along the length of the canal.*
  f. Administer the prescribed number of drops into the ear canal. *It is important that the full amount of prescribed medication be administered to penetrate the length of the canal and achieve full effectiveness.*
  g. Remain in the side-lying position for approximately 5 minutes after the instillation of drops. *This position allows the medication to penetrate into deeper portions of the canal and prevents it from running out when the head is moved upright.*
  h. Loosely place a small piece of cotton in the auditory meatus for 15 to 20 minutes. *The cotton helps keep the medication in the canal.*
- Educate to avoid getting water in the affected ear until it is fully healed. Cotton balls may be used while showering to prevent water from entering the ear canal. *The person should refrain from water sports and activities until approved by the primary care provider. Retained moisture in the ear canal can further impair skin integrity, increasing inflammation.*

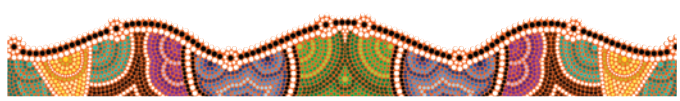
Community-based care

The person is ultimately responsible for carrying out the prescribed treatment regimen in external otitis and for implementing measures to prevent future episodes. Education is vital. Provide verbal and written instructions on use of the prescribed medications. Educating the person about care measures to prevent recurrent episodes is especially important in swimmers, divers and surfers (see Box 45.2).

Cellulitis of the surrounding tissue is a possible complication of external otitis. Instruct the person to report to the primary care provider any increase in pain, swelling or redness of surrounding tissues; fever; or other manifestations of infection such as malaise or increased fatigue.

BOX 45.2 Teaching to prevent otitis externa

- Stay out of the water until the acute inflammatory process is completely resolved. Ideally, allow 7 to 10 days before resuming water activities.
- Take precautions to keep the ear canal dry while in the water:
  a Use silicone ear plugs, which can keep water out of the ear without reducing hearing significantly.
  b Wear a tight-fitting swim cap or wetsuit hood, especially in cold ocean water. Although these do not prevent water from entering the ear, they protect the ear from the cold and possibly slow the formation of bony growths in the ears. They also protect the ear from sand and other water debris.
- Immediately after swimming, dry the ear canal. Allow water to drain by tilting the head and jumping to shake water out of the ear. Dry the outer ear with a towel, then use a hair dryer on the lowest setting several centimetres from the ear to dry the canal.
- Do not insert cotton swabs or other objects into the ear canal to dry it. This removes the protective layer of cerumen and may damage the skin of the canal, increasing the risk of bacterial infection. In addition, if debris such as sand is present, the swab may actually push debris further into the canal, forming an impacted mass.
- Consult primary care provider about using a drying agent in the ear canal after swimming. A 2% acetic acid solution or 2% boric acid in ethyl alcohol is effective in drying the canal and restoring its normal acidic environment.
- If it is necessary to remove impacted debris from the ear canal, irrigate the ear with warm tap water. A bulb syringe available over the counter or a 20 mL syringe attached to a short Teflon intravenous catheter (with the needle removed) is effective. With the head tilted towards the affected side, direct a stream of warm water towards the upper wall of the ear canal, allowing the water to run out into a bowl or sink. Repeated instillations may be necessary to break up and flush out impacted wax and debris.
- Follow manufacturer's directions for cleaning and disinfecting pools and spas (hot tubs). Use a pool test kit to check for adequate disinfectant and pH levels before entering.



THE PERSON WITH IMPACTED CERUMEN OR A FOREIGN BODY

The external auditory canal can be obstructed by cerumen or foreign bodies. The curved shape and narrow lumen of the canal make it particularly vulnerable to obstruction.

Pathophysiology and manifestations

As cerumen dries, it moves down and out of the ear canal. In some individuals it tends to accumulate, narrowing the canal.

Ageing is a risk factor for impaction because less cerumen is produced and it is harder and drier. The accumulation of cerumen is often aggravated by attempting to remove it using cotton-tipped swabs or hair pins, which pack it more deeply into the ear canal.

A variety of objects become foreign bodies in the ear canal. In adults, implements used to clean the ear canal may break and become lodged. Insects also may enter the ear canal and be unable to exit.

When the ear canal becomes occluded with either cerumen or a foreign body, the person experiences a conductive hearing loss in the affected ear. Manifestations include a sensation of fullness, along with tinnitus and coughing due to stimulation of the vagal nerve. The foreign body or impacted cerumen may be visualised on otoscopy. Impacted cerumen appears as a yellow, brown or black mass in the canal.

INTERPROFESSIONAL CARE

Treatment focuses on clearing the canal. If there is no evidence of tympanic membrane perforation, irrigation of the canal is often the initial therapy.

Impacted wax, objects or insects may require physical removal using an ear curette, forceps or right-angle hook inserted via an otoscope and ear speculum. Mineral oil or topical lignocaine drops are used to immobilise or kill insects prior to their removal from the ear. When an organic foreign body such as a bean or an insect is suspected, water should not be instilled into the ear canal because it may cause the object to swell, making its removal more difficult. Smooth, round objects present the biggest challenge to remove from the ear canal. Suction applied using a piece of soft intravenous tubing may be effective.

Nursing care

Nurses are often involved in identifying and relieving obstructions of the ear canal, especially in outpatient and community settings. Any person with evidence of a new conductive hearing loss or complaints of discomfort and fullness in one ear should be evaluated for possible obstruction. Inability to visualise the tympanic membrane or observation of a dark, shiny mass obstructing the canal may indicate a need for irrigation or other procedure to clear the canal. It is important to determine that the tympanic membrane is intact before irrigating; assessment by a doctor or advanced practitioner may be necessary if a ruptured membrane is suspected.

Because obstruction of the ear canal with cerumen or a foreign body is generally preventable, education is a key component of nursing care. People need to know appropriate care measures for the external ear. Although the ear canal rarely needs cleaning, the person prone to cerumen impaction requires education regarding the use of mineral oil or commercial products to soften wax, and irrigation to remove it. All people should understand the importance of not inserting anything smaller than a finger wrapped with a washcloth into the ear canal to avoid trauma to the canal or eardrum. Stress the risk of impacting cerumen against the tympanic membrane when using cotton-tipped swabs to clean the ear canal. Additionally, the swab may break and lodge in the canal. If ear drops have been prescribed, educate the person and a family member about how to instil them.

THE PERSON WITH OTITIS MEDIA

Otitis media, inflammation or infection of the middle ear, primarily affects infants and young children but may also occur in adults. It can persist from infancy through adolescence and adulthood (Burrow, Galloway & Weissofner, 2009). The tympanic membrane, which separates the middle ear from the external auditory canal, protects the middle ear from the external environment. The eustachian (auditory) tube connects the middle ear with the nasopharynx to help equalise the pressure in the middle ear with the atmospheric pressure. Unfortunately, this connecting tube also provides a route by which infectious organisms enter the middle ear from the nose and throat, causing otitis media, the most common disease of the middle ear. This is the most common cause of hearing loss in the Australian Indigenous population.

Pathophysiology

There are two primary forms of otitis media: (1) serous, and (2) acute or suppurative. Both forms are associated with upper respiratory infection and eustachian tube dysfunction. The eustachian tube is narrow and flat, normally opening only during yawning and swallowing. Allergies or upper respiratory tract infections can cause oedema of the tube lining, impairing its function. Air within the middle ear is trapped and gradually absorbed, creating negative pressure in this space.

Serous otitis media

Serous otitis media (also called *otitis media with effusion*) occurs when the eustachian tube is obstructed for a prolonged time, impairing equalisation of air pressure in the middle ear. Air within the middle ear space is gradually absorbed; the tube obstruction prevents more air from entering the middle ear. The resulting negative pressure in the middle ear causes sterile serous fluid to move from the capillaries into the space, forming a sterile effusion of the middle ear.

Upper respiratory infections or allergies such as hay fever predispose the person to serous otitis media. In addition, people with narrowed or oedematous eustachian tubes may also be subject to barotrauma or barotitis media. In these people, the middle ear cannot adapt to rapid changes in

barometric pressure such as those that occur during air travel or underwater diving. Barotrauma tends to occur during descent in an aeroplane because negative pressure within the middle ear causes the eustachian tube to collapse and lock. However, underwater diving places even greater stress on the eustachian tube and middle ear.

MANIFESTATIONS Typical manifestations of serous otitis media include decreased hearing in the affected ear and complaints of 'snapping' or 'popping' in the ear. On examination, the tympanic membrane demonstrates decreased mobility and may appear retracted or bulging. Fluid or air bubbles are often visible behind the drum. Severe pressure differences such as those occurring with barotrauma may cause acute pain, haemorrhage into the middle ear, rupture of the tympanic membrane or even rupture of the round window with sensory hearing loss and severe **vertigo** (a sensation of whirling or rotation). *Haemotympanum*, bleeding into or behind the tympanic membrane, may be observed on otoscopic examination.

Acute otitis media

The eustachian tube also provides a route for the entry of pathogens into the normally sterile middle ear, resulting in acute or suppurative otitis media. Acute otitis media typically follows an upper respiratory infection. Oedema of the eustachian tube impairs drainage of the middle ear, causing mucus and serous fluid to accumulate. This fluid is an excellent environment for the growth of bacteria, which may enter from the oronasopharynx via the eustachian tube. Although a viral upper respiratory infection may predispose the person to a middle ear infection, the bacteria *Streptococcus pneumoniae*, *Haemophilus influenza* and *Streptococcus pyogenes* account for most cases of otitis media in adults. Invasion and colonisation of the middle ear by bacteria and the resultant migration of white blood cells cause pus formation. Accumulated pus can increase middle ear pressure sufficiently to rupture the tympanic membrane. The bacterial infection may also migrate internally, causing mastoiditis, brain abscess or bacterial meningitis. A more common complication of otitis media is a persistent conductive hearing loss, which typically resolves when the middle ear effusion clears.

MANIFESTATIONS The person with acute otitis media experiences mild to severe pain in the affected ear. The person's temperature is often elevated. Diminished hearing, dizziness, vertigo and tinnitus are common associated complaints. Pus within the mastoid air cells often causes mastoid tenderness in acute otitis media. On otoscopic examination, the tympanic membrane appears red and inflamed or dull and bulging (see Figure 45.15). Decreased movement of the membrane is demonstrated by tympanometry or air insufflation. Spontaneous rupture of the tympanic membrane releases a purulent discharge. **Myringotomy** (an incision of the tympanic membrane) may be performed to relieve the pressure.

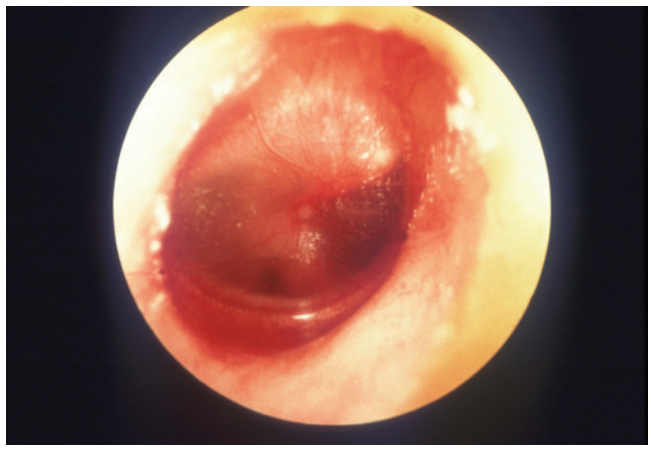


FIGURE 45.15 ■ A red, bulging tympanic membrane of otitis media

Source: © Medical-on-Line/Alamy..

INTERPROFESSIONAL CARE

The diagnosis of otitis media is usually based on the person's history and the physical examination. The tympanic membrane can be visualised and its mobility evaluated using a pneumatic otoscope that allows a puff of air to be instilled into the ear canal. Generally, the tympanic membrane moves slightly when air is instilled or the person performs the Valsalva manoeuvre. Less movement is seen in people with eustachian tube dysfunction and acute otitis media with effusion.

Diagnosis

- *Impedance audiometry*, also known as tympanometry, is an accurate diagnostic test for otitis media with effusion. A continuous tone is delivered to the tympanic membrane by an audiometer with a sealed probe tip. Compliance of the tympanic membrane and middle ear is measured by recording energy reflected from the membrane surface. With middle ear effusion, compliance is reduced.
- A *full blood count (FBC)* may be done to assess for an elevated WBC count and increased numbers of immature cells indicative of acute bacterial infection.
- If the tympanic membrane has ruptured or a tympanocentesis or myringotomy is performed, drainage is cultured to determine the infecting organism.

Medications

When eustachian tube dysfunction and serous otitis media do not spontaneously resolve or lead to hearing loss, a short course of an anti-inflammatory drug (e.g. oral prednisone for 7 days) is prescribed to reduce mucosal oedema of the tube and improve its patency.

Although a decongestant or antihistamine may be used, there is little evidence of their effectiveness in treating serous otitis media. Antibiotic/corticosteroid ear drops or ointments can be prescribed. See Chapter 12 for the nursing implications of corticosteroid medications.

The person with auditory tube dysfunction may be taught to auto-inflate the middle ear by performing the Valsalva manoeuvre or by forcefully exhaling against closed nostrils. Additionally, the person is advised to avoid air travel and underwater diving.

Acute otitis media usually is treated with antibiotic therapy, especially amoxicillin, trimethoprim-sulfamethoxazole, cefaclor or azithromycin for 5 to 10 days. This course of treatment is long enough to ensure eradication of the infective organism, yet short enough to reduce the incidence of bacterial resistance. (See Chapter 11 for further discussion of antibiotics.) Symptomatic relief may be provided by analgesics, antipyretics, antihistamines and local application of heat.

Surgery

A myringotomy or tympanocentesis may be performed to relieve excess pressure in the middle ear and prevent spontaneous rupture of the eardrum. To perform a tympanocentesis, the doctor inserts a 20-gauge spinal needle through the inferior portion of the tympanic membrane, allowing aspiration of fluid and pus from the middle ear to relieve pressure and, if necessary, obtain a specimen for culture. Myringotomy may be performed to relieve severe pain or when complications of acute otitis media, such as mastoiditis, are present. As soon as the pressure is released, pain subsides and hearing improves.

People who do not respond to antibiotic therapy may require myringotomy with insertion of ventilation (tympanostomy) tubes. Small tubes are inserted into the inferior portion of the tympanic membrane, providing for ventilation and drainage of the middle ear during healing. The tube is eventually extruded from the ear and the tympanic membrane heals. While the tube is in place, it is important to avoid getting any water in the ear canal because it may then enter the middle ear space.

Nursing care

People with otitis media are commonly treated in outpatient and community settings. The nursing role is primarily one of support and education. A comprehensive intersectoral and multidisciplinary approach specifically addressing prevention and early intervention will assist in improving awareness in the Australian Indigenous population, to reduce the incidence of this condition.

Health promotion

Health promotion for otitis media focuses on educating people about the importance of seeking medical care for prolonged, severe ear pain with or without drainage combined with an upper respiratory tract infection. Untreated or repeated attacks of otitis media can progress to a chronic form of otitis media, acute mastoiditis or eardrum perforation.

Assessment

Collect assessment data through a health history and physical examination (Chapter 44).

- *Health history:* recent upper respiratory infection; presence, intensity and nature of pain in affected ear; sense of fullness or pressure in the ear; change in hearing; snapping or popping sensation in the affected ear; presence of vertigo.
- *Physical examination:* temperature; hearing test; inspect tympanic membrane.

Nursing diagnoses and interventions

Pain can be a significant problem for people with otitis media, as can the risk of damage to delicate tissues of the middle ear by the infectious and inflammatory processes.

Pain

Tissue oedema, effusion of the middle ear and the inflammatory response can affect the pain-sensitive tissues of the middle ear in otitis media, causing acute discomfort. This discomfort is increased by pressure changes, such as those that occur during air travel or underwater diving.

- Assess pain for severity, quality and location. A thorough assessment is important to determine the source of the pain. *Unlike that of external otitis, the pain of otitis media is not aggravated by movement of the external ear.*
- Encourage the use of mild analgesics such as aspirin or paracetamol every 4 hours as needed to relieve pain and fever. *These non-prescription medications are effective in reducing the perception of pain. Aspirin also has anti-inflammatory properties that may help relieve the inflammation of the ear.*
- Advise to apply heat to the affected side unless contraindicated. *Heat dilates blood vessels, promoting the reabsorption of fluid and reducing swelling.*
- Instruct to avoid air travel, rapid changes in elevation or diving. *A rapid change in barometric pressure can increase the person's pain significantly.*
- Instruct to report promptly an abrupt relief of pain to the primary care provider. *Pain that subsides abruptly may indicate spontaneous perforation of the tympanic membrane with relief of pressure within the middle ear.*

Community-based care

The person who has otitis media needs educating regarding the disorder, its causes and prevention, and any specific treatment recommended or prescribed. Discuss the following topics with the person and family:

- antibiotic therapy and potential side effects
- importance of completing all ordered doses
- follow-up examinations in 2 to 4 weeks
- avoiding swimming, diving or submerging the head while bathing if ventilation tubes are in place.

If surgical intervention is necessary, educate the person and family members about the surgery and postoperative care. Provide instructions regarding any special postoperative precautions, such as avoiding water in the ear canals or avoiding sudden changes in air pressure.

THE PERSON WITH ACUTE MASTOIDITIS

The mastoid process is a portion of the temporal bone of the skull lying adjacent to the middle ear. It is full of air cavities called mastoid air cells or mastoid sinuses. The infection of acute otitis media generally extends into the mastoid air cells; effective treatment of acute otitis media eliminates the infection from the mastoid cells as well. When treatment is ineffective, pus remains in the mastoid air cells and acute **mastoiditis**, bacterial infection of the mastoid process, may develop.

The incidence of acute mastoiditis is low in countries where the prescription and use of antibiotics to treat acute otitis media is widespread. Its incidence is higher in countries where antibiotics are less likely to be prescribed.

Pathophysiology and complications

In acute mastoiditis, the bony septa between mastoid air cells are destroyed and cells coalesce to form large spaces. Portions of the mastoid process are eroded. With chronic infection, an abscess may form or bony sclerosis of the mastoid may result. Acute mastoiditis increases the risk of meningitis because only a very thin bony plate separates mastoid air cells from the brain. Fortunately, this complication is rare since the advent of effective antibiotic therapy for treating otitis media.

Manifestations

Manifestations of acute mastoiditis usually develop approximately 2 to 3 weeks after an episode of acute otitis media and include recurrent earache and hearing loss on the affected side. The pain is persistent and throbbing; tenderness is present over the mastoid process (behind the ear). It may also be red and inflamed. Swelling of the process can cause the auricle of the ear to protrude more than normal. Fever may be accompanied by tinnitus and headache, and profuse drainage from the affected ear may be noted.

INTERPROFESSIONAL CARE

In addition to the manifestations of acute mastoiditis, loss of septa between mastoid air cells may be noted on radiological examination. Acute mastoiditis is treated aggressively with antibiotic therapy tailored to the infecting organism. Antibiotics are continued for at least 14 days. Infections that do not respond to medical therapy or that pose a high risk of spreading to the brain may necessitate a *mastoidectomy*, the surgical removal of the infected mastoid air cells, bone and pus, and inspection of the underlying dura for possible abscess. The extent of tissue destruction determines the extent of surgery required. In a modified mastoidectomy, as much tissue is preserved as possible to avoid disruption of hearing. A radical mastoidectomy involves removal of middle ear structures, including the incus and malleus, as well as the diseased portions of the mastoid process. Unless reconstruction is performed at the time of surgery, this surgery results in conductive hearing loss. **Tympanoplasty**, surgical reconstruction of the middle ear, can restore or preserve hearing.

Nursing care

Prevention is the primary focus of collaborative and nursing care related to mastoiditis. Adequate, effective antibiotic treatment of acute otitis media prevents mastoiditis in nearly all instances.

Following surgical intervention, carefully assess the wound and drainage for evidence of infection or other complications. The person's hearing may be temporarily or permanently affected, depending on the extent of the surgery. If the person has impaired hearing in the unaffected ear as well, develop a means of communication with the person prior to surgery. If the hearing is preserved in the unaffected ear, position the person with that ear towards the door. Speak slowly and clearly; do not shout or speak unusually loudly. Be sure that family and staff know about the person's hearing loss and use appropriate communication techniques. Assist the person with ambulation initially because dizziness and vertigo are not unusual following surgery. Nursing care of the person having ear surgery is discussed in the box below.

Community-based care

When educating about acute mastoiditis, stress the importance of complying with the prescribed antibiotic therapy and recommendations for follow up. Instruct the person and family to report any adverse reactions to the primary care provider so that therapy can be adjusted. Educate the person and family about how to change the surgical dressing using aseptic technique. Provide referrals to appropriate community agencies for the person with a new hearing loss resulting from mastoiditis or its treatment.

THE PERSON WITH CHRONIC OTITIS MEDIA

Chronic otitis media involves permanent perforation of the tympanic membrane, with or without recurrent pus formation. Changes in the mucosa and bony structures (ossicles) of the middle ear often accompany chronic otitis media. It usually is the result of recurrent acute otitis media and eustachian tube dysfunction, but may also result from trauma or other diseases.

Marginal perforations, which usually occur in the posterior–superior portion of the tympanic membrane, are associated with more complications than central perforations. With marginal perforations, squamous epithelium may migrate from the ear canal into the middle ear, where it begins to desquamate and accumulate, forming a *cholesteatoma* (a cyst or mass filled with epithelial cell debris). Its incidence is highest in children and young adults. The desquamating epithelium continues to accumulate and remains infected, producing collagenases (enzymes) that destroy adjacent bone. The inflammatory process

NURSING CARE OF THE PERSON having ear surgery

PREOPERATIVE CARE

- Review Chapter 3 for routine preoperative care.
- Assess hearing and/or verify documentation of preoperative hearing assessment. *This data is important in evaluating the results of the surgical procedure.*
- Establish a means of communication to be used after surgery, *when hearing may be impaired*.
- Explain that blowing of the nose, coughing and sneezing need to be restricted postoperatively to prevent pressure changes in the middle ear and potential disruption of the surgical site. *Keeping the mouth open during a cough or sneeze minimises pressure changes in the middle ear. Providing education and the opportunity to practise before surgery promotes cooperation in the postoperative period.*

POSTOPERATIVE CARE

- Review Chapter 3 for routine postoperative care.
- Assess for bleeding and/or drainage from the affected ear. *Infection and haemorrhage are possible complications.*
- Administer anti-emetics as ordered to prevent vomiting. *Vomiting may increase the pressure in the middle ear, disrupting the surgical site.*
- Elevate the head of the bed and position the person on the unaffected side. *This position minimises the pressure in the middle ear.*
- Assess for vertigo or dizziness, especially with ambulation or movement in bed. Avoid unnecessary movements such as turning. *Take measures to ensure safety during ambulation. Surgery on the ear may disrupt equilibrium, increasing the risk of falling.*
- Assess hearing postoperatively. Stand on the unaffected side to communicate and use other measures such as written messages as needed for effective communication with the person with impaired hearing. Reassure the person that decreased hearing acuity immediately after surgery is expected. *Hearing improvement is an expected result of the ear surgery and typically does not occur until ear plugs are removed and oedema and drainage at the operative site have resolved. If no reconstruction of the middle ear is carried out or the cochlea is involved, permanent hearing loss in the affected ear may be an expected result.*
- Remind to avoid coughing, sneezing or blowing the nose. *These increase pressure in the middle ear.*

HEALTH EDUCATION FOR THE PERSON AND FAMILY

- Provide education and instructions for home care:
  a. To prevent contamination of the ear canal, avoid showers, shampooing and immersing the head until the doctor says you can do so.
  b. Keep the outer earplug clean and dry, changing it as needed. Do not remove inner ear dressing until instructed to do so by the doctor.
  c. Avoid blowing the nose; if you need to cough or sneeze, keep the mouth open.
  d. Do not swim or dive without doctor approval. Check with your doctor regarding air travel.
  e. Meclizine hydrochloride or other anti-emetic and/or antihistamine medication may be necessary for up to 1 month following surgery.
  f. Fever, bleeding, increased drainage, increased dizziness or decreased hearing after discharge may indicate a complication. Notify the doctor if any of these occur.

impairs the blood supply to the stapes, causing its destruction and conductive hearing loss. Cholesteatomas are benign and slow-growing tumours which can enlarge to fill the entire middle ear. Untreated, the cholesteatoma can progressively destroy the ossicles and erode into the inner ear, causing profound hearing loss.

Systemic antibiotics are prescribed for exacerbations of purulent otitis media. Tympanic membrane perforation is repaired with a tympanoplasty to restore sound conduction and the integrity of the middle ear. A cholesteatoma may require delicate surgery for its removal. If at all possible, radical mastoidectomy with removal of the tympanic membrane, ossicles and tumour is avoided.

As with other complications of acute otitis media, a priority of nursing care is prevention of chronic otitis media and cholesteatoma. People with chronic otitis media need to understand various treatment options and their risks and benefits, as well as the long-term risk of not treating a perforated tympanic membrane. They are also educated on how to instil ear drops, to clean the external auditory meatus and to not irrigate the ear when the tympanic membrane is perforated or if they think it might be.

If surgical treatment of chronic otitis media will affect the person's hearing, include this information in preoperative teaching. Teach the person and family how to use alternative means of communication if this will be necessary postoperatively. When an assistive device is ordered, teach the person and a family member about its use.

THE PERSON WITH OTOSCLEROSIS

Otosclerosis is a common cause of conductive hearing loss. Abnormal bone formation in the osseous labyrinth of the temporal bone causes the footplate of the stapes to become fixed or immobile in the oval window. The result is a conductive hearing loss.

Otosclerosis is a hereditary disorder with an autosomal dominant pattern of inheritance. It occurs most commonly in Caucasians and females. The progressive hearing loss typically begins in adolescence or early adulthood, and seems to be accelerated by pregnancy. Although both ears are affected, the rate of hearing loss is asymmetrical. Because bone conduction of sound is retained, the person may be able to use the telephone but have difficulty conversing in person. Tinnitus may also be associated with this condition.

On examination, a reddish or pinkish-orange tympanic membrane may be noted because of increased vascularity of the middle ear. The Rinne test (Chapter 44) shows bone sound conduction to be equal to or greater than air conduction, an abnormal finding.

People with otosclerosis may choose conservative treatment, relying on a hearing aid to improve their ability to hear and interact with others. Sodium fluoride may be prescribed to slow bone reabsorption and overgrowth. Surgical treatment involves a stapedectomy and middle ear reconstruction, or a stapedotomy. A *stapedectomy* is a microsurgical technique for removing the diseased stapes. A metallic prosthesis is then inserted, with one end connected to the incus and the other inserted into the oval window. *Stapedotomy* involves creation of a small hole in the footplate of the stapes and insertion of a wire or platinum ribbon prosthesis. An argon, KTP or CO_2 laser may be used for surgery. Surgery usually restores hearing for the person with otosclerosis.

Education and referral of the person to appropriate community agencies are important nursing care priorities for the person with otosclerosis. For the person who chooses surgical treatment, nursing care is similar to that for other people undergoing ear surgery. The following may be appropriate:

- *Risk of injury* related to hearing loss or postoperative vertigo.
- *Risk of disturbed auditory perception* related to bony sclerosis of the stapes.
- *Risk of impaired verbal communication* related to hearing loss.
- *Risk of anxiety* related to concern about transmission of a genetic disorder to children.

THE PERSON WITH AN INNER EAR DISORDER

Disorders affecting the inner ear are much less common than disorders of the outer or middle ear. Inner ear disorders affect equilibrium and may also affect sensorineural hearing, the perception of sound. Labyrinthitis and Ménière's disease are the most common diseases of the inner ear. Vertigo may be a disorder of the inner ear itself or a manifestation of other disorders.

Pathophysiology and manifestations

The labyrinth (the inner ear) contains the cochlea and the semicircular canals. The hair cells and neurons that allow sound perception and transmission to the auditory centre of the brain are in the cochlea. The semicircular canals filled with endolymph are the primary organs involved in maintaining equilibrium. Disruption of this portion of the ear by an inflammatory process or excess endolymph not only affects balance but may also result in permanent hearing loss.

Vertigo

Normally, the integration of input from the labyrinths, eyes, muscles, joints and neural centres maintains balance and posture. This input and integration can be affected by disorders of the labyrinth, vestibular nerve or nuclei, eyes, cerebellum, brainstem or cerebral cortex, causing vertigo. Vertigo, the sensation of movement when there is none, is a disorder of equilibrium. The sensation of whirling, rotation or movement is described as either subjective or objective.

People with subjective vertigo report the sensation of being in motion in a stable environment. This is not always a sense of spinning; the person may have a sense of tumbling or falling forwards or backwards. The sensation is reversed in objective vertigo; people report a sensation of stability in a moving environment. This motion may be perceived as the room spinning around the person or the ground rocking beneath the person's feet. Dizziness, which may be mistaken for vertigo, is a sensation of unsteadiness, lack of balance, light headedness or movement within the head. The person who is dizzy does not have the rotational sensation felt with vertigo.

Vertigo may be disabling, resulting in falls, injury and difficulty walking. Attacks of vertigo are often accompanied by nausea and vomiting, nystagmus and autonomic symptoms such as pallor, sweating, hypotension and salivation.

Labyrinthitis

Labyrinthitis, also called otitis interna, is inflammation of the inner ear. It is an uncommon disorder because the bony protection of the membranous labyrinth makes it difficult for organisms to enter the inner ear. However, bacteria, viruses and other organisms may enter and infect the inner ear through the oval window during acute otitis media, the cochlear aqueduct during meningitis, or the blood. Viral labyrinthitis is suspected when the person has a sudden onset of symptoms after an upper respiratory infection or when there is no evidence of concurrent otitis media. Labyrinthitis also may result from an autoimmune process of unknown aetiology.

MANIFESTATIONS Inflammation of the labyrinth typically causes vertigo, sensorineural hearing deficit and nystagmus (rapid involuntary eye movements).

Vertigo is the hallmark manifestation of inner ear disorders. The vertigo of labyrinthitis is severe and often accompanied by nausea and vomiting. Any movement can aggravate the vertigo, and falling is a significant risk if the person attempts to stand. Vertigo lasts days to weeks in labyrinthitis, making education a vital component of care.

Hearing loss in the ear affected by labyrinthitis may be temporary or permanent. If inflammation destroys tissue of the membranous labyrinth, the hearing loss may be complete and permanent.

The involuntary rhythmic eye movements of nystagmus may not be present in all people with labyrinthitis. When present, the eye movement is typically horizontal. Applying positive or negative pressure to the tympanic membrane of the affected ear may stimulate nystagmus, as will caloric testing (irrigating the ear canal with warm or cool water). Although nystagmus may also be a symptom of brainstem or cerebellar dysfunction, vertigo and hearing loss are not typically associated with those disorders.

Ménière's disease

Ménière's disease, also known as endolymphatic hydrops, is a chronic disorder characterised by recurrent attacks of vertigo with tinnitus and a progressive unilateral hearing loss.

This disorder affects men and women equally, with adults between the ages of 35 and 60 at highest risk. The cause of Ménière's disease is unclear, although the most common form of the disease is thought to result from viral injury to the fluid transport system of the inner ear. Other factors that may increase the risk of Ménière's disease include trauma, bacterial infections such as syphilis, autoimmune processes, vascular disorders, selected drugs and toxins (Grossman & Porth, 2014). A family history of the disease increases risk, suggesting a possible genetic link in some people.

Ménière's disease results from an excess of endolymph, the fluid in the membranous labyrinth of the inner ear. Although the precise pathophysiological mechanism leading to accumulation of endolymph is unclear, it is thought to result from impaired filtration and excretion of the fluid by the endolymphatic sac (Grossman & Porth, 2014). Excessive pressure resulting from the increased fluid volume causes neural organs of the cochlea to degenerate.

COURSE AND MANIFESTATIONS The onset of Ménière's disease may be gradual or sudden. It is characterised by recurrent attacks of vertigo, gradual loss of hearing and tinnitus. Attacks may be preceded by a feeling of fullness in the ears and a roaring or ringing sensation. The sensorineural hearing loss and tinnitus are usually unilateral but can become bilateral. Attacks of severe rotary vertigo occur abruptly and often unpredictably, lasting from minutes to hours. An attack may be linked to increased sodium intake, stress, allergies, vasoconstriction or premenstrual fluid retention. As the disease continues, hearing loss progresses and the vertigo can be severe enough to cause immobility, nausea and vomiting. Attacks are often accompanied by hypotension, sweating and nystagmus.

INTERPROFESSIONAL CARE

The manifestations associated with inner ear disorders are similar, making testing necessary to establish a diagnosis. Once the diagnosis is determined, collaborative care is directed towards managing symptoms and preventing permanent hearing loss. People with labyrinthitis or an acute attack of Ménière's disease may require hospitalisation to manage the vertigo and its effects.

Diagnosis

The following diagnostic studies may be ordered:

- *Caloric testing (electronystagmography)* evaluates the vestibulo-ocular reflex by identifying eye movements (nystagmus) in response to caloric testing. In people with impaired vestibular function, the normal nystagmus response is blunted or absent. This portion of the test is contraindicated in people who have a perforated tympanic membrane.
- *Rinne* and *Weber tests* of hearing (Chapter 44) show decreased air and bone conduction on the affected side if a sensorineural hearing loss is present. In Ménière's disease, audiology shows sensorineural hearing loss involving the low tones.
- *X-rays* and *CT scans* of the petrous bones are used to evaluate the internal auditory canal. In people with Ménière's disease, the vestibular aqueducts may be shorter and straighter than normal.
- *Glycerol test* is conducted by giving the person oral glycerol to decrease fluid pressure in the inner ear. An acute temporary hearing improvement is considered diagnostic for Ménière's disease.

Medications

A scopolamine patch may be used for people with recurrent vertigo, although adverse effects such as dry mouth, blurred vision and urinary retention may limit its use. In Ménière's disease, a diuretic such as hydrochlorothiazide may be prescribed to reduce endolymphatic pressure. A central nervous system depressant such as diazepam or lorazepam may halt an attack of vertigo. Parenteral droperidol provides both a sedative and an anti-emetic effect, making it a useful drug for acute attacks. Anti-vertigo/anti-emetic medications such as meclizine, prochlorperazine or hydroxyzine hydrochloride are prescribed to reduce the whirling sensation and nausea. If the nausea and vomiting are severe, intravenous fluids may be necessary to maintain fluid and electrolyte balance.

Treatments

Bed rest in a quiet, darkened room with minimal sensory stimuli and minimal movement provides the most comfort for the person experiencing an acute attack of vertigo.

Between acute attacks, management of the person with Ménière's disease is directed at preventing future attacks and preserving hearing. A low-sodium diet helps reduce labyrinthine pressure. The Furstenberg diet, a salt-free neutral ash diet, may be prescribed if moderate sodium restriction is ineffective in controlling attacks. People should avoid tobacco, which causes vasoconstriction and can precipitate an attack, along with alcohol and caffeine.

Surgery

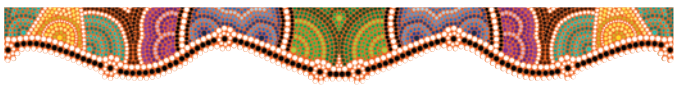
When episodes of vertigo are not controlled through medical interventions, surgery may be necessary. Surgical *endolymphatic decompression* relieves the excess pressure in the labyrinth; a shunt is then inserted between the membranous labyrinth and the subarachnoid space to drain excess fluid away from the labyrinths and maintain lower pressure. This procedure preserves hearing for most people. Vertigo is relieved in approximately 70% of people, but about half of people undergoing this procedure continue to experience sensations of fullness and tinnitus.

Destruction of a portion of the acoustic nerve is an alternative to shunting procedures. In a *vestibular neurectomy*, the portion of cranial nerve VIII that controls balance and sensations of vertigo is severed. This procedure relieves vertigo for up to 90% of people. Although there is a risk of damage to the cochlear portion of the nerve and resultant hearing loss, for most people hearing loss stabilises after neurectomy, even improving for some.

The surgery of last resort for Ménière's disease is a *labyrinthectomy*. The labyrinth is completely removed, destroying

cochlear function. This procedure is used only when hearing loss is nearly complete and vertigo is persistent. Although labyrinthectomy relieves vertigo in nearly all cases, the person may remain unsteady and have continued problems with balance.

After surgery on the inner ear, the person is positioned to minimise ear pressure and vertigo. Movement is restricted and assistance is provided when the person gets up. Anti-emetics and anti-vertigo medications are used to manage symptoms resulting from disruption of the inner ear. Complications include infection and leakage of cerebrospinal fluid.



Nursing care

The person with an inner ear disorder has multiple nursing care needs related to the manifestations of the disorder.

Health promotion

Health promotion focuses on identifying people with potential inner ear disorders. Persistent episodes of dizziness, ringing in the ears, balance problems or loss of hearing should be reported to a healthcare provider. People diagnosed early may have a lower risk of injury and can be taught strategies for maintaining, as near normal as possible, their work and social life.

Assessment

In addition to the following, assess the older person for other medical causes of imbalance and dizziness, such as neurological dysfunction, musculoskeletal and cardiovascular disorders, and endocrine problems.

- *Health history:* medication use; presence of vertigo, tinnitus, nausea and vomiting and hearing loss; balance problems; frequency and duration of symptoms; precipitating factors for an attack.
- *Physical examination:* vital signs, general health; hearing, nystagmus, balance.

Nursing diagnoses and interventions

The risk of trauma in people with inner ear disorders is great. Attacks of vertigo may occur without warning and can be so severe that the person is unable to remain upright. If frequent attacks are accompanied by nausea, nutrition may be compromised. Constant or intermittent tinnitus can interfere with sleep and rest. Finally, because nearly all inner ear disorders are associated with some degree of hearing loss, which may be progressive, the person has significant psychosocial needs.

Risk of trauma

Because of the unpredictable nature of attacks, the person with vertigo due to an inner ear disorder needs to learn strategies for dealing with an acute episode. Because vertigo tends to be chronic except in acute labyrinthitis, the emphasis is on helping the person develop strategies to reduce the frequency of attacks and the risk of injury.

- Monitor for vertigo, nystagmus, nausea, vomiting and hearing loss. *Monitoring is important to determine the severity of impairment, the duration of attacks and the person's ability to predict an impending attack.*
- Instruct to not get up without assistance during episodes of vertigo. *During attacks of vertigo, assistance reduces the risk of falling.*

CONSIDERATION FOR PRACTICE

During an acute attack of vertigo, keep on bed rest with the side rails raised and the call bell readily accessible.

- Educate to avoid sudden head movements or position changes *as sudden movement may precipitate an attack of vertigo.*
- Administer prescribed medications as ordered, including anti-emetics, diuretics and sedatives. *These medications may reduce the frequency, severity and duration of vertigo attacks.*
- Instruct to take the prescribed medication and lie down in a quiet, darkened room when an impending attack is sensed. *These measures help protect the person from injury and may shorten the duration and reduce the severity of the attack.*
- Advise to pull to the side of the road and wait for the symptoms to subside if an attack occurs while driving. *Perception and judgment necessary for safe driving may be impaired during an acute attack; pulling off the road is vital to protect the safety of the person and others.*
- Discuss the effect of unilateral hearing loss on the ability to identify the direction of sounds. To ensure safety, encourage the person to use other senses (e.g. when crossing the street). *Sound perception and differentiation of direction change when hearing is lost unilaterally, just as depth perception changes when vision is lost in one eye.*

Disturbed sleep pattern

The tinnitus often associated with inner ear disorders may be loud and continuous, interfering with the person's ability to concentrate, relax and sleep. It may be perceived as a continuous high-pitched whine, buzzing, ringing or humming sound. In some people, it may have a pulsatile quality.

- Refer for a complete hearing and ear examination if one has not been done. *Although most tinnitus is associated with hearing loss, often due to noise exposure, it may also be associated with treatable conditions such as impacted cerumen, hypertension, cerebrovascular disorders and other conditions.*
- Discuss options for masking tinnitus to promote concentration and sleep:
  a. ambient noise from a radio or sound system
  b. masking device or white-noise machine
  c. hearing aid that produces a tone to mask the tinnitus
  d. hearing aid that amplifies ambient sound.

  These techniques or devices help mask the subjective perception of tinnitus, allowing the person to focus on something other than the sound.

- Discuss the possible risks and benefits of medications to treat tinnitus. *Many medications have been used to treat tinnitus; oral antidepressants such as nortriptyline taken at bedtime have been shown to be most effective.*

Community-based care

Because disorders of the inner ear disrupt balance, safety is a primary focus of education. Assist the person to identify possible hazards in the home environment. Discuss the following points during the teaching session:

- Change positions slowly, especially when ambulating.
- Turn the whole body rather than just the head.
- Sit down immediately with the onset of vertigo and lie down if possible.
- Take prescribed anti-emetic and anti-vertigo medications.
- Wear MedicAlert® identification.
- If appropriate, discuss the surgical procedure, the immediate postoperative period and the long-term effects of the surgery.
- Discuss alternative communication techniques and associated community resources as needed.

THE PERSON WITH AN ACOUSTIC NEUROMA

An **acoustic neuroma**, or schwannoma, is a benign tumour of cranial nerve VIII. It typically occurs in adults between the ages of 40 and 50. They are common and account for about 9% of primary brain tumours. Although usually unilateral, people with neurofibromatosis type 2, a genetic disorder, frequently develop bilateral schwannomas (DeAngelis & Wen, 2012).

These tumours usually occur in the internal auditory meatus, compressing the auditory nerve where it exits the skull to the inner ear. Both the vestibular and the cochlear branches are affected; however, the tumour arises from the vestibular division of the auditory nerve twice as often. If allowed to grow, the tumour eventually destroys the labyrinth, including the cochlea and vestibular apparatus. As the tumour expands, it erodes the wall of the internal auditory meatus. The tumour may eventually impinge on the inferior cerebellar artery, which provides blood to the lateral pons and medulla, the brainstem and the cerebellum. An obstructive hydrocephalus can also occur. Cranial nerves VII (facial) and V (trigeminal) are often affected by the expanding tumour; the tumour frequently wraps around the facial nerve.

Early manifestations of an acoustic neuroma are those associated with disorders of the inner ear: tinnitus, unilateral hearing loss and nystagmus. Dizziness or vertigo may occur. As the tumour expands and occupies increasing amounts of space in the closed cranium, the person experiences neurological signs related to the area of the brain affected.

The presence of the tumour can generally be identified on CT or MRI scans. X-ray films of the petrous pyramid of the temporal bone may show erosion caused by the tumour. The treatment of choice for an acoustic neuroma is surgical excision. In surgery, every effort is made to preserve this nerve and its function as well as other cranial nerves that may be affected.

Postoperative nursing care focuses on preserving cerebral function. Position the person to minimise cerebral oedema and monitor frequently for signs of increased intracranial pressure. Because the gag reflex may be affected, assess the person carefully before food and fluids are allowed by mouth. Speech therapy is often prescribed for the person after surgery. Because deficits may not resolve for a long time after surgery, education and support are vital components of nursing care for the person. (See Chapter 41 for care of the person undergoing craniotomy.)

THE PERSON WITH HEARING LOSS

One in every six people in Australia is reported to be affected by hearing loss. In 2007–2008 the ABS National Health Survey showed that 3 million (13%) Australians had at least one long-term hearing disorder, the most common being complete or partial deafness (10%), followed by tinnitus (ringing in the ears), which affected 2% of the population (AIHW, 2012). Ear disease and/or hearing loss is exceptionally high (up to 70% in adults) in Australian Indigenous communities, especially in remote areas (Burrow et al., 2009).

Hearing loss impairs the ability to communicate in a world filled with sound and hearing individuals. A hearing deficit can be partial or total, congenital or acquired. It may affect one or both ears. In some types of hearing loss, the ability to perceive sound at specific frequencies is lost. In others, hearing is diminished across all frequencies.

People with a hearing loss often display signs that caregivers can recognise. The voice volume of the person with impaired hearing frequently increases and the person positions the head with the better ear towards the speaker. The person frequently may ask people to repeat what they have said or respond inappropriately to questions or statements. A question may elicit a blank look if the person has not heard or understood its content.

Pathophysiology and manifestations

Lesions in the outer ear, middle ear, inner ear or central auditory pathways can result in hearing loss. The process of ageing also can affect the structures of the ear and hearing. Hearing loss is classified as conductive, sensorineural or mixed, depending on which portion of the auditory system is affected. Profound deafness is often a congenital condition.

Conductive hearing loss

Anything that disrupts the transmission of sound from the external auditory meatus to the inner ear results in a conductive hearing loss. The most common cause of conductive hearing loss is obstruction of the external ear canal. Impacted cerumen, oedema of the canal lining, stenosis and neoplasms all may lead to canal obstruction. Other causes of conductive loss include a perforated tympanic membrane, disruption or fixation of the ossicles of the middle ear, fluid, scarring or tumours of the middle ear.

With conductive hearing loss, there is an equal loss of hearing at all sound frequencies. If the level of sound is greater than the threshold for hearing, speech discrimination is good. Because of this, the person with a conductive hearing loss benefits from amplification by a hearing aid.

Sensorineural hearing loss

Disorders that affect the inner ear, the auditory nerve or the auditory pathways of the brain may lead to a sensorineural hearing loss. In this type of hearing loss, sound waves are effectively transmitted to the inner ear. In the inner ear, however, lost or damaged receptor cells, changes in the cochlear apparatus or auditory nerve abnormalities decrease or distort the ability to receive and interpret stimuli.

A significant cause of sensorineural hearing deficit is damage to the hair cells of the organ of Corti. Damage may result from either loud impulse noise (e.g. an explosion) or loud continuous noise (e.g. machinery). Exposure to a high level of noise (e.g. standing close to the stage or speakers at a rock concert) on an intermittent or continuing basis damages the hair and supporting cells of the organ of Corti. Ototoxic drugs also damage the hair cells; when combined with high noise levels, the damage is greater and resultant hearing loss more profound. Ototoxic drugs include aspirin, furosemide, aminoglycosides, streptomycin, vancomycin, antimalarial drugs and chemotherapy such as cisplatin. Other potential causes of sensory hearing loss include prenatal exposure to rubella, viral infections, meningitis, trauma, Ménière's disease and ageing.

Tumours such as acoustic neuromas, vascular disorders, demyelinating or degenerative diseases, infections (bacterial meningitis, in particular) or trauma may affect the central auditory pathways and produce a neural hearing loss.

Sensorineural hearing losses typically affect the ability to hear high-frequency tones more than low-frequency tones. This loss makes speech discrimination difficult, especially in a noisy environment. Hearing aids are often not useful because they amplify both speech and background noise. The increased sound intensity may actually cause discomfort for the person.

Presbycusis

With ageing, the hair cells of the cochlea degenerate, producing a progressive sensorineural hearing loss. In **presbycusis**, gradual hearing loss associated with ageing, hearing acuity begins to decrease in early adulthood and progresses as long as the individual lives. Higher-pitched tones and conversational speech are lost initially. Hearing aids and other amplification devices are useful for most people with presbycusis.

Because the hearing loss of presbycusis is gradual, the person and family may not realise the extent of the deficit. The individual with a hearing impairment may be described as unsociable or paranoid. The family may worry that the person is becoming increasingly forgetful, absentminded or perhaps 'senile'. Depression, confusion, inattentiveness, tension and negative attitudes and/or behaviours have been noted in older adults with hearing impairments. Functional problems such as poor general health, reduced mobility and impaired interpersonal communication are also associated with hearing loss. Caregivers need to be alert for signs of impaired hearing such as cupping an ear, difficulty understanding verbal communication when the person cannot see the speaker's face, difficulty following conversation in a large group and withdrawal from social activities.

Tinnitus

Tinnitus is the perception of sound or noise in the ears without stimulus from the environment. The sound may be steady, intermittent or pulsatile and is often described as a buzzing, roaring or ringing.

Tinnitus is usually associated with hearing loss (conductive or sensorineural); however, the mechanism producing the sound is poorly understood. It is often an early symptom of noise-induced hearing damage and drug-related ototoxicity. Tinnitus is especially associated with salicylate, quinine or quinidine toxicity. Other aetiologies include obstruction of the auditory meatus, presbycusis, middle or inner ear inflammations and infections, otosclerosis and Ménière's disease. Most tinnitus, however, is chronic and has no pathological importance.

Tinnitus that is intermittent or slight enough to be masked by environmental sounds is often well tolerated. When it is loud, continuous and not responsive to treatment, tinnitus can be a significant stressor. It can interfere with activities of daily living, sleep and rest.

INTERPROFESSIONAL CARE

The best treatment for hearing loss is prevention. People need to know the risk of hearing damage and how to prevent it. Awareness of the effects of noise exposure, especially when combined with the ototoxic effects of aspirin or other drugs, is important to prevent sensorineural hearing loss.

Diagnosis

Hearing evaluation includes gross tests of hearing (such as the whisper test), the Rinne and Weber tests, and audiometry.

- *Rinne* and *Weber tests* compare air and bone sound conduction. When bone conduction of sound is better than air conduction, the hearing deficit is a conductive loss. The Rinne test can identify even mild conductive hearing losses. If both air and bone conduction are impaired, a sensorineural loss is indicated (see Chapter 44).
- *Audiometry* identifies the type and pattern of hearing loss. Specific sound frequencies are presented to each ear by either air or bone conduction.
- *Speech audiometry* identifies the intensity at which speech can be recognised and interpreted. *Speech discrimination* evaluates the ability to discriminate between various speech sounds.
- *Tympanometry* is an indirect measurement of the compliance and impedance of the middle ear to sound transmission. The external auditory meatus is subjected to neutral, positive and negative air pressure while the resultant sound energy flow is monitored.
- *Acoustic reflex testing* uses a tone presented at various intensities to evaluate movement of the structures of the middle ear.

Amplification

A hearing aid or other amplification device can help many people with hearing deficits. These assistive devices do nothing to prevent, minimise or treat the hearing loss itself. They amplify the sound presented to the hearing apparatus of the ear, which may bring the level of sound above the hearing threshold, allowing more accurate perception and interpretation of its meaning. When sound perception is distorted, a hearing aid may be less helpful because it simply amplifies the distorted sound.

Unfortunately, fewer than one-fifth of older people with a hearing deficit have and/or use a hearing aid. Denial of the deficit, other health problems, poor visual acuity, decreased manual dexterity and cost all contribute to this low usage. Hearing aids must be individually prescribed by an audiologist. Proper design, proper fit and regular maintenance are necessary for their effectiveness.

All hearing aids include a microphone, amplifier, speaker, earpiece and volume control. Most allow volume control, reduce background noise and can be adjusted for the person's pattern of hearing loss. Behind-ear and in-ear aids often include a telecoil, which amplifies sound from the telephone without feedback. The models also may allow direct audio input (e.g. MP3 player) or include Bluetooth capability for hands-free telephone use. Hearing aids are available in a variety of styles, each with advantages and disadvantages:

- Canal hearing aids (in-the-canal and completely-in-canal) are the least noticeable style, fitting in the ear canal. They are appropriate for mild to moderately severe hearing loss. These small and unobtrusive devices allow use of the telephone and can be worn during exercise. Because of their small size, the person must have good manual dexterity to insert, clean and change the batteries on canal hearing aids. For this reason, older people or people with impaired dexterity may be unable to use them.
- The in-ear style of hearing aid fits into the external ear and is used for mild to severe hearing loss (see Figure 45.16). Its larger size makes manipulation somewhat easier, although it still may be difficult for less dexterous individuals. A greater degree of amplification is possible with the in-ear aid. Many have a toggle switch for telephone usage.
- The behind-ear hearing aid allows finer adjustment of the level of amplification and is easier for the person to manipulate (see Figure 45.17). It can be used by people with mild to profound hearing loss. For the person who wears glasses, this style can be modified, with all components fitting into the temple of the eyeglasses.
- People with profound hearing loss may require a body hearing aid. The microphone and amplifier of this aid are contained in a pocket-sized case that the person clips on to clothing, slips into a pocket or carries in a harness. The receiver is attached by a cord to the case and clips on to the ear mould, which delivers the sound to the ear canal.

With both the in-canal and in-ear style, cleaning is important. Small portals may become plugged with cerumen, interfering with sound transmission.

For the person who does not have a hearing aid, an *assistive listening device* or 'pocket talker', with a microphone and ear buds, is useful. Pocket talkers are available over the counter or through an audiologist and are relatively inexpensive. The earpiece requires no special fitting and the external microphone allows the person to focus on the desired sound rather than simply amplifying all sounds. Assistive listening devices may also be used in conjunction with a hearing aid.

People with tinnitus may find a white-noise masking device helpful to promote concentration and rest. These devices conduct a pleasant sound to the affected ear, allowing the person to block out the abnormal sound.

Surgery

Reconstructive surgeries of the middle ear, such as a stapedectomy or tympanoplasty, may help restore hearing with a conductive hearing loss. Stapedectomy is the removal and replacement of the stapes. This procedure is used to treat hearing loss related to otosclerosis.

In a tympanoplasty, the structures of the middle ear are reconstructed to improve conductive hearing deficits. Chronic otitis media with necrosis and scarring of the middle ear is a common indication for this type of surgery.

For the person with a sensorineural hearing loss, a *cochlear implant* may be the only hope for restoring sound perception.

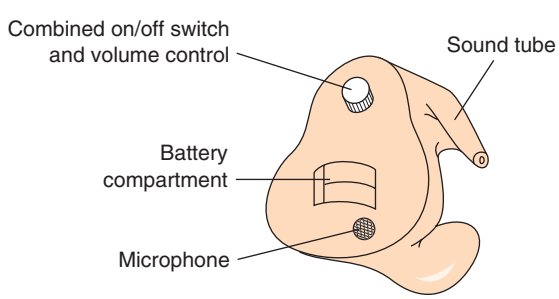


FIGURE 45.16 ■ An in-ear hearing aid

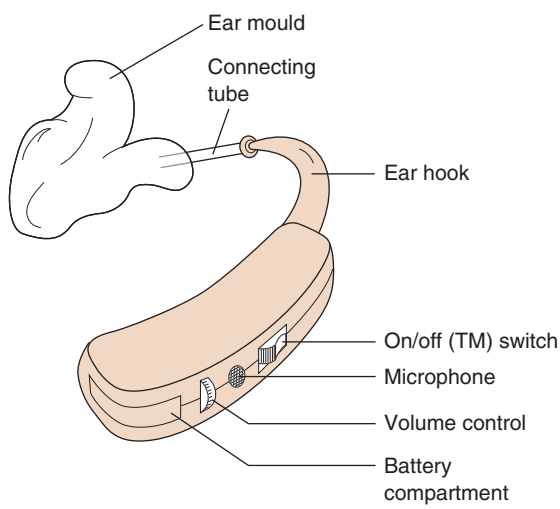

FIGURE 45.17 ■ A behind-ear hearing aid

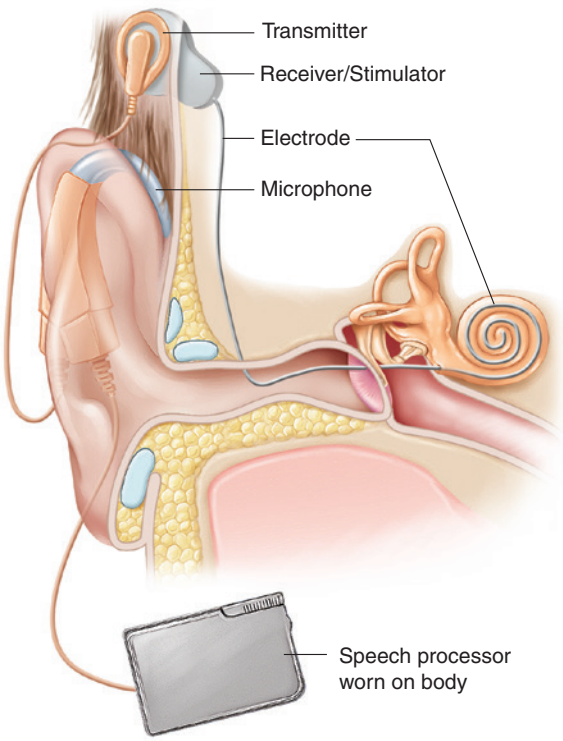

FIGURE 45.18 ■ A cochlear implant for hearing loss

The cochlear implant consists of a microphone, speech processor, transmitter and receiver/stimulator, and electrodes (see Figure 45.18). Its function is more similar to the way the ear normally receives and processes sounds than it is to a hearing aid. The microphone picks up sounds, sending them to the speech processor, which selects and processes useful sounds. The transmitter and receiver/stimulator receive signals from the speech processor, convert them to electrical impulses and send these impulses to the electrodes for transmission to the brain.

Cochlear implants provide sound perception but not normal hearing. The person is able to recognise warning sounds such as cars, sirens, telephones and doors opening or closing. They also receive stimuli to alert them to incoming communication so they can focus on the person speaking. Many people learn to interpret perceived sounds as words, especially when the hearing loss is acquired as an adult.

Nursing care

In planning and implementing nursing care for the person with a hearing deficit, the type and extent of hearing loss, the person's adaptation to the loss and the availability of assistive hearing devices are considered, as well as the person's ability and willingness to use assistive devices.

Health promotion

Healthcare personnel can be instrumental in preventing hearing loss through education. It is important to promote environmental noise control and the use of ear protection. Workplace Health and Safety legislation requires ear protection for work environments that consistently exceed 85 decibels. Education for primary prevention focuses on the following:

- care of the ears and ear canals, including cleaning and treatment of infection
- not placing hard objects into the ear canal
- use of plugs to protect the ears during swimming or diving
- avoiding intermittent or frequent exposure to loud noise
- monitoring for side effects with ototoxic medications
- hearing evaluation when hearing difficulty is present.

Assessment

- *Health history:* perceived ability to hear; effect of hearing loss on function and lifestyle; risk factors such as use of ototoxic medications; upper respiratory tract or frequent ear infection; noise exposure; presence of vertigo, tinnitus, unsteadiness or imbalance.
- *Physical examination:* apparent perception of normal speech; inspection of external ear, tympanic membrane; whisper, Rinne and Weber tests; tests of balance and cranial nerve function.

Nursing diagnoses and interventions

This section focuses on the problems of having a hearing deficit, impaired communication and social isolation for the person who is hearing impaired.

Disturbed auditory perception

Whether the person's hearing deficit is partial or total, impaired sound perception is the primary problem. The person needs to understand what causes the deficit and what to expect for the future. Nursing interventions focus on maximising available hearing and preventing further deterioration to the extent possible.

- Encourage the person to talk about the hearing loss and its effect on activities of daily living. *Hearing loss affects each individual in a different way. The person may be denying the extent of the deficit or grieving the loss. Listening and providing support encourage the person to develop coping strategies.*
- Provide information about the type of hearing loss. Refer the person to an audiologist for evaluation of the hearing loss and possible exploration of amplification devices. *With improved understanding of the deficit, the person can plan ways to compensate.*
- Replace batteries in hearing aids regularly and as needed. *Hearing aid batteries last approximately 1 week. If a battery is old or has been improperly stored, the life may be reduced further.*
- If the hearing aid has a toggle switch for microphone/telephone, be sure it is in the appropriate position. *This ensures proper amplification with the hearing aid.*

CONSIDERATION FOR PRACTICE

Check hearing aids for patency, cleaning out cerumen as necessary.

Impaired verbal communication

A hearing deficit impairs the person's ability to receive and interpret verbal communication. A hearing loss affects the person's ability to follow conversations, use the telephone and enjoy television or other forms of entertainment.

- Use the following techniques to improve communication:
  a. Wave the hand or tap the shoulder before beginning to speak.
  b. If the person wears corrective lenses, ensure that they are clean and encourage the person to wear them.
  c. When speaking, face the person and keep your hands away from your face.
  d. Keep your face in full light.
  e. Reduce the noise in the environment before speaking.
  f. Use a low voice pitch with normal loudness.
  g. Use short sentences and pause at the end of each sentence.
  h. Speak at a normal rate and do not overarticulate.
  i. Use facial expressions or gestures.
  j. Provide a magic slate for written communication.

  Individuals with hearing impairments often lip read, making good visibility of the speaker's face necessary. Excessive environmental noise interferes with the ability to perceive the message. Higher tones are typically lost with presbycusis and other types of hearing loss. Using short sentences and pausing give the person time to interpret the message. Overarticulating makes it more difficult to follow the flow and to lip read. Non-verbal cues and written messages enhance the person's understanding.
- Be sure the hearing aid is properly placed, is turned on and has fresh batteries. *The person may not be aware that the hearing aid is not functioning well.*
- Do not place intravenous catheters in the dominant hand. *The person may need to use that hand to write in order to communicate.*
- Rephrase sentences when there is difficulty understanding. *Hearing losses may affect different sound tones, making some words more difficult to comprehend. Using alternative words and phrases may increase the person's ability to perceive the message.*
- Repeat important information. *The nurse makes sure that the person understands the information.*
- Inform other staff about the person's hearing deficit and effective strategies for communication. *Consistent use of effective strategies for communication decreases the person's frustration.*

Social isolation

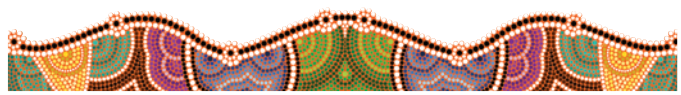
The person with impaired hearing often becomes socially isolated. This isolation may be self-imposed because of difficulty communicating, especially in a group. Often, however, the isolation comes about gradually and without intention. The person finds social settings such as family dinners or community gatherings increasingly difficult. Friends and family become frustrated trying to communicate with someone who has a hearing impairment and invitations to participate in social activities dwindle.

- Identify the extent and cause of the social isolation. Help to differentiate the reality of the isolation and its cause from the person's perception of isolation. *People with impaired hearing may be unaware that they are isolated. Identifying factors that contribute to isolation may provide the needed impetus to remedy the hearing loss. People may also experience paranoid thinking as a result of impaired communication and believe that friends and family have purposely begun to avoid interactions.*
- Encourage the person to interact with friends and family on a one-to-one basis in quiet settings. *People with impaired hearing are more successful in understanding conversations that take place in small groups and quiet settings.*
- Treat the person with dignity and remind friends and family that a hearing deficit does not indicate loss of mental faculties. *Inappropriate responses due to a hearing deficit can cause others to perceive the person as 'stupid' or demented.*
- Involve the person in activities that do not require acute hearing, such as draughts and chess. *The person has an opportunity to interact socially without the stress of straining to hear.*
- Obtain a pocket talker or encourage the person and family to do so.
- Refer the person to an audiologist for evaluation and possible hearing-aid fitting.
- Refer the person to resources such as support groups and senior citizen centres. *These groups provide new social outlets.*

Community-based care

Educating for home and community-based care for the person with hearing loss and family focuses on managing the deficit and developing coping strategies. Referral to an audiologist for evaluation of the deficit and the usefulness of a hearing aid may be appropriate. In addition, discuss the following topics as appropriate for each person:

- use, care and maintenance of a hearing aid
- strategies for coping with the hearing deficit
- voicing a preference for individual visits and small-group interactions rather than large social functions
- highlighting relevant resources available within the state and/or territory.



CHAPTER HIGHLIGHTS

- Structures of the external eye are vulnerable to trauma and infection. While usually minor, these problems can cause significant pain, scarring and clouding of the cornea, and loss or impairment of vision.
- Cataracts, glaucoma, age-related macular degeneration and diabetic retinopathy are leading causes of visual impairment in Australia. While these conditions cannot, in most cases, be prevented, they often can be treated or their progress slowed, preserving vision.
- Age, smoking, diabetes and long-term use of certain drugs are risk factors for cataract development. Removal of the clouded lens with insertion of an intraocular lens is the treatment of choice for cataracts. Surgery is elective, performed only when the cataract significantly impairs the ability to maintain ADLs and recreational activities.
- Glaucoma is progressive loss of visual fields associated with increased intraocular pressure and impaired aqueous humour drainage. Open-angle glaucoma, the predominant form of the disorder, can be controlled using medications and, as needed, laser surgery to promote aqueous humour drainage.
- Angle-closure glaucoma is a medical emergency requiring immediate treatment to lower intraocular pressure to preserve vision. Angle-closure glaucoma usually affects only one eye; however, the person is at risk of future attacks affecting the other eye.
- Age-related macular degeneration, a leading cause of blindness, cannot be effectively treated, although its progress may be slowed or halted through use of high-dose antioxidant vitamins and zinc if it is identified early. Macular degeneration affects the macula, the area of high-acuity central vision.
- Diabetic retinopathy eventually affects nearly all people with diabetes. It is a disease of the small blood vessels of the retina, leading to formation of aneurysms, retinal ischaemia and growth of fragile new vessels (neovascularisation) that easily rupture leading to haemorrhage. It is treated with laser surgery to seal fragile vessels.
- Otitis media is related to eustachian tube dysfunction, with impaired pressure equalisation of the middle ear. Otitis media may be either serous (sterile) or infectious (suppurative). Both cause acute discomfort with diminished hearing, snapping, popping and possible vertigo and systemic symptoms. The risk of complications, including rupture of the tympanic membrane, damage to structures of the middle ear and spread of infection to surrounding tissues, is greater with acute suppurative otitis media.
- Potential complications of acute otitis media include mastoiditis, chronic otitis media with tympanic membrane perforation and cholesteatoma formation. Hearing loss in the affected ear is a possibility with these disorders. The primary treatment is prevention through adequate treatment of acute otitis media.
- The primary manifestations of disorders of the inner ear are vertigo and possible hearing loss. Severe vertigo can interfere with safety, nutrition and the person's ability to maintain ADLs and life roles.
- The two main types of hearing loss are conductive and sensorineural. Presbycusis, hearing loss associated with ageing, is a type of sensorineural hearing loss. Hearing loss may be accompanied by tinnitus, the perception of sound without an environmental stimulus. Amplification devices (hearing aids) are the primary treatment for hearing loss.

CONCEPT CHECK

1 A nurse is working with a group of residents in a long-term care facility. All of the residents have moderate to severe hearing or vision impairment. Which of the following does the nurse identify as the highest priority of care?
1 preventing sensory deprivation
2 encouraging social interaction
3 promoting family relationships
4 maintaining resident safety

2 The nurse teaching a person with newly diagnosed glaucoma emphasises which of the following instructions?
1 turning the head side to side to compensate for impaired peripheral vision
2 using the prescribed eye drops as directed on a continuing basis
3 contacting the doctor if further decline in vision is noticed
4 avoiding coughing, sneezing or straining to have a bowel movement

3 A person with glaucoma has a history of heart failure. Which medication should the nurse discuss with the doctor before administering it?
1 brimonidine
2 dorzolamide
3 timolol
4 latanoprost

4 A person with Ménière's disease experiences frequent attacks of vertigo and tinnitus. Of the following teaching points, which one has the highest priority for this person?
1 Follow a low-sodium diet.
2 Stop smoking.
3 Take prescribed anti-emetic medications.
4 Sit down when an attack develops.

5 On a person's return from cataract surgery, the nurse in the ambulatory surgery recovery unit places the person:
1 in semi-Fowler's position
2 on the affected side
3 in a private room
4 in proximity to the nurses' station

6 A person calls her primary care provider's office with complaints of bright flashing lights to the side of her vision. The appropriate response by the nurse is to:
1 recommend that she lie down until the sensation has passed
2 advise her to make an appointment to have her blood pressure checked
3 initiate immediate referral to an ophthalmologist
4 reassure her that this is not unusual and should resolve without treatment

7 A person presents at the urgent care clinic with complaints of right ear pain. Which of the following should be included in physical assessment of this person? (Select all that apply.)
1 vital signs with temperature
2 inspection of the oral pharynx
3 manipulation of the ear pinna
4 palpation of cervical lymph nodes
5 inspection of the ear canal and tympanic membrane

8 An elderly resident in an assisted living facility complains to the nurse that his head 'feels stuffy' and he has ringing in his ears. The appropriate response by the nurse would be to
1 make an appointment with the resident's primary care provider

2 refer the person for evaluation by a local audiologist
3 provide non-prescription ear drops for daily use
4 inspect the ear canals for patency

9 The nurse caring for a person with a severe hearing deficit identifies which of the following as an appropriate goal towards improving the person's social interactions?
1 Will plan to have dinner with one or two friends weekly.
2 Will participate in senior centre communal lunches at least twice per week.
3 Will engage in activities such as card tournaments and dancing.
4 Will attend religious services of choice.

10 When assessing a person, the nurse notes absence of the red reflex in the person's right eye. On questioning, the person responds: 'Oh yes, my doctor told me I have cataracts. When do you think I should have them removed?' How should the nurse respond?
1 'It appears that the right eye is due for surgery.'
2 'Are you having difficulty reading or doing activities you enjoy?'
3 'Are you starting to experience pain in your right eye or frequent headaches?'
4 'Cataracts can be removed any time that it is convenient for you.'

UNIT 12 BUILDING CLINICAL COMPETENCE

Responses to altered sensory function

CLINICAL SCENARIO

You have been assigned to work with the following four people for the 0700 shift on a medical–surgical unit. Significant data obtained during report are as follows:

- Andrew Hardy, a 50-year-old type 1 diabetic with hypertension, is a new admission during the night shift with blood glucose of 33.4 mmol/L. On assessment, the person reveals that he has been seeing black spot floaters and flashing lights at times. He is now complaining of blurred vision.
- Gladys Harvey is an 84 year old who had right eye cataract surgery yesterday. Her vital signs have been stable since surgery. She has begun complaining of itching and slight discomfort in the right eye.
- Georgia Stanley is a 45 year old admitted with complaints of feeling like she is spinning or falling, and has ringing and a fullness feeling in her left ear. Her vital signs are T 37°C, P 78, R 16, BP 102/68. She is diaphoretic and complains of nausea. She is scheduled for x-rays and a CT scan of her head at 0800.
- Kenneth Koch, a 30 year old, is a postoperative person who had a right ear tympanoplasty yesterday because of hearing loss due to chronic otitis media. Vital signs are T 37.6°C, P 90, R 20, BP 136/86. The person is requesting medication for ear pain. Pain scale is 9 out of 10 on a scale of 10 being the highest.

Critical thinking questions

1 In what order would you visit these people after handover?

1. _____
2. _____
3. _____
4. _____

2 Which top two priority assessments would you choose for each of the people presented above? Can you explain, if asked, the rationale for your choices?

	Priority Assessment #1	Priority Assessment #2
Andrew Hardy		
Gladys Harvey		
Georgia Stanley		
Kenneth Koch		

3 Which is the correct treatment for a person such as Mr Hardy who has symptoms of diabetic retinopathy?

1. scleral buckling
2. enucleation
3. photorefractive keratectomy
4. laser photocoagulation

4 After cataract surgery, Ms Harvey is placed in which position to reduce intraocular pressure?

1. Sims' position on the unaffected side
2. semi-Fowler's position on the unaffected side
3. supine with the head elevated 10 degrees
4. prone position on the affected side

5 A low-sodium diet is ordered for Ms Stanley, who has Ménière's disease. Ms Stanley understands this diet when she picks which meal plan?

1. hot dog on a roll with tomato sauce and mustard
2. ham and cheese sandwich with potato salad
3. grilled chicken sandwich with lettuce and tomato
4. hamburger on a roll with potato chips

6 Which assessment data would be most indicative of hyphema, a potential result of blunt eye trauma?

1. eye pain, decreased visual acuity, seeing a reddish tint
2. hypertension, headache, facial pain
3. white eye reflex, pressure and blindness in affected eye
4. double vision, sunken eye, limited eye movement

7 Which techniques may improve communication with the person who has a hearing impairment? (Select all that apply.)

1. Speak loudly to enhance hearing.
2. Speak at a normal rate and avoid overarticulating.
3. Stand in front of a window so person can see the face.
4. Face the person to enhance lip reading.
5. Turn down the television or radio.
6. Use short sentences and pause frequently.

8 A prescription for gentamicin is ordered for a person with conjunctivitis. The nurse understands that a serious adverse effect of aminoglycosides is which effect?

1. damage to the eighth cranial nerve resulting in hearing loss
2. vasodilation leading to migraine headaches
3. leg pain caused by thromboembolism
4. stomach irritation leading to gastric ulcers

9 When evaluating for Ménière's disease, which diagnostic studies would you expect to be ordered? (Select all that apply.)

1. caloric testing
2. Rinne and Weber tests
3. troponins
4. complete blood cell count
5. glycerol test
6. blood glucose test

10 After eye surgery, which measures does the nurse instruct the person in?

1. Avoid lifting more than 7 kg.
2. Avoid coughing or sneezing.
3. Lie on the affected side.
4. Remove the eye patch when sleeping.

11 Which is the correct way to instil ear drops in the adult person with otitis media?

1. Have person hang head over side of bed, pull pinna of the ear straight up, instil ear drops and have person turn to instil drops to other ear.
2. Have person tilt head towards unaffected side, pull pinna of the ear down and back, instil ear drops and have person remain still for 3 minutes.

3. Have person lie on unaffected side, pull the pinna of the ear up and back, instil ear drops and have person remain still for 5 minutes.
4. Have person lie in Sims' position on unaffected side, pull the pinna of the ear back, instil ear drops and have the person turn to other side after 1 minute.

12 Which is the appropriate primary prevention to teach Mr Koch to prevent hearing loss?

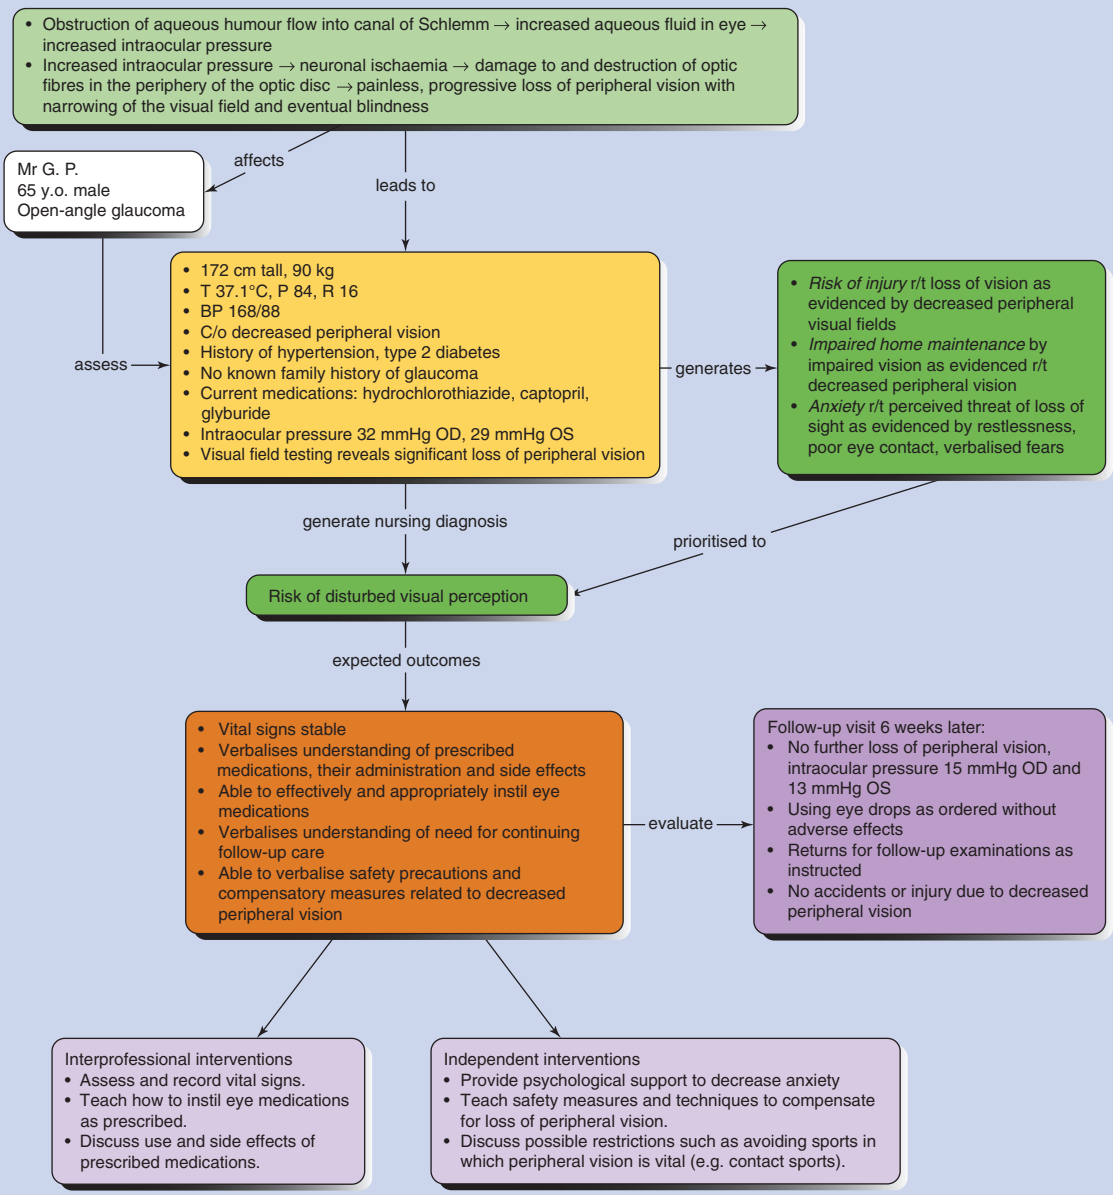
1. Cleanse the ear with ear swabs to prevent earwax build-up.
2. Avoid getting water in the ears when showering.
3. Monitor for ringing in the ears when taking paracetamol.
4. Wear ear protectors when exposed to loud noises.

CASE STUDY

George Panzarin is a 65-year-old Greek–Australian male who is seen in the eye clinic for a routine eye examination. He states he has not had any recent eye infections or eye injuries. He denies pain in the eyes. Vital signs are T 37.1°C, P 84, R 16, BP 168/88. His height is 172 cm and weight is 90 kg. His medical history indicates that he has hypertension and type 2 diabetes. He is taking hydrochlorothiazide, captopril and glyburide. He states that he is on an 8400 kilojoule diabetic diet but he is often non-compliant with the diet. He sees his medical doctor about once a year but has not had an eye exam in about 10 years. He is married with five grown children and six grandchildren. Mr Panzarin states he does not know if there is any family history of glaucoma because his father died of a heart attack at age 50 and his mother died of cancer at age 60.

The ophthalmologist performs a tonometry, which indicates an increase in intraocular pressure. A fundoscopic examination indicates pallor and increase in the size and depth of the optic cup on the optic disc. Visual field testing indicates significant peripheral vision loss. The results of these tests indicate a diagnosis of glaucoma.

Based on the medical diagnosis of open-angle glaucoma and the person's decreased peripheral vision, the nursing assessment *Risk of disturbed visual perception* is appropriate for planning care for Mr Panzarin.



UNIT 13

RESPONSES TO ALTERED REPRODUCTIVE FUNCTION

CHAPTER 46

A PERSON-CENTRED APPROACH TO ASSESSING THE MALE AND FEMALE REPRODUCTIVE SYSTEMS

MOIRA STEPHENS

LEARNING OUTCOMES

- Describe the anatomy, physiology and functions of the male and female reproductive systems, including the breasts.
- Explain the functions of the male and female sex hormones.
- Identify specific topics for consideration during a health history interview and assessment of a person with health problems involving the reproductive system and breast structures and/or functions.
- Describe normal variations in assessment findings for the older adult.
- Identify manifestations of impairment in the male and female reproductive system and breast structure or function.

CLINICAL COMPETENCIES

- Conduct and document a health history for men and women having or at risk of alterations to the reproductive system, including the breasts.
- Conduct and document a physical assessment of male and female reproductive system structures and functions, including the breasts.
- Monitor and interpret the findings of diagnostic tests and report abnormal findings.

EQUIPMENT NEEDED

- Disposable gloves
- Water-soluble lubricant
- A good light source
- Sterile cotton swabs (for culture)
- Culture media (for culture)
- A spatula, cotton swab or endocervical brush, slides and cytological fixative (for Pap smear)
- Vaginal speculum of appropriate size

KEY TERMS

Although the reproductive organs in men and women are very different, they share common functions: enabling sexual pleasure and reproduction. The reproductive organs, in conjunction with the neuroendocrine system, produce hormones important in biological development and sexual behaviour. Parts of the reproductive organs also enclose and are integral to the function of the urinary system. Assessment of the reproductive and urinary systems is often difficult for both the nurse and the individual, and requires sensitivity on the part of the nurse when asking questions about topics that the person may be hesitant to talk about. Skill and sensitivity in conducting physical examinations of an area of the body usually considered private is also required.

ANATOMY, PHYSIOLOGY AND FUNCTIONS OF THE MALE REPRODUCTIVE SYSTEM, INCLUDING THE BREASTS

The male reproductive system comprises the paired testes, scrotum, ducts, glands and penis (see Figure 46.1). The breasts are part of the male reproductive system and are also assessed. The location and functions of the male reproductive organs are summarised in Table 46.1.

The breasts

The male breast is comprised primarily of an areola (circular pigmented area) and a small nipple. These lie over a thin disk of undeveloped breast tissue that may not be overtly different from surrounding tissue. Approximately one in three men has a firm area of breast tissue 2 cm or larger; the limits of the normal size of this area have not been established (Bickley, 2012).

The penis

The penis is the genital organ that encloses the urethra (see Figure 46.1). It is homologous to the clitoris of the female. The penis is composed of a shaft and a tip called the glans, which is covered in the uncircumcised man by the foreskin (or prepuce). The shaft contains three columns of erectile tissue: the two lateral columns are called the corpora cavernosa and the central mass is called the corpus spongiosum.

Erection occurs when the penile masses become filled with blood in response to a reflex that triggers the parasympathetic nervous system to stimulate arteriolar vasodilation. The erection reflex may be initiated by touch, pressure, sights, sounds, smells or thoughts of a sexual encounter. After ejaculation, the arterioles vasoconstrict and the penis returns to a flaccid state.

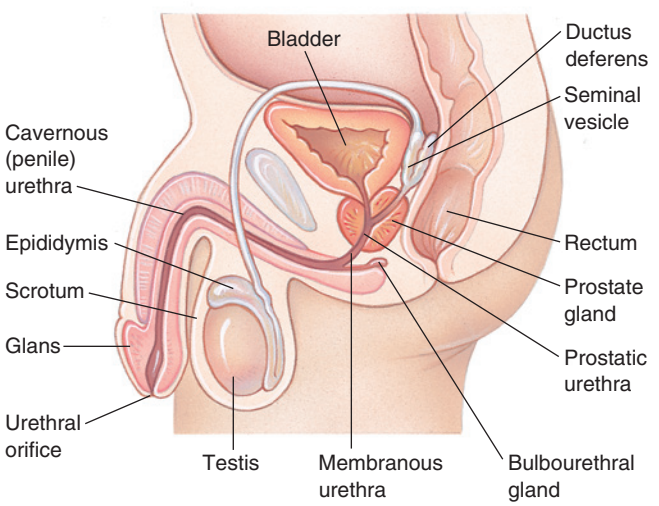


FIGURE 46.1 ■ The male reproductive system

The scrotum

The scrotum is a sac or pouch made of two layers. The outer layer is continuous with the skin of the perineum and thighs. The inner layer is made of muscle and fascia. The scrotum hangs at the base of the penis, anterior to the anus, and regulates the temperature of the testes. The optimum temperature for sperm production is about 2 to 3°C below body temperature. When the testicular temperature is too low, the scrotum contracts to bring the testes up against the body. When the testicular temperature is too high, the scrotum relaxes to allow the testes to lie further away from the body.

The testes

The testes develop in the abdominal cavity of the foetus and then descend through the inguinal canal into the scrotum. Approximately 30–45% of premature and 1–4.5% of full-term infant boys are born with at least one undescended testicle (Ashley, Barthold & Kolon, 2010), a condition that usually corrects itself within 1 year. This is cryptorchidism (the absence of one or both testes from the scrotum) and is distinct from monorchism (the condition of having one testicle). The testes are homologous to the female's ovaries. These paired organs are each about 4 cm long and 2.5 cm in diameter. They are suspended in the scrotum by the spermatic cord. Each is surrounded by two coverings: an outer tunica vaginalis and an inner tunica albuginea. Each testis is divided into 250 to 300 lobules, with each lobule containing one to four seminiferous tubules. The testes produce sperm and testosterone.

The seminiferous tubules are responsible for sperm production. Leydig's cells (or interstitial cells) lie in the connective tissue surrounding the seminiferous tubules and produce testosterone.

The ducts and semen

The seminiferous tubules lead into the efferent ducts and become the rete testis. From the rete testis, 10 000 to 20 000 efferent ducts join the epididymis, a long coiled tube that lies over the outer surface of each testis. The epididymis is the final

TABLE 46.1 Location and function of the male reproductive organs

MALE REPRODUCTIVE ORGAN	LOCATION	FUNCTION
Penis	Attached to front and sides of the pubic arch. Proximal, ventral surface is directly continuous with the scrotum.	Excretes semen and urine. Deposits sperm.
Scrotum	Hangs from body at root of penis.	Contains testes, epididymis and portions of the vas (ductus) deferens.
Testes	In the scrotal sac.	Produce sperm and testosterone.
Epididymis	Posterolateral to upper aspect of each testis.	Stores sperm. Promotes sperm maturation. Transports sperm to vas deferens.
Vas deferens (ductus deferens)	Between the epididymis and the seminal vesicle forming the ejaculatory duct.	Stores sperm. Transports sperm.
Urethra	Begins at bladder and passes through prostate and penis.	Serves as passageway for urine or semen.
Prostate gland	Encircles the urethra at the neck of the bladder.	Contributes to ejaculatory volume. Enhances sperm motility and fertility.
Seminal vesicles	Lie on posterior bladder wall.	Contribute to ejaculatory volume. Contain nutrients to sustain sperm and prostaglandins to facilitate sperm motility.
Bulbourethral (Cowper's) glands	Inferior to the prostate.	Secrete mucus into urethra. Neutralise traces of acidic urine in urethra.

area for the storage and maturation of sperm. When a man is sexually excited, the epididymis contracts to propel the sperm through the vas deferens to the ampulla, where the sperm are stored until ejaculation.

The seminal vesicles at the base of the bladder produce about 60% of the volume of seminal fluid. Seminal fluid is also made of secretions from the accessory sex organs, the epididymis, the prostate gland and Cowper's glands. Seminal fluid nourishes the sperm, provides bulk and increases its alkalinity. (An alkaline pH is essential to mobilise the sperm and ensure fertilisation of the ova.) Sperm mixed with this fluid is called **semen**. Each seminal vesicle joins its corresponding vas deferens to form an ejaculatory duct, which enters the prostatic urethra. During ejaculation, seminal fluid mixes with sperm at the ejaculatory duct and enters the urethra for expulsion.

The total amount of semen ejaculated is 2 to 4 mL, although the amount varies. The total ejaculate of a healthy male contains from 100 to 400 million sperm.

The prostate gland

The prostate gland is about the size of a walnut. It encircles the urethra just below the urinary bladder (see Figure 46.1). It is made of 20 to 30 tubuloalveolar glands surrounded by smooth muscle. Secretions of the prostate gland make up about one-third of the volume of the semen. These secretions enter the urethra through several ducts during ejaculation.

Spermatogenesis

Spermatogenesis is the series of physiological events that generate sperm in the seminiferous tubules. This process begins with puberty and continues throughout a man's life, with several hundred million sperm produced each day.

The inner layer of the seminiferous tubules consists of sustentacular cells (or Sertoli's cells), which contain the spermatocytes and sperm in different stages of development. Sertoli's cells secrete a nourishing fluid for the developing sperm, as well as enzymes that help convert spermatocytes to sperm. The events in spermatogenesis, which take 64 to 72 days, are as follows:

1. The spermatogonia (sperm stem cells) undergo rapid mitotic division. As these cells multiply, the more mature spermatogonia divide into two daughter cells. These daughter cells grow and become the primary spermatocytes (and eventually become sperm).
2. Primary spermatocytes divide by meiosis to form two smaller secondary spermatocytes, which in turn divide to form two spermatids. This process occurs over several weeks.
3. The spermatids elongate into a mature sperm cell with a head and a tail. The head contains enzymes essential to the penetration and fertilisation of the ova. The flagellar motion of the tail allows the sperm to move. The sperm cells then move to the epididymis to mature further and develop motility.

Functions of the male sex hormones

The male sex hormones are called **androgens**. Most androgens are produced in the testes, although the adrenal cortex also produces a small amount. **Testosterone**, the primary androgen produced by the testes, is essential for the development and maintenance of sexual organs and secondary sex characteristics

and for spermatogenesis. It also promotes metabolism, growth of muscles and bone, and libido (sexual desire).

ASSESSING THE MALE REPRODUCTIVE SYSTEM

The structures and functions of the male reproductive system are assessed by findings from a comprehensive assessment, which includes both a health assessment interview to collect subjective data and a physical assessment to collect objective data. In addition, a number of diagnostic tests may provide further information.

Health assessment interview

A health assessment interview to determine health issues with the male reproductive system may be conducted for different reasons; for example:

- during a health screening
- as part of a comprehensive health assessment
- during a focused assessment for a specific health problem (such as a discharge from the penis).

Men may be embarrassed to discuss health problems or concerns involving their reproductive organs so it is important for the nurse to ask questions in a non-judgmental, non-threatening and matter-of-fact manner. Consider the psychological, social and cultural factors that affect sexuality and sexual activity. Use words that the man can understand and do not be embarrassed or offended by the words he uses. The man may perceive the interview as less threatening if the discussion begins with more general questions and then progresses to specific questions. Ask questions in a way that gives the man permission to describe behaviours and manifestations. For example, rather than asking a man if he has difficulty achieving or maintaining an erection, ask him to describe any changes he has noticed in his erections.

If the man has identified a health problem, the nurse needs to analyse its onset, characteristics and course, severity, precipitating and relieving factors, and any associated symptoms, noting the timing and circumstances. For example, you may ask the man:

- When did you first notice that you were having difficulty urinating?
- Did you use a different brand of condoms before you noticed the rash on your penis?
- Describe the changes that occurred in your ability to have an erection after you started taking medicine for high blood pressure.

In questioning the man about past medical history, ask about chronic illnesses such as diabetes, chronic kidney failure, cardiovascular disease, multiple sclerosis, spinal cord tumours or trauma, or thyroid disease. The effects of these illnesses, as well as the treatment of the illnesses, may cause impotence (inability to achieve or maintain an erection). The following drugs may cause sexual function problems: antihypertensives, antidepressants, antispasmodics, tranquillisers, sedatives, antipsychotics and histamine$_2$-receptor antagonists. Psychosocial stressors also may contribute to impotence.

If the man was born to a woman treated during pregnancy with diethylstilbestrol (DES), a drug used in the 1940s and 1950s to prevent miscarriage, he may have congenital deformities of the urinary tract as well as decreased semen levels. If the man had mumps as a child, sterility is possible. Testicular cancer is a rare cancer with 76% of diagnoses occurring in men between 20 and 44 years of age. In Australia in 2011, there were 732 new cases diagnosed and 15 testicular-cancer-related deaths (Australian Institute of Health and Welfare (AIHW), 2015). There are two kinds of testicular cancer: testicular teratoma or non-seminoma, and seminoma. Non-seminoma is a cancer of the mature germ cells, mostly affecting men between the ages of 15 and 35, whereas seminoma develops in the immature germ cells, primarily affecting slightly older men between the ages of 25 and 55. Both kinds of testicular cancer can be treated successfully (cured), especially if detected early. The risk of testicular cancer is greatest in men who have a history of an undescended testicle, an inguinal hernia, testicular swelling with mumps, a history of maternal use of DES or oral contraceptives, and a family history of testicular cancer.

Explore the lifestyle and social history of the man; the use of alcohol, cigarettes or illicit drugs may affect sexual function. Unprotected sexual intercourse increases the potential for sexually transmitted infections, including hepatitis B and HIV infection. Ask about sexual preference. Unprotected sexual intercourse with same-sex partners further increases the risk of hepatitis B and HIV infection. Other questions about sexual activity may include number of sexual partners, history of premature ejaculation, impotence, any history of sexual trauma, use of condoms or other contraceptives, and current level of sexual satisfaction.

Interview questions categorised by functional health patterns are listed in the 'Functional health pattern interview' table below.

Physical assessment

Physical assessment of the male reproductive system may be performed as part of a comprehensive assessment or separately for men with identified sexual health problems. If conducted as part of a total physical assessment, this is usually the final

SAMPLE DOCUMENTATION

Assessment of the male reproductive system

12/10/2015 NURS 1000 hrs	23-year-old male, first visit to health department for problems he described as 'an unusual lump in his testicle'. He states that his girlfriend noticed a lump in his left testicle 2 weeks ago, which is still there. He also states that it is not painful. Palpation of his testicles confirms a 1 cm nodule in his left testicle. Palpation of inguinal lymph nodes revealed no enlarged nodes. Referred for testicular ultrasound ———— RN P.Tone

P.TONE RN

FUNCTIONAL HEALTH PATTERN INTERVIEW The male reproductive system

FUNCTIONAL HEALTH PATTERN	INTERVIEW QUESTIONS AND LEADING STATEMENTS
Health perception–Health management	■ Have you ever had problems with your reproductive organs (penis, testicles, prostate gland)? Explain. If so, how was the problem treated? ■ Have you ever had surgery on your reproductive organs? If so, what type, when, and what was the outcome? ■ Have you ever noticed any pain or swelling in your breasts? Explain. ■ Do you practise testicular self-examination? How often? ■ Have you ever noticed any pain or swelling in your testicles? Explain. ■ Do you smoke? If so, how much and for how long?
Nutritional–Metabolic	■ Describe your usual intake of food and fluids in a 24-hour period.
Elimination	■ Do you now or have you ever had a discharge from your penis? If so, describe the colour, odour, consistency, amount and frequency. ■ Have you ever had any bleeding from your penis? Explain. ■ Have you noticed any change in your urination, such as burning, frequency, urgency, difficulty starting the stream, size of the stream, dribbling or getting up frequently at night? Explain.
Activity–Exercise	■ Describe your usual activity in a 24-hour period. ■ Do you participate in sports or heavy lifting? If so, do you wear a protective cup or athletic support?
Sleep–Rest	■ Describe the quality of your rest and sleep.
Cognitive–Perceptual	■ Describe any pain you have had in the groin area, testicles, penis or scrotum. Where is it? Do you experience it in other parts of your body? How long does it last? What makes it worse or relieves it? ■ Has there been a change in the condition or colour of the skin on your scrotum or penis? Explain.
Self-perception–Self-concept	■ Has this problem affected how you feel about yourself? ■ Do you feel that your needs for intimacy and affection are being met?
Role–Relationships	■ Has having this condition affected your relationships with others? ■ Has having this condition interfered with your ability to work? Explain. ■ Has anyone in your family had problems with prostate cancer? Explain.
Sexuality–Reproductive	■ Are you currently in a sexual relationship? If so, has this condition interfered with your usual sexual activity? ■ How long have you been with your current partner? Have you had any other partners during this time? ■ What is your sexual preference? ■ Has having this problem affected your relationship with your spouse or sexual partner? ■ Are you satisfied with your current level of sexual functioning? ■ Have you ever had any problem with achieving or maintaining an erection or ejaculation? ■ Do you use any medications to facilitate your sexual ability? Describe. ■ Do you use condoms every time you have sexual contact?
Coping–Stress–Tolerance	■ Has having this condition created stress for you? If so, does your health problem seem to be more difficult when you are stressed? ■ Have you experienced any kind of stress that makes the condition worse? Explain. ■ Describe what you do when you feel stressed.
Value–Belief	■ Describe how specific relationships or activities help you cope with this problem. ■ Describe specific cultural beliefs or practices that affect how you care for and feel about this problem. ■ Are there any specific treatments that you would not use to treat this problem?

TABLE 46.2 Age-related changes in the male reproductive system

AGE-RELATED CHANGE	SIGNIFICANCE
Prostate gland	
• A significant number of older men have some degree of benign prostatic hyperplasia.	Although ageing does not cause prostate cancer, its incidence does increase with age. The following 2011 data describe incidence per 100 000 men (AIHW, 2015): 55–59 years of age—377 60–64 years of age—608 65–69 years of age—895 70–74 years of age—883
Penis, testes and scrotum	
• Epithelial tissue and mucosa of seminal vesicles are thinner and have reduced capacity to hold fluid. • Sclerosis of penile arteries and veins may occur.	Although men may father children throughout life, the sperm count is reduced in some men. Changes in the vascular system of the penis may mean the ageing man takes longer to achieve an erection and ejaculation or may be impotent.

'system' to be assessed. Problems of the male reproductive system may involve the urinary system, making an assessment of both systems important. (See Chapter 25 for assessment of the urinary system). The nurse must feel comfortable with the examination of people of the opposite gender; if either the nurse or the individual is not comfortable, a nurse of the same gender should be asked to conduct this part of the assessment. Normal age-related findings for the older man are summarised in Table 46.2.

The male reproductive system is assessed by inspection and palpation. Explain the procedures for the examination thoroughly and in a matter-of-fact way to decrease anxiety and embarrassment. If the man is unfamiliar with his internal genitalia, charts may be used to illustrate the parts that will be examined. Ask the man to empty his bladder (to be more comfortable during the examination), remove his clothing and put on a gown. The assessment may be done with the man sitting or standing. Expose only those body parts being examined to preserve modesty. Ensure that the examining room is warm and private. Put on gloves before beginning and wear them throughout the examination.

Diagnostic tests

The results of diagnostic tests of the structures and functions of the male reproductive system are used to support the diagnosis of a specific sexual problem, injury or disease; to provide information to identify or modify the appropriate medications or treatments used to treat the condition; and to help nurses monitor the man's responses to treatment and nursing care interventions. Diagnostic tests used to assess the male reproductive system are described in the 'Diagnostic tests' table below and summarised in the bulleted list that follows. More information is included in the discussion of specific health problems or diseases in Chapter 47.

- Hormone changes and syphilis are diagnosed with blood tests, discussed in Chapters 47 and 49. Gonorrhoea, as well as other sexually transmitted infections, is diagnosed by cultures and smears of discharge or mucous membranes.
- Prostate cancer may be diagnosed following a raised PSA reading. Relapse is monitored by measuring prostate specific antigen (PSA). PSA is a glycoprotein secreted by

DIAGNOSTIC TESTS The male reproductive system

NAME OF TEST Prostate specific antigen (PSA)

PURPOSE AND DESCRIPTION The PSA level is raised in prostate carcinoma, benign prostatic hypertrophy and following prostate examination. PSA is used to monitor recurrence of prostate cancer. PSA as a screening test is unproven and the predictive value of a raised PSA in healthy men is low.

Normal value: There is no specific normal level but most doctors consider below 4 ng/mL as normal and would recommend a biopsy of the prostate if the result was greater than 0.4 ng/mL

RELATED NURSING CARE No special physical preparation is needed but psychological care is always a consideration, particularly because of the potential implications of a raised PSA result.

NAME OF TEST Prostate ultrasound

PURPOSE AND DESCRIPTION Conducted to identify testicular torsion or masses and to evaluate prostate enlargement. Uses high-frequency sound waves, passed through tissues of various densities, to produce a visual graphic of tissue being examined.

RELATED NURSING CARE A full bladder may be required for the study. Note that if the man has frequency, urgency of micturition or urinary incontinence he may be most anxious about this requirement.

DIAGNOSTIC TESTS The male reproductive system (continued)

NAME OF TEST Prostate biopsy
- Transrectal biopsy
- Transurethral biopsy

PURPOSE AND DESCRIPTION Conducted to diagnose prostate cancer—35–45% of men undergoing the procedure are diagnosed with prostate cancer and approximately 5% of people suffer complications which are commonly associated with post-procedure infection. A transrectal ultrasound (TRUS) is often used to guide the placement of the needle during the procedure.

- A transrectal biopsy is performed with a spring-loaded needle, inserted through the rectal wall and into the prostate gland to remove one or more tissue samples.
- A transurethral biopsy is performed by inserting a cystoscope through the urethra and using a cutting loop to remove small samples of prostate tissue.

RELATED NURSING CARE Prior to the procedure, the man should be advised to stop taking any medications with anticoagulant properties—such as warfarin, heparin, aspirin, Cartia, for example—and antibiotics may be prescribed to commence up to 3 days prior to the procedure. The procedure takes 15 to 20 minutes and may be performed either under a local anaesthetic or with sedation. Advise the man to avoid strenuous activity for 4 hours post procedure and to avoid heavy lifting and sexual activity for the following 24 hours. Explain that there may be some discomfort in the biopsy area for 1 to 2 days, there may be some blood in the urine or from the rectum, and semen may appear dark. Following a transurethral biopsy, a urinary catheter may remain in place for a few hours after the procedure and antibiotics will be prescribed. Excess bleeding, pain or signs of infection should be reported.

NAME OF TEST Gonorrhoea culture

PURPOSE AND DESCRIPTION A culture is performed to evaluate for gonorrhoea. A swab is used to collect a sample of discharge from the infected area (urethra, penis, anus or throat), smeared on a slide and a Gram stain is conducted to identify the organism (*Neisseria gonorrhoeae*). A urine sample is used in some tests.

RELATED NURSING CARE No special physical preparation is needed but psychological care is required. If the test is positive, request the names of all sexual partners and emphasise the need for treatment to eradicate the infection.

NAME OF TEST Venereal disease research laboratory (VDRL); Rapid plasma reagin (RPR); Fluorescent treponemal antibody absorption (FTA-ABS)

PURPOSE AND DESCRIPTION These blood tests are conducted to screen for syphilis. Positive findings can be made within 1 to 2 weeks after the primary lesion appears or 1 to 4 months after the initial infection. The FTA-ABS test is used to detect antibodies to the syphilis-causing bacteria *Treponema pallidum.* It is considered the most accurate and is often used if findings from the VDRL or RPR are questionable, but it remains positive after treatment and so cannot be used to monitor treatment efficacy.

RELATED NURSING CARE No special physical preparation is needed but psychological care is required. If the test is positive, request the names of all sexual partners and emphasise the need for treatment to eradicate the infection.

NAME OF TEST Semen analysis

PURPOSE AND DESCRIPTION Evaluates volume; liquefaction time; sperm count, morphology and motility; pH; white blood cell count and fructose level. Antisperm antibody testing may also be performed.

Normal values:
Volume: > 2 mL
pH: 7.2–7.8
Sperm count (concentration): > 20 x 10^6/mL
Motility: > 50% motile in a forwards direction and/or > 25% with rapid forwards motility
% normal sperm: > 30% with 'normal' morphology
WBC: < 1 x 10^6/mL
Sperm antibodies: less than 50% antibodies detected (World Health Organization, 2010)

RELATED NURSING CARE The man is asked to bring in a fresh specimen of semen within 1 hour of ejaculation and following 4–5 days of abstinence.

the cells of the prostatic ductal epithelium and is present in all men and increases with age over 50.
- The prostate may be examined by ultrasound to identify testicular torsion or masses, by digital rectal examination and by a prostate biopsy to accurately diagnose cancer or benign hypertrophy of the prostate.
- Semen analysis is done to evaluate semen volume, sperm count and motility, and percentage of abnormal sperm.

Regardless of the type of diagnostic test, and after the person gives informed consent, the nurse is responsible for fully explaining the procedure and any special preparation needed, assessing for any medication use that might affect the outcome of the tests, supporting the man during the examination as necessary, documenting the procedures as appropriate and monitoring the results of the tests.

MALE REPRODUCTIVE SYSTEM ASSESSMENTS

Technique/normal findings	Abnormal findings
Breast and lymph nodes	
Inspect and palpate both breasts, including areola and nipple. *Breast tissue should not be swollen, tender or enlarged (although soft, fatty and enlarged breast tissue does occur with obesity in men).*	■ A smooth, firm, mobile, tender disc of breast tissue behind the areola indicates gynaecomastia, overdevelopment of breast tissue in men. Gynaecomastia requires additional investigation to determine the cause but is generally caused by an alteration in the testosterone/oestrogen ratio precipitated by high levels of sex-hormone-binding globulin (SHBG). There are a number of health conditions and also medications which may cause gynaecomastia. ■ A hard, irregular nodule in the nipple area suggests cancer.
Palpate the axillary and supraclavicular lymph nodes. *Lymph nodes should not be palpable.*	■ Enlarged axillary nodes are common with infections of the hand or arm but may be caused by cancer. ■ Enlarged supraclavicular nodes may indicate breast cancer or lymphoma.
External genitalia Inspect and palpate the inguinal and femoral area for bulges. Ask the man to bear down or cough as you palpate (see Figure 46.2). *There should be no bulging with coughing or bearing down.*	■ A bulge that increases with coughing or straining suggests a hernia.
Inspect the penis. If the man is uncircumcised, retract the foreskin, or ask him to do so. When non-erect, the penis is normally soft, flaccid and non-tender. *The foreskin should be without lesions, of colour equal with the penis and should retract easily. The glans is normally free of lesions.*	■ Priapism is the presence of a prolonged, painful erection of the penis that is not related to sexual stimulation. It is a urological emergency as it may lead to necrosis and/or erectile dysfunction if untreated. It may be idiopathic in origin or associated with health conditions such as leukaemia, sickle cell disease, pelvic tumours, spinal cord injury or some medications. ■ Phimosis (tightness of prepuce that prevents retraction of foreskin) may be congenital or due to recurrent balanoposthitis (generalised infection of glans penis and prepuce). ■ Narrow or inflamed foreskin can cause paraphimosis, retraction of the foreskin that causes painful swelling of the glans. ■ Balanitis (inflammation of the glans) is associated with bacterial or fungal infections. ■ Ulcers, vesicles or warts suggest a sexually transmitted infection. ■ Nodules or sores seen in uncircumcised men may be cancer.

FIGURE 46.2 ■ Palpating the male inguinal area for bulges

Technique/normal findings	Abnormal findings
Inspect the external urinary meatus. Press the glans between the thumb and forefinger (see Figure 46.3). Replace the foreskin if appropriate. *The external urinary meatus is normally in the centre of the glans, without redness or discharge.*	■ Erythema or discharge indicates inflammatory disease or infection. Further assessment is required.

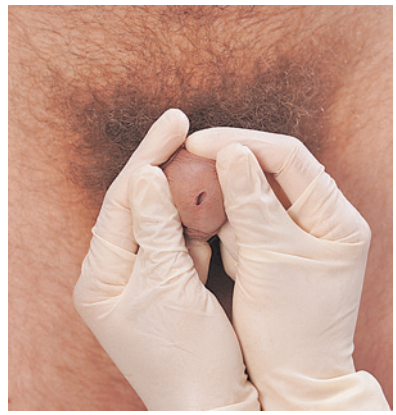

FIGURE 46.3 ■ Inspecting the external urinary meatus of the male

Inspect the skin on the shaft of the penis. *The skin on the shaft of the penis should be free of redness or lesions.*	■ Excoriation or inflammation suggests lice or scabies.
Palpate the shaft of the penis. *The shaft of the penis should not be tender.*	■ Induration with tenderness along the ventral surface suggests urethritis or urethral stricture with inflammation.
Inspect the scrotum. Further assess any swelling in the scrotum using transillumination: darken the room and place a lighted flashlight against the skin of the scrotum. *The normal scrotum and epididymis appear as dark masses with regular borders.*	■ A unilateral or bilateral poorly developed scrotum suggests cryptorchidism (failure of one or both testes to descend into the scrotum). ■ Swelling of the scrotum may indicate indirect inguinal hernia, hydrocoele (accumulation of fluid in the scrotum) or scrotal oedema. Swellings containing serous fluid will transilluminate. Swellings containing blood or tissue will not transilluminate.
Palpate each testis and epididymis. *The testes should not be tender or swollen.*	■ Tender, painful scrotal swelling occurs in acute epididymitis, acute orchitis, torsion of the spermatic cord and strangulated hernia. ■ A painless nodule in the testis is associated with testicular cancer.
Prostate The prostate gland is assessed by digital rectal examination (DRE). (See Chapter 20, Figure 20.20 for the technique used to palpate the prostate through the rectal wall.)	
With a gloved index finger, palpate the posterior rectal wall for the rounded, two-lobed structure of the posterior prostate. *The prostate is normally non-tender, with two lateral lobes that are divided, smooth and about 2.5 cm long.*	■ Enlargement (1 cm protrusion into the rectum) with obliteration of the median sulcus suggests benign prostatic hypertrophy. ■ Enlargement with asymmetry and tenderness suggests prostatitis. ■ A hard irregular nodule is suspicious of carcinoma.

GENETIC CONSIDERATIONS Male reproductive system disorders

- Although the exact genetic predisposition for some men to have prostate cancer is unknown, the findings of a number of studies have suggested that a family history may increase the relative risk. Risk appears to be two to three times greater for men with an affected brother, rather than an affected father, or who are diagnosed before the age of 65 and have a first-degree relative with the disease (Kiciński, Vangronsveld & Nawrot, 2011).
- A family history of testicular cancer is a risk factor for cancer of the testes.
- Men who have XX chromosomes (instead of XY) often have altered testicular development because they are missing a gene called the sex-determining region Y gene (SRY), which is responsible for the development of secondary sex characteristics in men.

Genetic considerations

When conducting a health assessment interview and a physical assessment, it is important for the nurse to consider genetic influences on the health of an adult. Several diseases of the male reproductive system have a genetic component. During the health assessment interview, it is especially important to ask about a family history of testicular or prostate cancer. During the physical assessment, assess for any manifestations that might indicate a genetic disorder (see the box above). If data are found to indicate genetic risk factors or alterations, ask about genetic testing and refer for appropriate genetic counselling and evaluation. Chapter 7 provides further information about genetics in medical–surgical nursing.

ANATOMY, PHYSIOLOGY AND FUNCTIONS OF THE FEMALE REPRODUCTIVE SYSTEM, INCLUDING THE BREASTS

The female reproductive system consists of the external genitalia (mons pubis, labia, clitoris, vaginal and urethral openings and glands) and the internal organs (vagina, cervix, uterus, fallopian tubes and ovaries). The breasts are a part of women's reproductive organs. In women, the urethra and urinary meatus are separated from the reproductive organs; however, they are so close to each other that a health problem with one often affects the other. The location and function of the female reproductive organs are summarised in Table 46.3.

TABLE 46.3 Location and function of the female reproductive organs

FEMALE REPRODUCTIVE ORGAN	LOCATION	FUNCTION
Mons pubis (mons veneris)	Anterior and superior to the pubis.	Enhances sexual sensations. Protects and cushions pubic symphysis during intercourse.
Labia majora	Extend from mons pubis to perineum.	Protect labia minora, urethral and vaginal openings. Enhance sexual arousal.
Labia minora	Enclosed by the labia majora.	Protect clitoris. Inferiorly, merge to form posterior ring of vaginal introitus (fourchette). Lubricate vulva. Enhance sexual arousal.
Vestibule	Area enclosed by labia minora.	Contains openings for urethra, vagina, Bartholin's glands and Skene's glands.
Bartholin's (greater vestibular) glands	Posterior on each side of the vaginal orifice. Open onto the sides of the vestibule in the groove between the labia minora and hymen.	Secrete clear, viscid mucus during intercourse.
Skene's (lesser vestibular, paraurethral) glands	Open onto the vestibule on each side of the urethra.	Drain urethral glands. Produce lubricating mucus.
Clitoris	Small bud of erectile tissue just below the superior joining of the labia minora.	Stimulates and elevates levels of sexual arousal.
Perineum	Skin-covered muscular area between vaginal opening and anus.	Provides support for pelvic organs.
Mammary glands	Contained within breasts. Anterior to pectoral muscles of thorax.	Produce human milk. Play a role in sexual arousal.
Ovaries	Lie on each side of the uterus below and behind the uterine tubes.	Produce and secrete ova. Produce the hormones oestrogen and progesterone.
Fallopian tubes (uterine tubes, oviducts)	One tube extends medially from the area of each ovary and empties into the upper portion (fundus) of the uterus.	Transport ova.
Uterus (adnexa of the uterus are composed of the uterine tubes and ovaries)	Anterior to the rectum and posterior/superior to the bladder.	Receives, retains and nourishes the fertilised ovum. Contracts rhythmically to expel infant. Cyclically sheds lining when ovum is not fertilised.
Cervix	Lower portion of uterus extending into the vagina.	Connects uterine cavity with vagina. Opens to allow passage of menstrual flow and infant.
Vagina	Extends from the external orifice in the vestibule to the cervix.	Receives penis and semen during intercourse. Passageway for menstrual flow and expulsion of infant at birth.

The breasts

The breasts (or mammary glands) are located between the third and seventh ribs on the anterior chest wall. They are supported by the pectoral muscles and are richly supplied with nerves, blood and lymph (see Figure 46.4). A pigmented area called the areola is located slightly below the centre of each breast and contains sebaceous glands and a nipple. The nipple is usually protrusive and becomes erect in response to cold and stimulation.

The breasts are made of adipose tissue, fibrous connective tissue and glandular tissue. Cooper's ligaments support the breast and extend from the outer breast tissue to the nipple, dividing the breast into 15 to 25 lobes. Each lobe is made of alveolar glands connected by ducts that open to the nipple.

The external genitalia

The external genitalia collectively are called the vulva. They include the mons pubis, the labia, the clitoris, the vaginal and urethral openings, and glands (see Figure 46.5).

The mons pubis is a pad of adipose (fat) tissue covered with skin. It lies anterior to the symphysis pubis. After puberty, the mons is covered with hair.

The labia are divided into two structures. The *labia majora* are folds of skin and adipose tissue covered with hair following puberty. The labia majora are outermost and begin at the base of the mons pubis and end at the anus. The *labia minora*, located between the clitoris and the base of the vagina, are enclosed by the labia majora. They are made of skin, adipose tissue and some erectile tissues. They are usually light pink and hairless.

The area between the labia is called the vestibule and contains the openings for the vagina and the urethra as well as the Bartholin's glands. Skene's glands open on to the vestibule on each side of the urethra. Bartholin's and Skene's glands secrete lubricating fluid during the sexual response cycle prior to menopause.

The clitoris is an erectile organ analogous to the penis in the male. It is formed by the joining of the labia minora. Like the penis, it is highly sensitive and distends during sexual arousal.

The vaginal opening, called the introitus, is the opening between the internal and the external genitals. Prior to rupture from intercourse or trauma, the introitus is surrounded by a connective tissue membrane called the hymen.

The internal organs

The vagina, cervix, uterus, fallopian tubes and ovaries are the internal organs of the female reproductive system (see Figure 46.6). The ovaries are the primary reproductive organs in women and also produce female sex hormones. The vagina, uterus and fallopian tubes serve as accessory ducts for the ovaries and a developing foetus.

The vagina

The vagina is a fibromuscular tube about 8 to 10 cm in length located posterior to the bladder and urethra, and anterior to the rectum. The walls of the vagina are membranes that form folds, called rugae. These membranes are composed of mucus-secreting stratified squamous epithelial cells. The vagina serves as a route for the excretion of secretions, including menstrual fluid; an organ of sexual response; and as a passageway for the birth of an infant.

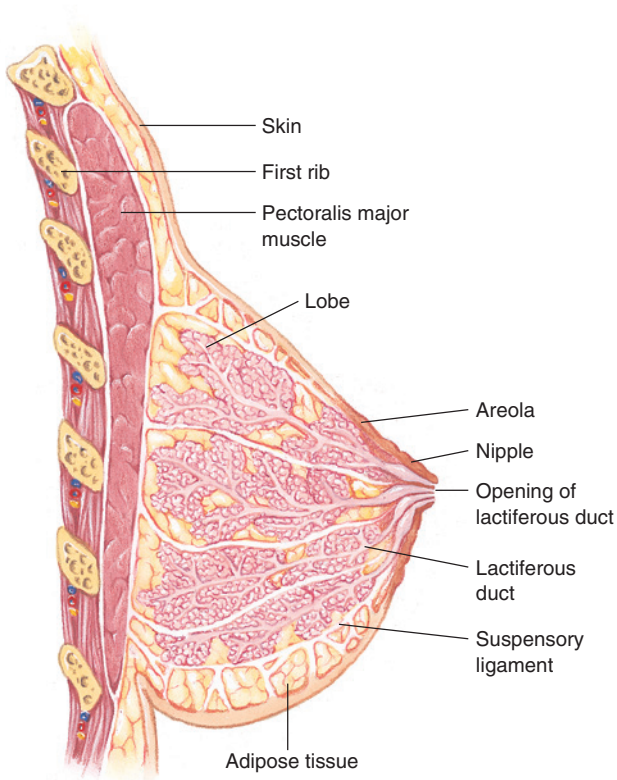

FIGURE 46.4 ■ Structure of the female breast

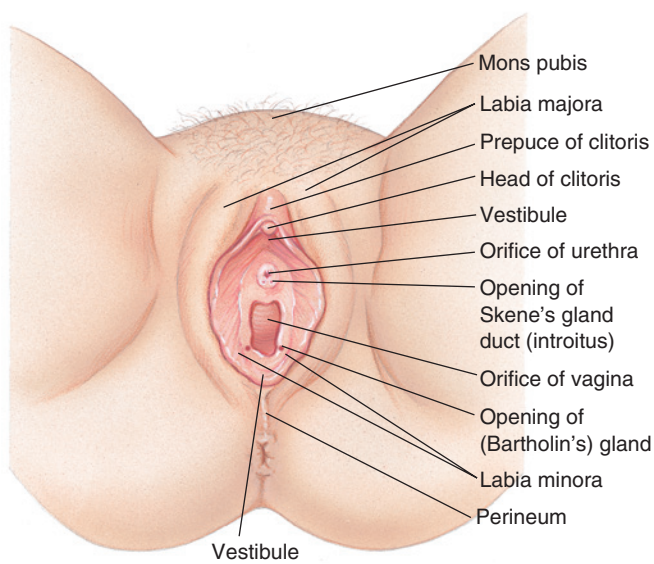

FIGURE 46.5 ■ The external organs of the female reproductive system

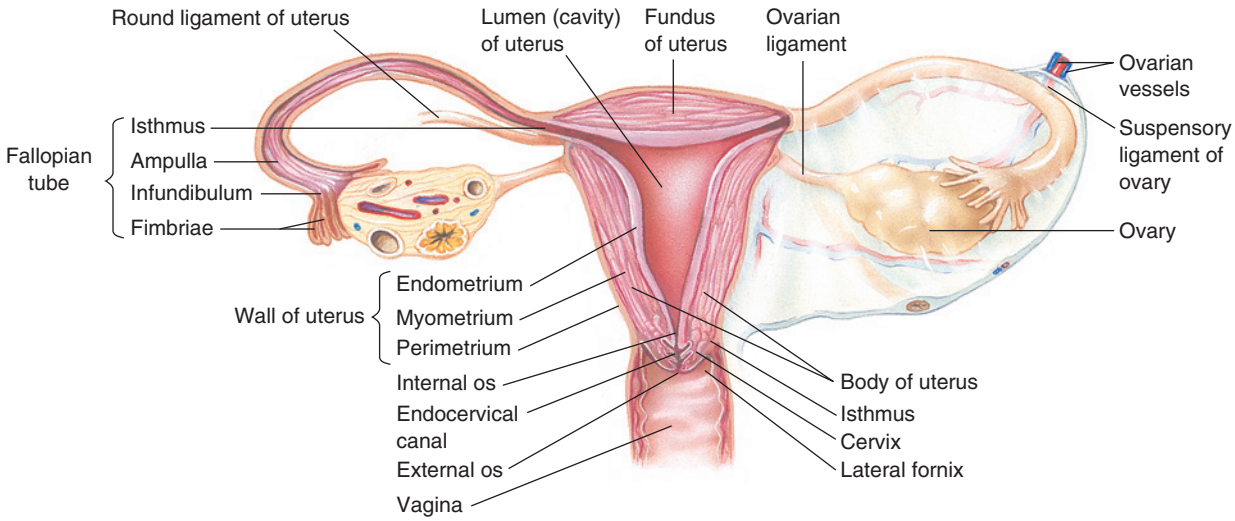

FIGURE 46.6 ■ The internal organs of the female reproductive system

The walls of the vagina are usually moist and maintain a pH ranging from 3.8 to 4.2. This pH is bacteriostatic and is maintained by the action of oestrogen and normal vaginal flora. **Oestrogen** stimulates the growth of vaginal mucosal cells so that they thicken and have increased glycogen content. The glycogen is fermented to lactic acid by Döderlein's bacilli (lactobacilli that normally inhabit the vagina), slightly acidifying the vaginal fluid. The upper end of the vagina contains the uterine cervix in an area called the fornix.

The cervix

The cervix is essentially the 'neck of the uterus' and is the lower, narrow part of the uterus which is cylindrical in shape and protrudes through the upper anterior vaginal wall forming a conduit between the uterus and the vagina. The cervix is a firm structure, protected by mucus that changes consistency and quantity during the menstrual cycle and during pregnancy. The uterine opening of the cervix is called the internal os; the vaginal opening is called the external os. The space between these openings, the endocervical canal, serves as a route for the discharge of menstrual fluid, the entrance for sperm and expulsion of the infant during birth.

The uterus

The uterus is a hollow, pear-shaped muscular organ with thick walls located between the bladder and the rectum. It has three parts: the fundus, the body and the cervix. It is supported in the abdominal cavity by the broad ligaments, the round ligaments, the uterosacral ligaments and the transverse cervical ligaments. The uterus receives the fertilised ovum and provides a site for growth and development of the foetus.

The uterine wall has three layers. The perimetrium is the outer serous layer that merges with the peritoneum. The myometrium is the middle layer and makes up most of the uterine wall. This layer has muscle fibres that run in various directions, allowing contractions during **menstruation** (the periodic shedding of the uterine lining in a woman of childbearing age who is not pregnant) or childbirth and expansion as the foetus grows. The endometrium lines the uterus; its outermost layer is shed during menstruation.

The fallopian tubes

The fallopian tubes are thin cylindrical structures about 10 cm long and 1 cm in diameter. They are attached to the uterus on one end and are supported by the broad ligaments. The lateral ends of the fallopian tubes are open and made of projections called fimbriae that drape over the ovary. The fimbriae pick up the ovum after it is discharged from the ovary.

The fallopian tubes are made of smooth muscle and are lined with ciliated, mucus-producing epithelial cells. The movement of the cilia and contractions of the smooth muscle move the ovum through the tubes towards the uterus. Fertilisation of the ovum by the sperm usually occurs in the outer portion of a fallopian tube.

The ovaries

The ovaries in the adult woman are flat, almond-shaped structures located on either side of the uterus below the ends of the fallopian tubes. They are homologous to the man's testes. They are attached to the uterus by a ligament and are also attached to the broad ligament. The ovaries store the female germ cells and produce the female hormones oestrogen and progesterone. A woman's total number of ova is present at her birth as oogenesis, the formation and development of a female reproductive cell ovum, occurs during gestation.

Each ovary contains many small structures called ovarian follicles. Each follicle contains an immature ovum, called an oocyte. Each month, several follicles are stimulated by follicle-stimulating hormone (FSH) and luteinising hormone (LH) to mature. The developing follicles are surrounded by layers of follicle cells, with the mature follicles called graafian follicles. The graafian follicles produce oestrogen, which stimulates the development of endometrium. Each month in the menstruating woman, one or two of the mature follicles eject an oocyte in a process called ovulation.

The ruptured follicle then becomes a structure called the corpus luteum. The corpus luteum produces both oestrogen and progesterone to support the endometrium until conception occurs or the cycle begins again. The corpus luteum slowly degenerates, leaving a scar on the surface of the ovary.

Functions of the female sex hormones

The ovaries produce oestrogens, progesterone and androgens in a cyclical pattern. Oestrogens are steroid hormones that occur naturally in three forms: oestrone (E1), oestradiol (E2) and oestriol (E3). Oestradiol is the most potent and is the form secreted in greatest amount by the ovaries. Although oestrogens are secreted throughout the menstrual cycle, they are at a higher level during certain phases of the cycle.

Oestrogens are essential for the development and maintenance of secondary sex characteristics. In conjunction with other hormones, they stimulate the female reproductive organs to prepare for growth of a foetus. Oestrogens are responsible for the normal structure of skin and blood vessels. They also decrease the rate of bone resorption, promote increased high-density lipoproteins, reduce cholesterol levels and enhance the clotting of blood. Oestrogens also promote the retention of sodium and water.

Menopause, a normal physiological process, occurs as a result of the gradual decrease and final cessation of oestrogen production by the ovaries. Menstruation ceases and the tissues that had been supported by oestrogen change. Long-term effects of oestrogen deprivation increase the risk of osteoporosis and cardiovascular disease. Menopause is discussed in Chapter 48.

Progesterone primarily affects the development of breast glandular tissue and the endometrium. During pregnancy, progesterone relaxes smooth muscle to decrease uterine contractions. It also increases body temperature.

Androgens are responsible for normal hair growth patterns at puberty and may also have metabolic effects.

Oogenesis and the ovarian cycle

Oogenesis is the process of maturation of oocytes. It begins before birth and is completed after puberty, continuing until menopause. During prenatal oogenesis, the total number of a woman's ova develop and are present as primary oocytes in ovarian follicles. Each month from puberty until menopause, the remaining events of oogenesis, known as postnatal oogenesis, occur. Collectively, these events are known as the **ovarian cycle**.

The ovarian cycle has three consecutive phases that occur cyclically each 28 days (although the cycle may be longer or shorter), as follows:

- The follicular phase lasts from the 1st to the 10th day of the cycle.
- The ovulatory phase lasts from the 11th to the 14th day of the cycle and ends with ovulation.
- The luteal phase lasts from the 14th to the 28th day.

During the follicular phase, the follicle develops and the oocyte matures. These processes are controlled by the interaction of FSH and LH. On day 1 of the cycle, gonadotropin-releasing hormone (GnRH) from the hypothalamus increases and stimulates increased production of FSH and LH by the anterior pituitary. FSH and LH stimulate follicular growth and the oocyte increases in size. The structure, now called the primary follicle, becomes a multicellular mass surrounded by a fibrous capsule, the theca folliculi. As the follicle continues to increase in size, oestrogen is produced and a fluid-filled space (the antrum) forms within the follicle. The oocyte is enclosed by a membrane, the zona pellucida. By about day 10, the follicle is a mature graafian follicle and bulges out from the surface of the ovary. There are always follicles at different stages of development in each ovary, but usually only one follicle becomes dominant and matures to ovulation, while the others degenerate.

The ovulatory phase begins when oestrogen levels reach a level high enough to stimulate the anterior pituitary and a surge of LH is produced. The LH stimulates meiosis in the developing oocyte and its first meiotic division occurs. The LH also stimulates enzymes that act on the bulging ovarian wall, causing it to rupture and discharge the antrum fluid and the oocyte. The oocyte is expelled from the mature ovarian follicle in the process called ovulation.

During the luteal phase, the surge in LH also stimulates the ruptured follicle to change into a corpus luteum and then stimulates the corpus luteum to begin immediately producing progesterone and oestrogen. The increase of progesterone and oestrogen in the blood has a negative feedback effect on the production of LH, inhibiting the further growth and development of other follicles.

If pregnancy does not occur, the corpus luteum begins to degenerate and its hormone production ceases. The declining production of progesterone and oestrogen at the end of the cycle allows the secretion of LH and FSH to increase and a new cycle begins. The ovarian cycle is compared with the menstrual cycle in Figure 46.7.

The menstrual cycle

The endometrium of the uterus responds to changes in oestrogen and progesterone during the ovarian cycle to prepare for implantation of the embryo. The endometrium is receptive to implantation of the embryo for only a brief period each month, coinciding with the time when the embryo would normally reach the uterus from the uterine tube (usually 7 days).

The **menstrual cycle** begins with the *menstrual phase*, lasting from days 1 to 5. The inner endometrial (functionalis) layer detaches and is expelled as menstrual fluid (fluid and blood) for 3 to 5 days. As the maturing follicle begins to produce oestrogen (days 6 to 14), the proliferative phase begins. In response, the functionalis layer is repaired and thickens, while spiral arteries increase in number and tubular glands form. Cervical mucus changes to a thin, crystalline substance, forming channels to help the sperm move up into the uterus.

The final phase, lasting from days 14 to 28, is the secretory phase. As the corpus luteum produces progesterone, the rising levels act on the endometrium, causing increased vascularity, changing the inner layer to secretory mucosa, stimulating the secretion of glycogen into the uterine cavity and causing the

D Menstrual cycle

FIGURE 46.7 ■ Comparison of the ovarian and menstrual cycles. *A*, Fluctuating levels of follicle-stimulating hormone (FSH) and luteinising hormone (LH), the pituitary gonadotropins regulating the ovarian cycle. *B*, Fluctuating levels of ovarian hormones that cause endometrial changes during the menstrual cycle. *C*, Changes in the ovarian follicles during the 28-day menstrual cycle. *D*, Corresponding changes in the endometrium during the menstrual cycle

cervical mucus again to become thick and block the internal os. If fertilisation does not occur, hormone levels fall. Spasm of the spiral arteries causes hypoxia of the endometrial cells, which begin to degenerate and slough off. As with the ovarian cycle, the process begins again with the sloughing of the functionalis layer.

ASSESSING THE FEMALE REPRODUCTIVE SYSTEM

The structures and functions of the female reproductive system are assessed by findings from a comprehensive assessment which includes both a health assessment interview to collect subjective data and a physical assessment to collect objective data. In addition, a number of diagnostic tests may provide further information.

Information from the health assessment interview is used to individualise the questions that are asked; for example, a woman who is postmenopausal would not be asked specific questions about her menstrual cycle, but it would be important to ask about vaginal dryness. Sample documentation of an assessment of the female reproductive system is included in the box below.

Health assessment interview

A health assessment interview to determine problems with the female reproductive system may be conducted for different reasons, for example:

- during a health screening
- as part of a comprehensive health assessment
- during a focused assessment for a specific health problem (such as severe menstrual cramping).

Women may be embarrassed to discuss health problems or concerns involving their reproductive organs; therefore it is important for the nurse to ask questions in a non-judgmental, non-threatening, matter-of-fact and sensitive manner. Consider the psychological, social and cultural factors that affect sexuality and sexual activity. Use words that the woman can understand and do not be embarrassed or offended by the words that she uses. The woman may perceive the interview as less threatening if the discussion begins with more general questions and then progresses to specific questions, and if questions are asked in a way that gives the woman permission to describe behaviours and manifestations. For example, ask about menstrual and childbirth histories before asking questions about sexually transmitted infections.

The focused interview for the female reproductive system is usually extensive. However, the questions may in many instances be tailored to the specific health problem of the woman. As with the assessment of other body systems, analyse and document the onset of the problem, its duration, frequency, precipitating and relieving factors, any associated symptoms, treatment, self-care and outcome. For example, ask the woman:

- Have you noticed vaginal bleeding after intercourse that isn't related to menstruation?
- Does anything relieve the vaginal itching and discharge?
- Have you had any fever or abdominal pain with this vaginal infection?

Ask about menstrual history, obstetric history, use of contraceptives, sexual history, use of medications and reproductive system examinations. Ask about the use of condoms during intercourse because unprotected sexual intercourse increases the risk of sexually transmitted infections, including

SAMPLE DOCUMENTATION

Assessment of the female reproductive system

2/10/2015
NURS
1000 hrs

30-year-old female, first visit to health department for problems she described as 'pain and burning down below' and 'It really hurts to pee'. Also states she had unprotected sex on a date about 2 weeks ago. Oral temperature 38.5°C. Vaginal examination findings of vesicles and red ulcerations on labia majora and vaginal mucosa. Inguinal lymph nodes enlarged and tender to palpation. Culture of ulcerations taken and specimen sent to the laboratory for analysis.——————— RN T. Tunn

T. TUNN. RN

hepatitis B and HIV infection. Also ask about smoking because a history of smoking increases the risk of circulatory problems in the woman taking oral contraceptives and increases the risk of cancer of the cervix.

Chronic conditions may affect the function of the female reproductive system. Diabetes mellitus increases the risk of vaginal infections and vaginal dryness, both of which interfere with sexual pleasure. Chronic heavy menstrual flow may result in anaemia. Thyroid and adrenal conditions may affect secondary sex characteristics, the menstrual cycle and the ability to become pregnant.

Obtaining any family history of cancer is important. The risk of endometrial cancer is higher in women with a family history of endometrial, breast or colon cancer; the risk of ovarian cancer is higher in women with a family history of ovarian or breast cancer; and the risk of breast cancer is higher in women with a family history of breast cancer. Exposure to DES (diethylstilbestrol, a synthetic form of oestrogen) in utero increases the risk of cancer of the cervix and vagina. Exposure to asbestos poses a risk of cancer of the ovary. The risk of breast cancer is also greater if the woman has a history of fibrocystic disease.

Carefully explore with the woman any history of vaginal bleeding and vaginal discharge. Ask about the onset of vaginal bleeding, any related factors, the colour (pink, red, dark red, brown), the character (thin, watery, presence of mucus, size and number of clots), the amount (spotting, how many pads or tampons in a specific amount of time) and relationship to her menstrual cycle. Ask about the onset of any vaginal discharge; the colour (white, green, grey), character (thin, thick, curd-like), odour, itching and if a rash is present.

Questions about sexual activity may include sexual preference, number of sexual partners, use of condoms, femidoms or other contraceptives, and current level of sexual satisfaction. Ask about any experiences or history of **anorgasmia** (absence of orgasm), **dyspareunia** (painful intercourse) or other problems with intercourse, and any history of sexual trauma.

Interview questions categorised by functional health patterns are listed in the following 'Functional health pattern interview' table.

Physical assessment

Physical assessment of the female reproductive system may be performed as part of a comprehensive assessment or separately for women with identified sexual health problems. If conducted as part of a total physical assessment, this is usually the final system to be assessed. The nurse must feel comfortable with the examination of people of the opposite gender. If either the nurse or the individual

FUNCTIONAL HEALTH PATTERN INTERVIEW The female reproductive system

FUNCTIONAL HEALTH PATTERN	INTERVIEW QUESTIONS AND LEADING STATEMENTS
Health perception–Health management	■ Have you ever had problems with your reproductive organs (ovaries, tubes, uterus, vagina) or with menstruation or menopause? Explain. If so, how was this problem treated? ■ Do you routinely take any prescribed or herbal medications for symptoms of menopause? If so, what and when do you take it? ■ Did you ever take hormone replacement therapy for menopausal symptoms? ■ Do you practise breast self-examination? When and how often do you do this? ■ Have you noticed any lumps in your breasts or discharge from your nipples? If so, describe. ■ Have you ever had a breast examination or mammogram? When was your last one? How often do you have these? ■ When was your last gynaecological examination? Pap smear? How often do you have these done? ■ Do you use birth control? If so, what do you use? ■ What do you do to provide self-care if you have mood swings or menstrual cramps? ■ Have you ever had a sexually transmitted infection or an infection of the reproductive organs? What was it? How was it treated? ■ Do you use douches or vaginal sprays? If so, what type and how often? ■ Do you smoke? If so, how much and for how long?

(continued)

FUNCTIONAL HEALTH PATTERN INTERVIEW The female reproductive system (continued)

Nutritional–Metabolic	■ Do you notice a change in your appetite right before your menstrual period? ■ Have you gained weight recently? If so, why do think this happened? ■ Describe your usual food intake for a 24-hour period.
Elimination	■ When was your last menstrual period? ■ At what age did you start/end having menstrual periods? ■ Describe the length, amount of flow and clotting with your menstrual periods. ■ Do you ever have bleeding between your menstrual periods? If so, describe the type and amount. ■ Describe any unusual vaginal discharge you have had (colour, consistency, odour, itching or rash). ■ Have you noticed any changes in urination (frequency, urgency, burning)? ■ Have you noticed changes in bowel elimination during your menstrual periods?
Activity–Exercise	■ Describe your usual activities of daily living. ■ Have you noticed any change in activity or energy during your menstrual period? ■ Have you noticed any change in activity or energy since menopause (if applicable)? If so, how?
Sleep–Rest	■ How long do you sleep at night? Is your sleep restful? ■ Do night sweats wake you? ■ Do menstrual cramps ever wake you at night?
Cognitive–Perceptual	■ Do you have pain or other symptoms (such as headache, mood swings, irritability, bloating, constipation, diarrhoea and/or breast tenderness) before your menstrual period? Describe. What do you do about this? ■ Do you have cramping before or during your menstrual period? Describe the type of cramping, how long it lasts and what you do to be more comfortable. ■ Do you ever have vaginal itching, pain, burning or dryness? If so, is it affected by sexual intercourse? Does dryness interfere with intercourse?
Self-Perception–Self-Concept	■ Has this problem affected how you feel about yourself as a woman? ■ Do you believe your needs for intimacy and affection are being met?
Role–Relationships	■ How has having this condition affected your relationships with others? ■ Has having this condition interfered with your ability to work? Explain. ■ Has anyone in your family had problems with breast or ovarian cancer? Explain.
Sexuality–Reproductive	■ Are you currently in a sexual relationship? If so, has this condition interfered with your usual sexual activity? ■ How long have you been with your current partner? Have you had any other partners during this time? ■ What is your sexual preference? ■ Has having this problem affected your relationship with your spouse or sexual partner? ■ Have you ever been pregnant? How many times? Have you ever had a miscarriage? ■ Do you practise birth control? If so, what do you use? ■ Do you ensure that your partner of the opposite gender uses a condom every time you have intercourse? ■ Do you use a vaginal condom?
Coping–Stress–Tolerance	■ Has having this condition created stress for you? If so, does your health problem seem to be more difficult when you are stressed? ■ Have you experienced any kind of stress that makes the condition worse? Explain. ■ Describe what you do when you feel stressed.
Value–Belief	■ Describe how specific relationships or activities help you cope with this problem. ■ Describe specific cultural beliefs or practices that affect how you care for and feel about this problem. ■ Are there any specific treatments that you would not use to treat this problem?

is not comfortable, a nurse of the same gender should be asked to conduct this part of the assessment. The female reproductive system is assessed by inspection and palpation. Ask the woman to void before having the examination. Prior to the examination, collect all necessary equipment and explain the techniques to the woman to decrease anxiety. Put on disposable gloves before beginning the examination and wear them throughout the examination. Ask the woman to remove her clothing and put on a gown. Ensure that the examining room is private and warm.

Explain the procedures for the examination thoroughly and in a matter-of-fact way to decrease anxiety and embarrassment. If the woman is unfamiliar with her reproductive organs, charts may be used to illustrate the parts that will be examined. Carefully explain the procedure for the examination and show the speculum to the woman. The assessment may be done with the woman in the sitting or supine position to examine the breasts and in the lithotomy position to assess the external genitalia and internal organs. Expose only those body parts being examined to preserve modesty. Normal age-related findings for the older woman are summarised in Table 46.4.

The examination usually begins with examination of the breasts with the woman in the sitting and supine positions. The nurse then helps the woman move to the lithotomy position on the examining table, with the feet in the stirrups and the buttocks level with the foot of the table. This position may induce feelings of vulnerability for the woman and anxiety related to past experiences. Older or frail women may not be able to tolerate this position. In this case, the woman may be examined in the supine position. Although the entire examination is described here, the internal examination is conducted only by a nurse with advanced practice in the procedure. However, nurses are often asked to assist with the examination and should be able to explain the examination to a woman and answer her questions about the procedure.

Diagnostic tests

The results of diagnostic tests of the structures and functions of the female reproductive system are used to monitor the health of female reproductive structures; to support the diagnosis of a specific sexual problem, injury or disease; to provide information to identify or modify the appropriate medications or treatments used to treat the condition; and to help monitor the woman's responses to treatment and nursing care interventions. Diagnostic tests to assess the female reproductive system are described in the 'Diagnostic tests' table below and summarised in the following bulleted list. More information is included in the discussion of specific health problems or diseases in Chapter 48.

- Blood tests are used to diagnose a variety of hormone changes and sexually transmitted infections. These tests are discussed in Chapters 48 and 49.
- Sexually transmitted infections are often diagnosed with cultures and smears of a discharge or mucous membranes.
- A mammogram is used to detect breast tumours, often followed by an ultrasound and breast biopsy for a definitive diagnosis. The type of biopsy conducted depends on many factors, including the size, location, appearance and characteristics of the breast abnormality.
- The Papanicolaou (Pap) smear and the HPV DNA test are conducted to diagnose premalignant and malignant

TABLE 46.4 Age-related changes in the female reproductive system

AGE-RELATED CHANGE	SIGNIFICANCE
Breasts	
• Atrophy, with sagging of breast tissue. • Linear strands may appear from shrinkage and fibrotic changes.	Although ageing does not cause breast cancer, the incidence rises in older women; age-related changes may make finding tumours more difficult.
External genitalia	
• Labia flatten and vulvar adipose tissue and hair decreases. • ↓ collagen and adipose tissues in the vaginal canal, resulting in loss of rugae, shortening and narrowing of vaginal canal. • ↓ vaginal lubrication, epithelium becomes thinner and avascular. • More alkaline pH of vagina. • Cervix becomes smaller.	Vagina is more easily irritated, increasing the risk of vaginal infections. Lubricants are necessary for comfortable intercourse.
Internal organs	
• Uterus shrinks. • Fallopian tubes shrink and shorten. • Ovaries are smaller and thicker. • With menopause, hormone production of oestrogen decreases. • Loss of oestrogen may cause pelvic floor muscles to weaken. • Loss of oestrogen causes changes throughout the body, including loss of skin tone (wrinkling) and growth of facial hair.	With the completion of menopause, the menstrual cycles end and the woman is infertile. Weakening of the pelvic floor muscles may contribute to involuntary incontinence with increased intra-abdominal pressure (as with coughing and sneezing). Skin is dry and thin.

DIAGNOSTIC TESTS The female reproductive system

Screening tests, smears and cultures

NAME OF TEST Papanicolaou smear (Pap test)

PURPOSE AND DESCRIPTION Conducted to diagnose malignant and premalignant lesions of the cervix; to assess the effects of hormone replacement therapy; to identify viral, bacterial, fungal and parasitic conditions; and to evaluate response to chemotherapy or radiation therapy to the cervix. Cells are obtained during a pelvic examination, with a wooden spatula, a cotton swab or an endocervical brush. The sample collected may be smeared on a glass slide or put into a special liquid preservative and then the cells in suspension are processed onto a slide. The cells are then stained and examined.

RELATED NURSING CARE Explain that the test should be done during a time when the woman is not menstruating and that she should not have intercourse, douche or use vaginal medications for 36 hours prior to the examination. Ask the woman to void prior to the examination. Reassure the woman, explain the procedure and what to expect.

NAME OF TEST HPV test (HPV DNA test, genital human papilloma test)

PURPOSE AND DESCRIPTION Routinely used as a screening tool for human papillomavirus (HPV) in women after the age of 30. Conducted in conjunction with a pelvic examination and Pap smear. A finding of 'low-grade changes' on the Pap smear with HPV indicates the likely presence of HPV and the need for further testing. A positive test for HPV indicates the presence of a high-cancer type of HPV, but does not specify which type is present.

RELATED NURSING CARE Explain that the test should be done during a time when the woman is not menstruating and that she should not have intercourse, douche or use vaginal medications for 36 hours prior to the examination. Ask the woman to void prior to the examination.

NAME OF TEST Chlamydia culture

PURPOSE AND DESCRIPTION Performed to screen for or diagnose chlamydial infections. A swab of cells from the infected area is taken and either smeared on a slide and analysed or cultured. Although usually taken from the urethra, vagina or cervix, cultures may also be taken from the throat and rectum.

RELATED NURSING CARE Assess if the woman is pregnant or has enlargement of inguinal lymph nodes. Withhold antibiotics (if prescribed) until after obtaining the specimen. Instruct not to douche before the examination. If the test is positive, request the names of all sexual partners and emphasise need for treatment to eradicate the infection.

NAME OF TEST Gonorrhoea culture

PURPOSE AND DESCRIPTION A culture is performed to evaluate for gonorrhoea. A swab is used to collect a sample of discharge from the infected area (cervix, urethra, anus or throat), smeared on a slide and a Gram stain is conducted to identify the organism (*N. gonorrhoeae*). A urine sample is used in some tests.

RELATED NURSING CARE No special physical preparation is needed but psychological care is required. Instruct not to douche before the examination. If the test is positive, request the names of all sexual partners and emphasise the need for treatment to eradicate the infection.

NAME OF TEST Trichomonas, bacteria, candidae (yeast)

PURPOSE AND DESCRIPTION A culture is performed to identify vaginal organisms or blood cells. A specimen of vaginal discharge is obtained with a swab, placed in solution and examined under the microscope immediately after it is collected (referred to as a wet mount).

RELATED NURSING CARE Request not to douche before the examination.

NAME OF TEST Venereal disease research laboratory (VDRL); Rapid plasma reagin (RPR); Fluorescent treponemal antibody absorption (FTA-ABS)

PURPOSE AND DESCRIPTION These blood tests are conducted to screen for syphilis. Positive findings can be made within 1 to 2 weeks after primary lesion appears or 1 to 4 months after the initial infection. The FTA-ABS test is used to detect antibodies to the syphilis-causing bacteria *Treponema pallidum.* It is considered the most accurate and is often used if findings from the VDRL or RPR are questionable, but it remains positive after treatment and so cannot be used to monitor treatment efficacy.

RELATED NURSING CARE No special physical preparation is needed but psychological care is required. If the test is positive, request the names of all sexual partners and emphasise the need for treatment to eradicate the infection.

NAME OF TEST Syphilis (dark-field examination)

DIAGNOSTIC TESTS The female reproductive system (continued)

PURPOSE AND DESCRIPTION A specimen is obtained from a lesion believed to be caused by syphilis (*T. pallidum*) and examined under the microscope.

RELATED NURSING CARE No special physical preparation is needed but psychological care is required. If the test is positive, request the names of all sexual partners and emphasise the need for treatment to eradicate the infection.

Breast examinations

NAME OF TEST Mammogram

PURPOSE AND DESCRIPTION Used to detect tumours in the breast. Breasts are flattened in the mammography machine and low-dose x-rays are taken.

RELATED NURSING CARE Ask the woman not to apply body powder or underarm deodorant prior to the test.

NAME OF TEST Breast ultrasound

PURPOSE AND DESCRIPTION This examination uses high-frequency sound waves passing through tissues to detect masses in the breast. May be performed if lesions are identified in a mammogram.

RELATED NURSING CARE No special physical preparation is needed but psychological care is required.

NAME OF TEST Breast biopsy

- Fine-needle aspiration
- Core-needle biopsy
- Vacuum-assisted mammotome
- Large-core surgical biopsy
- Open surgical biopsy

PURPOSE AND DESCRIPTION

- A fine-needle aspiration is conducted to withdraw fluid from cysts and may be used to sample cells from masses in the breast. A 22- to 25-gauge needle is used to collect 5 to 6 samples of fluid or cells.
- A core needle biopsy is conducted to obtain a sample of tissue from a solid mass or calcium deposits in the breast. A 10-, 11- or 12-gauge needle is used to collect 5 to 6 tissue samples.
- A vacuum-assisted mammotome is primarily used to evaluate calcifications. An 11- or 14-gauge needle is inserted through a small (6 mm) incision and 8 to 10 samples are removed.
- A large-core surgical biopsy is performed to evaluate breast masses or calcification identified with a mammogram, but that are non-palpable. An incision is made and a 5 to 20 mm cylinder of breast tissue (about the size of a wine cork) is removed.
- An open surgical biopsy is performed to evaluate breast masses, hard-to-reach lesions, multiple lesions and masses with calcifications. A 3.8 to 5 cm incision is made and a golf ball size (or larger) area of tissue is removed.

RELATED NURSING CARE For all types of test, wearing a well-fitted, comfortable bra, applying ice packs and mild analgesics decrease discomfort post procedure.

- Explain that, depending on the medical officer, some procedures may be performed with or without a local anaesthetic.
- Explain that for a core-needle biopsy or a mammotome a local anaesthetic is used, but no stitches are required.
- Explain that for a large-core biopsy, a local anaesthetic will be administered and stitches will be used to close the incision.
- Explain that for an open surgical biopsy, a general anaesthetic is usually used and the incision will require stitches and leave a scar.

Tests of the internal reproductive system

NAME OF TEST Ultrasound (abdominal, vaginal)

PURPOSE AND DESCRIPTION Used to detect the presence of space-occupying lesions, such as fibroid tumours, cysts, abscesses and neoplasms. The abdomen is coated with transducing gel and a graphical visualisation is made. For a vaginal ultrasound, a transducer is covered with a condom or vinyl glove coated with transducer gel and then introduced into the vagina.

RELATED NURSING CARE Explain need to increase intake of fluids and tell the woman not to void until the test is completed to ensure a full bladder for the abdominal ultrasound. (This lifts the pelvic organs higher in the abdomen and improves visualisation.) An empty bladder is required for the vaginal ultrasound.

NAME OF TEST Hysterosalpingogram

PURPOSE AND DESCRIPTION Used to diagnose causes of infertility and abnormalities of the uterus or fallopian tubes. A contrast medium is instilled through the cervix and its passage through the uterus and the fallopian tubes is monitored using serial x-rays.

RELATED NURSING CARE Assess for allergy to seafood (iodine) or previous contrast media. Explain that the procedure is briefly painful.

(continued)

DIAGNOSTIC TESTS The female reproductive system (continued)

NAME OF TEST Colposcopy

PURPOSE AND DESCRIPTION Conducted to further study abnormal Pap tests and as screening for women exposed to intrauterine DES. A binocular microscope is used to directly visualise the cervix.

RELATED NURSING CARE No special physical preparation is needed but psychological care is required.

NAME OF TEST Conisation, Loop electrosurgical excision of transformation zone (LEETZ), Loop electrosurgical excision procedure (LEEP)

PURPOSE AND DESCRIPTION A conisation, LEETZ or LEEP is performed to remove cervical tissue for evaluation (most often for cervical cancer). A cone-shaped area of tissue surrounding the cervical os is removed.

RELATED NURSING CARE Explain that the procedure requires general anaesthesia; however, local anaesthesia may also be used for the procedure. Postoperative self-care includes rest for 2 to 3 days. Explain that minor vaginal bleeding and discharge are expected for several days after the procedures; perineal pads (not tampons) should be used. Sexual intercourse should be avoided until discharge stops. Notify medical officer of increased bleeding or signs of infection (pain, foul-smelling discharge, fever) occur.

NAME OF TEST Endometrial biopsy

PURPOSE AND DESCRIPTION Performed to identify endometrial hyperplasia or endometrial cancer. The cervix is cleaned and tissue is obtained transcervically from the endometrium, either by curettage or vacuum aspiration.

RELATED NURSING CARE Explain that the procedure is briefly painful and causes vaginal bleeding. Advise to use perineal pads and avoid tampons and sexual intercourse while bleeding.

NAME OF TEST Cervical biopsy

PURPOSE AND DESCRIPTION Performed for women when Pap test results indicate possible cervical cancer or cervical intraepithelial neoplasia (CIN), and for screening women at high risk of vaginal and cervical cancers from intrauterine exposure to DES. Cervix is cleaned and a sample of tissue is taken for analysis.

RELATED NURSING CARE Explain that minor vaginal bleeding and discharge are expected for several days after the procedures; perineal pads (not tampons) should be used. Sexual intercourse should be avoided until discharge stops. Notify the healthcare provider if increased bleeding or signs of infection (pain, foul-smelling discharge, fever) occur.

NAME OF TEST Laparoscopy

PURPOSE AND DESCRIPTION This examination is conducted to visualise the organs in the peritoneal cavity (uterus, fallopian tubes, ovaries); to withdraw fluid for analysis; and to perform a tubal ligation. A fibre-optic scope is inserted through small abdominal incisions and carbon dioxide is inserted into the peritoneal cavity for better visualisation.

RELATED NURSING CARE Ask the woman to void prior to the examination and explain that a general anaesthetic will be used. Explain that shoulder pain is common after the procedure (referred pain from the retained carbon dioxide gas); that some vaginal bleeding may occur and the woman should use a perineal pad; and to report excess bleeding, pain or signs of infection to the healthcare provider.

conditions of the cervix and to monitor positive HPV tests. These tests may also be used to assess the effects of hormone replacement, identify other infective organisms and evaluate response to therapy.

- Space-occupying lesions and abnormalities of the vagina, cervix or uterus may be evaluated with ultrasound, a hysterosalpingogram, a colposcopy, a cervical biopsy, a laparoscopy and/or an endometrial biopsy.

Regardless of the type of diagnostic test, the nurse is responsible for explaining the procedure and any special preparation needed, assessing for any medication use that might impact on findings of the tests, supporting the woman during the examination, documenting the procedures as appropriate and following up with regard to the results of the tests.

Genetic considerations

When conducting a health assessment interview and a physical assessment, it is important for the nurse to consider genetic influences on the health of an individual. Several conditions that affect the female reproductive system have a genetic component. During the health assessment interview it is especially important to ask about a family history of ovarian or breast cancer. During the physical assessment, assess for any manifestations that might indicate a genetic disorder (see the box below). If findings indicate genetic risk factors or conditions, discuss genetic testing with the woman and refer her for appropriate genetic counselling and evaluation. Chapter 7 provides further information about genetics in medical–surgical nursing.

GENETIC CONSIDERATIONS Female reproductive system disorders

- There is a clear genetic link in some types of breast and ovarian cancers. Two breast-cancer-susceptibility genes have been identified: BRCA1 and BRCA2. If a woman has either of these genes, she is at increased risk of having breast or ovarian cancer at some point in her life.
- A family history of endometrial, colon or breast cancer increases a woman's risk of endometrial cancer.
- Turner's syndrome is a disorder in a female caused by complete or partial absence of one of the two X chromosomes. The disorder is characterised by short stature and the lack of sexual development at puberty. Other physical effects include a webbed neck, heart defects and kidney abnormalities.

FEMALE REPRODUCTIVE SYSTEM ASSESSMENTS

Technique/normal findings	Abnormal findings
Breasts	
Inspect both breasts simultaneously with the woman seated in the following positions: arms at sides, arms overhead, hands pressed on hips, leaning forwards. Inspect breast size, symmetry, contour, skin colour, texture, venous patterns and lesions. Lift the breasts and inspect the lower and lateral aspects. *Breasts normally vary in size and shape and one breast may normally be larger than the other. Colour should be consistent with the skin tone and texture smooth. There should be no redness, swelling, prominent veins or lesions.*	■ Retractions, dimpling and abnormal contours suggest benign lesions, but may also suggest malignancy. ■ Thickened, dimpled skin with enlarged pores (called peau d'orange, orange peel or pig skin) and unilateral venous patterns are also associated with malignancy. ■ Redness may be seen with infection or cancer.
Inspect the areolae and nipples. *The colour of the areolae should be consistent with the woman's skin colour (ranging from dark pink to dark brown) and Montgomery tubercles may be present. The nipples should be equal bilaterally in size, centrally located in each breast and free of lesions or discharge. Nipples are usually everted, but may normally be inverted or flat.*	■ Peau d'orange may be noted first in the areola. ■ Recent unilateral inversion of the nipple or asymmetry in the directions in which the nipples point suggests cancer.
Palpate both breasts, axillae and supraclavicular areas. Figure 46.8 illustrates a possible pattern for breast palpation. Various palpation patterns may be used as long as every part of each breast is palpated, including the axillary tail (also called tail of Spence), which is the breast tissue that extends from the upper outer quadrant towards and into the axillae.	■ Tenderness may be related to premenstrual fullness, fibrocystic disease or inflammation. Tenderness may also indicate cancer. ■ Nodules in the tail of the breast may be enlarged lymph nodes. ■ Hard, irregular, fixed unilateral masses that are poorly delineated suggest cancer. ■ Bilateral, single or multiple, round, mobile, well-delineated masses are consistent with fibrocystic breast disease or fibroadenoma. ■ Swelling, tenderness, erythema and heat may be seen with mastitis.

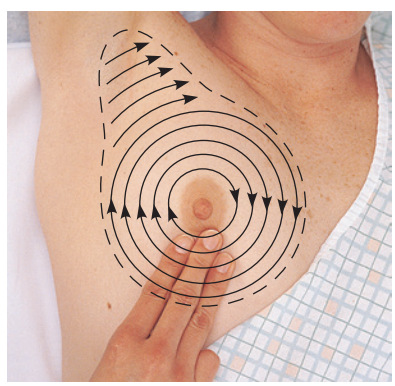

FIGURE 46.8 ■ Possible pattern for palpation of the breast

Technique/normal findings	Abnormal findings
Ask the woman to assume a supine position with a small pillow under the shoulder and the arm over the head, and repeat the systematic palpation sequence. Describe identified masses by location, size, shape, consistency, tenderness, mobility and delineation of borders. *Breasts should feel smooth, firm and elastic, without palpable masses. Prior to the menstrual cycle, there may be increased nodularity and tenderness.*	
Palpate the nipple, then compress it between the thumb and index finger. Note the colour of any discharge. *Nipples should be firm and elastic, normally without discharge (although some women normally have a clear discharge, and a milky substance may be expressed during pregnancy and lactation).*	■ Loss of nipple elasticity is seen in cancer. ■ Bloody or serous discharge is associated with intraductal papilloma. ■ Milky discharge not due to prior pregnancy and found on both sides suggests galactorrhoea (lactation not associated with pregnancy or breastfeeding), which is sometimes associated with a pituitary tumour. ■ Unilateral discharge from one or two ducts can be seen in fibrocystic breast disease, intraductal papilloma or carcinoma.
Axillae Inspect the skin of the axillae. *There should be no redness, irritation, lesions or enlarged lymph nodes on palpation.*	■ Rash may be due to allergy or other causes. ■ Signs of inflammation and infection may be due to infection of the sweat glands. ■ Palpate all sections of both axillae for palpable nodes (see Figure 46.9). ■ Enlarged axillary nodes are most often due to infection of the hand or arm but can be caused by malignancy. ■ Enlarged supraclavicular nodes are associated with lymphatic metastases from abdominal or thoracic cancer.
External genitalia Help the woman to the lithotomy position with the knees flexed and separated.	
Inspect and palpate the labia majora. *The labia majora should be equal in size and free of lesions or bulging.*	■ Excoriation, rashes or lesions suggest inflammatory or infective processes. ■ Bulging of the labia that increases with straining suggests a hernia. ■ Varicosities may be present on the labia.
Inspect the labia minora. Separate the labia majora for better visualisation. *The labia minora should be symmetrical, dark pink and moist, without redness or lesions.*	■ Inflammation, irritation, excoriation or caking of discharge in tissue folds suggests vaginal infection or poor hygiene. ■ Ulcers or vesicles may be symptoms of sexually transmitted infection.

FIGURE 46.9 ■ Palpating the axillary lymph nodes

Technique/normal findings	Abnormal findings
Palpate the inside of the labia minora between thumb and forefinger. *There should be no nodules, ulcers or lesions.*	■ Small, firm, round cystic nodules in labia suggest sebaceous cysts. ■ Wart-like lesions suggest condylomata acuminata (genital warts). ■ Firm, painless ulcers suggest chancre of primary syphilis. ■ Shallow, painful ulcers suggest herpes infection. ■ Ulcerated or red raised lesions in older women suggest vulvar cancer.
Inspect the clitoris. *The clitoris is normally not enlarged.*	■ Enlargement may be a symptom of a masculinising condition.
Inspect the vaginal opening. *There should be no swelling, discolouration, lacerations, discharge or lesions visible in the vaginal opening.*	■ Swelling, discolouration or lacerations may be caused by trauma. ■ Discharge or lesions may be symptoms of infection. ■ Fissures or fistulas may be related to injury, infection, spreading of a malignancy or trauma.
Palpate Skene's glands. Using the index finger, 'milk' Skene's glands on both sides and over the urethra and inspect for possible discharge (see Figure 46.10). *There should be no discharge or tenderness present.*	■ Discharge from Skene's glands and/or tenderness suggests infection.

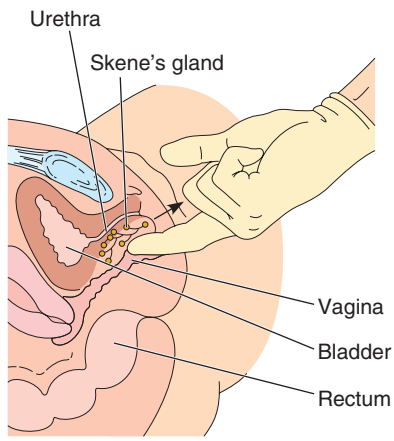

FIGURE 46.10 ■ Palpating Skene's glands

Palpate Bartholin's glands at the posterior labia majora (see Figure 46.11). *There should be no masses, redness, swelling or tenderness on palpation.*	■ A non-tender mass in the posterolateral portion of the labia majora is indicative of a Bartholin's cyst. ■ Swelling, redness or tenderness, especially if unilateral, may indicate abscess of Bartholin's glands.

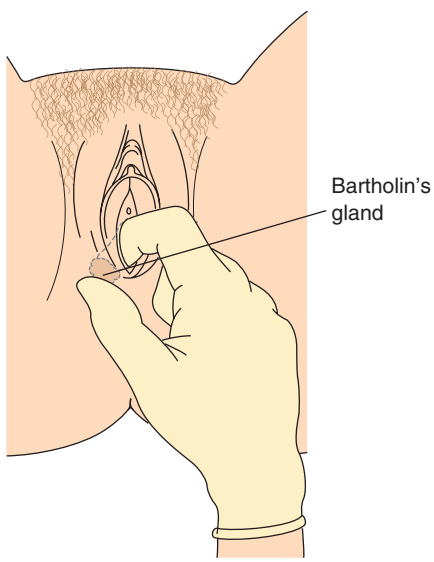

FIGURE 46.11 ■ Palpating Bartholin's glands

Inspect the vaginal orifice for bulging and urinary incontinence. Ask the woman to strain or 'bear down'. *No bulging should be visible with straining.*	■ Bulging of the anterior vaginal wall and urinary incontinence suggest a cystocele. ■ Bulging of the posterior wall suggests a rectocele. ■ Protrusion of the cervix or uterus into the vagina indicates uterine prolapse.

Technique/normal findings	Abnormal findings
Inspect and palpate the perineum. The perineum should be free of redness or lesions. *Episiotomy scars are a normal finding.*	■ Inflammation, lesions and growths may be seen in infections or cancer. ■ Fistulas may be the result of injury, trauma, infection or spreading of a malignancy.
Vagina and cervix	
Use a vaginal speculum to inspect the vaginal walls and cervix. See the guidelines in Box 46.1. *The vaginal opening varies, depending on age, sexual history and vaginal births. Vaginal mucosa is normally pink and moist, without discharge or odour. There should be no bulging or loss of urine. The cervix is normally smooth and pink, without lesions, and has a consistency similar to the tip of the nose.*	■ Bluish colour of the cervix and vaginal mucosa may be a sign of pregnancy. ■ A pale cervix is associated with anaemia. ■ A cervix to the right or left of the midline may indicate a pelvic mass, uterine adhesions or pregnancy. ■ Projection of the cervix more than 3 cm into the vaginal canal may indicate a pelvic or uterine mass. ■ Transverse or star-shaped cervical lacerations reflect trauma causing tearing of the cervix. ■ An enlarged cervix is associated with infection. ■ Nabothian cysts (small, white or yellow raised, round areas on the cervix) are considered normal but may become infected. ■ Cervical polyps may be cervical or endometrial in origin.
Palpate the cervix, uterus and ovaries. See the guidelines in Box 46.2. *The cervix can be moved slightly without discomfort. The uterus is normally at the level of the pubis, moves freely and is non-tender. The ovaries (about the size of a walnut) are firm, smooth, mobile and slightly tender on palpation. The ovaries are not usually palpable 3 to 5 years after menopause. A small amount of clear drainage is normal.*	■ The uterus may be retroverted (tilted backwards) or retroflexed (angled backwards). ■ Pain on movement of the cervix during manual examination suggests pelvic inflammatory disease (PID). ■ Softening of the uterine isthmus (Hegar's sign), softening of the cervix (Goodell's sign) and uterine enlargement may be objective signs of pregnancy. ■ Firm, irregular nodules that vary greatly with size and are continuous with the uterine surface are likely to be myomas (fibroids). ■ Unilateral or bilateral smooth, compressible adnexal masses are found in ovarian tumours. ■ Profuse menstrual bleeding is seen with endometrial polyps, dysfunctional uterine bleeding (DUB) and use of an intrauterine device. ■ Irregular bleeding may be associated with endometrial polyps, DUB, uterine or cervical carcinoma, or oral contraceptives. ■ Postmenopausal bleeding is seen with endometrial hyperplasia, oestrogen therapy and endometrial cancer.

BOX 46.1 Guidelines for intravaginal assessment and use of the vaginal speculum

The size of the speculum that is used for an internal examination of the female reproductive system depends on the age of the woman and the size of her vagina. Two types of specula are available. The Graves speculum, used most often for examinations of adult women, is available in lengths of 9 to 13 cm and widths of 2 to 4 cm. The Pederson speculum, which is narrower, may be used to examine adolescents or adult women who are virgins, who have never had a baby or who are postmenopausal with vaginal atrophy. The speculum should be warm. If cultures or smears are to be obtained, neither water nor gel should be used to warm or to lubricate the speculum.

If cells are to be taken for cytological studies, the woman should not douche, use vaginal medications or take a tub bath for 24 hours before the examination. Finally, the examination is usually deferred if the woman is menstruating or has a vaginal infection.

The general procedure is as follows:

1. Place the index and middle finger of one hand into the vagina, just inside the introitus, and press the fingers towards the rectum. Hold the speculum in the other hand.
2. Ask the woman to bear down and insert the closed blades of the speculum into the vagina at an oblique angle until the ends of the blades reach the fingertips (see the accompanying figure). Withdraw the fingers and rotate the speculum to a transverse position.
3. Continue to insert the speculum until it reaches the end of the vagina. Depress the lever of the speculum to open the blades. If the cervix is not in full view, try closing the blades, withdrawing the speculum about halfway and inserting it again at a more downward angle. When the cervix is in full view, fix the depressed lever to an open position.
4. Inspect the cervix. The normal cervix is pink and midline. Assess colour, position, size, projection into the vagina, surface and shape, and any discharge.

If a Pap smear to collect cervical cells for cytological studies is done, the following procedure may be used:

1. To collect cells from the vaginal pool, roll a sterile cotton-tipped applicator on the vaginal wall below the cervix. Paint the smear on the slide and spray the slide with fixative.

BOX 46.1 Guidelines for intravaginal assessment and use of the vaginal speculum (continued)

2. To collect endocervical cells, place the groove of the spatula snugly against the cervical os and rotate it 360 degrees. In a single stroke, spread the material from both sides of the spatula on a slide and immediately spray with fixative. Note: some clinics/practices may use a contour tip brush to collect endocervical cells instead of the spatula.

If cultures are to be done, take a specimen from the vagina and/or cervix with a sterile, cotton-tipped applicator and then either spread the specimen on a culture plate or place it in a culture container. Follow institutional protocols for preparing specimens for vaginal infections from suspected organisms.

At the end of the examination, loosen the lever control and slowly withdraw the speculum, closing the blades slowly and rotating the speculum while observing all areas of the vaginal wall. Assess the colour of the mucosa and the colour and appearance of any discharge.

Inserting the vaginal speculum

BOX 46.2 Guidelines for bimanual pelvic examination

The bimanual pelvic examination is done to palpate the cervix, uterus and ovaries. The examiner's hand that will be used intravaginally and which is gloved is held with the index and middle fingers extended, the thumb abducted and the fourth and fifth fingers folded on the palm of the hand. The extended fingers are lubricated.

The general procedure is as follows:

1. Spread the labia with the thumb and finger of the opposite hand and insert the lubricated fingers into the vagina with the palm upwards.
2. Place the opposite hand on the abdomen; it is used to press on the abdomen and gently move the internal genitals towards the intravaginal fingers (see the accompanying figure).
3. Ask the woman to take deep breaths to relax the abdominal wall.
4. Palpate the cervix, assessing size, contour, position, surface, consistency, tenderness and mobility. The cervix should be freely movable and non-tender.
5. Palpate the uterus by pressing downwards on the abdomen while placing the intravaginal fingers in the anterior fornix and gently lifting against the abdominal hand. Assess the size, shape, surface, consistency, position, mobility and tenderness of the uterus. The normal uterus is freely movable and non-tender.
6. Palpate the adnexal areas, which surround the uterus and contain the fallopian tubes and ovaries. Because these structures are small, palpation may not be possible. If the ovaries are palpable, they should be smooth and firm. The normal ovary is sensitive to touch, firm and highly movable.
7. Withdraw the fingers. Provide tissues for the woman to wipe her genital area.

Bimanual pelvic examination

CONCEPT CHECK

1 In the male, sex hormones are called:
   1 androgens
   2 steroids
   3 prostaglandins
   4 testerones

2 When assessing the breasts of an obese man, the nurse may notice what physical change?
   1 phimosis
   2 gynaecomastia
   3 enlarged axillary nodes
   4 absent areola

3 You are assessing an 82-year-old woman. She tells you that she is suddenly having menstrual bleeding. What should you tell her?
   1 'This is normal, and sometimes happens even at your age.'
   2 'Do you have menstrual cramps with the bleeding?'
   3 'You need to see a doctor because you should not be bleeding.'
   4 'Are you sexually active?'

4 Which blood test may be used to monitor prostate cancer?
   1 PSA
   2 VDRL
   3 CBC
   4 WBC

5 Atrophy and sagging of breast tissue is associated with:
   1 poor nutrition
   2 smoking
   3 normal ageing
   4 breast cancer

6 Oogenesis is the process of oocyte development and continues until which biological event?
   1 birth
   2 adolescence
   3 menopause
   4 death

7 Cessation of menstruation in young women is a normal response to which biological event?
   1 implantation of an embryo
   2 onset of menopause
   3 onset of puberty
   4 beginning spermatogenesis

8 Which of the following diagnostic tests may be used to detect HPV?
   1 colposcopy
   2 mammogram
   3 culture
   4 Pap smear

9 Which assessment technique is primarily used to determine abnormalities of the breast?
   1 inspection
   2 auscultation
   3 palpation
   4 percussion

10 At which anatomical location would you palpate Bartholin's glands?
   1 above the clitoris
   2 posterior to the labia majora
   3 inferior to the urinary meatus
   4 internal vaginal wall

CHAPTER 47

NURSING CARE OF MEN WITH REPRODUCTIVE SYSTEM AND BREAST DISORDERS

REBEKKAH MIDDLETON, PETER THOMAS

LEARNING OUTCOMES

- Explain the pathophysiology, manifestations, complications, interprofessional care and nursing care of men with disorders of the male reproductive system, including disorders of sexual function, the penis, the testes and scrotum, the prostate gland and the breast.
- Compare and contrast the risk factors for cancer of the penis, testes and prostate gland.
- Discuss the purposes, nursing implications and person-centred education required for medications and treatments used to treat disorders of sexual function, the penis, the testes and scrotum, the prostate gland and the breast.
- Describe the various surgical procedures used to treat men with disorders of the male reproductive system.

CLINICAL COMPETENCIES

- Assess functional health status of men with reproductive system and breast disorders, and monitor, document and report abnormal manifestations.
- Use evidence-based research to provide information and education to men having a radical prostatectomy.
- Determine nursing priorities, based on assessed data, to select and implement individualised nursing interventions for men with disorders of the reproductive system and breast.
- Administer or teach men how to knowledgeably and safely administer topical, oral and injectable medications used to treat disorders of the male reproductive system.
- Provide skilled care to men undergoing prostate surgery.
- Revise care plans as needed to provide effective interventions to promote, maintain or restore functional health status to men with disorders of the reproductive system and breast.

KEY TERMS

Men are subject to disorders of the penis, scrotum and testes, prostate gland and breast. These disorders may be inflammatory, structural, benign or malignant. Young men are at increased risk of testicular cancer (Russell, 2014). As men age, both benign and malignant conditions of the prostate gland become common. Many of the disorders pose significant risk to the man's fertility and sexual and urinary function, and some are life threatening. This chapter discusses disorders of the male reproductive system, including disorders of sexual expression and the male breast. Because many of the treatments and disorders of the male reproductive system have the potential to affect erection and ejaculation, these problems are discussed first.

DISORDERS OF MALE SEXUAL FUNCTION

THE MAN WITH ERECTILE DYSFUNCTION

Erectile dysfunction (ED) is the inability of the male to attain and maintain an erection sufficient to permit satisfactory sexual intercourse. **Impotence**, a term often used synonymously with erectile dysfunction, may involve a total inability to achieve erection, an inconsistent ability to achieve erection or the ability to sustain only brief erections. ED has many possible causes (see Table 47.1) and may or may not be associated with a loss of **libido** (sexual desire).

Erectile dysfunction is a common problem. In Australia, one in five men over the age of 40 experience significant erectile problems and about one in 10 men are completely unable to have erections (Andrology Australia, 2014). The incidence of the problem increases with age. Most problems with erection are the result of a disease, injury or chemical substance (such as prescribed medications, alcohol, nicotine, cocaine, barbiturates, amphetamines, methadone, opiates or marijuana) that decreases blood flow in the penis (WebMD, 2015). Because this is a problem primarily of ageing men, the discussion of pathophysiology focuses on this age group.

TABLE 47.1 Causes of erectile dysfunction

MAJOR PATHOLOGICAL CAUSES

Neurogenic
- Spinal cord injury
- Stroke
- Parkinson's disease
- Multiple sclerosis
- Epilepsy
- Alzheimer's disease
- Guillian–Barré syndrome

Endocrinological
- Diabetes mellitus
- Hypogonadism
- Hypothyroidism

Inflammatory
- Prostatitis
- Cystitis

Activity intolerance
- Pulmonary problems
- Anaemias
- Myocardial infarction
- Congestive heart failure
- Hepatic diseases
- Kidney failure

Substance dependency
- Alcohol
- Marijuana
- Narcotics
- Sedatives
- Tobacco

Arterial
- Atherosclerosis
- Hypertension
- Aortic aneurysm
- Sickle cell anaemia

Mechanical
- Decreased penile distensibility
- Congenital disorders
- Morbid obesity
- Hydrocoele
- Hip or pelvic fractures

Psychogenic
- Depression
- Stress
- Fatigue
- Fear of failure

Compulsive food disorders
- Compulsive overeating
- Anorexia nervosa
- Bulimia

MAJOR IATROGENIC CAUSES

Medications

Antihypertensives
- Hydrochlorothiazide
- Spironolactone
- Methyldopa
- Clonidine
- Prazosin
- Propranolol

Psychotropic agents
- Phenothiazines
- Butyrophenones
- Tricyclic antidepressants
- MAO inhibitors
- Diazepam

Endocrinological agents
- *Endocrinological agents*
- LHRH agonists
- Oestrogen compounds
- Progesterone

Other
- Antiparkinsonian agents
- Anticholinergic agents
- Immunosuppressive agents
- Antihistamines
- Non-steroidal anti-inflammatory drugs

Procedures and infections

Surgery
- Coronary artery bypass
- Pelvic lymphadenectomy
- Radical prostatectomy
- Radical cystectomy
- Abdominal perineal resection
- Sympathectomy
- Aortic aneurysm repair
- Transplant surgeries
- Spinal surgery

Other
- Severe healthcare-associated infection
- Radiation therapy to pelvis

Pathophysiology

Age-related changes in sexual function involve cellular and tissue changes in the penis, decreased sensory activity, hypogonadism and the effects of chronic illness. In the penis, a change from elastic collagen to a more rigid collagen results in decreased distensibility (a less rigid erection). This, in turn, interferes with the veno-occlusive mechanism, which prevents blood from 'leaking' out of the penis into the general vasculature prematurely. Problems with this mechanism result in incomplete erections. Vibrotactile sensation over the skin of the penis declines with age. This decline may explain why some older men require longer stimulation to achieve an erection. Hypogonadism, common in ageing men, results in decreased testosterone levels. There may be a relationship between lower androgen levels and erectile function.

Many illnesses affect erectile function. Damage to arteries, smooth muscles and fibrous tissues are the most common causes of impotence. Diseases such as diabetes, kidney disease, chronic alcohol misuse, liver disease, atherosclerosis, hypertension and vascular disease are responsible for organic ED. Innervation and blood flow to the penis may be damaged during surgery—prostate surgery, in particular, but also by surgery to the bladder, lower bowel and/or spine. Given the effects of ageing on the vasculature of the penis, the increased incidence of chronic illness and the multiple medications and treatments required to manage those illnesses, it is not surprising that many older men have problems with ED.

INTERPROFESSIONAL CARE

The management of men with ED is growing in importance and scale. Because the population as a whole is ageing, so the incidence is increasing proportionately. Another factor is the gradual change in the willingness of men and their partners to discuss sexual concerns. Although sexuality is still a very sensitive and private area for most people, the knowledge that help is available is causing men to seek answers. Many older men are coming to believe that loss of erectile function is not an inevitable part of ageing.

Diagnosis

The diagnostic tests that may be ordered for the man include blood studies, penile monitoring and penile blood flow.

Blood chemistry, testosterone, prolactin, thyroxin and prostate-specific antigen (PSA) levels are measured to identify metabolic and endocrine problems that may be causing the dysfunction. Nocturnal penile tumescence and rigidity (NPTR) monitoring helps differentiate between psychogenic and organic causes. These tests can be performed in a sleep laboratory, although home testing with portable devices is an alternative. The number and quality of erections occurring during REM sleep can be determined. Cavernosometry and cavernosography of the corpora are used to evaluate arterial inflow and venous outflow of blood in the penis.

Medications

ED can be treated with medications taken orally, injected directly into the penis or inserted into the urethra at the tip of the penis.

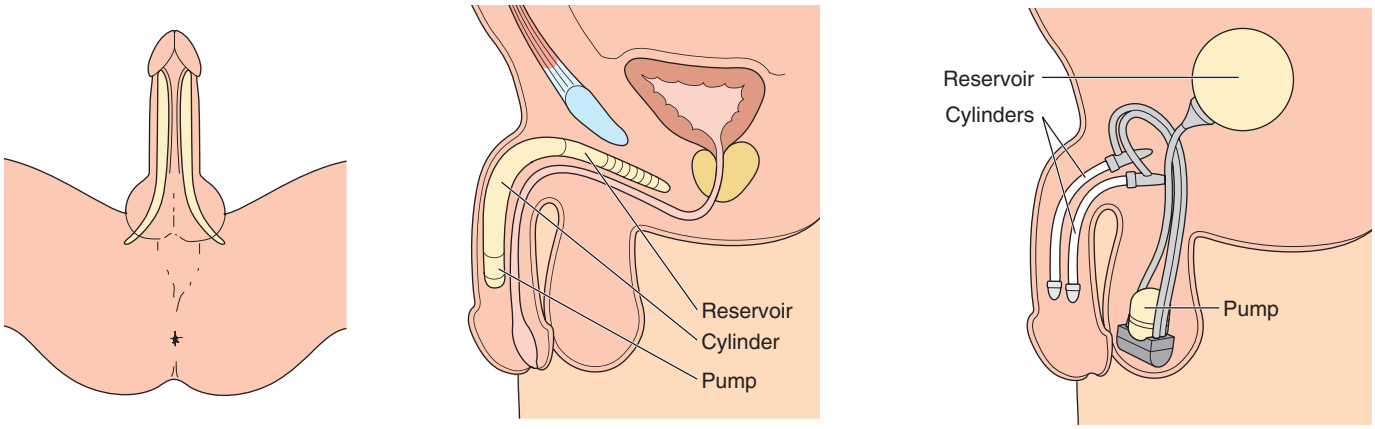
- *Oral medications:* oral medications used to treat ED include sildenafil citrate (Viagra), vardenafil hydrochloride (Levitra) or tadalafil (Cialis). Viagra and Levitra are taken an hour before sexual activity; they enhance the effects of nitrous oxide to facilitate relaxation of the smooth muscle in the penis during sexual stimulation to increase blood flow. Both drugs should be taken no more than once a day and should not be taken by men who are also taking nitrate-based drugs (for health problems) or alpha-blockers (used to treat hypertension and prostate enlargement). Cialis is a selective phosphodiesterase type-5 inhibitor that allows smooth muscle relaxation to facilitate inflow of blood into the penis. Its action lasts for 36 hours, but an erection only occurs with sexual stimulation. Cialis should not be taken if the man is also taking nitrates, alpha-blockers, erythromycin or rifampicin (antibiotics), ketoconazole or itraconazole (antifungals) or protease inhibitors (for HIV).
- *Injectable medications:* hormone replacement therapy with testosterone injections (250 mg IM every 3 weeks) or topical patches (Testogel) may be used for men with documented androgen deficiency and who do not have prostate cancer. Injectable medications, including papaverine and prostaglandin E injections (Alprostadil/Caverject), may be used. When injected directly into the penis, papaverine relaxes the arterioles and smooth muscles of the cavernosum, thus inducing tumescence (swelling). An erection usually develops that lasts from 30 minutes to 4 hours. Prostaglandin E functions much as papaverine does, but has fewer side effects. One problem with this treatment is its mode of delivery. There is a high attrition rate and men report dissatisfaction with lack of spontaneity, loss of interest in sex, physical limitations, cost and, occasionally, pain.

Mechanical devices

A frequently prescribed mechanical device for ED is the vacuum constriction device (VCD) (vacuum pump). The VCD draws blood into the penis with a vacuum, trapping it there with a constricting band at the base of the penis. After the device is removed for intercourse, a single small band, often called an O-ring, is left at the base of the penis to maintain the erection. If the man can attain an erection but cannot maintain it, an O-ring alone can be used.

Surgery

Surgical treatment for ED involves either revascularisation procedures or implantation of prosthetic devices. Venous or arterial procedures are generally not successful. The result is often temporary because the underlying cause of the vascular insufficiency is usually not corrected. Implantation of penile prostheses is now common (see Figure 47.1). Men are generally satisfied with their prostheses and they rank the inflatable type highest. Partners are also more likely to report satisfaction with the penile implant, although not to the same degree as men. Some partners report that the implanted penis is harder than a normal erect penis and therefore causes pain. Also, the man can have intercourse for a prolonged period of time and some partners do not find prolonged penetration enjoyable. Education for both the man and their partner is mandatory. Counselling by a sex therapist may be needed to facilitate adaptation to the implant.



A Semi-rigid **B** Self-contained **C** Inflatable

FIGURE 47.1 ■ Types of penile implants. *A*, With semi-rigid rods implanted in the corpora cavernosa, the penis is always in a state of semi-erection, which may not be acceptable to the man. *B*, With a self-contained penile implant, the penis remains flaccid until the man compresses a pump at the head of the penis, which transfers fluid from a reservoir to a cylinder within the penis to achieve an erection. The man presses a release valve to return the fluid to the reservoir. *C*, With an inflatable penile implant, the penis remains flaccid until the man compresses a pump in the scrotum, which transfers fluid from an abdominal reservoir to cylinders in the corpora cavernosa to achieve an erection. Pressing a release valve returns the fluid to the reservoir

Nursing care

Nurses in any healthcare setting may encounter men with ED, either through routine examinations or through careful assessment of men's conditions and treatments that may incidentally cause ED. Nurses employed in clinics, operating rooms and surgical units with urological services commonly encounter men being treated for ED. Nurses in a variety of settings, including long-term and residential care, encounter men who have had surgical interventions, such as penile implants.

Nursing diagnoses and interventions

Because nurses often complete the man's health history, they are most likely to discover problems of ED. (See the 'Functional health pattern interview' in Chapter 46 for appropriate questions to elicit information.) Once a problem is known, nurses are involved in giving information, providing emotional support and referring men to doctors or counsellors. Although there are many possible nursing interventions, this section focuses on nursing care related to sexual dysfunction and self-esteem.

Sexual dysfunction

Many men who lose erectile function are not aware of the cause. Often the man blames the loss on unrelated factors, such as age, a medication for an illness, a dangerous illness or his sexual partner. Not knowing causes anxiety, which may disrupt the relationship with his partner or lead him to discontinue an important medication.

- Assess for risk factors for ED. Be especially alert to men who have recently begun medications or had recent surgery that could cause ED. *Awareness of risk factors helps the nurse to prioritise care, although nurses must remember that almost all ageing men have at least one risk factor for ED.*
- Assess for sexual dysfunction. Men have shown increasing willingness and comfort to discuss sexual concerns, and expect nurses to be aware of the physiological effects of their disease and side effects of treatment on all aspects of their health. *If a problem exists, information obtained in a sexual assessment guides the nurse in deciding if the next step should be health education, referral or both.*
- Perform a detailed assessment of current sexual practices. *It is essential for healthcare providers to understand the man and his partner's sexual pattern in order to provide appropriate, individualised care.*
- Discuss previous methods of coping with ED. *Awareness of coping strategies can provide insight for the nurse and guide health education.*
- Provide information about treatment options. *The man needs to know the details of the intervention, the chances for success and the possible complications.*

CONSIDERATION FOR PRACTICE

Many men will not volunteer information about sexual function unless asked, but when the concept is raised, which should be done in a sensitive, non-judgmental but matter-of-fact way, are open about concerns and appreciate being asked.

Situational low self-esteem

The man with ED often believes himself to be 'less than a man'. In addition, the insertion of a penile implant with a semi-rigid prosthesis may result in disturbances in body image related to changes in sexual activity, as well as the appearance and embarrassment of a permanent semi-erection.

- Collect data during the health history, in a non-judgmental manner, about physiological function, other chronic illnesses and feelings about sexual inadequacy. *This information is necessary to establish the database for individualised interventions.*
- If the man has had a penile implant, teach him and his partner how to use the pump, including how to inflate and deflate the device. Suggest he practise inflation and deflation during the postoperative period. Suggest wearing snug-fitting underwear with the penis placed in an upright position on the abdomen, and loose trousers. Provide information about length of healing and that sexual activity may resume within 6 to 8 weeks post surgery. *Practising using the pump will maintain the pump position and promote tissue growth around the implant. The type of clothing worn can improve the ability to conceal a semi-rigid prosthesis and decrease embarrassment. Recovery from surgery is necessary before resuming sexual activity.*

Community-based care

Many nurses find that men with ED and their partners have lived in isolation with the problem for many years. The partner may even be unaware of the problem. The partner may believe that the man is seeing someone else or that he has lost his attraction to the partner. The man may have kept his problem a secret because an intense feeling of shame makes him unable to admit that he cannot perform sexually. Many men greet the information about the high incidence of ED with a sense of relief that they are not alone in having this problem. All men and their partners need to be aware of support services available to them. Referral sources include:

- Andrology Australia: www.andrologyaustralia.org
- Impotence Australia: www.impotenceaustralia.com.au/site/
- The Australian and New Zealand Infertility Counsellors Association: www.fertilitysociety.com.au/anzica/

THE MAN WITH EJACULATORY DYSFUNCTION

There are many types of ejaculatory dysfunction. **Retrograde ejaculation** (seminal fluid discharged into the bladder) may develop in ageing men but is usually related to treatment of prostate conditions or testicular cancer. *Premature ejaculation* is usually psychogenic in origin, although diabetes can cause the problem as well. *Delayed ejaculation* can be related to ageing changes, such as decreased vibrotactile sensation over the penis or decreased libido secondary to hypogonadism. Delayed ejaculation and inability to ejaculate at all may be caused by certain medications, such as antihypertensives, antidepressants, anxiolytics and narcotics.

Of these problems, premature ejaculation has proved most responsive to intervention. The man can experiment with ways to decrease sensitivity (such as wearing condoms). Using relaxation and guided imagery can delay orgasm. Mechanical devices, such as constrictive rings around the base of the penis, can help the man delay ejaculation and sustain an erection.

Nursing care focuses on assessment of the problem and health education for all types of ejaculatory dysfunction. The man's partner can be taught how to avoid excessive stimulation that would result in premature ejaculation. If the problem persists, the man should be referred to a specialist.

DISORDERS OF THE PENIS

THE MAN WITH PHIMOSIS OR PRIAPISM

Two less common disorders of the penis are phimosis and priapism. Although uncommon, these disorders can cause problems with urination and sexual activity. In some cases, they are considered a medical emergency because decreased blood flow to the penis may result in tissue ischaemia and necrosis.

Pathophysiology

Phimosis is constriction of the foreskin in uncircumcised men so that it cannot be retracted over the glans penis. Phimosis may be congenital or it may be related to chronic infections under the foreskin that lead to adhesions. The main problem with this condition is that it prevents adequate hygiene, which may lead to malignant changes of the penis. It also may interfere with urinary elimination and intercourse. In a related disorder, called *paraphimosis*, the foreskin is tight and constricted and is not able to cover the glans penis. The glans becomes engorged and oedematous and is painful. Paraphimosis may result from long-term retraction of the foreskin, such as occurs in placement of an indwelling catheter in the uncircumcised male (Grossman & Porth, 2013). The tight foreskin can result in ischaemia of the glans.

Priapism is an involuntary, sustained, painful erection that is not associated with sexual arousal. The prolonged erection may result in ischaemia and fibrosis of the erectile tissue with high risk of subsequent impotence (Grossman & Porth, 2013). The disorder, classified as either primary or secondary, is caused by impaired blood flow in the corpora cavernosa. Primary priapism results from conditions such as tumours, infection or trauma. Secondary priapism is caused by blood disorders (e.g. leukaemia, thalassaemia and thrombocytopenia), neurological disorders (e.g. spinal cord injury or stroke), kidney failure and some medications (see Box 47.1). Men who use intracavernous injection therapy or Cialis for ED are at risk of priapism.

BOX 47.1 Factors implicated in the aetiology of priapism

Illnesses/conditions
- Thalassaemia
- Metastatic cancer
- Leukaemia
- Spinal cord trauma

Drugs
- Papaverine
- Alcohol
- Psychotropic drugs
- Marijuana
- Warfarin
- Cocaine

INTERPROFESSIONAL CARE

Severe phimosis or paraphimosis may require surgical circumcision. If infection is present, the appropriate antibiotic is administered.

Treatment of priapism includes iced saline enemas, intravenous ketamine (Ketalar) administration to induce anaesthesia and spinal anaesthesia. Blood may be aspirated from the corpus through the dorsal glans, followed by catheterisation and pressure dressings to maintain decompression. If necessary, more aggressive surgery to create vascular shunts to maintain blood flow is performed. When priapism is prolonged, it increases the risk of subsequent ED.

Nursing care

Nursing care for men with priapism focuses on assessing the penis, monitoring urinary output and providing pain control. Assessment of the penis includes inspection for degree of erection and changes in colour due to ischaemia and palpation of the penis for firmness and degree of rigidity. Monitor urine output, assessing for oliguria or signs of acute urinary retention. Pain is treated with analgesics.

The man usually has moderate to severe anxiety related to pain, the treatment and the threat to his sexual function. The treatment may sound bizarre and painful, especially since the area is already extremely sensitive. The man may be acutely embarrassed by the erection and needs reassurance that the nurse understands that the erection is not within his control.

THE MAN WITH CANCER OF THE PENIS

Cancer of the penis is a rare cancer in Australia, occurring in 108 men in 2011 (Australian Institute of Health and Welfare (AIHW), 2015f). It most commonly affects men between the ages of 45 and 60. The cause is unknown. Penile cancer is rare in Jewish and Muslim men, populations in which routine circumcision is practised, although the correlation between circumcision and this cancer is unclear. Phimosis and poor genital hygiene are risk factors, as are human papillomavirus (HPV) and HIV infection. Ultraviolet light exposure (such as that used to treat psoriasis) also may play a role (Grossman & Porth, 2013).

Pathophysiology

Squamous cell carcinoma accounts for 95% of all penile cancers (Grossman & Porth, 2013). The tumour usually develops as a nodular or wart-like growth or a red velvety lesion on the glans or foreskin. The tumours tend to grow slowly. Penile cancer spreads to the superficial or deep inguinal nodes and very late in the disease may spread to the bone, liver or lungs. If the lesion is treated before inguinal node involvement, chances for a cure are good. Most of these lesions are painless but there may be significant ulceration and bleeding. Purulent, foul-smelling discharge may be evident under the foreskin. Occasionally, men with penile cancer may present with enlarged inguinal lymph nodes.

INTERPROFESSIONAL CARE

Cancer of the penis is diagnosed by a biopsy of the lesion, including any suspicious inguinal lymph nodes. The cancer is staged according to the size of the tumour, extent of invasion, status of inguinal lymph nodes and the presence or absence of distant metastasis. Small, localised lesions may be treated with fluorouracil cream, external-beam radiation, laser therapy or surgical excision. Larger lesions with superficial or deep infiltration of penile structures require partial or total amputation of the penis. Chemotherapy (discussed in Chapter 13) may be administered to men with distant metastasis.

Nursing care

Health education can help prevent this disease or provide early detection and intervention. Teach men about genital hygiene (including retraction of the foreskin if uncircumcised and washing the glans penis while bathing or showering) and the risks of unprotected sex, and encourage condom use. Encourage men to shield their genitals when having ultraviolet light therapy. Discuss the importance of seeking prompt treatment for any lesion or abnormal drainage noted on the penis.

If the man has a penile amputation (*penectomy*), nurses help cope with challenges associated with a shortened or absent

penis, including the potentially devastating effect on body image and self-concept. If a total penectomy is performed, the surgeon creates a perineal urethrostomy, preserving urinary continence. However, the man must void in the sitting position, reinforcing the feeling of loss. Dribbling of urine after voiding may be a problem for a few weeks. The man should be taught to perform careful perineal hygiene following surgery, using mild soap and water. Sitz baths may be helpful to relieve pain and to promote healing. If an inguinal lymph node dissection is performed, the man may experience persistent lymphoedema of the lower extremities.

DISORDERS OF THE TESTIS AND SCROTUM

THE MAN WITH A BENIGN SCROTAL MASS

Most scrotal masses are benign and can be managed in a manner that is satisfactory to the man. The most common are hydrocoeles, spermatocoeles and varicocoeles (see Figure 47.2).

Pathophysiology

A **hydrocoele**, the most common cause of scrotal swelling, is a collection of fluid within the tunica vaginalis. The swelling ranges from slightly larger than the testicle to larger than a grapefruit. The cause of chronic hydrocoele in men over the age of 40 years is an imbalance between production and reabsorption of fluid within the layers of the scrotum. Hydrocoeles also may occur secondary to trauma, infection or a tumour. A hydrocoele may be differentiated from a solid mass by transillumination or ultrasound of the scrotum. If the hydrocoele becomes large enough to cause embarrassment or significant pain, the fluid is aspirated and an agent is injected into the scrotal sac to sclerose the tunica vaginalis. Hydrocoeles are not associated with infertility.

A **spermatocoele** is a mobile, usually painless mass that forms when efferent ducts in the epididymis dilate and form a cyst. It is thought to result from leakage of sperm due to trauma or infection. Treatment is usually not necessary. Spermatocoeles are not associated with infertility.

A **varicocoele** is an abnormal dilation of a vein within the spermatic cord. It is caused by incompetent or congenitally missing valves that allow blood to pool in the spermatic cord veins. The dilated vein forms a soft mass that may be painful. Most varicocoeles occur on the left side after puberty. A major concern with this condition is that it can decrease blood flow through the testis, interfere with spermatogenesis and cause infertility. Varicocoeles can be felt by scrotal palpation. Scrotal ultrasound is also frequently used for diagnosis. If infertility is a concern, the spermatic vein may be ligated or occluded with a sclerosing agent or balloon catheter. If the varicocoele is small and infertility is not a concern, a scrotal support is recommended.

Nursing care

Nursing care focuses on reducing anxiety and providing health education about comfort measures. Almost all men are aware of the possible pain associated with scrotal manipulation. They need information and reassurance about pain management if surgical treatment is necessary. External bleeding is minimal after surgery; however, some men do develop scrotal haematomas, manifested by scrotal oedema and a purple discolouration.

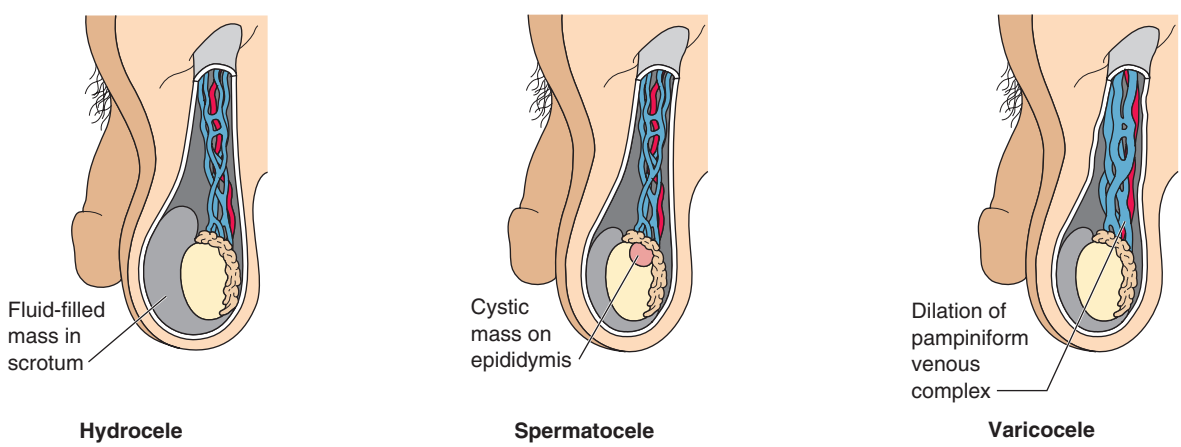


FIGURE 47.2 ■ Common disorders of the scrotum. Hydrocoeles and spermatocoeles do not usually require treatment unless they become large and cause pain. Varicocoeles are usually treated to prevent infertility

THE MAN WITH EPIDIDYMITIS

Epididymitis is an infection or inflammation of the epididymis, the structure that lies along the posterior border of the testis. This disorder is more often seen in sexually active men who are less than 35 years of age.

Sexually transmitted urethritis caused by *Chlamydia trachomatis* or *Neisseria gonorrhoeae* is the usual precipitating factor for epididymitis in younger men. Men who practise unprotected anal intercourse may acquire sexually transmitted epididymitis from *Escherichia coli*, *Haemophilus influenzae*, *Cryptococcus* or tuberculosis. In men older than age 35, epididymitis is usually associated with a urinary tract infection or prostatitis. Chemical epididymitis is associated with an inflammatory response to the reflux of urine into the ejaculatory ducts from urethral strictures, congenital structural anomalies or increased abdominal pressure from excessive heavy lifting. This type is usually self-limiting and does not require treatment.

Infectious epididymitis spreads by ascending the vas deferens from an already infected urethra or bladder. Early manifestations include pain and local oedema, which can progress to erythema and oedema of the entire scrotum, especially on the side of the involved epididymis. Complications of the disorder include abscess formation, infarction of the testis and infertility.

INTERPROFESSIONAL CARE

The infection is diagnosed with a specimen culture from a urethral swab or epididymal aspiration. Severe epididymitis may be treated with intravenous antibiotics and hospitalisation. Less acute forms of the disease are treated with antibiotic therapy. The man's sexual partner should also be treated with antibiotics if the causative organism is sexually transmitted.

Nursing care

Nursing care involves symptomatic relief and health education. Ice packs and a scrotal support may be applied to the scrotum to relieve pain. Ensure the man knows that complete resolution of the infection may take weeks to months and that treatment should continue until the infection is gone. Provide information about the possibility of infertility because the man may wish to seek evaluation for this problem at a later date.

THE MAN WITH ORCHITIS

Orchitis is an acute inflammation or infection of the testes. It most commonly occurs as a complication of a systemic illness or as an extension of epididymitis. Infection may reach the testes through the vas deferens and the lymphatic and vascular channels. Trauma, including vasectomy and other scrotal surgeries, may cause inflammation of the testes.

The most common infectious cause of orchitis in postpubertal men is mumps. Other causes include scarlet fever or pneumonia. The manifestations have a sudden onset, usually within 3 to 4 days after the swelling of the parotid glands. Manifestations include a high fever, increased WBCs and unilateral or bilateral scrotal redness, swelling and pain. If both testes are involved, permanent sterility may result, but this is rare (Grossman & Porth, 2013).

INTERPROFESSIONAL CARE

Treatment is supportive and symptomatic, including antibiotic therapy if urine cultures are positive. Bed rest, scrotal support and elevation, hot or cold compresses, and analgesics for pain are prescribed. If a hydrocoele occurs, it is aspirated. Nursing care is similar to that of the man with epididymitis and other scrotal disorders.

THE MAN WITH TESTICULAR TORSION

Testicular torsion, twisting of the spermatic cord with scrotal swelling and pain, is a potential medical emergency. The condition occurs most often in males between birth and age 20, but can occur at any age. Testicular torsion may occur spontaneously or it may follow trauma or physical exertion. The torsion of the arteries and veins decreases or stops testicular circulation, with resultant vascular engorgement and ischaemia.

Testicular torsion is usually diagnosed by history and physical examination. Testicular scanning may be used to determine if blood flow to the testicle is reduced, or a prostate ultrasound may be done to identify masses or torsion. Surgical treatment, which involves detorsion of the testicle and fixation to the scrotum, must begin as quickly as possible. If the testicle is necrotic or has sustained significant damage, an *orchidectomy* (surgical removal of a testis) is performed.

THE MAN WITH TESTICULAR CANCER

Testicular cancer accounts for only 1% of all cancers in men; however, it most commonly affects men between 15 and 50 years of age (Cancer Council South Australia, 2012). In 2011, an estimated 732 men in Australia were diagnosed with this cancer (AIHW, 2015c). Survival from testicular cancer has improved dramatically as a result of treatment with effective combination chemotherapy.

The cause of testicular cancer is unknown, but both congenital and acquired factors have been associated with tumour development. About 5% of cases develop in a man with a history of undescended testicle (*cryptorchidism*). Testicular cancer is more common on the right side, which parallels the incidence of cryptorchidism (Papadakis & McPhee, 2015).

Risk factors

Risk factors for testicular cancer are listed below:

- age
- cryptorchidism
- genetic predisposition, especially in identical twins and brothers
- Klinefelter's syndrome
- cancer of the other testicle
- other risk factors under investigation, including occupational risks, presence of multiple atypical naevi, HIV infection, cancer in situ, body size and maternal hormone use (American Cancer Society, 2012).

Pathophysiology

Approximately 95% of testicular malignancies are germ-cell tumours (Grossman & Porth, 2013). Germ-cell tumours are classified, depending on their origin and ability to differentiate, as seminomas and non-seminomas. Seminomas are the most common type and are believed to arise from the seminiferous epithelium of the testes. Non-seminomas contain more than one cell type; they include embryonal carcinoma, teratoma, choriocarcinoma and yolk cell carcinoma. The most common type in men ages 20 to 30 is embryonal carcinomas. Testicular cancer may also arise from specialised cells of the gonadal stroma. These tumours are named for the cells from which they originate: Leydig cell, Sertoli cell, granulosa cell and theca cell tumours.

Manifestations

The first sign of testicular cancer may be a slight enlargement of one testicle with some discomfort. The man may also have an abdominal ache and a feeling of heaviness in the scrotum. Local spread of the cancer to the epididymis or spermatic cord is inhibited by the outer covering of the testicles, the tunica albuginea. Therefore, spread by lymphatic and vascular channels to other organs often causes distant disease before large masses develop in the scrotum. Lymphatic dissemination usually leads to disease in retroperitoneal lymph nodes, whereas vascular dissemination can lead to metastasis in the lungs, bone or liver. Bilateral presentation of testicular cancer is unusual. Manifestations of testicular cancer are summarised in the box below. Manifestations of metastasis include lower extremity oedema, back pain, cough, haemoptysis or dizziness. Human chorionic gonadotropin (hGC)-producing tumours may cause breast enlargement (*gynaecomastia*).

MANIFESTATIONS Testicular cancer

COMMON
- Painless swelling on one testicle

OCCASIONAL
- Dull ache in pelvis or scrotum
- Painless nodule on one testicle

UNCOMMON
- Acute pain in scrotum

RARE
- Infertility
- Gynaecomastia

METASTATIC SYMPTOMS
- Neck mass
- Respiratory symptoms
- Gastrointestinal disturbance
- Lumbar back pain

INTERPROFESSIONAL CARE

Care focuses on diagnosis, elimination of the cancer and prevention or treatment of metastasis. Once testicular cancer is suspected, the man undergoes a number of screening tests to help identify the disease and its stage. If the disease is confined to the testicle, it is classified as stage I. Stage II disease is limited to the testicle and regional lymph nodes. Stage III disease involves metastasis above the diaphragm or extensive visceral involvement. Often, the man does not undergo biopsy before the beginning of treatment, but instead receives a definitive diagnosis after orchidectomy. Most men treated for testicular cancer will live a normal lifespan.

Diagnosis

Diagnosis may be made by various laboratory tests. Serum studies are done to identify tumour markers. Germ-cell tumours produce biochemical markers such as beta-hCG and alpha-fetoprotein (AFP) that can be measured using radioimmunoassay techniques. Elevated levels provide strong evidence of testicular cancer. These markers are also measured after surgery to help determine the presence of residual disease that remains undetected by other means. Persistent elevation may indicate the need for further therapy. Serum lactic acid dehydrogenase (LDH) levels are elevated in testicular cancer and may be significantly elevated when metastatic disease is present. LDH is a less specific indicator of testicular cancer than beta-hCG and AFP.

Medications

Progress in chemotherapy to treat testicular cancer is one of the chief reasons why most men survive the disease. The man who has an advanced disease receives platinum-based combination chemotherapy. Two frequently used combinations are: (1) cisplatin, bleomycin and etoposide (BEP); and (2) etoposide plus cisplatin (EP). Toxicity from the BEP regimen can be significant, with nausea, vomiting, hair loss, bone marrow suppression, nephrotoxicity, ototoxicity and peripheral neuropathy. Decreasing the number of BEP cycles to three (rather than four) or using the EP regimen reduces both the mortality and morbidity associated with chemotherapy. Chemotherapy is discussed in Chapter 13.

Surgery

Radical orchidectomy is the treatment used in all forms and stages of testicular cancer. A modified retroperitoneal lymph node dissection that preserves the nerves necessary for ejaculation often is performed at the same time.

Radiation therapy

Radiation therapy is used for stage I seminoma to treat cancer in the retroperitoneal lymph nodes, the most frequent site for distant metastasis. The man may experience temporary diarrhoea, nausea or a decline in bone marrow function, such as thrombocytopenia or leucopenia. These problems are usually mild and respond well to symptomatic treatment or time. Damage to the contralateral testicle is minimised by careful shielding. Pre-treatment and post-treatment analysis of sperm number and function is necessary. The most common long-term complication is dyspepsia or ulcer disease. Radiation therapy is discussed in Chapter 13.

Nursing care

Health promotion

Unfortunately, most men who develop testicular cancer do not have overt risk factors. Therefore, beginning at about the age of 15, all men should perform monthly testicular self-examination, as described in Box 47.2.

Nursing diagnoses and interventions

Nursing care of the man with testicular cancer is complex. The nurse must consider the reactions to the diagnosis, the change in body image accompanying treatment and sexual and reproductive issues. Although chances of a cure are excellent, the long-term effect on quality of life may be extensive, requiring a change in life goals.

Deficient knowledge

The nurse often initiates and reinforces health education about what to expect after radical orchidectomy. The man's knowledge about surgery is assessed and postoperative routines such as early ambulation are explained (see Chapter 3).

- Explain pain-control methods. In addition to the usual analgesics used to control postoperative incisional pain, ice bags may be applied to the scrotum. A scrotal support provides relief, especially when the man ambulates. *Surgery results in incisional pain and the scrotum is tender and slightly swollen.*

BOX 47.2 Testicular self-examination

- Examine your testicles when you are taking a warm shower or bath, or just after if you prefer to use a mirror to compare size.
- The scrotum, testicles and hands should be soapy to allow easy manipulation of the tissue.
- Gently roll each testicle between the thumb and fingers of each hand. If one testicle is substantially larger than the other or if you feel any hard lumps, consult your doctor immediately.
- Normal scrotal contents may be confusing. Just above and behind the testicle is the epididymis. It feels soft and tender overall, although parts of it may be rather firm. This is normal. The spermatic cord, a small, round, movable tube, extends up from the epididymis. It feels firm and smooth. Of greatest concern is any hard lump felt directly on the testicle, even if it is painless.
- Choose a day out of each month on which to examine yourself. Most men choose an easy day to remember, such as the first or last day of the month. Note this day on your calendar to help you remember.
- Start examinations young so that you become aware of what your testicles normally feel like. This way you will detect changes more readily.

- Educate the man about the manifestations of complications. The incision is closed with steri-strips or staples, and, although rare, wound dehiscence is possible. If the incision gapes open or if there is bleeding beyond slight oozing after 24 hours, the man should contact the surgeon. Another rare complication is a haematoma in the scrotum caused by bleeding from the spermatic cord stump. *Rapid onset of scrotal oedema is a sign of this problem. Because the man is usually discharged early, complications may not become apparent until he is at home.*

Ineffective sexuality patterns

The effect of testicular cancer and its treatment on sexual and reproductive function is varied. If the man has a retroperitoneal lymph node dissection, severing of the sympathetic plexus may result in retrograde ejaculation or failure to ejaculate. Infertility may be caused by ejaculation disorders, surgery, chemotherapy or radiation therapy.

- Assess the man's pre-diagnosis sexual function. To assess this, the nurse must establish an atmosphere of trust, openness and permission to discuss sexual concerns. After the initial shock of the diagnosis, men report intense concern about sexual and reproductive issues, which can be relieved only by information. *Knowledge of the man's usual sexual function can guide health education.*
- Discuss the possibility of preserving sperm in a bank prior to treatment. *This option may help relieve the man's fears about his ability to father children in the future, but must be completed prior to initiating treatment with surgery, chemotherapy or radiation therapy.*
- Help coping with feelings about altered sexual function and appearance. Explain that testicular implants can be inserted to preserve appearance. *Many men, regardless of whether they are in a significant relationship, deeply grieve the loss of the ability to father children. It is important to maintain body image despite disfiguring surgery.*

Community-based care

Families need to be included in health education for a variety of reasons. If the man is of reproductive age, his partner will have significant anxiety and will also require information. For the teenager, parents need information about the effect on sexual function and are often very involved in postoperative care. The man needs the support of the people he loves, and knowledgeable loved ones can give effective support.

Provide health education and reinforcement of the need for follow up, especially if the retroperitoneal lymph nodes were not surgically explored. For men with a risk of recurrence, surveillance with periodic physical examinations, chest x-ray films, tumour markers and computed tomography (CT) scans of the retroperitoneal nodes could continue for a minimum of 5 years, and possibly 10 years, after orchidectomy.

DISORDERS OF THE PROSTATE GLAND

THE MAN WITH PROSTATITIS

Prostatitis refers to different types of inflammatory disorders of the prostate gland. *Prostatodynia* is a condition where the man experiences the symptoms of prostatitis but shows no evidence of inflammation or infection. Manifestations of prostatitis and prostatodynia are summarised in the box below.

Pathophysiology and manifestations

The National Institutes of Health in the United States has defined four types of prostatitis. To gain a consistent approach to classification, Australia and New Zealand have adopted these definitions. The types are known as: acute bacterial prostatitis, chronic bacterial prostatitis, chronic prostatitis/pelvic pain syndrome and asymptomatic inflammatory prostatitis. Men with asymptomatic inflammatory prostatitis have no subjective symptoms, but are diagnosed when a biopsy or prostatic fluid examination is conducted.

Acute bacterial prostatitis

Acute bacterial prostatitis is most often caused by an ascending infection from the urethra or reflux of infected urine into the ducts of the prostate gland. *E. coli* is the most common causative organism; other causative organisms include *Pseudomonas, Klebsiella* and *Chlamydia*.

Symptoms of acute bacterial prostatitis include fever, malaise, muscle and joint pain, urinary frequency and urgency, dysuria and urethral discharge. The man often experiences dull, aching pain in the perineum, rectum or lower back. On rectal examination, the prostate is enlarged and painful.

Chronic bacterial prostatitis

Men with chronic bacterial prostatitis often present with a history of recurrent urinary tract infections. The causative organisms are most often *E. coli*, *Proteus* or *Klebsiella*. Calculi may form in the prostate and contribute to the chronicity of the problem.

The manifestations of chronic bacterial prostatitis include urinary frequency and urgency, dysuria, lower back pain and perineal discomfort. Epididymitis may be associated with the prostatitis.

Chronic prostatitis/chronic pelvic pain syndrome

This type of prostatitis is both the most common and the least understood of the syndromes (Yuan et al., 2014). The two types (inflammatory and non-inflammatory) are based on the presence of white blood cells in the prostatic fluid.

- *Inflammatory prostatitis* is believed to be an autoimmune disorder, but the actual cause is unknown. Men with this type of prostatitis have lower back pain; urinary manifestations; pain in the penis, testicles, scrotum, lower back and rectum; decreased libido; and painful ejaculations. They do not have bacteria in their urine, but have leukocytes in the urine and abnormal inflammatory cells in prostatic secretions.

MANIFESTATIONS Prostatitis and prostatodynia

ACUTE BACTERIAL PROSTATITIS
- Onset (may be abrupt): obstruction, irritation or pain upon voiding; frequency; and urgency
- Positive cultures of infectious organism
- Non-urinary symptoms: chills, fever, low back and pelvic floor pain

CHRONIC BACTERIAL PROSTATITIS
- Urinary symptoms sometimes similar to those of the acute form, except less sudden, less dramatic or even absent
- Positive cultures of causative organism not always obtainable

CHRONIC PROSTATITIS
- Perineal, suprapubic, lower back or genital pain
- Irritation upon voiding
- Post-ejaculatory pain
- Negative cultures of organisms

PROSTATODYNIA
- Pelvic, lower back or perineal pain
- Irritation or obstruction upon voiding
- No evidence of inflammation in the prostate
- No urinary tract infection
- Normal prostatic secretions

- *Non-inflammatory prostatitis* (prostatodynia) has manifestations that imitate those of inflammatory prostatitis, but no evidence of urinary or prostatic infection or inflammation can be found. The cause is not known, but is believed to be the result of a problem outside the prostate gland, such as obstruction of the bladder neck. Treatment is mainly symptomatic.

Asymptomatic inflammatory prostatitis

This type of prostatits is generally diagnosed during investigation of other genitourinary complaints. No symptoms are evident in the man. Leukocytes are found in the seminal fluid from the prostate.

INTERPROFESSIONAL CARE

Diagnosis

It is often difficult to diagnose prostatitis. Urine and prostatic secretion examination and cultures are obtained to determine the presence and type of blood cells and/or bacteria. X-ray studies and ultrasound may be useful to visualise pelvic structures.

Medications

Bacterial prostatitis is treated with antibiotics appropriate for the causative organism. Oral antibiotics are usually administered up to 4 weeks for acute bacterial prostatits, but men with the chronic form must take antibiotics for a much longer period. This can

be up to 4 months, and they may still relapse as soon as the antibiotic is discontinued. Non-bacterial prostatitis does not usually respond satisfactorily to drug therapy, although relief from symptoms is possible. Non-steroidal anti-inflammatory drugs are often useful for pain but it can be difficult to manage pain in chronic prostatitis where moderate relief may be obtained only. At times opioid analgesia may be necessary to control chronic pain but need careful monitoring and evaluation. Anticholinergics may assist in reducing voiding symptoms. Prostatodynia is treated symptomatically to relieve muscle tension, usually with alpha-adrenergic blocking agents or muscle relaxants.

Nursing care

Educating men with prostatitis focuses on symptom management. Men with acute and chronic bacterial prostatitis should be taught to increase fluid intake to approximately 3 L daily and to void every few hours. These measures help decrease irritation when voiding and assist in minimising the effects of increased fluid loss due to fever and infection. Management of fever is important in reducing fluid loss and minimising discomfort. Regular bowel movements help ease potential pain associated with defecation. It is important to educate the man on the need to complete the course of antibiotic therapy. Men with chronic prostatitis/chronic pelvic pain syndrome need to know that the condition is not contagious and does not cause cancer (Grossman & Porth, 2013). Referral sources for information include Andrology Australia <www.andrologyaustralia.org/> and HealthInsite <www.healthinsite.gov.au/>.

THE MAN WITH BENIGN PROSTATIC HYPERPLASIA

Benign prostatic hyperplasia (BPH), a non-malignant enlargement of the prostate gland, is a common disorder of the ageing male, thought to be associated with endocrine changes although its exact cause is unknown. The prostate, very small at birth, grows at puberty and reaches adult size around age 20. Almost one in four Australian men aged 40–49 years receive treatment for prostate problems, and this increases to three in every four men aged 70 years and older (Andrology Australia, 2015a). Some men remain asymptomatic even though their prostate may have begun to grow larger. The problem that brings men to a healthcare provider is usually the associated urinary dysfunction.

Risk factors

Although the exact cause of BPH is unknown, risk factors include:

- age
- family history
- risk factors similar to heart disease (i.e. obesity, high blood pressure, type 2 diabetes mellitus)
- diet high in meat and fats (Andrology Australia, 2015a).

Pathophysiology

The two necessary preconditions for BPH are age of 50 or greater and the presence of testes. Men who are castrated before puberty do not develop BPH. The androgen that mediates prostatic growth at all ages is dihydrotestosterone (DHT), which is formed in the prostate from testosterone. Although androgen levels decrease in ageing men, the ageing prostate appears to become more sensitive to available DHT. Oestrogen, produced in small amounts in men, appears to sensitise the prostate gland to the effects of DHT. Increasing oestrogen levels associated with ageing or a relative increase in oestrogen related to testosterone levels may contribute to prostatic hyperplasia.

FAST FACTS

Urinary problems with BPH:

- A hesitant, interrupted weak stream.
- Urgency with leaking or dribbling of urine.
- More frequent urination in small amounts, especially at night (nocturia).

BPH begins as small nodules in the periurethral glands, which are the inner layers of the prostate. The prostate enlarges through formation and growth of nodules (hyperplasia) and enlargement of glandular cells (hypertrophy). These changes occur over a long period of time. The pathophysiological effects result from a combination of factors, including urethral resistance to the effects of BPH, intravesical pressure during voiding, detrusor muscle strength, neurological functioning and general physical health.

Manifestations

The expanding prostatic tissue compresses the urethra (see Figure 47.3) and causes partial or complete obstruction of the outflow of urine from the urinary bladder. The detrusor muscles hypertrophy to compensate for increased resistance to urinary flow; however, eventually decreased bladder compliance and bladder instability result.

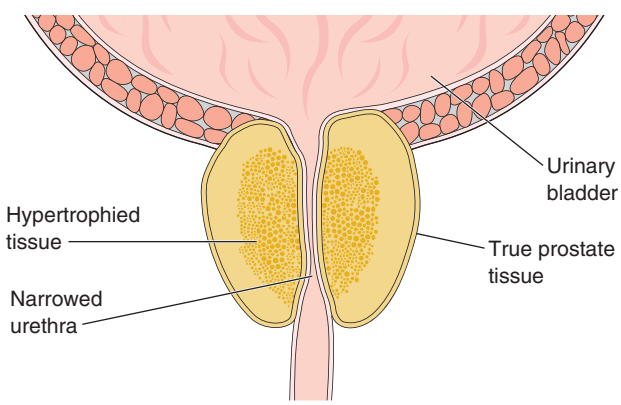

FIGURE 47.3 ■ Benign prostatic hyperplasia

MANIFESTATIONS Benign prostatic hyperplasia

- Diminished force of urinary stream
- Hesitancy in initiating voiding
- Post-void dribbling
- Sensation of incomplete emptying
- Urinary retention
- Nocturia
- Frequency
- Urgency
- Urge incontinence
- Dysuria

As a result, the man with BPH has manifestations from obstruction (decreased force of stream, increased time to initiate and complete void, hesitancy, incomplete bladder emptying and post-void dribbling) and irritation (frequency, urgency, incontinence, nocturia, dysuria and bladder pain). Urinary retention may become chronic, resulting in overflow incontinence with any increase in intra-abdominal pressure. There is little correlation between the size of the prostate gland and the urinary manifestations. Manifestations of BPH are summarised in the box above.

Complications

Unless the enlarging mass is reduced, multiple complications may occur. Acute urinary retention is quite common in men with BPH (van Vuuren, Heyns & Zarrabi, 2011; Eifler, 2014). As urine is retained in the bladder, increasing bladder distension occurs. Diverticula (outpouchings) on the bladder wall result from the distension. The distension may also obstruct the ureters. Infection, more common in retained urine and in diverticula, may ascend from the bladder to the kidneys. Hydroureter, hydronephrosis and renal insufficiency are possible complications. Renal calculi risk is increased in men with BPH, due to the alkalisation of the retained or residual urine.

INTERPROFESSIONAL CARE

Care of men with BPH focuses on diagnosing the disorder, correcting or minimising the urinary obstruction and preventing or treating complications. There is no way to reverse BPH. Treatment is often determined by the severity of the manifestations and the presence of complications. Mild cases are often monitored over time, and may remain stable or improve.

Diagnosis

A diagnosis of BPH involves both physical examination and laboratory tests not only to diagnose the disease but also to differentiate it from prostate cancer. A digital rectal examination (DRE) is done to examine the external surface of the prostate; in BPH it is asymmetrical and enlarged. Examination of the creatinine levels of the blood is conducted to assess for kidney damage.

The urine is examined for WBCs, RBCs and bacteria. Urinary function is assessed by measuring residual urine (amount of urine remaining in the bladder after voiding) with ultrasonography or post-voiding catheterisation (more than 100 mL is considered high) and through uroflowmetry, which measures urine flow rate. Normal is greater than 14 mL/sec. A finding of less than 10 mL/sec indicates obstruction.

PSA levels are obtained to rule out prostate cancer. PSA may be slightly elevated, but cannot be used to determine BPH. PSA is a glycoprotein produced only in the cytoplasm of benign and malignant prostate cells; the serum level corresponds with the volume of both benign and malignant prostate tissue. Further information is provided in the next section under diagnosis of prostate cancer.

In addition, the man's own subjective experiences with BPH are included in the diagnosis and treatment. For example, the International Prostate Symptom Score uses a scale of 0 (not at all) to 5 (almost always) to collect data about areas such as feeling as though the bladder did not empty with urinating, the need to urinate within 2 hours after urinating, starting and stopping the stream several times while urinating and straining to urinate. This questionnaire also asks how many times during the night the man gets up to urinate and how he feels about having the disorder.

Medications

Treatment with medications is based on two considerations: the hyperplastic tissue is androgen dependent and smooth muscle contraction within the prostate can exacerbate urinary obstruction. The first consideration is usually addressed by treatment for mild prostate enlargement with an anti-androgen agent such as finasteride (Proscar) that inhibits the conversion of testosterone to DHT and causes the enlarged prostate to shrink in size. These agents may cause impotence, decreased libido and decreased volume of ejaculate. Individual and family education includes the information that crushed tablets should not be handled by pregnant women because the drug may be absorbed through the skin and be harmful to a male foetus.

Excessive smooth muscle contraction in BPH may be blocked with the alpha-adrenergic antagonists such as terazosin (Hytrin) and tamsulosin (Flomaxtra). These medications relieve obstruction and increase the flow of urine. They may cause orthostatic hypotension. Individual and family education includes advice about making position changes slowly to avoid dizziness and accidental falls, how to take and record blood pressure, and to check with the healthcare provider before taking any medication for coughs, colds or allergies (because these over-the-counter medications may contain an adrenergic agent).

Surgery

Men who have urinary retention, recurrent urinary tract infection, haematuria, renal calculi or renal insufficiency secondary to BPH are candidates for surgical intervention. Surgical treatment may be performed by minimally invasive surgery or through transurethral surgery, open surgery or by laser surgery.

MINIMALLY INVASIVE SURGERY Because medications are not effective for all men, a number of procedures have been developed to relieve the manifestations of BPH that are less invasive than traditional surgery.

Transurethral microwave thermotherapy uses a transurethral probe to deliver microwaves directly to the prostate. It uses heat to destroy excess prostate tissue. During the procedure, a cooling system protects the urinary tract. The procedure takes about an

hour and can be performed on an outpatient basis. Although microwave procedures do not cure BPH, they do reduce urinary manifestations. The procedures do not cause impotence or incontinence.

The *transurethral needle ablation* (TUNA) system uses low-level radio frequency through twin needles to burn away a region of the enlarged prostate. Shields protect the urethra. TUNA improves the flow of urine through the urethra. It does not cause impotence or incontinence.

TRANSURETHRAL SURGERY A *transurethral resection of the prostate (TURP)* is the most common surgical procedure used. Obstructing prostate tissue is removed using the wire loop of a resectoscope and electrocautery, inserted through the urethra (see Figure 47.4). No external incision is necessary. During the procedure a resectoscope is used to remove obstructing tissue one piece at a time. The tissue is flushed into the bladder with fluid and then flushed out at the end of the operation. This surgery has potential risks, however, including postoperative haemorrhage or clot retention, inability to void and urinary tract infection. Other possible complications are incontinence, impotence and retrograde ejaculation.

In the *transurethral incision of the prostate* (TUIP) procedure, small incisions are made in the smooth muscle where the prostate is attached to the bladder. The gland is split to reduce pressure on the urethra. No tissue is removed, so this procedure is most appropriate for men with smaller prostate glands. TUIP can be done on an outpatient basis and has the additional advantage of less risk of postoperative retrograde ejaculation than is associated with TURP or other prostatectomy procedures.

LASER SURGERY Another minimally invasive procedure used to treat BPH is laser therapy. In laser surgery, a laser beam is delivered via a cystoscope transurethrally to cut, coagulate and vaporise excessive prostatic tissue with several short bursts of energy. An advantage of laser surgery is decreased blood loss and a more rapid recovery time. However, this method may not be as effective for larger prostates.

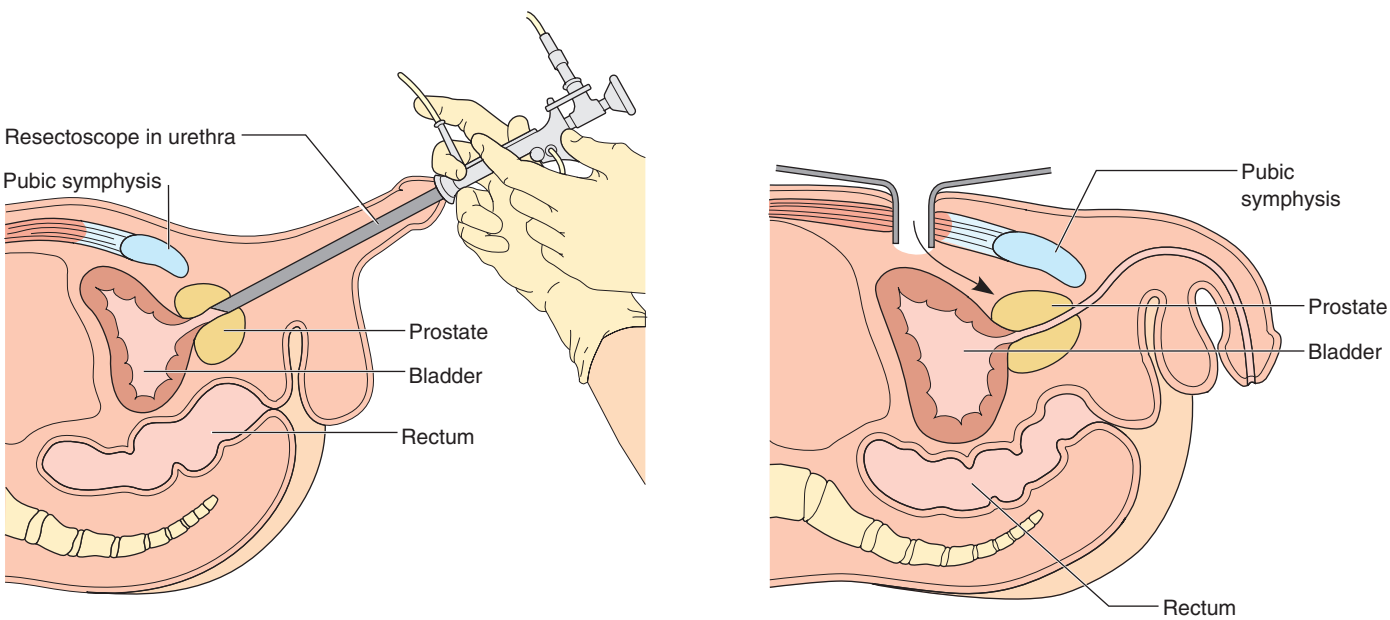
OPEN SURGERY When the prostate gland is very large, an open prostatectomy may be used. These procedures are discussed in the section on prostate cancer that follows. Nursing care for the man having prostate surgery (prostatectomy) is outlined in the box below.

New treatments

Newer treatments for BPH include minimally invasive procedures such as balloon urethroplasty and placement of intraurethral stents to maintain patency of the urethra. Balloon urethroplasty is a simple procedure in which a balloon-tipped catheter is inserted into the narrowed portion of the urethra and inflated. Inflation of the balloon widens the urethra, relieving obstruction. These procedures can be done as outpatient surgery.

Alternative and complementary therapies

Phytotherapy is the use of plants or plant extracts for medical treatment. Several plant extracts have been used for years in Europe to treat BPH, including *Serenoa* (saw palmetto berry), the bark of *Pygeum africanum*, the roots of *Echinacea*, *purpurea* and *Hypoxis rooperi* and the leaves of the trembling poplar. The mechanism of action of these extracts is unknown, but men report they are effective in relieving manifestations (Papadakis & McPhee, 2015). A Cochrane review has found that *Serenoa* has no clinical benefit over placebo (Tacklind et al., 2011).



A Transurethral resection of the prostate

B Retropubic prostatectomy

FIGURE 47.4 ■ *A*, In a transurethral resection of the prostate, a resectoscope inserted through the urethra is used to remove excess prostate tissue. *B*, In a retropubic prostatectomy, prostate tissue is removed through an abdominal incision

NURSING CARE OF THE MAN having a prostatectomy

PREOPERATIVE CARE

- Assess the man's and family's knowledge about the surgery. *Some men are confused about the surgical approach because there are several, quite different methods.*
- Inform the man that he will have a urinary catheter when he returns from surgery and he may have a drain(s) in his incision. He also will be wearing sequential pneumatic compression stockings. *This knowledge can reduce anxiety postoperatively and increase cooperation with postoperative care.*
- Ensure that a signed consent form is in the chart and that all other preoperative tasks outlined in Chapter 3 are completed.
- Bowel preparation with oral neomycin sulfate (Neosulf) may be ordered. *This cleanses the bowel if a perineal approach will be used.*
- Communicate willingness to address any concerns or anxiety. *Men may be anxious about the outcome of their surgery and potential long-term effects of the surgery on their sexuality. When a prostatectomy is performed for prostate cancer, additional fears include the extent of the cancer and surgery, chances for cure and possible end-of-life issues.*

POSTOPERATIVE CARE

- Maintain the usual postoperative assessments (see Chapter 3) and follow aseptic techniques in urinary drainage and irrigation care. Monitor vital signs closely for the first 24 hours and regularly thereafter. *The man who has had prostate surgery is at risk of haemorrhage and infection. Vital sign changes may be early manifestations and can assist in recognising deterioration.*
- Maintain an accurate fluid balance chart, including amounts of irrigating solution used. Frequently assess patency of any catheters and drains. Monitor colour and character of urine. *Catheters may become occluded by blood clots or kinks, interfering with urinary drainage and increasing the risk of haemorrhage.*
- Assess and manage the man's pain. *The man may have at least three types of pain: incisional pain, bladder spasms and abdominal cramps due to intestinal gas. Analgesics and non-steroidal anti-inflammatory drugs (NSAIDs) are administered on a routine and prn basis to control incisional pain. Bladder spasms may be accompanied by strong urges to void and urine leakage around the catheter. Oral oxybutynin hydrochloride may be used to relieve bladder spasms.*
- Maintain anti-embolic stockings and pneumatic compression devices as ordered. Assist with leg exercises and ambulation as ordered. *The man who has had prostate surgery is at risk of developing thromboemboli; these are important preventive measures.*
- Encourage the man to maintain a liberal fluid intake of 2 to 3 L a day. *Increased fluids reduce burning on urination after catheter removal and the risk of urinary tract infection.*

THE MAN WITH A TRANSURETHRAL RESECTION OF THE PROSTATE (TURP)

- For the first 24 to 47 hours, monitor for haemorrhage, evidenced by frankly bloody urinary output, presence of large blood clots, decreased urinary output, increasing bladder spasms, decreased haemoglobin and haematocrit, tachycardia and hypotension. Notify the doctor if any of these manifestations occur. *Postoperative haemorrhage may be either arterial or venous and may be precipitated by movement, bladder spasms or an obstructed urinary drainage system.*
- Instruct the man with a three-way indwelling catheter with traction to keep his leg straight while the traction is applied. An 18 Fr. to 22 Fr. three-way catheter with a 30 to 45 mL balloon usually is inserted following a TURP. *The inflated balloon is pulled down into the prostatic fossa and the catheter tubing is pulled down and taped to the man's leg to apply pressure against the operative site, preventing bleeding.*
- Explain that the presence of a urinary catheter will cause the sensation of needing to void, but it is important not to strain to try to void around the catheter or when having a bowel movement. Explain that bladder spasms—experienced as lower abdominal pressure or pain—and a desire to urinate may occur. Ensure that the man understands that this is an expected sensation and that medications can help alleviate this discomfort. *Pressure on the urethra by the large catheter and on the internal sphincter by the catheter's balloon stimulate the micturition reflex. Straining to void or to have a bowel movement may stimulate bladder spasms and increase pain; it also may increase the risk of bleeding. Administer pain medications at regular intervals.*
- If the man has continuous bladder irrigation (CBI), assess the catheter and the drainage tubing at regular intervals. Maintain the rate of flow of irrigating fluid to keep the output light pink or colourless. Assess the urinary output every 1 to 2 hours for colour, consistency, amount and presence of blood clots; assess for bladder spasms. *CBI is used to prevent the formation of blood clots which could obstruct urinary output. Bladder distension resulting from output obstruction increases the risk of bleeding. Irrigating fluids are continuously infused and drained at a rate to keep urine light pink or colourless. Indicators of obstruction and bleeding are: urine has frank blood; urine contains multiple blood clots, decreased urinary output, or the man has bladder spasms.*
- Assess for fluid volume excess and hyponatraemia, called TURP syndrome, manifested by hyponatraemia, decreased haematocrit, hypertension, bradycardia, nausea and confusion. If these manifestations occur, notify the doctor. *TURP syndrome results from the absorption of irrigating fluids during and after surgery. Untreated, it may result in arrhythmias, seizures or both.*
- If the man does not have CBI, follow organisational policy and protocols for irrigating the indwelling catheter (usually when the urine contains frank blood or has numerous larger blood clots, or when bladder spasms increase). In most instances, using sterile technique, the catheter is gently irrigated with 50 mL of irrigating solution at a time, until the obstruction is relieved or the urine is clear. Ensure equal input and output of irrigating fluid. *Intermittent irrigation may be used to prevent obstruction of urinary drainage.*

(continued)

NURSING CARE OF THE MAN having a prostatectomy (continued)

- Following catheter removal, assess the amount, colour and consistency of urine. Explain to the man that he may experience burning on urination, that dribbling after urination is a common experience and that the urine may contain small blood clots after catheter removal. *The CBI and catheter usually are removed in the 24 to 48 hours following surgery. Urinary control may be improved by teaching the man to start and stop the urine stream several times during each voiding and by practising pelvic floor exercises. Regaining full control may take up to 1 year.*

THE MAN WITH A RETROPUBIC PROSTATECTOMY

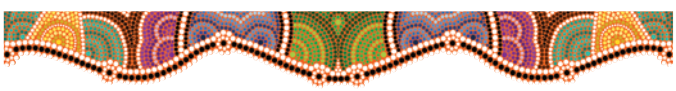
- Assess the abdominal incision for the presence of urine. *Because the bladder is not entered during a retropubic prostatectomy, no urine should be found on the dressing.*
- Assess the abdominal incision for increased or purulent drainage and the man for an increased temperature and pain. *These manifestations indicate the presence of infection.*

THE MAN WITH A SUPRAPUBIC PROSTATECTOMY

- Assess urinary output from both the suprapubic and the urethral catheters. *The man with a suprapubic prostatectomy often has two separate closed drainage systems: one from the suprapubic incision and one from a urethral catheter.*
- Assess the abdominal dressing for urinary drainage and change saturated dressings frequently. Consult with a wound care specialist if necessary. *Urine is highly irritating to the skin.*
- Following removal of the urethral catheter (usually 2 to 4 days after surgery) and based on protocols, clamp the suprapubic catheter and encourage the man to void. Assess residual urine by unclamping the suprapubic catheter and measuring urinary output after voiding. *If residual urine is 75 mL or less with several voidings, the suprapubic catheter is removed.*

THE MAN WITH A PERINEAL PROSTATECTOMY

- Assess perineal incision for drainage and manifestations of infection. *Location of the incision in the perineum increases the risk of infection.*
- Do not take rectal temperatures or administer enemas. *Insertion of a thermometer or enema tubing into the rectum may precipitate bleeding.*
- Use a T-binder or padded scrotal support to hold the dressing in place. Following removal of the dressing and perineal sutures, heat lamps or sitz baths may be used. *The location of the dressing makes application difficult: heat lamps or sitz baths provide heat and promote healing.*
- Teach the man to perform perineal irrigations with sterile normal saline as ordered and after each bowel movement. *Because of the proximity of the incision to the anus, special wound care is necessary to prevent infection.*



Nursing care

Most men are unsure of the function of the prostate gland and even of the prostate's exact location, though its relationship to sexual and urinary function is at least generally known. This lack of knowledge, coupled with the growing number of treatment options, is confusing to many men. There are many similarities between the nursing care of men with BPH and that of men with prostate cancer (see the prostate cancer section that follows).

Nursing interventions

This section provides interventions related to deficient knowledge, urinary retention, risk of infection and risk of imbalanced fluid volume.

Deficient knowledge

- Explain the anatomy and physiology of the prostate gland, as well as normal changes that occur with ageing. *Men must know about their bodies in order to make accurate decisions about treatment.*
- Discuss treatment options, including information about effects on erectile function, ejaculation and fertility. *Counsel the man to discuss specific concerns with his urologist. Many different treatment options are available; the choice should be a mutual decision between the man, his partner and the urologist.*
- Discuss effects of prostate surgery, including urinary retention and urinary incontinence. *These common transient postoperative effects are related to the surgical procedure and the postoperative indwelling catheter.*
- Explain to the man having a TURP that a catheter will be placed into the bladder, with the tubing taped to his inner thigh, and that irrigation fluid will be infusing into and out of the catheter for the first 36 to 72 hours following surgery. *The catheter and irrigation are necessary to remove blood clots from the bladder and allow drainage of urine. Gentle traction is applied to the catheter to apply pressure to the operative site (prostatic fossa) and prevent excessive bleeding.*
- Explain that, following removal of the catheter, he will most likely have urinary frequency and urgency. He may also experience dribbling of urine after voiding. Stress the importance of increasing oral fluid intake and regular pelvic floor exercises. *Urinary manifestations are related to the surgical procedure and the indwelling catheter. Increased fluid intake helps decrease dysuria. Pelvic floor exercises strengthen periurethral muscles and decrease post-voiding urine leakage.*

Urinary retention

- Educate the man about the manifestations of acute urinary retention: dysuria, overflow incontinence, bladder pain and

distension, no urine output. *Acute urinary retention is a potential complication of BPH, requiring immediate medical attention.*

- Provide health education about how the risk of developing urinary retention increases when the man with BPH takes over-the-counter (OTC) decongestant medications or prescription medications such as antidepressants, anticholinergics, calcium channel blockers, antipsychotics and medications to treat Parkinson's disease. *OTC decongestants may contain alpha-adrenergic agonists that increase smooth muscle tone of the prostate, bladder neck and proximal urethra. The prescribed medications may relax detrusor muscle contractions. Both actions may increase the risk of urinary retention (Keller et al., 2012; Barkin, 2011).*
- Suggest avoiding intake of large volumes of liquid at any one time. *A single intake of a large volume of liquid results in rapid bladder filling and increases the risk of urinary retention.*
- Teach how to use the double-voiding technique: urinate, then sit on the toilet for 3 to 5 minutes, then urinate again. *This technique may relieve mild to moderate urinary retention.*

CONSIDERATION FOR PRACTICE

In addition to avoiding a large amount of fluids at one time, it is also important to teach the man to limit liquids that stimulate voiding, such as coffee, caffeine-containing beverages and alcoholic beverages.

Risk of infection

- Monitor WBC and vital signs. *Infection is indicated by an increase in WBCs, body temperature and pulse rate.*
- Maintain sterile procedures when changing irrigation fluids and emptying Foley catheter draining bag. *Sterile procedures are necessary to prevent infection.*

Risk of imbalanced fluid volume

A prostatectomy brings increased risk of imbalanced fluid volume as a result of excessive bleeding from the operative site (prostatic fossa) as well as absorption of irrigating fluid. Report manifestations indicating hypovolaemic shock, excess bleeding and/or TURP syndrome immediately.

- Monitor pulse and blood pressure. *Manifestations of hypovolaemic shock include an increasing pulse and a decreasing blood pressure.*
- Monitor colour of drainage in urinary drainage bag (see Table 47.2). *The appearance of dark or red-coloured urine and irrigation fluid in the urinary drainage bag is an excellent indicator of bleeding after a prostatectomy.*
- Monitor for manifestations of transurethral resection (TURP) syndrome: nausea and vomiting, confusion, hypertension, bradycardia and visual disturbances. *The absorption of isotonic bladder irrigating fluids during and after surgery may cause this hypervolaemic, hyponatraemic state. Treatment includes diuresis and, in severe cases, hypertonic saline administration (Papadakis & McPhee, 2015).*

TABLE 47.2 Significance of character of urine after prostatectomy and related nursing care

URINE COLOUR	NURSING IMPLICATIONS
Light red to red	Normal on day of surgery and first postoperative day.
Very dark red	May indicate increased venous bleeding or inadequate dilution. Catheter at risk of occlusion. Increase flow rate of irrigant. If urine does not clear, notify doctor.
Bright red	May indicate arterial bleeding. Increase flow rate of irrigant, monitor vital signs and notify doctor.
Contains blood clots	Occasional blood clot normal. If clots are frequent, catheter may become obstructed. Increase flow rate of irrigant.
Clear to light pink	Normal throughout hospitalisation.

Community-based care

Depending on the man's choice of treatment, the procedure may be performed on an outpatient basis. The man having a TURP, although hospitalised for the surgery, may be discharged quite quickly after surgery if there are no complications. Discharge instructions after prostate surgery are provided in the 'Meeting individualised needs' box below. Home care often involves care of an indwelling urinary catheter. The nurse should educate the man how to care for the catheter and drainage bag, including the following information:

- Change from the daytime leg drainage bag to a larger night drainage bag. A larger bag suspended from the bed frame at night permits gravity drainage of urine and prevents reflux of urine back into the bladder.
- Avoid strapping the leg bag on too tightly, which can decrease venous return and increase risk of thrombophlebitis and embolic complications such as pulmonary emboli.
- Place a soft cloth between the leg bag and thigh to decrease friction and absorb dampness under the bag, reducing the risk of skin irritation.
- Empty the leg bag every 3 to 4 hours during waking hours to prevent overfilling.
- Promptly report any unexpected changes in urine colour, consistency or odour, haematuria, evidence of frank bleeding or large blood clots, as well as a lack of or significant decrease in urine output.

THE MAN WITH PROSTATE CANCER

Cancer of the prostate is the most common form of cancer present in Australian men over 50 (excluding some forms of skin cancer), with over 19 000 men diagnosed annually, accounting for one-third of all new diagnoses of cancer in

MEETING INDIVIDUALISED NEEDS **Discharge instructions for men after prostate surgery**

Activity
The healing period lasts from 4 to 8 weeks. Avoid strenuous activity and heavy lifting. Do not drive for 2 weeks. Take long walks; take stairs slowly and carefully. Continue exercises that you did in the hospital to prevent blood clots in the legs. You can take showers; avoid baths while the catheter is in place.

Bleeding
Bleeding can occur any time after surgery. It is fairly common after a bowel movement, coughing or increased exercise. If you notice blood in the urine, increase fluids and rest until the urine is clear. If heavy bleeding blocks the catheter, call the doctor immediately. Avoid aspirin and NSAIDs (e.g. Nurofen) for at least 2 weeks.

Bowel movements
Keep bowel movements regular and soft to avoid pressure on the prostate area. Drink fruit juices and take mild laxatives or stool softeners as ordered.

Diet
Resume your normal diet. Increase fluids to 10 glasses daily. Avoid alcohol unless otherwise advised by your doctor.

Sexual intercourse
Do not have sex for 6 weeks after surgery to avoid bleeding. You may still have erections even with the catheter in place. When you resume sex, ejaculate flows back into the bladder, so you will express little or no semen.

Urination
After your catheter is removed, you may experience some burning, stinging or leakage for several weeks and you may pass small blood clots occasionally. These symptoms will disappear as the area heals. It is best to use pads to control leakage.

Work
If work is not strenuous, you may return in 4 weeks; otherwise, wait 6 to 8 weeks.

Please call immediately if:
- You are unable to urinate.
- Bleeding is not controlled by fluids and rest, or is excessive.
- You have chills and fever or severe abdominal pain.
- Your scrotum becomes swollen and tender.
- You have pain in one calf, chest pain or difficulty breathing.

men (AIHW, 2015b). It is the second most common cause of deaths from cancer in men, with one in nine men developing prostate cancer in their lifetime (Prostate Cancer Foundation of Australia (PCFA) 2015). Men living in rural and regional areas are at greater risk of prostate cancer, where the mortality rate is 21% higher than in capital cities (AIHW & Australasian Association of Cancer Registries, 2012). This is attributed to lack of awareness and education about prostate cancer, along with distances from testing and treatment, poor general practitioner awareness and limited access to specialists. The number of deaths annually from prostate cancer in men is equivalent to the number of women who die from breast cancer, approximately 3300 (PCFA, 2015). It is projected that prostate cancer will remain the most common cancer in men, representing the biggest burden in 2025 (AIHW, 2015d).

When diagnosed early, prostate cancer is curable. If the man presents with metastatic prostate disease, it is incurable, so control of disease progression is key. The incidence of prostate cancer increases with age. Most diagnoses (85%) are made in men over 65 years of age (Cancer Council Australia 2015), with 1 in 7 men at risk up to age 75 (AIHW, 2015e). In New Zealand, the incidence of prostate cancer is lower, with 1 in 13 men being diagnosed up to age 75 (Prostate Cancer Foundation of New Zealand, 2015). It is more prevalent in men in Western countries and less common in men from South-East Asia. This may be due to the extent to which PSA and digital rectal examination screening are used; hence, caution should be taken when interpreting variations in prevalence. Many men are found to have prostate cancer on autopsy; usually the cancer has produced no manifestations or complications.

Risk factors

In addition to age, other risk factors being investigated are as follows:
- genetic and hereditary factors, with risk increased in men who have a family history of the disease
- ethnicity—more common in Western countries and less common in Asian countries, particularly South-East Asia
- having a vasectomy, believed to increase the levels of circulating free testosterone
- dietary factors, including a diet high in animal fat and excessive supplemental vitamin A.

FOCUS ON CULTURAL DIVERSITY
Risk and incidence of prostate cancer

- The incidence of prostatic cancer is lower for Indigenous Australian men than it is for non-Indigenous men (Condon et al., 2013).
- Prostatic cancer is the second most common cancer for Indigenous males, following lung cancer (Australian Bureau of Statistics, 2012; Diaz et al., 2015).

Pathophysiology

The prostate gland consists primarily of glandular epithelial cells. The exact aetiology of prostate cancer is unknown, although androgens are believed to have a role in its development. Almost all primary prostate cancers are adenocarcinomas and develop in the peripheral zones of the prostate gland. This location increases the risk of local spread to the prostatic

capsule. Despite its proximity to the rectum, metastasis to the bowel is uncommon because a tough sheet of tissue, Denonvilliers' fascia, acts as an effective physical barrier.

As the tumour enlarges, it may compress the urethra, obstructing urinary flow. The tumour may metastasise and involve the seminal vesicles or bladder by direct extension. Metastasis by lymph and venous channels is common.

Manifestations

Men with early-stage prostate cancer are often asymptomatic. Pain from metastasis to bones is often the initial manifestation noted. Urinary manifestations depend on the size and location of the tumour and the stage of the malignancy. They are often much like manifestations of BPH: urgency, frequency, hesitancy, dysuria and nocturia. The man may also notice haematuria or blood in the ejaculate (Grossman & Porth, 2013). Manifestations of prostate cancer are summarised in the box below.

MANIFESTATIONS Prostate cancer

GENITOURINARY
- Urinary symptoms—frequency, urgency, poor flow, difficulty commencing voiding, incomplete emptying
- Dysuria
- Haematuria
- Abnormal prostate on digital rectal examination
- Nocturia
- Haematospermia
- Erectile dysfunction

MUSCULOSKELETAL
- Bone or joint pain
- Migratory bone pain
- Back, hip and pelvic pain

NEUROLOGICAL
- Nerve pain
- Bilateral lower extremity weakness
- Bowel or bladder dysfunction
- Muscle spasms

SYSTEMIC
- Weight loss
- Fatigue

Complications

Death usually occurs secondary to debility caused by multiple sites of skeletal metastasis, especially to the vertebrae. Compression fractures of the spine are common, resulting in the possible loss of mobility and bowel and bladder function. Tumours may eventually involve bone marrow, resulting in severe anaemias and impaired immune function.

INTERPROFESSIONAL CARE

Care of the man with prostate cancer focuses on diagnosis, elimination or containment of the cancer, and prevention or treatment of complications. There are currently no clinical strategies to prevent the development of prostate cancer. Therefore, early detection remains the main emphasis for intervention related to this disease.

Diagnosis

Although an increasing number of men are now diagnosed with asymptomatic prostate cancer, many men with prostate cancer have either locally advanced cancer or distant metastasis at the time of diagnosis. The definitive diagnosis can be made only by biopsy (prostate biopsy is discussed in Chapter 46); however, other tests may suggest the presence of prostate cancer.

A digital rectal examination (DRE) is useful in assessing the prostate gland. Any hardness in the gland may indicate cancer; however, hardness may be a result of calcification due to prolonged inflammation or prostatic stones. DRE only allows the posterior surface of the gland to be palpated. Anterior lesions are not able to be detected using DRE. PSA levels are used to diagnose and stage prostate cancer and to monitor response to treatment. PSA is not a true tumour marker, but measurement of PSA has made dramatic differences to earlier diagnosis of prostate cancer in men. PSA levels rise in the presence of benign prostatic enlargement, prostatitis and other non-malignant conditions due to the fact that PSA is organ specific rather than cancer specific. Levels depend on age, and there is no specific normal or abnormal level. An increase over time is more significant than one reading. The PSA test is used with a DRE to help detect prostate cancer in men age 50 or older, and is also used to monitor effects of treatment.

While the normal range for PSA is 0–4.0 ng/mL, normal ranges for serum PSA for men of different ages in Western countries are as follows:
- 40–49 years: average 0.65 ng/mL, upper limit of normal 2.0 ng/mL
- 50–59 years: average 0.85 ng/mL, upper limit of normal 3.0 ng/mL
- 60–69 years: average 1.39 ng/mL, upper limit of normal 4.0 ng/mL
- 70–79 years: average 1.64 ng/mL, upper limit of normal 5.5 ng/mL (Andrology Australia, 2013).

Transrectal ultrasonography (TRUS) may be used when the DRE is abnormal or if the PSA is elevated. In this test, a small probe is inserted into the rectum. The probe gives off sound waves that create a picture of the prostate on a video screen. Guided by this picture, the doctor inserts a narrow needle through the rectal wall into the prostate gland and the needle removes a sample of tissue for examination. Other tests that may be ordered include a urinalysis or cystoscopy. Bone scan, magnetic resonance imaging (MRI) or CT scans may be performed to determine the presence of tumour metastasis.

Grade and stage help to determine prognosis and guide treatment decisions. Grade (cancer cell differentiation) is determined by the pathologist. Prostate cancer is staged with a variety of tests. Table 47.3 outlines treatment options according to the stage of the cancer.

Diagnosis is reached following a combination of history taking, DRE, PSA testing and prostate biopsy or alternative.

TABLE 47.3 Prostate cancer staging and treatment

STAGE	DESCRIPTION	TREATMENT
Localised	Cancer is confined to prostate, non-palpable, focal involvement; well differentiated	Close observation and follow up Interstitial or external-beam radiation therapy Prostatectomy Brachytherapy (radioactive seeds implanted in prostate)
Locally advanced	Cancer has broken through the capsule of the prostate, palpable, involves one or both lobes; poorly differentiated	Careful observation in selected people Hormone therapy Prostatectomy Interstitial or external-beam radiation therapy Ultrasound-guided percutaneous cryosurgery
Advanced	Extension of the tumour outside the prostate capsule, possible seminal vesicle involvement, cancer has metastasised, often to bone or lymph nodes	Adjunctive hormone therapy Chemotherapy/interstitial radiation Steroids External-beam radiation therapy Radical prostatectomy Palliative surgery (TURP)

Research for prevention

Toremifene (Fareston) to treat men with abnormal prostate growth might help prevent the growths from becoming malignant. The drug, which blocks some of the effects of oestrogen, had previously been used to treat advanced breast cancer in women. Men who have prostate intraepithelial neoplasia (PIN) have about a 30% chance of developing prostate cancer in 1 year and about a 65% chance within 2 years. A larger study is now in progress. In addition, other studies reported that men who took statins (to treat high cholesterol) were less likely to have prostate cancer.

In May 2012, the National Institute for Health and Clinical Excellence in the United Kingdom recommended the use of abiraterone (Zytiga). This drug was developed by Cancer Research UK and has been found to extend the lives of some people with advanced prostatic cancer following chemotherapy.

Treatments

The treatment of prostate cancer is complex and depends on the grade and stage of the cancer, as well as the age, general health and preference of the man. In some cases—for example, when the man with a slow-growing tumour is elderly or has a limited life expectancy—watchful waiting is the treatment of choice. Treatments for prostate cancer include surgery, radiation therapy and hormone manipulation.

SURGERY Surgery for prostate cancer includes several types of prostatectomies. For very early disease in older men, cure may be achieved with a simple prostatectomy (such as TURP), discussed in the section on benign prostate hyperplasia.

- *Radical prostatectomy* involves removal of the prostate, prostate capsule, seminal vesicles and a portion of the bladder neck. The entire prostate gland with that component of the urethra within the gland and seminal vesicles is removed, so the urethra below the prostate is then connected to the bladder. The surgery can be performed by open surgery or by using laparoscopic surgery, where small incisions are made in the abdomen and a laparoscope is inserted and used to remove the prostate. Varying degrees of urinary incontinence are experienced by men following this surgery, with approximately 10% having ongoing incontinence 12 months on. Erectile dysfunction is commonly experienced by men following this surgery, with up to 85% of men having problems with getting and maintaining an erection. There are strategies to reduce this incidence and treatment if ED persists (Andrology Australia, 2014) (see Table 47.4). Some surgeons do the surgery from an area other than the operating room by using a robotic interface. Nursing research reporting men's satisfaction with a discharge program following a radical prostatectomy is discussed in the 'Translation to practice' box below.
- *Retropubic prostatectomy* may be performed because it allows adequate control of bleeding, visualisation of the prostate bed and bladder neck, and access to pelvic lymph nodes.
- *Perineal prostatectomy* is often preferred for older men or those who are poor surgical risks. This approach requires less time and involves less bleeding.
- *Suprapubic prostatectomy* is rarely used, usually when problems with the bladder are expected. Control of bleeding is more difficult because the surgical approach is through the bladder.

TABLE 47.4 Potential complications related to radical prostatectomy and radiation therapy

RADICAL PROSTATECTOMY	RADIATION THERAPY
Erectile dysfunction	Erectile dysfunction*
Urethral stricture	Urethral stricture
Fistula/rectal injury	Rectal/anal stricture*
Urinary incontinence	Cystitis
Surgical/anaesthetic risk	Diarrhoea
	Proctitis
	Rectal ulcer
	Bowel obstruction*
	Urinary incontinence

*Delayed complications; may appear months or years after completion of therapy.

TRANSLATION TO PRACTICE Evidence-based practice: improve discharge teaching

The period immediately after discharge for a radical prostatectomy is one that is often a difficult time for men and their families as they cope with the emotional and physical demands of cancer surgery. Knowledge deficits about how long it will take to recover and how to provide care at home can significantly affect recovery. Nurses must recognise the need to provide discharge teaching prior to hospital discharge, and make it part of actual practice for every man they treat.

IMPLICATIONS FOR NURSING

Discharge education for men is essential and needs to include how to manage potential side effects following surgery, including urinary incontinence, ED and other side effects associated with radiotherapy and hormone therapy, such as bladder irritation and cystitis. Early discussion of side effects and clear management strategies are vital for men as they prepare to go home. Use of printed information sheets about preoperative and postoperative radical prostate surgery, along with a health education checklist and a discharge bag containing a urinary leg bag, urinary collection bag, wound supplies, incontinence product samples and a community resources brochure, are good strategies to ensure information is clear. Catheter care is one of the most valuable types of information required by men. Nurses are now, and will continue to be, challenged to provide the type and amount of information needed for self-care at home. Essential information that needs discussion and advice with the man following surgery is outlined below:

- pelvic floor exercises to promote continence and discussion about regular undertaking of the exercises
- education on preventing constipation and ensuring adequate fluid intake
- awareness and avoidance of bladder irritants such as tea, coffee, alcohol and diet soft drinks
- advice on how to source and use incontinence pads for men
- discussion with the doctor about medication to assist erections is important from a psychological, as well as a physical, perspective
- referral to support organisations.

CRITICAL THINKING IN PERSON-CENTRED CARE

1. You are caring for a 75-year-old man who has had a radical prostatectomy for prostate cancer. His wife tells you they have always had an active sex life and she hopes this surgery will not change that. What would you say to her?
2. Why is the risk of infection high for a man providing self-care at home following a radical prostatectomy? Which interventions would you suggest during health education to reduce this risk?
3. If you were developing a list of community resources for men following prostate surgery, what would you include? How would your list vary for the following situations?
   - a 64-year-old man with a wife and four married children who all live close
   - a 77-year-old man who lives alone and has no family
   - a 90-year-old man who will go to a residential care facility after discharge
   - a 56-year-old homosexual man who lives with his partner.

For men with locally advanced (beyond the prostatic capsule) cancer, surgery is controversial because of the likelihood of hidden lymph node metastasis and relapse. TURP is not performed as curative therapy but may be used to relieve urinary obstruction for men with advanced disease.

Surgical intervention is now available for men with urinary sphincter insufficiency, which is the main cause of incontinence after prostatectomy. An artificial urinary sphincter is surgically implanted (see Figure 47.5). To be eligible, the man must be able to manipulate the pump placed in the scrotum and have adequate cognitive function to know when a problem with the appliance occurs.

RADIATION THERAPY Radiation therapy may be used as a primary treatment for prostate cancer. Long-term problems of impotence and urinary incontinence may be avoided and survival rates often are comparable. Radiation may be delivered either by external beam or interstitial implants of radioactive seeds of iodine, gold, palladium or iridium (*brachytherapy*). Brachytherapy is used when there are no major or acute lower urinary tract symptoms. Interstitial radiation has a lower risk of impotence and rectal damage than external-beam radiation. See Chapter 13 for nursing care of the person receiving radiation therapy.

Radiation therapy has a palliative role for men with metastatic prostate cancer, reducing the size of bone metastasis, therefore controlling symptoms of controlling pain and restoring some function, such as continence or the ability to ambulate for men with spinal cord compression.

HORMONAL MANIPULATION Androgen deprivation therapy is used to treat advanced prostate cancer by aiming to achieve castration and hence increase survival rate by suppressing testosterone, since prostate cancer is androgen dependent. Many cells in the growing tumour are androgen dependent and either cease to grow or die if deprived of androgens. Unfortunately, other cancer cells thrive without androgen and are unaffected by therapy to reduce circulating androgens. Therefore, the effects of hormone manipulations vary from complete but temporary regression of the tumour to no response at all. Strategies to induce androgen deprivation vary from orchidectomy to oral administration of hormonal agents. Table 47.5 compares surgical and hormone therapies. In addition, new drugs are being developed that block the effects of male hormones and research is being conducted to demonstrate what mix of hormones is best and at what time in the perioperative period they are most effective.

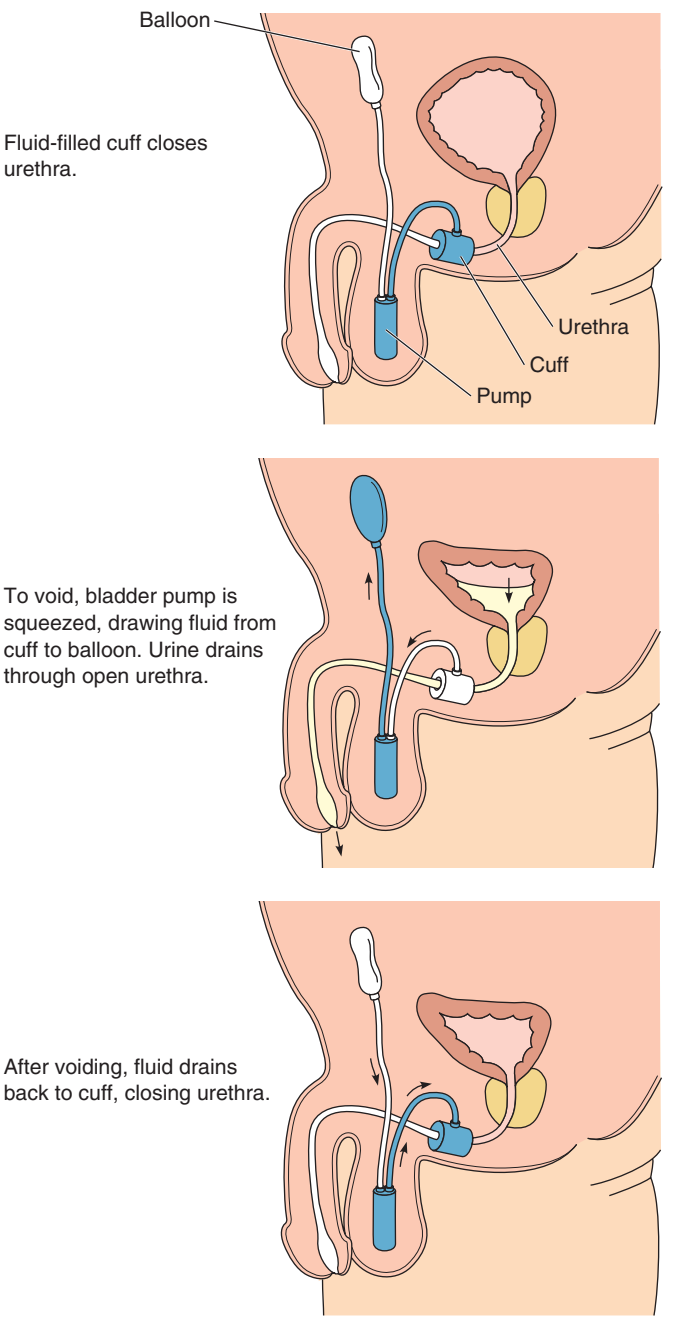


FIGURE 47.5 ■ Method of operation of an artificial urinary sphincter

Nursing care

Nurses plan and provide interventions to help prevent prostate cancer and to facilitate a return to functional health status. Interventions may range from health education to using knowledge and skill in physical care following a radical prostatectomy. A nursing care plan for a man with prostate cancer is given below.

Health promotion

Nurses are in a unique position to increase public awareness about early detection of prostate cancer. Every encounter with men and their families—in clinics, hospital units or in the home—is an opportunity to provide information about early detection and identify needs. Several studies have shown a positive correlation between increased awareness of and participation in prostate cancer screening procedures. Organisations such as Cancer Council Australia and Andrology Australia have information about early detection of prostate cancer, which are useful in educating the public.

One risk factor that can be easily changed is diet. Men should know that they can lower their risk of prostate cancer by eating less red meat and fat, and increasing their intake of fruit and vegetables, particularly tomatoes, pink grapefruit and watermelon, as these are high in lycopenes, which help prevent damage to DNA and may help lower prostate cancer risk. Other substances that may help lower the risk are vitamin E and selenium.

All men should be given information about the limitations and benefits of testing for early detection and of treatment so they can make an informed decision. Currently, routine screening of PSA as a diagnostic tool for prostatic cancer is not recommended by Australian cancer authorities. An elevated PSA may indicate that there is a problem with the prostate; however, it may not be cancer. Factors such as the man's level of concern about having cancer, age and family history should be discussed prior to having a PSA level taken. Diagnosis of cancer is made following physical assessment and a transrectal ultrasound and biopsy of the prostate (Andrology Australia, 2015b).

Assessment

Collect the following data through the health history and physical examination (see Chapter 46). Note that a digital rectal examination (DRE) is an advanced nursing assessment.

- *Health history:* risk factors, urinary elimination patterns and manifestations, haematuria, pain.
- *Physical assessment:* DRE to assess prostate size, symmetry, firmness and nodules.

Nursing diagnoses and interventions

The nursing care of men with prostate cancer must be holistic, sensitive and individualised. Nursing interventions discussed for the man with BPH may also be appropriate. This section focuses on problems with urinary incontinence, sexual function and pain.

Urinary incontinence (reflex, stress, total)

Urinary incontinence is a disturbing complication following treatment for prostate cancer. Both radical prostatectomy and external-beam radiation therapy can cause urinary incontinence, ranging from a few drops when the man lifts a heavy object (*stress incontinence*) to no control at all. Older men may experience *urge incontinence*, the involuntary passage of urine soon after a strong sense of urgency to void. Total and unpredictable loss of urine is classified as total incontinence. The man's reaction to incontinence may be severe even if the incontinence is not great. Many men have significant anxiety at the prospect of an incontinent episode in

TABLE 47.5 Surgical and hormone* therapy in the management of advanced prostate cancer

TREATMENT	ADVANTAGES	DISADVANTAGES
Orchidectomy	Inexpensive Immediate effect (i.e. men report diminished pain from metastasis in the OR recovery room)	Body image issues due to loss of testicles
Oestrogen compounds (diethylstilbestrol)	Inexpensive Effects reversible	Increased risk of cardiovascular problems (e.g. DVT) More likely to cause gynaecomastia, hypertrophy of breast tissue
Luteinising hormone-releasing hormone agonist (LHRH) (leuprolide)	Effects reversible No cardiovascular risk Monthly administration	Very expensive Subcutaneous injection route Slow onset: up to 3 weeks Can lead to exacerbation of clinical symptoms
Steroidal anti-androgens (megestrol acetate (Megace))	Effects reversible No cardiovascular risk Inexpensive Less risk of ED Less risk of osteoporosis	May not drop testosterone levels sufficiently Weight gain Increased risk of hepatotoxicity
Non-steroidal anti-androgens (flutamide; often used in conjunction with LHRH)	Do not alter circulating androgens Block some side effects of LHRH May be effective if other methods fail	Very expensive

*All hormonal manipulations have the potential disadvantage of loss of libido, erectile dysfunction, hot flushes and gynaecomastia.

public because they feel shame and often guilt about the loss of control.

- Assess the degree of incontinence and its effects on lifestyle. *The nurse needs to determine previous urinary patterns and the type of incontinence currently being experienced to plan appropriate interventions.*
- Teach pelvic floor exercises to help restore continence and discuss regularity of performing the exercises. *Pelvic floor or Kegel exercises can almost always improve stress incontinence, with the possibility of eliminating it.*
- Teach methods to control dampness and odour from stress incontinence:
  - Do not attempt to prevent accidental voiding by restricting fluids. *Not only will the man continue to have incontinent episodes, but also his urine will become concentrated, exacerbating the problem with odour and increasing risk of UTI.*
  - Manage occasional episodes (one to three small-volume accidents per day) with an absorbent pad worn inside the underwear and changed as needed. Most pads are made with a polymer gel that controls odour. *Appropriate measures help promote good hygiene, decrease anxiety and increase comfort.*
- Refer to a physiotherapist or a continence specialist for additional measures to promote continence. *Special exercises, restricting some types of fluids and other measures such as bladder training can help the man deal with incontinence.*
- Explore options such as an external collection device (external catheter or suprapubic catheter) for the man with total incontinence. *This device may improve the man's self-esteem and allow resumption of social activities.*
- Encourage verbalising feelings about the impact of incontinence on quality of life. The degree of incontinence does not necessarily correlate with the perceived level of suffering. *Listening to these concerns with sensitivity can help the man work through these feelings and may allow him to move towards a healthy adaptation to his disability.*

Sexual dysfunction

Surgical treatment for prostate cancer may cause erectile dysfunction and changes in ejaculatory function. Hormone therapy for advanced prostate cancer lowers libido and may also cause ED. The diagnosis of cancer and body image changes caused by hormone therapy may lower self-esteem, which in turn can diminish sexual desire and willingness to interact sexually with a partner. Most older men are active sexually and fully capable of sustaining an erection. They are likely to fear the effect of treatment on their sexual health. They may allow their anxiety to guide their decision about treatment or they may refuse all interventions because of this fear. Reactions vary greatly and the nurse must maintain a non-judgmental approach to education and support.

- Assess the man's pre-treatment sexual function. *Knowledge of previous sexual function is necessary to plan appropriate interventions.*
- Teach the man about the actual or potential effects of therapy on sexual function. *The incidence of ED varies with different therapies for prostate cancer.*
- Provide an opportunity for the man and his partner to discuss the implications of and their concerns about the diagnosis and treatment of sexual function. *The treatments for prostate cancer often affect the physiology of erection. The man and his partner need support and counselling during the period of adjustment. Sexual activity should not be resumed until 6–8 weeks following surgery. Stress and anxiety can exacerbate ED, so management of these need to be discussed and strategies put in place to manage them.*

NURSING CARE PLAN A man with prostate cancer

Bill Burns, a 76 year old, lives with his wife in a small retirement community in Victoria. His wife had a stroke 2 years ago and Mr Burns does all the cooking and housework. He has been in good health for most of his life, having only mild osteoarthritis in his knees and hands. He has noticed a gradual onset of urinary urgency and frequency over the past 2 years, but has never had incontinence. During a routine checkup, the doctor at the local general practice performs a digital rectal examination and palpates a hard nodule on the surface of Mr Burns's prostate. Following discussion with Mr Burns and his wife, a PSA is performed. After his PSA is found to be elevated, Mr Burns is referred to a urologist, who diagnoses prostate cancer. Mr Burns chooses to have surgery, and a radical retropubic prostatectomy and lymph node dissection are performed. The lymph nodes are negative for metastasis. Following surgery, Mr Burns' recovery is uncomplicated. However, the nurse caring for him is concerned about his ability to care for his indwelling catheter because of his arthritis and his wife's physical disabilities from the stroke. The nurse makes a referral to community health to ensure he can manage his care at home. An initial home health assessment is scheduled for the day after Mr Burns is discharged from the hospital.

ASSESSMENT

The community health nurse notes that the house is clean and neat. Mr Burns is dressed, but still wearing his night urinary drainage bag, even though it is 1300 hrs. Mr Burns tells the nurse that his main problem is going to get groceries because he is embarrassed to be seen with the drainage bag. He says he has not been able to remove the drainage bag and attach the leg bag because of his arthritis. Physical assessment findings include the pelvic incision healing without signs of infection. There is no tenderness in his calves, chest pain or shortness of breath. The urine is yellow, without odour. Mr Burns states that he sees no need for the pelvic exercises since he is no longer in the hospital. He also expresses the belief that he is cured of cancer and questions the need for follow-up care.

NURSING DIAGNOSES

- *Risk of stress urinary incontinence* related to surgical procedure.
- *Ineffective health maintenance* related to inability to care for the urinary drainage system, not understanding the need for postoperative exercises and questions about follow-up care.

PLANNING

Establish realistic outcomes for Mr Burns through education and support.

Expected outcomes

- Regain urinary continence after catheter removal.
- Change the urinary drainage bag with the appropriate assistance.
- Verbalise the rationale for performing postoperative exercise.
- Verbalise the need for continued follow-up care.

IMPLEMENTATION

- Discuss the possibility of stress incontinence after the catheter is removed.
- Reinforce the need for ongoing pelvic floor exercises while the catheter is still in place.
- Explore Mr Burns's support system to identify people who could assist him with catheter care and arrange a teaching session with them.
- Teach Mr Burns the importance of follow-up care, relating the care to the history of the disease.

EVALUATION

Good friends from Mr Burns's bowling club have assisted him with care of his drainage bag and have reminded him to do his pelvic floor exercises several times a day while the catheter is in place. When the catheter is removed, Mr Burns has only a small amount of leaking of urine after voiding. He understands that it may take several weeks for this to resolve. Efforts to help him understand the need for continued medical care are less successful. He continues to state that he is cured, his wife needs him and he sees no need to see his doctor.

CRITICAL THINKING IN THE NURSING PROCESS

1. Outline a health education plan for Mr Burns related to the *Risk of altered skin integrity* related to urinary incontinence.
2. As a result of Mr Burns's refusal to have ongoing medical care, he might be labelled as non-compliant. Would you make this assumption? Why or why not?
3. If you were the community health nurse making a home visit and found that Mr Burns had no urinary drainage for 16 hours, which assessments would you make? How would you handle this problem?

REFLECTION ON THE NURSING PROCESS

1. Consider some strategies you might use to engage Mr Burns in understanding the need for ongoing medical care.
2. How would you know that your education strategies with Mr Burns were successful for the long term?

- Discuss medical and surgical treatments for ED (see the first section of this chapter). *Many men are as devastated by the loss of erectile function as they are by the diagnosis of cancer. Information about achieving erection and maintaining sexual intimacy is essential to quality of life.*
- Refer for sexual counselling as appropriate. Refer to support groups. *The man and his partner may require therapy beyond that provided by nurses.*

CONSIDERATION FOR PRACTICE

A therapeutic approach to assessing how the man feels is to use an opening statement such as, 'Some men are very concerned about the effects of [type of treatment] on their ability to have an erection. Tell me how you feel about it.'

Acute/chronic pain

There are many causes of pain in men with advanced prostate cancer. It is not unusual for a man to have three or four distinct pains simultaneously, all from different sources. The most common cause of pain is metastasis to the spinal column, usually the thoracic spine. Other sources of pain include fractures, lymphoedema of the lower extremities and muscle spasms. Because most men with prostate cancer are over the age of 65, many also have pain associated with pre-existing conditions, such as osteoarthritis, unrelated to the cancer.

- Assess the intensity, location and quality of the pain. A cardinal rule of successful pain management is the importance of reducing or eliminating the cause of pain. *Appropriate interventions are based on a careful assessment of the man's pain.*
- Provide optimal pain relief with prescribed analgesics. *It is important that the man and his family understand that pain medications should be used on a regular basis to maintain comfort and should not be delayed until pain is severe.*
- Teach the man and his family non-invasive methods of pain control. *Various modalities can be successful in alleviating pain or reducing its perception, thus enhancing the comfort of the person (see Chapter 8).*

Community-based care

Depending on the type of treatment, the following topics should be addressed in preparing the man and his family for home care:

- for the man having a surgical procedure: manifestations of infection and excessive bleeding, catheter care, wound care, pain management
- for the man receiving radiation therapy:
  - danger of radiation damage to others (sleep in a room alone for a week; and avoid close contact with pregnant women, infants and children)
  - condom use during sexual contact (ejaculate may be discoloured, distressing the sexual partner)
- the importance of keeping appointments with healthcare providers and having yearly PSA and rectal examinations
- if appropriate, community services, such as support groups, community-based nurses and hospice

MALE BREAST DISORDERS

THE MAN WITH GYNAECOMASTIA

Gynaecomastia, the abnormal enlargement of the glandular tissue in the male breast, is thought to result from a change in the ratio of testosterone to oestrogen, where the level of oestrogen is elevated. It is common during puberty, affecting one breast in as many as 50% of adolescent males, but usually resolves within 1 to 2 years. Any condition that increases oestrogen activity or decreases testosterone production can contribute to gynaecomastia. Conditions that increase oestrogen activity include obesity, testicular tumours, kidney and liver disease, and adrenal carcinoma. Conditions that decrease testosterone production include chronic illness such as tuberculosis or Hodgkin's disease, injury, orchitis and some genetic conditions (such as Klinefelter's syndrome). Drugs can contribute to gynaecomastia, particularly certain antidepressants, antihypertensives, anabolic steroids, marijuana, opiates, extreme amounts of alcohol and chemotherapeutic agents. Gynaecomastia after adolescence is usually bilateral. If it is unilateral, biopsy may be necessary to rule out breast cancer.

No treatment is necessary for the transient gynaecomastia of puberty. If the condition becomes chronic, however, creating psychological discomfort, surgery may be necessary to remove the subcutaneous breast tissue. When related to an underlying disorder, treatment of that disorder is required. If the cause is due to drugs, ceasing that drug usually decreases the breast tissue within a month. Where there is no hormonal problem and in severe cases, tamoxifen can be given to decrease oestrogen activity. Tamoxifen is used in treating breast cancer and is not approved for management and treatment of gynaecomastia, although improvements have been reported by men taking the drug.

Nursing care for the man with gynaecomastia includes health education about the cause and treatment of the condition, and emotional support for the psychosocial implications of this feminising condition.

THE MAN WITH BREAST CANCER

Although male breast cancer is rare, accounting for about 0.2% of all male cancer cases in Australia, it is as serious to the men who have it as it is to the women. Breast cancer accounts for about 0.1% of all male cancer deaths in Australia (AIHW, 2015a).

The aetiology of male breast cancer is unclear; hormonal, genetic and perhaps environmental factors appear to be important.

Male breast cancer is clinically and histologically similar to female breast cancer, although lobular cancer is rare in males. Most tumours are oestrogen-receptor positive. Because many men believe that breast cancer is only a woman's disease, they often delay seeking medical attention for symptoms, and thus may present with advanced disease.

Treatment of male breast cancer is much like the treatment of female breast cancer, beginning with modified radical mastectomy, node dissection and staging to determine the

therapeutic options. Radiation, chemotherapy and hormonal therapy (usually tamoxifen) are the conventional adjuncts to surgery. Castration (surgical removal of the testes) is the most successful palliative measure in men with advanced breast cancer, resulting in tumour regression and prolonging life.

Nursing care for the man with breast cancer is essentially the same as for the woman with breast cancer (see Chapter 48). The nurse has an opportunity to help the man and his family cope with the psychosocial effects of having breast cancer. He may feel embarrassment or shame about his condition, as well as fear about the life-threatening nature of the disease. His family may share those feelings. By listening with understanding and empathy, the nurse can help the man and his family resolve their feelings and move towards healing.

CHAPTER HIGHLIGHTS

- Disorders of male sexual function include erectile dysfunction (ED) and ejaculatory dysfunction. Many different illnesses, medications and surgical procedures may affect male sexual function. Treatments include medications, mechanical devices and surgical procedures. It is important for nurses to initiate a discussion of sexual concerns during assessments and to recognise that many male reproductive treatments and surgeries may result in sexual dysfunction.
- Phimosis and priapism are disorders of the penis that can cause problems with urination and sexual activity, and may in some cases be considered medical emergencies. The risk of cancer of the penis, although rare, is increased by phimosis, poor genital hygiene and viral HPV and HIV infections.
- Benign scrotal masses include hydrocoele, spermatocoele and varicocoele. Epididymitis may be associated with a urinary tract infection, prostatitis, urethral strictures or a sexually transmitted infection.
- The testes may be infected (orchitis), twisted (testicular torsion) or develop cancer. Testicular cancer is the most common cancer in men between the ages of 15 and 40. Monthly testicular self-examination is critical to early detection and treatment of cancer.
- The prostate gland may be inflamed or infected (prostatitis), enlarged (benign prostatic hyperplasia (BPH)) or develop cancer. BPH is a common disorder of the ageing male that causes problems with urination as the enlarging prostate gland constricts the urethra. Treatments include medications and various types of surgery, depending on the size of the prostate and the age and health status of the man.
- Cancer of the prostate is the most common type of cancer in Australian men. When diagnosed early, prostate cancer is curable. Diagnosis is often based on an increasing level of PSA and an abnormal DRE. The cancer is treated with surgery, radiation or hormonal manipulation.
- The male breast may become enlarged (gynaecomastia) or develop cancer.

CONCEPT CHECK

1 When conducting a health assessment, which of the following statements would most likely elicit information about sexual concerns?
1. 'Following your prostate surgery, when did you first notice you had problems with sexual intercourse?'
2. 'Why do you think you should be sexually active at your age?'
3. 'Do you miss having sex?'
4. 'Tell me about your experience with sexual function since you developed prostate enlargement.'

2 You are conducting a health education session for young men. Which topic would be appropriate to teach them about reducing the risk of cancer of the penis?
1. wearing a condom during sexual intercourse
2. retracting the foreskin of the penis when showering
3. avoiding tight pants and very hot showers
4. maintaining a regular testicular self-examination schedule

3 Which disease of the male reproductive system is a risk if a man also has a sexually transmitted infection (gonorrhoea)?
1. epididymitis
2. hydrocoele
3. erectile dysfunction
4. gynaecomastia

4 Which of the following statements is true of testicular cancer?
1. The incidence increases with age.
2. It occurs most between ages 15 and 40.
3. It rarely occurs in brothers.
4. Severe pain is the initial manifestation.

5 You are educating a man with chronic prostatitis how to care for himself at home. Which simple measures can be used to decrease discomfort?
1. take cold showers and restrict oral fluids
2. wear a scrotal support and take anti-inflammatory drugs
3. increase oral fluid intake to 3 L/day and void often
4. increase fibre intake and avoid sexual activity

6 Which diagnostic tests are used to differentiate BPH from prostate cancer? (Select all that apply.)
1. pelvic ultrasound
2. digital rectal examination
3. blood chemistry
4. PSA level
5. sperm count

7 The enlarging prostate in BPH typically is manifested by assessment of problems with:
1. bowel elimination
2. urinary elimination
3. peripheral vascular function
4. skin integrity

8 You are caring for a man who has returned to the unit from the recovery room following a TURP. His urinary drainage bag is filled with dark-red fluid with obvious clots. He is having painful bladder spasms. What would you do first?
1. assess his intake and output since surgery
2. administer pain medication in the form of oral oxybutynin hydrochloride
3. report your assessments to his urologist
4. nothing, because these manifestations are expected following a TURP

9 Which cancer is the most common malignancy in Australian men?
1 prostate cancer
2 testicular cancer
3 lung cancer
4 colon cancer

10 Which nutritional information should be included in a community program to reduce the risk of prostate cancer?
1 increase fibre intake
2 decrease lycopene intake
3 avoid foods high in sodium
4 decrease red meat and fat intake

CHAPTER 48

NURSING CARE OF WOMEN WITH REPRODUCTIVE SYSTEM AND BREAST DISORDERS

MOIRA WILLIAMSON

KEY TERMS

amenorrhoea 1791
dysfunctional uterine bleeding (DUB) 1790
dysmenorrhoea 1789
endometriosis 1799
fibrocystic changes (FCC) 1813
leiomyoma 1798
menopause 1810
menorrhagia 1791
metrorrhagia 1791
premenstrual syndrome (PMS) 1786

LEARNING OUTCOMES

- Explain the pathophysiology, symptoms, complications, interprofessional care and nursing care of disorders of female sexual function, menstrual disorders, structural disorders and reproductive tissue disorders.
- Describe the surgical procedures used to treat female reproductive system disorders.
- Discuss alternative and complementary therapies used by women to relieve symptoms associated with menstrual disorders.
- Compare and contrast the risk, incidence, pathophysiology, symptoms, diagnosis, treatment and nursing care for cancer of the cervix, endometrium, ovary and vulva.
- Describe the physiological process of menopause.
- Discuss treatment, including alternative and complementary therapies, used by women to relieve symptoms associated with menopause disorders.
- Discuss the health education for women and their families for women with disorders of the reproductive system and breast.
- Discuss cancer screening, the purposes, nursing implications and medications and treatments.

CLINICAL COMPETENCIES

- Assess the functional status of women with reproductive system and breast disorders, and report, monitor and document abnormal symptoms.
- Use evidence-based research to design interventions to promote early diagnosis and treatment of all Australian women with cervical and breast cancer, with particular focus on the health disparities for women from areas of social disadvantage; for example, women living in remote and rural areas of Australia or Indigenous women.
- Determine nursing priorities based on assessed data to select and implement individualised nursing interventions for women with reproductive system and breast disorders.
- Administer medications used to treat female reproductive system and breast disorders knowledgeably and safely.
- Provide skilled care for the woman having a cervical dilation and curettage (D&C), laparoscopy, hysterectomy, mastectomy and breast reconstruction.
- Integrate an interdisciplinary approach into the care of women with reproductive system and breast disorders.
- Provide health education appropriate for community-based self-care of female reproductive and breast disorders.
- Revise the plan of care as needed to provide effective interventions to promote, maintain or restore functional health status to women with reproductive system and breast disorders.

Disorders of the female reproductive system range from a minor discomfort of menstrual cramps to life-threatening diseases such as cancer. Many of these disorders can occur at any point in a woman's adult life. They may affect her sexuality, ability to bear children and sense of wellbeing as a woman.

A holistic approach to meet the needs of women who experience reproductive system changes and disorders is required to ensure that their physical, emotional and educational needs are met. The ability to reproduce affects self-esteem, feelings of femininity and general health; both sensitivity and understanding from caregivers is essential. Often women are required to disclose personal information when providing a medical and family history, and undergoing diagnostic tests. Women may find providing intimate information embarrassing and uncomfortable. When planning and implementing care, nurses must consider the woman within the context of her culture, socioeconomic and educational level, and lifestyle. It is also important that the nurse not make assumptions or judgments about sexual orientation.

This chapter summarises disorders of female sexual function and discusses the physiological process of menopause, menstrual disorders, structural disorders and disorders of female reproductive tissue, including the breast. Sexually transmitted infections, including vaginal infections and pelvic inflammatory disease, are discussed in Chapter 49. Many of the disorders result in actual or potential health problems requiring nursing care that is evidence based. To avoid repeating strategies and interventions for each disorder, they have been divided between the nursing care discussions as appropriate. Treatment of cancer with chemotherapy and radiation is discussed in Chapter 13.

DISORDERS OF FEMALE SEXUAL FUNCTION

Women maintain the capacity for sexual activity and orgasm long after menopause (see the 'Meeting individualised needs' box below). In a typical sexual event, two physiological sexual responses occur: vasocongestion and myotonia. Sexual stimulation results in vasocongestion of the blood vessels surrounding the vagina, causing engorgement, increased lubrication and genital swelling and enlargement. Arousal, or myotonia, increases muscular tension, resulting in voluntary and involuntary muscle contraction.

The sexual response cycle has four phases: excitement, plateau, orgasm and resolution. These phases always occur in the same sequence; however, the duration of each phase may vary. Sexual arousal typically ends in orgasm (climax), but does not always do so. A refractory period, or period in which the sexual organs are incapable of responding to stimulus, does not occur in the female. Multiple orgasms are physically possible in all women.

Factors affecting women's sexuality are often not discussed or raised by health professionals. Although nurses may not conduct sexual counselling (unless trained to do so), they should be able to obtain a sexual history without embarrassment, discuss sexual concerns with women and make appropriate referrals.

MEETING INDIVIDUALISED NEEDS Sexual function in the ageing woman

The belief that older women are no longer interested in expressing their sexuality may occur within society. This view results from myths, taboos and stereotypical views held by some within society. Two commonly held myths are that menopause causes the demise of a woman's sexuality and that hysterectomy results in the inability of a woman to function sexually. Loss of sexual function is not an inevitable result of ageing, although physical changes related to ageing do affect the female sexual response. These physical changes, along with chronic conditions common in ageing women, may alter a woman's sexual function. In addition, the sexual response can be altered by some medications used to treat the chronic conditions associated with ageing. The role of the nurse is to provide information about ways to achieve optimal sexual health, including educating women about the myths and misinformation around changes in sexual functioning.

Physiological changes

Changes in ageing women's sexual function begin in the perimenopausal period as oestrogen levels decrease. Oestrogen-sensitive cells are found throughout the central nervous system and the cardiovascular system. These cells are involved in the female sexual response. With menopause comes a decrease in the levels of oestradiol, which affects nerve transmission and the response in the peripheral vascular system. As a result, the timing and degree of vasocongestion during the sexual response are affected.

Specific changes in the female sexual response occur in all phases. During the plateau phase, the capacity for vasocongestion decreases, as does muscle tension. In the orgasmic phase, the contractions are fewer and less intense. During the resolution phase, vasocongestion subsides more quickly.

Nursing care

The nurse's role centres on educating women about the physiological and psychological changes associated with menopause and assisting ageing women to reach optimal sexual functioning. Provide education on how the effects of chronic illness and the medications used to treat these illnesses affect sexual functioning. Educating about the importance of maintaining a healthy lifestyle, which includes a balanced diet, weight-bearing and aerobic exercises, stress management and routine health examinations is important.

For problems related to vaginal dryness and dyspareunia, water-soluble vaginal lubricants or vaginal gels can be used before intercourse. Intercourse on a regular basis and oestrogen replacement therapy (ordered by a medical practitioner) can also be recommended. Women who experience joint pain or other musculoskeletal pain due to conditions such as arthritis can benefit from education on how to adapt positions for intercourse.

Pathophysiology

Disorders of sexual function include dyspareunia, inhibited sexual desire and orgasmic dysfunction.

Dyspareunia

The woman with dyspareunia (pain during intercourse) may find it difficult to express her feelings to her partner. This condition may manifest itself as decreased desire or inhibited orgasm. The causes of dyspareunia range from organic to psychogenic.

Physical conditions, such as imperforate hymen, vaginal scarring or vaginismus, may cause dyspareunia. *Vaginismus* is a rare condition in which the vaginal muscles at the introitus contract so tightly that an erect penis cannot be inserted. An early traumatic event, such as sexual abuse, fear of men or rape, may contribute to this disorder. However, it is estimated that most dyspareunia is psychogenic in origin. The woman develops an anxiety–fear–guilt cycle in which negative thoughts become associated with the act of vaginal penetration, initiating a conditioned involuntary reflex. However, other sexual activity may be pleasurable. The woman's partner needs to be included in any discussion or education sessions to assist with their understanding of the issues affecting their partner's responsiveness.

Inhibited sexual desire

Inhibited sexual desire is complex and may be a result of pathophysiological processes or may be psychogenic in origin. Inhibited sexual desire often is rooted deeply in childhood education or personal experiences that may be too painful to recall. Cultural and religious values can also affect the processing of sexual stimuli. Fear of pregnancy or sexually transmitted infections (STIs) and depression can also contribute to decreased libido.

Orgasmic dysfunction

Female orgasm inhibition (anorgasmia) is the most prevalent sexual problem in women. However, fewer than 20% of cases are physiological in origin. It is estimated that between 8% and 15% of women have never experienced an orgasm in the waking state. Psychogenically induced anorgasmia may result from unresolved conflicts about sexual activity. Organic causes of anorgasmia include the presence of disease that results in general debilitation or that affects the sexual response cycle, or the use of medications that depress the central nervous system (CNS).

Primary anorgasmia exists when a woman has never experienced an orgasm during the waking state, either through self-stimulation, partner stimulation or intercourse. Secondary anorgasmia exists when a woman who previously experienced orgasms is no longer able to do so.

Nursing care

Nursing care focuses on identifying the type of sexual dysfunction with a thorough history, including the onset, duration, frequency and context or situation in which the problem occurs. The woman's partner should be included in discussions.

The woman and her partner may require education about varied normal sexual responses. The goal is to increase self-awareness and understanding of communication and how this impacts on sexual desire. The differences in the behaviours that men and women consider sexually stimulating may need to be discussed. Sex therapists may provide training in stimulation techniques (masturbation) after inhibitions about this practice are discussed. Group therapy may be encouraged to help the woman discuss her problem and to decrease the sense of isolation it gives her.

MENSTRUAL DISORDERS

Monthly menstruation normally involves some minor discomfort, including breast tenderness, a feeling of heaviness and congestion in the pelvic area, uterine cramping and lower backache. Many women, however, experience more serious effects, both physiological and psychological. This section discusses premenstrual syndrome, dysmenorrhoea and abnormal uterine bleeding. (The menstrual cycle is discussed in Chapter 46.)

THE WOMAN WITH PREMENSTRUAL SYNDROME

Premenstrual syndrome (PMS) is a complex group of symptoms. Women can present with a range of these (e.g. mood swings, breast tenderness, fatigue, irritability, food cravings and depression) that are limited to 2 to 14 days before menstruation and relieved by the onset of menses. However, the usual time frame for symptoms to be present for most women who experience PMD is approximately 7 days a month. For a small number of women, PMS is so disabling that it is given the psychiatric label of premenstrual dysphoric disorder (PMDD).

The syndrome is seen less frequently during the teens and twenties, and is more common in women aged between 30 and 45 years of age. The cause is unknown; however, it is linked to stress.

Pathophysiology

Although the pathophysiology of PMS is not clearly understood, hormonal changes such as altered oestrogen–progesterone ratios, increased prolactin levels and rising aldosterone levels during the luteal phase of the menstrual cycle may contribute to the problem. Increased aldosterone results in sodium retention and oedema. Decreased levels of monoamine oxidase in the brain are associated with depression, and reduced levels of serotonin can lead to mood swings.

Manifestations

Symptoms of PMS occur during the luteal phase of the menstrual cycle (7 to 10 days prior to the onset of the menstrual flow), abating when the menstrual flow begins. The multisystem effects of PMS are shown below. Although PMS may produce a variety of physiological and psychological symptoms, the exact nature of these symptoms and their intensity are individualised for each woman with this disorder. The symptoms may even differ from month to month in the same woman.

INTERPROFESSIONAL CARE

If no organic cause can be identified, the goals of care are to relieve symptoms and develop self-care patterns that will help the woman anticipate and cope more effectively with future episodes of PMS. There are no definitive diagnostic tests for PMS. The regular recurrence of symptoms preceding the onset of menses for at least 2 to 3 months leads to a diagnosis of PMS. The treatment of PMS integrates a self-monitored record of symptoms. Women can then be educated on ways of relieving symptoms, such as undertaking regular exercise, ensuring healthy eating patterns and reducing the level of stress in their lives. However, there are a variety of treatments available (Women's Health & Research Institute of Australia, 2014).

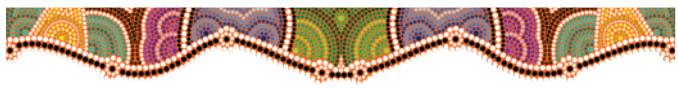
Medications

If the symptoms of PMS are severe or incapacitating, ovulation may be suppressed by the use of gonadotropin-releasing hormone (GnRH) agonists, oral contraceptives or danazol. Progesterone and antiprostaglandin agents such as non-steroidal anti-inflammatory drugs (NSAIDs) may help relieve cramping. Diuretics may be prescribed to relieve bloating. Selective serotonin reuptake inhibitors (SSRIs) such as fluoxetine (Prozac), sertraline (Zoloft) and paroxetine (Aropax) may be used to manage mood and some physical symptoms of PMS.

Alternative and complementary therapies

Alternative and complementary therapies the woman with PMS may find helpful focus on diet, exercise, relaxation and stress management.

- A diet high in complex carbohydrates with limited simple sugars and alcohol is recommended to minimise reactive hypoglycaemia, which can contribute to the symptoms of PMS.
- Reduced sodium intake helps minimise fluid retention. Increased intake of calcium (1200 mg per day), magnesium (360 mg per day) and vitamin E (400 international units per day) may be helpful (Mayo Foundation for Medical Education and Research, 2014).
- Caffeine should be restricted to reduce irritability.
- Herbal remedies include ginger, chasteberry, St John's wort and evening primrose oil (Mayo Foundation for Medical Education and Research, 2014). However, there is limited research to support the use of alternative therapies. Woman may feel psychologically, however, that these herbal remedies are of benefit. Therefore, discussion about alternative therapies with the healthcare provider is recommended.
- Exercise is beneficial, but adequate rest also is necessary.
- Techniques for relaxation and stress management include deep abdominal breathing, meditation, muscle relaxation and guided imagery.



Nursing care

Nursing diagnoses and interventions

Nursing care for the woman with PMS focuses on relieving symptoms. Most women experiencing PMS require interventions to manage pain and enhance coping.

Acute pain

The woman with PMS may have pain from headache (including migraine), menstrual cramps, excessive fluid retention, breast swelling, joint and muscle pain, and backache.

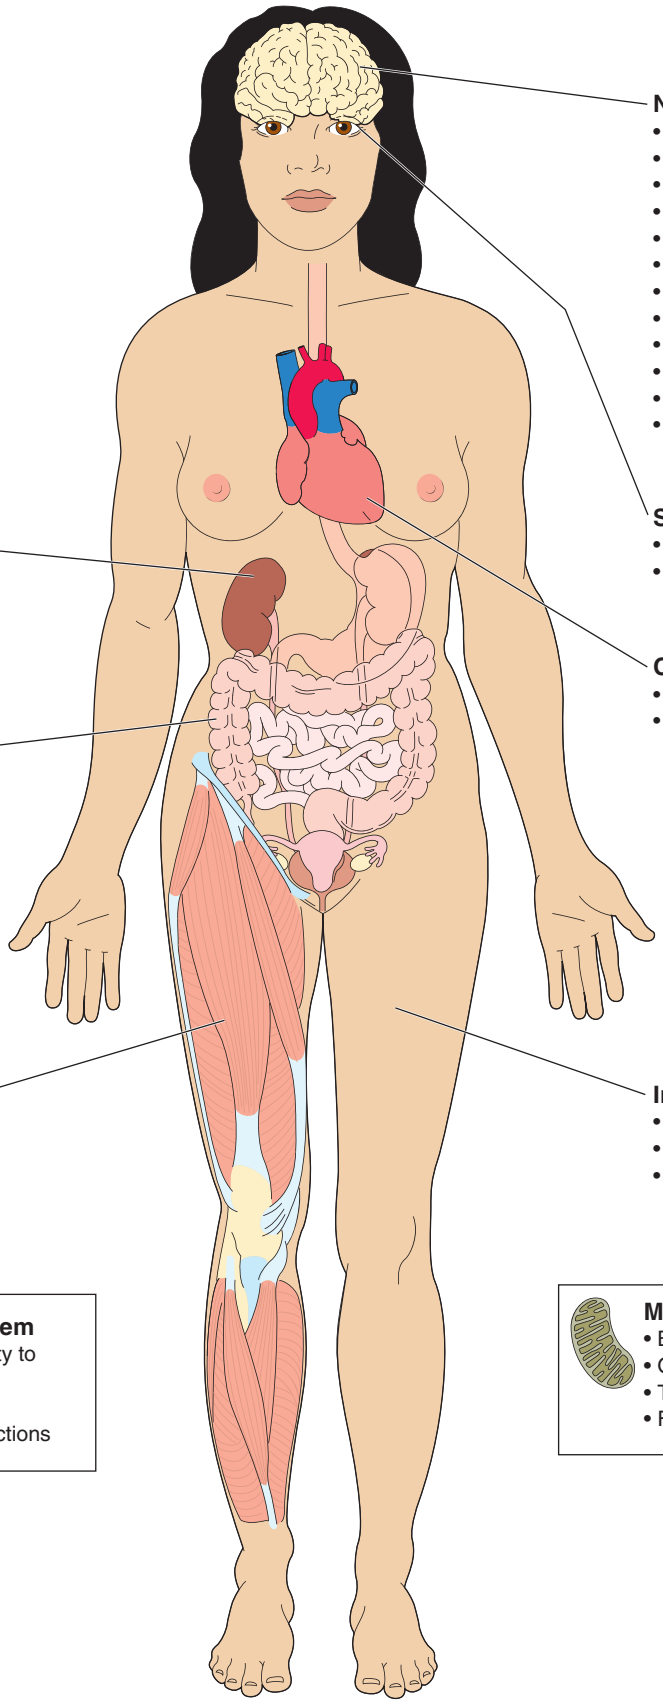
- Teach effective pharmacological and non-pharmacological self-care measures to relieve pain: application of heat, relaxation techniques (such as breathing exercises, imagery techniques or meditation) and exercise. *Heat relieves muscle spasms and dilates blood vessels, increasing blood supply to the pelvis and uterine muscles. Relaxation and exercise aid the release of naturally produced pain relievers called endorphins.*
- Review daily activities and suggest ways to balance rest periods and activity. *During rest periods, energy and oxygen requirements decrease, increasing the amount of energy and oxygen available to muscles.*
- Review symptoms and, if possible, correlate these with dietary patterns and activity levels. Encourage the woman to keep a diary of PMS symptoms. *Maintaining a diary of PMS symptoms, activity and foods eaten can provide data to identify modifiable causes of discomfort.*
- If appropriate, suggest sexual activity as a way to lessen menstrual cramps. *Orgasm may help relieve dysmenorrhoea.*

Ineffective coping

Many women experience wide mood swings during episodes of PMS, sometimes exhibiting self-destructive or aggressive behaviours towards others. These mood swings can interfere with a woman's ability to manage her responsibilities at home, in the community or at work.

- Encourage the woman to keep a journal of her menstrual cycle and to document her mood changes in the 7 to 10 days prior to menstruation. *Recognising the signs and timing of PMS is the first step in developing methods to cope with the problem.*
- Explore possible ways to rearrange or reschedule activities when experiencing PMS. *Planning ahead enables the woman to assume more control and promotes coping methods.*
- Explore what, if any, self-care measures have helped with mood alterations in the past. *Encourage healthful coping mechanisms, such as relaxation techniques and exercise. Some women may rely on alcohol or other medications during PMS, which only exacerbate the symptoms.*

MULTISYSTEM EFFECTS OF PMS



Neurological
- Syncope
- Vertigo
- Dizziness
- Paraesthesia
- Headache
- Inability to concentrate
- Depression
- Irritability
- Anxiety
- Mood swings
- Anger
- Aggressive behaviour

Sensory
- Conjunctivitis
- Visual disturbances

Cardiovascular
- Bruising
- Palpitations

Urinary
- Cystitis
- Oliguria

Gastrointestinal
- Constipation
- Nausea
- Vomiting

Musculoskeletal
- Backache
- Pelvic stiffness

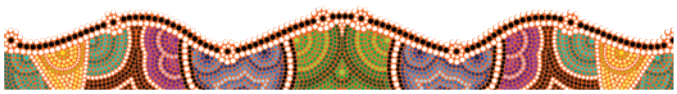
Integumentary
- Acne
- Herpes recurrence
- Urticaria

Immune system
- ↑ Susceptibility to infection
- Asthma
- ↑ Allergic reactions

Metabolic processes
- Breast tenderness
- Oedema
- Transient weight gain
- Food cravings

Community-based care

Provide health education that enables the woman and her family to understand that PMS is not caused by a pathological process but is a physiological response to hormonal changes of the menstrual cycle. With an understanding of the condition, the woman is better able to manage anxiety and to become actively involved in techniques to reduce the symptoms. Education should also include dietary measures, relaxation techniques and exercise, stress-reduction techniques, mental health promotion and support systems.



THE WOMAN WITH DYSMENORRHOEA

Dysmenorrhoea (pain or discomfort associated with menstruation) is experienced by a significant number of menstruating women. *Primary dysmenorrhoea* occurs without specific pelvic pathology and is most often seen in girls who have just begun menstruating, becoming less severe after the mid twenties or giving birth. *Secondary dysmenorrhoea* is related to identified pelvic disease.

Pathophysiology

In primary dysmenorrhoea, excessive production of prostaglandins stimulates uterine muscle fibres to contract. As the muscles contract, uterine circulation is compromised, resulting in uterine ischaemia and pain. These contractions can range from mild cramping to severe muscle spasms. Psychological factors, such as anxiety and tension, may contribute to dysmenorrhoea. Secondary dysmenorrhoea is related to underlying organic conditions that involve scarring or injury to the reproductive tract. Endometriosis, fibroid tumours, pelvic inflammatory disease or ovarian cancer may result in painful menses.

Manifestations

Symptoms of primary dysmenorrhoea (see the box below) may be severe enough to disrupt activities of daily living, sexual function and even fertility.

MANIFESTATIONS Primary dysmenorrhoea

- Abdominal pain beginning with onset of menses and lasting 12 to 48 hours
- Pain radiating to lower back and thighs
- Headache
- Nausea
- Vomiting
- Diarrhoea
- Fatigue
- Breast tenderness

INTERPROFESSIONAL CARE

Care of the woman with menstrual pain focuses on identifying the underlying cause, re-establishing functional capacity and managing pain.

A careful history is taken and a physical assessment is performed to rule out any underlying organic cause of dysmenorrhoea. If no organic cause can be found, the diagnosis is primary dysmenorrhoea. In addition, attitudes and expectations about menstruation and lifestyle disruption are identified and explored.

Diagnosis

Various diagnostic tests are performed to identify structural abnormalities, hormonal imbalances and pathological conditions that could cause menstrual pain. Diagnostic tests are described in Chapter 46.

Diagnosis is made based on a comprehensive history of the signs and symptoms. As the onset of primary dysmenorrhoea usually occurs following the onset of menarche, the age group for this presentation is normally between 11 and 13 years of age. Therefore, it is not appropriate for a vaginal examination and pelvic ultrasound to be undertaken unless there are physical signs on abdominal palpation of ovarian masses. For this group of young teenagers, treatment with non-steroidal anti-inflammatory drugs (NSAIDs) is recommended (Davis & de Costa, 2011).

The second group of women who experience primary dysmenorrhea is older teenage women who may be sexually active. Performing a vaginal examination for women in this age group needs to be carefully assessed on an individual basis. For this age group, treatment may be offered in the form of the combined oral contraceptive pill (Davis & de Costa, 2011). If the young woman is sexually active, it is important to discuss the importance of cervical screening, contraception and sexually transmitted infections (STIs). If symptoms persist after commencing treatment, a pelvic examination and diagnostic procedures (including a Papanicolaou (Pap) smear and cervical and vaginal cultures; ultrasound of the pelvis and vagina; and computed tomography (CT) scan or magnetic resonance imaging (MRI) to detect structural abnormalities, malignancy or infections) are undertaken. Laboratory tests used to assess possible causes of dysmenorrhoea are as follows:

- *follicle-stimulating hormone (FSH)* and *luteinising hormone (LH) levels* to assess the function of the pituitary gland. The results are correlated with the time of the menstrual cycle
- progesterone and oestradiol levels to assess ovarian function
- thyroid function tests (T_3 and T_4) to assess thyroid function.

Laparoscopy is used to diagnose structural defects and blockages caused by scarring, endometriosis, tumours and cysts (see Figure 48.1). See the box below for nursing care of the woman having a laparoscopy. A dilation and curettage (D&C) of the uterus may be performed to obtain tissue for evaluation or to relieve dysmenorrhoea and heavy menstrual bleeding. (This procedure is discussed later in this chapter.)

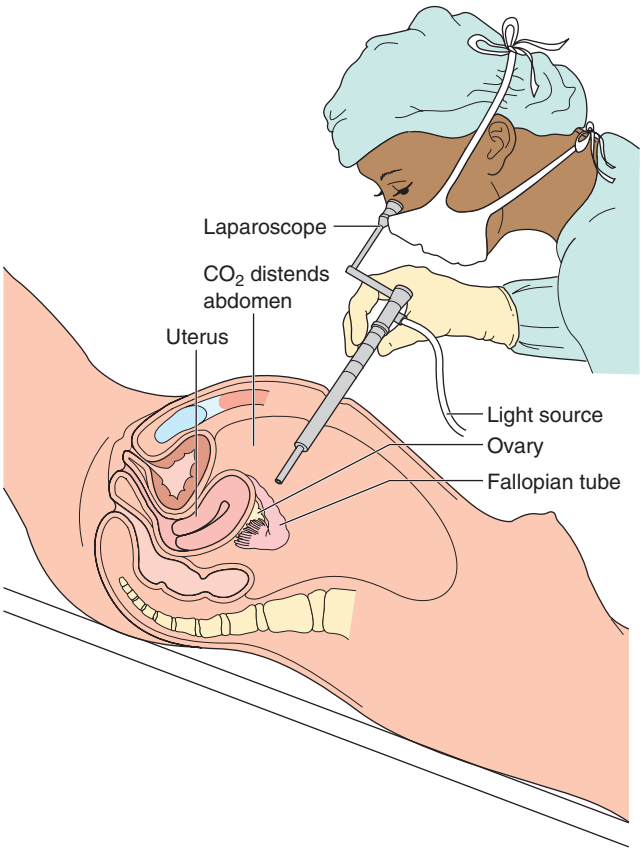


FIGURE 48.1 ■ Laparoscopy. In this surgical procedure, a flexible, lighted instrument (laparoscope) is inserted through a periumbilical incision. Laparoscopy allows visualisation of the pelvic cavity

Medications

Dysmenorrhoea may be treated with analgesics, prostaglandin inhibitors such as NSAIDs or oral contraceptives (see the 'Medication administration' box below).

Alternative and complementary therapies

The complementary therapies listed for the woman with PMS may also be useful for the woman with dysmenorrhoea. Other helpful activities are regular physical exercise, supplementing the diet with zinc and calcium, and using herbal remedies such as *Viburnum prunifolium*, black cohosh, evening primrose oil and blue cohosh. Using a heated pad on the abdomen or taking a warm bath also helps reduce pain.

Nursing care

Nursing care for the woman with primary dysmenorrhoea focuses on controlling symptoms and providing health education about the normal physiology of the menstrual cycle and self-care measures. Care of the woman with secondary dysmenorrhoea varies according to the underlying cause and is discussed in this chapter within sections on specific disorders. Nursing interventions previously described for the woman with PMS are also appropriate for the woman with dysmenorrhoea.

THE WOMAN WITH DYSFUNCTIONAL UTERINE BLEEDING

Dysfunctional uterine bleeding (DUB) refers to vaginal bleeding that is usually painless but is abnormal in amount, duration or time of occurrence. The types of DUB include primary and secondary amenorrhoea, oligomenorrhoea, menorrhagia, metrorrhagia and postmenopausal bleeding.

A number of factors may predispose a woman to DUB. These factors include stress, extreme weight changes, use of

NURSING CARE OF THE WOMAN having a laparoscopy

PREOPERATIVE CARE

- Orient the woman to the environment.
- Instruct the woman to empty the bladder prior to the surgical procedure.
- Explain to the woman that referred shoulder pain or expulsion of gas through the vagina may occur postoperatively. *During the procedure, the woman's abdomen is insufflated with carbon dioxide gas to distend the abdomen and facilitate visualisation of the pelvic organs. The examination table is then tilted so that the intestines will fall away from the pelvic organs. Some carbon dioxide gas may remain in the abdomen after the procedure.*
- Explain that pain should be minimal. However, pain relief is available if required. Instruct the woman to report excessive pain immediately. *Excessive pain signals infection or other postoperative complication.*

POSTOPERATIVE CARE

- Routine postoperative observations include pulse, blood pressure, respiratory rate, oxygen saturation level and consciousness.
- It is important to monitor vaginal bleeding. *Minor bleeding is normal; excessive bleeding may indicate haemorrhage.*
- Change the perineal pad, recording blood loss. Teach the woman proper perineal hygiene, emphasising the need to change pads at least every 4 hours. Keep a pad count to monitor blood loss. Proper perineal hygiene reduces the risk of postoperative infection. *Pad count is an indication of blood loss.*

MEDICATION ADMINISTRATION The woman with dysmenorrhoea

EXAMPLES OF ORAL CONTRACEPTIVES

Norethisterone and ethinylestradiol (Brevinor)
Ethinylestradiol (Microgynon 30)

Oral contraceptives inhibit ovulation and help reduce cramping and bleeding. Side effects of oral contraceptives include breast tenderness, weight gain, nausea, midcycle bleeding, mood swings, depression, chloasma (skin discolouration) on the face and chest, hypertension, vascular complications, vaginal candidiasis, migraines and glucose intolerance. Oral contraceptives are contraindicated in women with personal or family history of breast cancer in first-degree relatives, hypertension, history of stroke or transient ischaemic attack (TIA), smoking, history of oestrogen-dependent cancer, pregnancy, liver disease or thrombophlebitis.

Nursing responsibilities

- Assess the woman for potential contraindications to medication therapy.

Health education for the woman and family

- Take the medication as prescribed until otherwise indicated by a health professional or until side effects prevent you from continuing to take it.
- If you are taking oral contraceptives, be sure to take them at the same time every day.
- Report any suspected pregnancy and any side effects such as nausea, rash, drowsiness, stomach pain, ringing in the ears, tenderness in the calf or shortness of breath.
- Do not smoke while taking oral contraceptives.
- Wear TED stockings when travelling long distances when you may not be very active, such as long plane flights or car travel.

oral contraceptive agents or intra-uterine devices (IUDs), and postmenopausal status. DUB is usually related to hormonal imbalances or pelvic neoplasms, either benign or malignant.

Pathophysiology

The types of DUB outlined above will now be discussed.

- **Amenorrhoea** is the absence of menstruation. *Primary amenorrhoea*, absence of menarche by age 16 (or by age 14 if secondary sex characteristics fail to develop), may be caused by structural abnormalities, hormonal imbalances, polycystic ovary disease or an imperforate hymen. Because a certain percentage of body fat is required for menstruation to occur, anorexia nervosa, bulimia or excessive athletic training can also cause primary amenorrhoea. *Secondary amenorrhoea*, absence of menses for at least 6 months in a previously menstruating female, may also be caused by anorexia nervosa, excessive athletic activity or training, or a large weight loss. Other causes include hormonal imbalances and ovarian tumours. Normal (physiological) secondary amenorrhoea occurs during pregnancy, breastfeeding and menopause.
- *Oligomenorrhoea* (scant menses) usually is related to hormonal imbalances.
- **Menorrhagia** (excessive or prolonged menstruation) may result from thyroid disorders, endometriosis, pelvic inflammatory disease, functional ovarian cysts or uterine fibroids or polyps. Clotting disorders and anticoagulant medications also can cause menorrhagia.
- **Metrorrhagia** (bleeding between menstrual periods) may be caused by hormonal imbalances, pelvic inflammatory disease, cervical or uterine polyps, uterine fibroids or cervical or uterine cancer. Because cancer is a possible cause of metrorrhagia, early evaluation and treatment are extremely important. *Mittelschmerz* (midcycle spotting associated with ovulation) occurs in many women and is not considered metrorrhagia.
- *Postmenopausal bleeding* may be caused by endometrial polyps, endometrial hyperplasia or uterine cancer. The possibility of cancer makes early evaluation and treatment essential.

Hormonal imbalances, especially progesterone deficiency with relative oestrogen excess, result in endometrial hyperplasia. Oestrogen stimulates endometrial proliferation. However, without the support provided by progesterone, sloughing occurs, resulting in vaginal bleeding that may be irregular, prolonged or profuse. Defects in the follicular phase shorten the proliferative phase of the menstrual cycle, resulting in spotting and breakthrough bleeding. Defects during the luteal phase result in excessive amount or duration of flow due to persistence of the corpus luteum. This leads to a deficiency of progesterone, resulting in vaginal bleeding. *Anovulation*, absence of ovulation, is associated with both oestrogen and progesterone deficiencies. Emotional upsets or stress can cause hormonal imbalances and thus affect menstruation. Pelvic neoplasms, discussed later, also cause abnormal bleeding.

INTERPROFESSIONAL CARE

The care of the woman with DUB focuses on identifying and treating the underlying disease. A careful history is taken and a physical examination is performed. Abdominal and pelvic examinations are performed to rule out abdominal masses. The woman may need to keep a menstrual history and basal body temperature chart for several months to determine whether ovulation is occurring.

Diagnosis

A variety of diagnostic tests are used to diagnose the cause of DUB. Diagnostic tests are discussed in Chapter 46 and include a Pap smear to rule out or identify cervical carcinoma, a pelvic ultrasound to identify luteal cysts, a hysteroscopy to detect abnormalities of the uterine cavity or an endometrial biopsy to obtain endometrial tissue for histological examination.

Laboratory studies may include:

- a *full blood count (FBC)* to rule out systemic disease as a contributing factor to DUB and to evaluate its effects.

- *thyroid function studies*, including measurement of triiodothyronine (T_3), thyroxine (T_4) and thyroid-stimulating hormone (TSH) levels, to rule out hyper- or hypothyroidism as a cause of DUB.
- *endocrine studies* to evaluate pituitary and adrenal function. Pituitary dysfunction may first be manifested by menstrual irregularities.
- *serum progesterone levels* to determine the level of progesterone deficiency.

Medications

For many women, hormonal agents can correct menstrual irregularities. For anovulatory DUB, oral contraceptives may be prescribed for 3 to 6 months. Progesterone or medroxyprogesterone also may be prescribed to regulate uterine bleeding.

Ovulatory DUB may be treated with progestins during the luteal phase. Oral iron supplements may be prescribed to replace iron lost through menstrual bleeding.

Surgery

Surgical intervention emphasises the least invasive method that provides effective relief, beginning with a therapeutic D&C, then endometrial ablation and, finally, hysterectomy.

THERAPEUTIC D&C In a therapeutic D&C, the cervical canal is dilated and the uterine wall is scraped. D&C, the most frequently performed minor gynaecological surgical procedure, is used to diagnose and treat DUB and other disorders of the female reproductive system. It may be performed to correct excessive or prolonged bleeding. D&C is contraindicated in any woman who has been taking anticoagulant medications or whose condition precludes the use of regional or general anaesthesia. Nursing care of the woman having a D&C is described in the box below.

ENDOMETRIAL ABLATION In an endometrial ablation, the endometrial layer of the uterus is permanently destroyed using laser surgery or electrosurgical resection. It is performed in women who do not respond to pharmacological management or D&C. The woman needs to understand that this procedure ends menstruation and reproduction.

HYSTERECTOMY Hysterectomy, or removal of the uterus, may be performed when medical management of bleeding disorders is unsuccessful or malignancy is present, particularly if the woman no longer wishes to bear children. In premenopausal women, the ovaries are usually left in place; in postmenopausal women, a total hysterectomy, or panhysterectomy, may be performed; this procedure involves removal of the uterus, fallopian tubes and ovaries. However, removal of the ovaries may significantly impact on the woman's future 'cardiovascular, psychosexual, cognitive and mental health' and, therefore, this needs to be considered before removing the ovaries (Hickey, Ambekar & Hammond, 2010).

FAST FACTS

- Hysterectomy is a commonly performed elective surgery for Australian women.
- This surgery is most often performed in women who are between the ages of 40 and 44.
- The three conditions most associated with hysterectomy are uterine leiomyomas (fibroids), endometriosis and uterine prolapse (Women's Health Queensland Wide Inc., 2011).

Hysterectomy may involve an abdominal, vaginal or laparoscopic approach. The choice depends on the underlying disorder, the need to explore the abdominal cavity and the preference of the surgeon and woman. Nursing care of the woman undergoing a hysterectomy is described in the box below.

Abdominal hysterectomy is performed when a pre-existing abdominal scar is present, when adhesions are thought to be present or when a large operating field is necessary. The surgical incision may be either longitudinal, made in the midline from umbilicus to pubis, or a *Pfannenstiel incision*, also known as the bikini cut.

Vaginal hysterectomy, removal of the uterus through the vagina, is desirable when the uterus has descended into the vagina or if the urinary bladder or rectum have prolapsed into the vagina. Vaginal

NURSING CARE OF THE WOMAN having a dilation and curettage (D&C)

PREOPERATIVE CARE

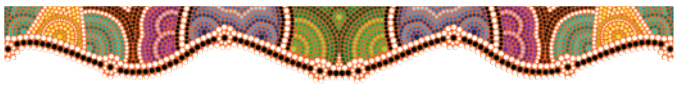
- Orient the woman to the environment.
- Provide education and reassurance.
- If indicated and possible, ask the woman to come in 24 hours before surgery for insertion of a laminaria tent. *This device absorbs cervical secretions and slowly dilates the cervix.*
- Instruct the woman to remain NBM (nil by mouth) after midnight on the day of surgery.

POSTOPERATIVE CARE

- Monitor circulation and sensation in the legs and avoid compression of the popliteal area. *The lithotomy position requires the woman's legs to be elevated, which can impair circulation.*
- Asses and monitor blood loss.
- Instruct the woman to use perineal pads and avoid using tampons for 2 weeks. *This reduces the risk of infection and allows tissues to heal.*
- Explain that the onset of the next menstrual period may be delayed.
- Explain that intercourse and anything inserted into the vagina should be avoided until after the postoperative checkup and after vaginal discharge has ceased. *This precaution reduces the risk of infection.*
- Instruct the woman to rest for several days after surgery, avoid heavy lifting and report any bleeding that is bright red or exceeds that of a normal menstrual period. *Vigorous activity, lifting or straining interferes with healing and may cause haemorrhage.*

hysterectomy leaves no visible abdominal scar. Laparoscopy-assisted vaginal hysterectomy (LAVH) is most often performed.

Laparoscopic hysterectomy is when a hysterectomy is performed by making three to four incisions in the abdomen. The organs can then be viewed by inserting the laparoscope through one of the incisions; the surgical instruments are then inserted through the remaining incisions. The benefits of this procedure are a shorter hospital stay and a quicker recovery (Women's Health Queensland Wide Inc., 2011).



Nursing care

DUB usually causes the woman anxiety. Her self-image, sexuality or reproductive capacity may be threatened, and she may fear the possibility of cancer. She may be embarrassed to discuss her menstrual history and hygiene practices.

Nursing diagnoses and interventions

Interventions for the woman with DUB commonly address problems with anxiety and sexual function.

Anxiety

The anxiety associated with abnormal uterine bleeding can be intense. Until the cause of the bleeding is identified and has been addressed, the woman may fear cancer or other life-threatening conditions.

- Discuss the results of tests and examinations with the woman. *This allows for open exchange of information.*
- Provide information about the causes, treatments, risks, long-term effects of treatments and prognosis. *This allows the woman to assume responsibility for her own health and become involved in her own treatment plan.*
- Evaluate coping strategies and psychosocial support systems. Teach coping strategies if indicated. The possibility of surgery or cancer represents a crisis for the woman and her support system. *Support groups can provide assistance for the woman through crisis intervention.*

Sexual dysfunction

The woman with DUB may be unwilling to express herself sexually, particularly if bleeding is frequent or heavy. Offer information about engaging in sexual activity during menstruation.

NURSING CARE OF THE WOMAN having a hysterectomy

PREOPERATIVE CARE

- Assess the woman's understanding of the procedure. Provide explanation, clarification and emotional support as needed. Reassure that the anaesthesia will eliminate any pain during surgery and that medication will be administered postoperatively to minimise discomfort. *The woman who understands the procedure to be performed and what to expect after surgery will be less anxious.*
- Check the chart to ensure that the consent form has been signed.
- Perform preoperative procedures as per policy.
- Administer preoperative medications as indicated.

POSTOPERATIVE CARE

- Assess for signs of haemorrhage. *Haemorrhage is more common after vaginal hysterectomy than after abdominal hysterectomy.*
- Monitor vital signs every 4 hours and measure intake and output. *These data are important indicators of haemodynamic status and complications.*
- Once the catheter has been removed, measure the amount of urine voided.
- Assess for complications, including infection, ileus, shock or haemorrhage, thrombophlebitis and pulmonary embolus.
- Assess vaginal discharge; provide health education about perineal care.
- Assess incision and bowel sounds regularly.
- Encourage turning, coughing, deep breathing and early ambulation.
- Encourage fluid intake.
- Teach to splint the abdomen and cough deeply. Instruct to restrict physical activity for 4 to 6 weeks. Heavy lifting, stair climbing, douching, tampons and sexual intercourse should be avoided. The woman should shower, avoiding tub baths, until bleeding has ceased. *Infection and haemorrhage are the greatest postoperative risks; restricting activities and preventing the introduction of any foreign material into the vagina helps reduce these risks.*
- Explain to the woman that she may feel tired for several days after surgery and needs to rest periodically.
- Explain that appetite may be depressed and bowel elimination may be sluggish. *These are after-effects of general anaesthesia, handling of the bowel during surgery and loss of muscle tone in the bowel while empty.*
- Teach the woman to recognise signs of complications that should be reported:
  a temperature greater than 37.7°C
  b vaginal bleeding that is greater than a typical menstrual period or is bright red
  c urinary incontinence, urgency, burning or frequency
  d severe pain.
- Encourage the woman to express feelings that may signal a negative self-concept. Correct any misconceptions. *Some women believe that hysterectomy means weight gain, the end of sexual activity and the growth of facial hair.*
- Provide information on risks and benefits of hormone replacement therapy (HRT), if indicated. *If the ovaries have also been removed, the woman is immediately thrust into menopause and may want or need HRT.*
- Reinforce the need to obtain gynaecological examinations regularly, even after hysterectomy.

Explain that conception is possible during this time (therefore birth control measures are required) and that orgasm may help relieve symptoms. *Orgasm causes a release of tension and vascular congestion, and frequently provides at least temporary relief of symptoms.*

- Provide an opportunity for the expression of concerns related to alterations in lifestyle and sexual functioning. Some women have had a prolonged period of sexual abstinence related to DUB. *Allowing women to verbalise concerns can assist them in working collaboratively with the healthcare provider to minimise the impact of illness and optimise function.*

CONSIDERATION FOR PRACTICE

If the nurse is not comfortable with frank discussions about sexual activities, referral is indicated. Nurses, however, should be open to discussing sexuality and sexual activities with women. If the nurse is not comfortable they cannot expect the woman to be.

Community-based care

Provide support, appropriate reassurance and information to help the woman and her family better understand her disorder and the therapeutic interventions indicated. Education on the following topics should be included:

- administration and side effects of prescribed medications, including iron
- the need to maintain a balanced diet, increasing iron-rich foods such as eggs, beans, liver, beef and shellfish. (Inform the woman that while orange juice may improve the absorption of iron, foods high in calcium and oxalic acid, such as spinach, may reduce its absorption.)
- importance of maintaining a fluid intake of 2 to 3 L a day
- the need to immediately report recurring episodes of DUB, particularly in postmenopausal women, to the healthcare provider
- the importance of the woman looking after her mental health.

STRUCTURAL DISORDERS

Structural disorders of the female reproductive system include displacement disorders and fistulas.

THE WOMAN WITH A UTERINE DISPLACEMENT

The uterus may be displaced within the pelvic cavity or may descend into the vaginal canal. Displacement of the uterus within the pelvic cavity is classified according to the direction of the displacement (see Figure 48.2):

- *Retroversion* of the uterus is a backwards tilting of the uterus towards the rectum.
- *Retroflexion* involves a flexing or bending of the uterine corpus in a backwards manner towards the rectum.
- *Anteversion* is an exaggerated forwards tilting of the uterus.
- *Anteflexion* is a flexing or folding of the uterine corpus upon itself.

Prolapse of the uterus into the vaginal canal can vary from mild to complete prolapse outside of the body. First-degree, or mild, prolapse involves a descent of less than half the uterine corpus into the vagina. Second-degree, or marked, prolapse involves the descent of the entire uterus into the vaginal canal, so that the cervix is at the introitus to the vagina. Third-degree prolapse, or *procidentia*, is complete prolapse of the uterus outside the body, with inversion of the vaginal canal (see Figure 48.3). Prolapse of the uterus is often accompanied by *cystocoele* (herniation of the bladder into the vagina) or *rectocoele* (herniation of the rectum into the vagina).

Pathophysiology

Displacement or prolapse of the uterus, bladder or rectum can be a congenital or an acquired condition. Congenital tilting or flexion of the uterus is rare. More commonly, tilting or flexion disorders in which the uterus remains within the pelvic cavity are related to the scarring and inflammation of pelvic inflammatory disease, endometriosis, pregnancy and tumours.

Downwards displacement of the pelvic organs into the vagina results from weakened pelvic musculature, usually attributable to stretching of the supporting ligaments and muscles during pregnancy and childbirth. Unrepaired lacerations from childbirth, rapid deliveries, multiple pregnancies, congenital weakness or loss of elasticity and muscle tone with ageing may contribute to these disorders.

Manifestations

The symptoms of displacement disorders are listed below.

MANIFESTATIONS Displacement disorders

UTERINE DISPLACEMENT WITHIN THE PELVIC CAVITY

- Dysmenorrhoea
- Backache
- Dyspareunia
- Infertility

UTERINE PROLAPSE

- Backache
- Urinary incontinence
- Bearing-down sensation
- Haemorrhoids
- Constipation
- Dyspareunia

CYSTOCOELE/RECTOCOELE

- Bearing-down sensation
- Haemorrhoids
- Constipation
- Urinary incontinence
- Faecal incontinence

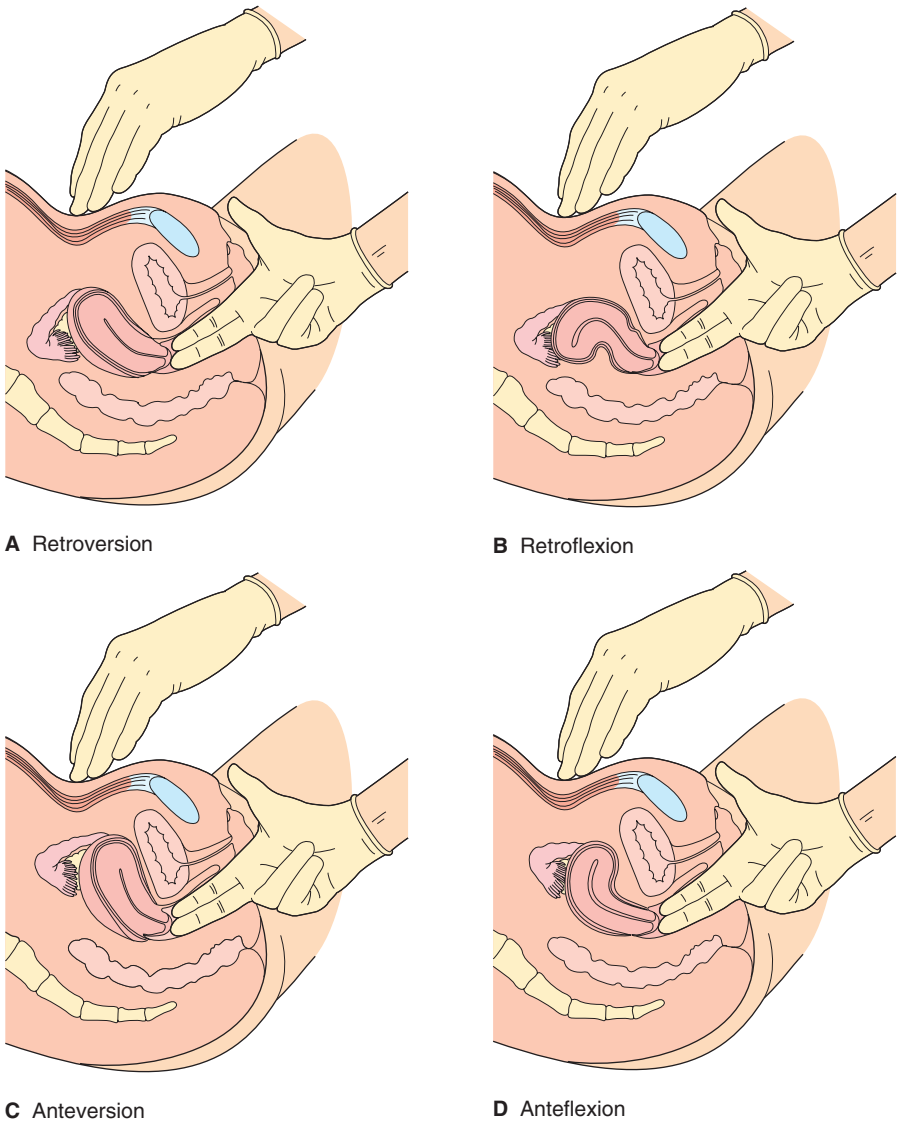


FIGURE 48.2 ■ Displacements of the uterus within the uterine cavity. *A*, Retroversion is a backwards tilting. *B*, Retroflexion is a backwards bending. *C*, Anteversion is a forwards tilting. *D*, Anteflexion is a forwards bending

INTERPROFESSIONAL CARE

Interprofessional care focuses on identifying the cause of the structural disorder, correcting or minimising the condition, relieving pain, preventing or treating infection, and supporting and educating the woman.

A careful history is taken and a physical examination is performed. Diagnosis of uterine displacement is made after physical examination. If herniation of the rectum or bladder is suspected, the woman is asked to bear down or cough during the examination so the prolapse can be palpated and any leakage of urine or faeces visualised. A history of infections, multiple pregnancies in rapid succession and rapid labours support this diagnosis.

Treatment may include Kegel (pelvic floor) exercises to strengthen weakened pelvic muscles. Kegel exercises can be useful in the early stages of downwards displacement. These exercises are discussed in Chapter 26.

Surgery

Several surgical procedures are used to repair structural disorders. For women presenting with a cystocoele, *anterior colporrhaphy* (repair of the cystocoele) is the most common procedure. The anterior repair shortens the pelvic muscles, providing tighter support for the bladder. The *Marshall–Marchetti–Krantz procedure* involves resuspension of the urinary bladder in correct anatomical position. A rectocoele is repaired with a posterior colporrhaphy, which shortens the pelvic muscles, providing a tighter support for the rectum.

A prolapsed uterus may be surgically repositioned and the supporting muscles shortened to provide greater support. In postmenopausal women or women with procidentia, hysterectomy is the preferred treatment.

Pessary

When surgery is contraindicated, a *pessary* (a removable device) may be inserted into the vagina to provide temporary support for the uterus or bladder. At regular intervals, the pessary is removed, cleaned and reinserted.

FIGURE 48.3 ■ Prolapse of the uterus can vary from mild to complete. In third-degree uterine prolapse, or procidentia, the uterus prolapses completely outside the body, with inversion of the vagina

Source: © M. English, MD/Custom Medical Stock Photo.

Nursing care

Nursing care focuses on education about the disorder, proposed treatments and self-care measures for relief of symptoms.

Nursing diagnoses and interventions

Nursing interventions for the woman with a displacement disorder address problems with urinary incontinence and anxiety.

Stress incontinence

Relaxation of the pelvic floor can lead to stress incontinence. This can prove both troublesome and embarrassing, and can increase the incidence of urinary tract infection.

- Teach Kegel exercises. These exercises strengthen perineal muscle tone, minimise urinary leakage and minimise descent of the bladder and rectum into the vagina. *In postmenopausal women, oestrogen supplements also can improve muscle tone in the perineal area.*
- Suggest the use of perineal pads (ranging from thin panty liners to full-thickness incontinence pads) or special underwear (such as Depend) to absorb urine leakage. *Using pads or undergarments often allows the woman to once again take part in her usual social activities.*
- Explain perineal care and proper use of perineal pads. Cleansing the perineum from front to back and applying and removing perineal pads the same way minimises cross-infection from the anus to the vaginal and urethral openings. *Incontinence pads need to be changed frequently to minimise surface bacterial counts.*
- Suggest reducing or eliminating caffeine intake. *Reducing caffeine intake can reduce urinary frequency and urgency.*
- Stress the importance of cleaning the perineal area. *Urine is very irritating to the skin.*

Anxiety

Anxiety is common in women with a displacement disorder. Many women have a limited understanding of their reproductive anatomy. This lack of knowledge often compounds the anxiety. The nurse can use models to explain structural disorders and treatment options available.

- Encourage questions from the woman and her partner. *This helps assess the level of understanding so that health education can be more effective.*
- Explain that the relief from discomfort and fatigue may positively influence sexual expression and reassure the woman that the capacity for orgasm will not be affected. *Many women and their partners have major concerns about the effects of the disorder and its treatment on their sex life and capacity for sexual pleasure.*
- Explore coping mechanisms that have been previously successful. *This can help relieve anxiety and boost selfesteem.*

Community-based care

If surgery is the treatment of choice, health education centres on what to expect in the preoperative and postoperative periods. If medical treatment is used initially, education focuses on measures to relieve the symptoms, such as Kegel (pelvic floor) exercises, use of incontinence pads or the use, care and insertion of a pessary.

As obesity is a risk factor associated with relaxation of the pelvic and abdominal muscles, dietary counselling may be indicated. Preoperatively, a diet high in fibre may alleviate constipation, a particular concern during the postoperative period.

THE WOMAN WITH A VAGINAL FISTULA

A fistula is an abnormal opening or passage between two organs or spaces that are normally separated, or an abnormal passage to the outside of the body. Vaginal fistulas may be vesicovaginal or rectovaginal. A *vesicovaginal fistula* is an abnormal opening between the urinary bladder and the vagina, leading to incontinent leakage of urine through the vagina. A *rectovaginal fistula* (less common) is an abnormal opening between the rectum and vagina, causing incontinent leakage of stool or flatus through the vagina.

Vesicovaginal or rectovaginal fistulas may develop as a complication of childbirth, gynaecological or urological surgery, or radiation therapy for gynaecological cancer. Cancer of the bladder is sometimes involved. The woman with a vaginal fistula often presents with a complaint of involuntary leakage of urine or flatus and symptoms of infection.

INTERPROFESSIONAL CARE

Fistulas are diagnosed by pelvic examination. Diagnosis of a vesicovaginal fistula can be made by instilling dye into the urinary bladder through a catheter and observing the vagina for leakage. If no leakage is detected, a tampon or vaginal pack is inserted into the vagina and the woman is asked to ambulate. If an abnormal opening is present, the tampon will absorb the dye. Dye may also be injected intravenously because it is excreted by the kidneys. Urine and vaginal cultures may be performed to rule out infections. Antibiotics are administered if infection is present.

A small vaginal fistula may resolve spontaneously. Otherwise, surgery is performed after inflammation has subsided—often a period of several months. Rarely, in the presence of a large, highly inflamed rectovaginal fistula, a temporary colostomy is performed, allowing inflammation and irritation to subside (see Chapter 23).

Nursing care

Nursing care for the woman with repair of a vaginal fistula is similar to that for the woman with a displacement disorder. Health education is an important component of nursing care. Stress the importance of careful perineal cleansing to reduce irritation and prevent further tissue breakdown. Perineal pads or special underwear may be used to absorb urine or faecal drainage. For the woman with a rectovaginal fistula, provide information about avoiding gas-forming foods to minimise embarrassment from odour.

DISORDERS OF FEMALE REPRODUCTIVE TISSUE

Both benign and malignant tissue disorders affect the female reproductive system. Benign tumours and cysts include Bartholin's gland cysts, cervical polyps, endometrial cysts and polyps, ovarian cysts and uterine leiomyomas (fibroids). Endometriosis is a condition in which endometrial tissue implants outside the uterus in various locations in the pelvic cavity. Malignant tumours of reproductive tissue include cervical cancer, endometrial cancer, ovarian cancer and vulvar cancer.

THE WOMAN WITH CYSTS OR POLYPS

A *cyst* is a fluid-filled sac. A *polyp* is a highly vascular solid tumour attached by a pedicle or stem. Cysts or polyps of the female reproductive system can occur in the vulva, cervix, endometrium or ovaries.

Pathophysiology

Following are different types of female reproductive tissue cysts and polyps:

- *Bartholin's gland cysts* are the most common cystic disorder of the vulva. These cysts are caused by the infection or obstruction of Bartholin's gland.
- *Cervical polyps* are the most common benign cervical lesion in women of reproductive age. These polyps tend to occur in women over age 40 who have borne several children and have a history of using oral contraceptives. It is possible that cervical polyps develop from endocervical hyperplasia. The polyp develops at the vaginal end of the cervix, has a stem and is highly vascular.
- *Endometrial cysts and polyps* are caused by endometrial overgrowth and are often filled with old blood. (The dark colour leads to the label 'chocolate cysts'.) Endometrial cysts are the result of endometrial implants on the ovary and are associated with endometriosis. Endometrial polyps, in contrast, are intrauterine overgrowths, similar to cervical polyps, and usually have a stalk.
- *Ovarian cysts* are classified as follicular cysts and corpus luteum cysts. Follicular cysts develop as a result of failure of the mature follicle to rupture or failure of an immature follicle to reabsorb fluid after ovulation. Corpus luteum cysts develop as a result of increased hormone secretion by the corpus luteum after ovulation. Most functional cysts regress spontaneously within two or three menstrual cycles.
- *Polycystic ovarian syndrome* (POS, also known as *Stein–Leventhal syndrome*) is an endocrine disorder characterised by an excess of androgens and a long-term lack of ovulation. The exact cause is unknown. As a part of the disease, as many as 8 to 10 cysts form in the ovaries from a failure to release ova. Symptoms include amenorrhoea or irregular menses, hirsutism, obesity, acne, hypertension, sleep apnoea and infertility. Women with POS often have insulin resistance and are at increased risk of early-onset type 2 diabetes, as well as heart disease, breast cancer and endometrial cancer.

Manifestations and complications

The causes and symptoms of benign cysts and polyps of the female reproductive system are presented in Table 48.1. Complications associated with these disorders include infection, rupture, infertility, haemorrhage and recurrence.

INTERPROFESSIONAL CARE

Care focuses on identifying and correcting the disorder and preventing its recurrence. A careful history is taken and a physical examination is performed, including inspection and visualisation. Examination of the reproductive tract reveals the

TABLE 48.1 Benign cysts and polyps of the female reproductive system

SITE	TYPE	AETIOLOGICAL ORIGIN	SYMPTOMS
Ovary	Functional cysts	Ovulation—include follicular cysts and corpus luteum cysts	May resolve spontaneously; can cause pain, menstrual irregularity or amenorrhoea
	Polycystic ovarian syndrome	Unknown; possible hypothalamic–pituitary dysfunction	Hirsutism, obesity; amenorrhoea or irregular menses; hyperinsulinaemia; infertility
Vulva	Bartholin cysts	Obstruction or infection of Bartholin's gland	Pain, redness, perineal mass, dyspareunia
Endometrium	Chocolate cysts	Endometrial overgrowth; filled with old blood	
	Endometrial polyps	Unknown	Bleeding between periods
Cervix	Cervical polyps	Unknown	Bleeding after intercourse or between periods

presence of most cysts and polyps. The menstrual history may reveal menstrual irregularities.

Diagnosis

Diagnostic tests that may be used to diagnose cysts and polyps of the female reproductive system include laparoscopy to visualise ovarian cysts, ultrasound or x-ray to differentiate cysts from solid tumours and a pregnancy test when luteal cysts are suspected. Laboratory analysis will demonstrate elevated LH and testosterone levels, as well as a reverse in FSH/LH in the woman with POS.

Medications

Antibiotics are used to treat infection or abscess, and oral contraceptives are used to promote regression of functional ovarian cysts. Clomiphene (Clomid, Serophene) may be prescribed to stimulate ovulation in the woman with POS who wishes to become pregnant. Dexamethasone suppresses ACTH and adrenal androgens and may be added to increase the likelihood of ovulation.

Surgery

Cervical polyps are visible through a vaginal speculum and usually are removed with a clamp, using a twisting motion. To remove endometrial cysts or polyps, a transcervical approach is used. The specimen is sent to the laboratory for evaluation and chemical or electrical cauterisation is applied after cyst removal. For Bartholin's gland cysts and any abscesses, the lesion is incised and drained and a drainage device is left in place. Follicular cysts may be punctured through laser surgery or a wedge resection of the ovary may be performed to restore ovulation. Rarely, *oophorectomy* (removal of the ovary) is performed if the cysts are very large.

Nursing care

Nursing care focuses on relieving pain and preventing recurrence and complications. Address the following topics for self-care at home:

- the condition, its treatment and measures to relieve pain
- the importance of keeping follow-up appointments
- symptoms of infection (for post-surgical care) and the need to notify the health professional should they occur
- if cervical polypectomy is performed, advise use of external pads for 1 week. The woman must be able to state the signs of excessive bleeding and recognise that saturating more than one pad in an hour indicates the need for immediate follow up
- the importance of long-term follow-up care for the woman with POS.

THE WOMAN WITH LEIOMYOMA

Leiomyomas (*fibroid tumours*) are benign tumours that originate from smooth muscle of the uterus. They are the most common form of pelvic tumour, believed to occur in 60% of women older than 45 years of age (Okolo, 2008).

Pathophysiology

The actual cause of fibroid tumours is not clearly understood, but there is a strong association with oestrogen stimulation. Fibroid tumours usually develop in the uterine corpus and may be intramural, subserous or submucous (see Figure 48.4):

- *Intramural fibroid tumours* (the most common type) are embedded in the myometrium. They usually present as an enlargement of the uterus.
- *Subserous fibroid tumours* lie beneath the serous lining of the uterus and project into the peritoneal cavity. They may become pedunculated (on a stem) and displace or compress other tissues, such as the ureter or bladder.
- *Submucous fibroid tumours* lie beneath the endometrial lining of the uterus. They displace endometrial tissue and are more likely to cause bleeding, infection and necrosis than the other types.

Manifestations

Small tumours may be asymptomatic. The rate of growth varies, but they may increase in size during pregnancy or with use of oral contraceptives or HRT. Large fibroid tumours can crowd other organs, leading to pelvic pressure, pain, dysmenorrhoea, menorrhagia and fatigue. Depending on the location of the tumour, constipation and urinary urgency and frequency may occur. Most fibroid tumours shrink with menopause.

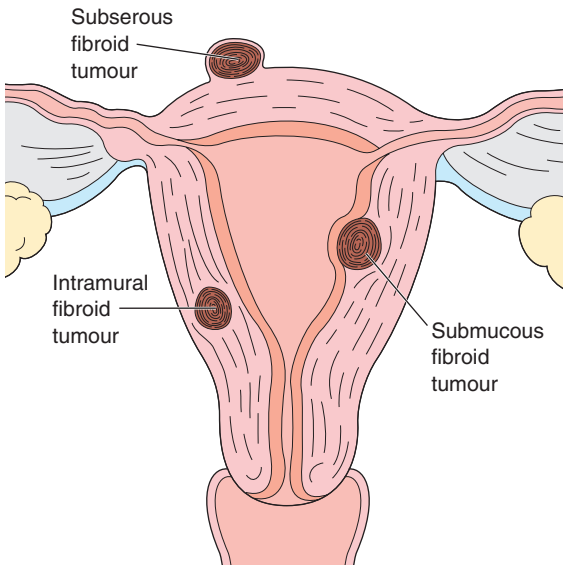

FIGURE 48.4 ■ Types of uterine fibroid tumours (leiomyomas). Intramural fibroid tumours lie within the uterine wall. Subserous fibroid tumours lie beneath the serous lining of the uterus and project into the peritoneum. Submucous fibroid tumours lie beneath the endometrial lining of the uterus

INTERPROFESSIONAL CARE

Treatment of the woman with uterine fibroids depends on the size and location of the tumours, the severity of the symptoms and her age and childbearing status. Tests used to diagnose uterine fibroids may include ultrasound to differentiate leiomyoma from endometriosis, and laparoscopy to visualise subserosal leiomyomas.

In asymptomatic women who wish to bear children, the fibroid tumours are monitored. Follow up is recommended two to three times per year to monitor growth.

Medications

Leuprolide acetate (Lupron) is used to decrease the size of the tumour if surgery is contraindicated or not desired. Gonadotropin-releasing hormone (GnRH) agonists are also administered.

Surgery

Myomectomy, removal of the tumour without removing the entire uterus, is the surgical procedure of choice for young women who wish to retain reproductive capability. Laparoscopic laser technique is used for many women. A hysterectomy is performed if tumours are large and if bleeding or other problems continue in perimenopausal women. A hysterectomy usually requires a hospital stay of 3 to 4 days and a 6-week recovery time. A non-surgical method of treatment is a *uterine fibroid embolisation*. In this procedure, a catheter is guided through the femoral artery to the uterus, where tiny particles are injected into the artery supplying the fibroid to cut off the fibroid's blood supply.

Nursing care

If surgery is deferred, health education emphasises the importance of regular follow-up assessments to monitor tumour growth. If a hysterectomy is performed, education emphasises appropriate preoperative and postoperative care. Dietary modifications to increase iron intake, prevent constipation and promote healing are important.

THE WOMAN WITH ENDOMETRIOSIS

Endometriosis is a condition in which multiple, small, usually benign implantations of endometrial tissue develop most commonly in the pelvic cavity, but also occasionally in other areas of the body, such as the lungs. Endometriosis affects 10–15% of women of childbearing age and is more common in women who postpone childbearing. Risk factors for endometriosis include early menarche, regular periods with a cycle of less than 27 days, menses lasting more than 7 days, heavier flow, increased menstrual pain and a history of the condition in first-degree female relatives.

Pathophysiology

The cause of endometriosis is unclear, but several theories have been proposed. The metaplasia theory asserts that endometrial tissue develops from embryonic epithelial cells as a result of hormonal or inflammatory changes. The theory of retrograde menstruation suggests that menstrual tissue backs up through the fallopian tubes during menses, implants on various pelvic structures and survives. The transplantation theory asserts that endometrial implants spread via lymphatic or vascular routes.

The abnormally located endometrial tissue responds to cyclical ovarian hormone stimulation, and bleeding at the time of menstruation occurs at the sites of implantation. Scarring, inflammation and adhesions may develop. Endometriosis is a slowly progressive disease, responsive to ovarian hormone stimulation. Thus, the implants regress during pregnancy and atrophy at menopause unless the woman is receiving HRT. Because progressive scarring may interfere with the ability to conceive, women with significant endometriosis are encouraged to have children early if they wish to do so.

Manifestations

Symptoms of endometriosis, which usually occur during the luteal phase of the menstrual cycle, are summarised below.

INTERPROFESSIONAL CARE

Endometriosis may be difficult to diagnose, but a history of dysmenorrhoea, dyspareunia and infertility strongly suggests this diagnosis. Interventions depend on the severity of

MANIFESTATIONS Endometriosis

- Heavy, throbbing pain of the lower abdomen and pelvis, radiating down the thighs and around the back. (The degree of pain, however, is not indicative of the severity of the disease.)
- Feeling of rectal pressure and discomfort when having a bowel movement.
- Dyspareunia.
- Dysfunctional uterine bleeding.
- Infertility.

symptoms, the extent of the disease and the woman's age and desire for childbearing. Treatment goals focus on pain management and restoring fertility.

Diagnosis

Diagnostic tests are ordered to rule out other medical conditions and identify the endometrial implants. The tests include pelvic ultrasound and laparoscopy (see Chapter 46), as well as an FBC with differential to rule out pelvic abscesses and infectious processes. A low haemoglobin and haematocrit may be noted if menorrhagia accompanies endometriosis or tissue implants bleed significantly during menses. A definitive diagnosis can be made when a laparoscopy is performed and a biopsy of tissue is undertaken (Endometriosis Australia, 2014).

Medications

Medications include analgesics to control pain and prostaglandin synthesis inhibitors such as NSAIDs. Hormone therapy may include oral contraceptives or progesterone to induce pseudopregnancy or danazol (Azol) to induce amenorrhoea and involution of endometrial tissue. Prolonged use of danazol, however, may result in masculinising effects. GnRH is used to elevate levels of oestrogen and progesterone and minimise bleeding.

Surgery

Surgical interventions include laparoscopy with laser ablation (excision or removal) of endometrial implants. Refractory endometriosis may be treated with total hysterectomy.

Nursing care

Nursing care includes providing pain relief, engaging the woman in health education about her condition and the treatment options, and helping her cope with treatment outcomes. The severity of the disease and its symptoms are not necessarily related. Advanced disease may exhibit few symptoms, whereas early disease may be quite painful. A nursing care plan for a woman with endometriosis is found below.

Nursing diagnoses and interventions

Interventions for pain, discussed previously, are also appropriate for the woman with endometriosis. A priority for care for women with this disorder is anxiety related to the risk of loss of reproductive function.

Anxiety

Anxiety about the unsure prognosis related to infertility is a particular problem for young women who plan to have a family in the future.

- Encourage expression of fears and anxiety about infertility and answer questions honestly and based on evidence. *Knowledge helps relieve anxiety and fear.*
- Provide information on fertility awareness methods, including measurement of basal body temperature and other techniques for recognising ovulation. *Understanding these techniques helps the woman optimise the conditions for conception.*

NURSING CARE PLAN A woman with endometriosis

Joy Smith is a 29-year-old school teacher. She has been in a permanent relationship with her partner for the past 4 years. Joy describes a history of severe dysmenorrhoea and menorrhagia, a feeling of pelvic heaviness and pain that radiates down her thighs. Joy is seeking assistance with the above symptoms, as she is not coping with the ongoing effect of the symptoms on her health and lifestyle. She also discusses her own and her partner's desire to have children. However, at the current time she is reluctant to have sex as she experiences severe discomfort and pain. Her partner has been supportive. However, it is affecting their relationship. Following review, endometriosis is suspected and a diagnostic laparoscopy has been scheduled.

ASSESSMENT

Registered Nurse and Nurse Practitioner Christian Bright interviews Joy and makes the following assessments: BP 110/70, P 68, R 18, T 36.7°C. Joy's weight is 59 kg and within normal limits for her height. Review of laboratory findings indicates a haemoglobin level of 98 g/L (normal range: 115 to 165 g/L) and a haematocrit of 33.1% (normal range: 38% to 47%). Physical examination reveals pelvic tenderness on manipulation of the cervix and small masses that are palpable on abdominal/pelvic examination.

DIAGNOSES

- *Chronic pelvic pain* related to the endometriosis and endometrial pelvic implants.
- *Anxiety* related to effect of endometriosis on fertility.
- *Deficient knowledge* related to diagnosis and treatment options.
- *Ineffective sexuality pattern* related to the symptoms of endometriosis.

NURSING CARE PLAN A woman with endometriosis (continued)

PLANNING

- Identify the location, type, duration and history of the pain.
- Recommend analgesics and heat therapy.
- Provide information on biofeedback, relaxation and imagery to lessen pain.
- Discuss with Joy and her partner, David, the causes of endometriosis and its symptoms.
- Encourage Joy and David to discuss their feelings about the effect of the disease on their sex life, lifestyle and fertility.
- Refer the couple to appropriate counselling if required.
- Refer the couple to support organisations such as Endometriosis Australia www.endometriosisaustralia.org/.

Expected outcomes

- Develop effective self-care measures to deal with the pain and discomfort.
- Verbalise decreased anxiety.
- Demonstrate understanding of the disease and treatment options.
- Verbalise an improvement in sexual functioning and a decrease in interpersonal stress between Joy and her partner.

IMPLEMENTATION

- Initiate each of the steps outlined in the planning section detailed above.
- Monitor the effectiveness of the plan by monitoring Joy's response to:
  - analgesics, heat therapy and biofeedback
  - relaxation and imagery to lessen pain.
- Ongoing discussion with Joy and David about their sexual relationship and infertility issues.

EVALUATION

Two years after the initiation of treatment, Joy and David have become parents of a baby girl. Joy states that the discomfort and other symptoms of endometriosis have eased. Relaxation and imagery have effectively minimised her pain and brought about improvement in her function as a mother and sexual partner. Counselling has improved the interpersonal and sexual relations between Joy and David. Dietary management has improved her anaemia, although the menorrhagia persists. Joy and David are trying to have a second baby. They will be followed up and referred to an infertility clinic if conception does not occur within 1 year.

CRITICAL THINKING IN THE NURSING PROCESS

1. Explain the pathophysiological basis for Joy's anaemia.
2. How would you handle the situation if Joy and David were extremely uncomfortable and embarrassed about discussing their sexual problems?
3. Develop a plan of care for Joy for *Situational low self-esteem* related to the symptoms of endometriosis.

REFLECTION ON THE NURSING PROCESS

1. Outline what you have learned from Joy's case study. How would you incorporate this into your future nursing practice?
2. Which strategies would you use in your future nursing practice to assist women who are experiencing endometriosis and subsequent infertility?

Community-based care

Explain the cause of the disorder and the various treatment options, including their side effects. Discuss fertility awareness methods and the risks and benefits of long-term use of oral contraceptives. Stress the importance of regular exercise, smoking cessation and weight control. If surgical treatment is chosen, provide preoperative and postoperative education.

THE WOMAN WITH CERVICAL CANCER

Cancer of the cervix is the second most common cancer in women worldwide and the fourteenth most common in women in Australia (Cancer Australia, 2015a). The lower incidence in Australia is primarily the result of screening with Pap tests and the introduction of the HPV vaccine Gardasil, which has been shown to be 100% effective against HPV types 6, 11, 16 and 18, which are responsible for 70% of cervical cancer cases and 90% of genital warts in women (Australian Institute of Health and Welfare (AIHW), 2011).

The incidence of diagnosis with cervical cancer prior to 85 years of age is one in 62 women (Cancer Council Australia, 2015a) However, it is important to remember that cervical cancer begins to appear in women in their twenties. According to the AIHW (2011), effective screening with the Pap smear test and treatment have reduced the death rate in women as a result of cervical cancer. However, the mortality rate remains high for Aboriginal and Torres Strait Islander women (see 'Fast facts' box), and health professionals need to provide health education and work towards lowering this unacceptable mortality rate (AIHW, 2013).

Risk factors

Risk factors for cervical cancer include first intercourse before 16 years of age, multiple sex partners or male partners with multiple sex partners, a history of sexually transmitted infections and infection with HIV. The most important risk factor is infection with HPV. Other risk factors include smoking and poor nutritional status, family history of cervical cancer and exposure to diethylstilbestrol (DES) in utero.

Pathophysiology

Most cervical cancers (90%) are squamous cell carcinomas that begin as neoplasia in the cervical epithelium. *Precancerous dysplasia* (*cervical intraepithelial neoplasia (CIN)*, *cervical carcinoma in*

FAST FACTS

- The Australian Institute of Health and Welfare (AIHW) (2011) reports that cervical cancer rates in Australia are at a historic low. Incidence rates have decreased since the introduction in 1991 of the National Cervical Screening Program (NCSP). However, for people from Aboriginal and Torres Strait Islander heritage, the incidence rates are double that of the non-Indigenous population. The mortality rate for cervical cancer is five times higher in Aboriginal and Torres Strait Islander women in comparison with the non-Indigenous population.
- Nearly 100% of women with cervical cancer have evidence of cervical infection with human papillomavirus (HPV) (see Chapter 49).
- The National Cervical Screening Program for Australian women recommends that all women aged 18 to 69 years who have ever been sexually active, whether vaccinated or unvaccinated, should have cervical screening by Pap smear every 2 years (Department of Health, 2012).

situ) is estimated to occur in one of eight women before the age of 20, and is often associated with HPV infection. Studies have also found a strong association with reproductive infections with *Chlamydia trachomatis*. (These infections are discussed in Chapter 49.) The precursor lesions may spontaneously regress (60%), persist (30%) or progress and undergo malignant change (10%). Only about 1% become invasive. Systems of grading of dysplastic changes in the cervix use the term *cervical intraepithelial neoplasia (CIN)* or the Bethesda system (see Table 48.2). Carcinoma in situ is localised; invasive cancer spreads to deeper layers.

Cancer in situ most often develops in the transformation zone where the columnar epithelium of the cervical lining meets the squamous epithelium of the outer cervix and vagina. Squamous cell cancers spread by direct invasion of accessory structures, including the vaginal wall, pelvic wall, bladder and rectum. Although metastasis is most frequently confined to the pelvic area, distant metastasis may occur through the lymphatic system.

Manifestations

Pre-invasive cancer is limited to the cervix and rarely causes symptoms. Invasive cancer causes vaginal bleeding after intercourse or between menstrual periods, and a vaginal discharge that increases as the cancer progresses. These changes are subtle and may be more readily noticed by the postmenopausal woman. Symptoms of advanced disease include referred pain in the back or thighs, haematuria, bloody stools, anaemia and weight loss.

INTERPROFESSIONAL CARE

The goals of treatment are to eradicate the cancer and minimise complications and metastasis. The type of treatment depends on the degree of malignant change, the size and location of the lesion and the extent of metastasis.

Diagnosis

Diagnostic tests used to diagnose cervical cancer include a Pap smear, colposcopy and cervical biopsy. (See Chapter 46 for further information about these procedures.) A loop diathermy technique (loop electrosurgical excision procedure (LEEP)) allows simultaneous diagnosis and treatment of dysplastic lesions found on colposcopy. This procedure is performed in the healthcare provider's office, using a wire for both cutting and coagulation during excision of the dysplastic region of the cervix. An MRI or CT of the pelvis, abdomen or bones may be performed to evaluate the spread of the tumour.

Medications

Chemotherapy is used for tumours not responsive to other therapy, tumours that cannot be removed or as adjunct therapy if metastasis has occurred (see Chapter 13).

Surgery

When combined with colposcopy, laser surgery is a viable treatment method provided that the cancer is limited to the cervical epithelium. Cryosurgery, which involves the use of a probe to freeze tissue, causing necrosis and sloughing, is also used for non-invasive lesions. Conisation (see Figure 48.5) is performed to treat microinvasive carcinoma when colposcopy

TABLE 48.2 Classification systems for Pap smears

DYSPLASIA/NEOPLASIA	CIN (CERVICAL INTRAEPITHELIAL NEOPLASIA)	BETHESDA SYSTEM	NUMERICAL
Benign	Benign	Normal	1
Benign with inflammation	Benign with inflammation	Normal	2
		Atypical squamous cells of undetermined significance (ASC-US)	
Moderate dysplasia	CIN I	Low-grade squamous intraepithelial lesion (SIL)	3
Severe dysplasia	CIN II	High-grade SIL	3
Carcinoma in situ	CIN III	High-grade SIL	4
Invasive cancer	Invasive cancer	Invasive cancer	5

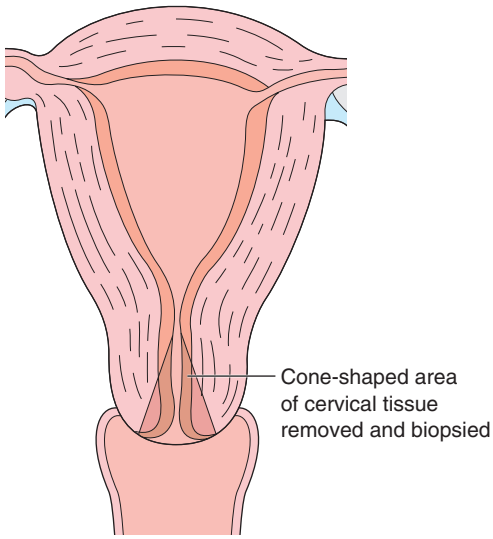

FIGURE 48.5 ■ Conisation, the surgical removal of a cone-shaped section of the cervix, is used to treat microinvasive carcinoma of the cervix

cannot define the limits of the invasion. For invasive lesions, hysterectomy or radical hysterectomy (removal of the uterus, fallopian tubes, lymph nodes and ovaries) is performed.

A *pelvic exenteration*, the removal of all pelvic contents including the bowel, vagina and bladder, is performed if the cancer recurs without involvement of the lymphatic system. An anterior exenteration is the removal of the uterus, ovaries, fallopian tubes, vagina, bladder, urethra, and lymphatic vessels and nodes. An ileal conduit is created for excretion of urine. A posterior exenteration is the removal of the uterus, ovaries, fallopian tubes, bowel and rectum. A colostomy is created for excretion of faeces (see Chapter 23).

Radiation therapy

Radiation therapy is used to treat invasive cervical cancer. External radiation beam therapy and intracavity cesium irradiation can be used. Radiation is discussed in Chapter 13.

Nursing care

Nursing care involves helping the woman deal with the physical and psychological effects of a potentially life-threatening illness, providing information needed to make informed decisions and minimising the adverse effects of therapy. Pain relief measures are important, as is counselling for the woman and her family. The woman should be educated and encouraged to perform self-care activities and to resume normal everyday activities and sexual functioning to the extent possible. A nursing care plan for a woman with cervical cancer is found below.

NURSING CARE PLAN A woman with cervical cancer

Kay Young is a 45-year-old divorced mother of two children aged 15 and 13. She was married at age 28 and had several sexual partners prior to her marriage. She has had three sexual partners since her marriage ended. Last year she was treated with cryosurgery for genital warts. A Pap smear taken 2 weeks ago showed atypical cells and she has come in for a repeat test.

ASSESSMENT

Laura Jones, Registered Nurse and Nurse Practitioner, the admitting nurse, interviews Kay and records the following assessment findings: BP 130/80, P 72, R 18, T 37.3°C. Kay weighs 64.5 kg. Examination of the cervix reveals a large necrotic lesion at the 7 o'clock position. She has reduced her smoking to less than 10 cigarettes per day and she does not drink alcohol.

Kay is extremely fearful and anxious, and has told no one about her abnormal Pap smear. She reveals that she has had back pain radiating down her thighs for several months and a foul vaginal discharge that increases after intercourse. Until 2 weeks ago, she had not had a Pap smear for 5 years. Laura Jones performs a repeat Pap smear, which is positive for squamous cell carcinoma of the cervix. A CT scan and lymphangiography are scheduled. Laparoscopy shows the disease to be widespread in the pelvic cavity.

DIAGNOSES

- *Personal conflict* related to Kay having to make a decision about the various treatment options that she could undertake.
- *Chronic and acute pain* related to disease progress and the management of the metastasis, including recovering from surgery.
- *Risk of impaired skin integrity* related to side effects of the treatment options such as radiation.
- *Fear for her wellbeing and future* related to diagnosis and management of cervical cancer.
- *Anticipatory grieving* related to potential loss of life and the effect of this on her children.
- *Anxiety* related to her diagnosis and prognosis, and the future wellbeing of her two children.

PLANNING

- Discuss treatment alternatives, including the prognosis with each option.
- Administer pain medications as prescribed.
- Examine skin surfaces daily before and after radiation therapy.
- Provide information on biofeedback training and relaxation techniques for control of moderate pain.
- Refer to a local cancer support group so that she can interact with cancer survivors. (If in a rural or remote

(continued)

NURSING CARE PLAN A woman with cervical cancer (continued)

area provide resources and/or online and/or telephone contacts.)
- Refer Kay to a social worker in preparation for her altered level of functioning and for assistance with finding care for her two children while she is undergoing treatment. (Kay lives in an urban area in Australia. Social worker services might not be immediately available if Kay lived in a rural or remote rural area.)

Expected outcomes
- Gain knowledge to make informed decisions about treatment options.
- Develop strategies for pain control.
- Maintain skin and tissue integrity during radiation treatment.
- Express her feelings about the fear of cancer and death, and her concerns related to her children.
- Develop effective coping strategies for dealing with life-threatening illness and pain.

IMPLEMENTATION
- Initiate each of the steps outlined in the planning section detailed above.
- Monitor the effectiveness of the plan by monitoring Kay's response to:
  - analgesics
  - radiation therapy.
- Ongoing discussion with Kay about the implementation of the plan and her psychosocial wellbeing.

EVALUATION
Kay has begun radiation therapy following pelvic exenteration. She controls her pain with relaxation and imagery techniques, requiring only occasional analgesics. She uses a water-based lotion to soothe the skin surface and is careful not to remove the skin markings. She seems optimistic and has quit smoking. She and her family have continued to attend the cancer support group meetings. Kay is planning for the future and has talked with her children and extended family about what it means to live with cancer.

CRITICAL THINKING IN THE NURSING PROCESS
1. Compare and contrast your education plan for health promotion interventions to decrease the risks of cervical cancer for a young woman aged 17 and an older woman aged 70. Would they differ and, if so, how?
2. Develop an education plan to help Kay cope with the effects of radiation.
3. During a home visit, Kay informs the nurse that she has been so tired since beginning radiation treatments that all she can do is sit in her chair. Design a plan of care for assisting Kay to cope with *Fatigue*.

REFLECTION ON THE NURSING PROCESS
1. Outline what you have learned from Kay's case study. How would you incorporate this into your future nursing practice?
2. Which strategies would you use in your future nursing practice to assist women who are undergoing treatment for cervical cancer?

Health promotion

The National Cervical Screening Program in Australia recommends that women should begin annual screening for cervical cancer with the Pap test every 2 years from age 18 (or 2 years after first sexual intercourse—whichever is later) and to continue throughout their life until age 69. Women who are 70 years of age and older and who have had three or more normal Pap smears in the past 10 years may be advised by their general practitioner that it is safe to stop having Pap smears (Department of Health, 2012). Screening should be done every year with regular Pap tests, or every 2 years using liquid-based tests. Alternately, cervical cancer screening with HPV DNA tests and Pap tests may be performed every 3 years. Screening for women who have had a total hysterectomy (including the cervix) is not recommended unless the surgery was done as a treatment for cancer. Women who have had a hysterectomy without removal of the cervix should continue to follow National Cervical Screening Program guidelines.

It is vital that nurses educate women of all ages about controlling risk factors for cervical cancer and about the importance of screening for this cancer throughout the lifespan. Educate young women about the relationship between early sexual activity, multiple partners and risk of STIs and cervical cancer. Discuss safer-sex alternatives and using condoms for protection. Emphasise the importance of continued screening examinations for the older woman who may not see a health professional on a regular basis. Encourage women under the age of 26 to receive Gardasil, the vaccine developed to prevent cervical cancer, precancerous genital lesions and genital warts due to HPV types 6, 11, 16 and 18. Gardasil is given as three injections over a 6-month period and does not protect against HPV in a woman already infected. For this reason, the Therapeutic Goods Administration in Australia recommends that the vaccine be routinely given to girls aged 12 and 13 (Department of Health, 2011).

Assessment

Collect the following data through a health history and physical examination (see Chapter 46):
- *Health history:* history of STIs, sexual history, partner's sexual history, family history of cervical cancer, vaginal bleeding or discharge, smoking history, maternal treatment with DES.
- *Physical assessment:* pelvic examination, abdomen, lymph glands.
- *Psychological assessment:* anxiety, coping strategies and stress levels.

Nursing diagnoses and interventions

This section discusses nursing interventions for the woman who has been diagnosed with cervical cancer and requires surgical and/or radiation treatment. Other interventions that may be appropriate for the woman with cervical cancer are discussed in the sections on other female reproductive system cancers.

Fear

Many people believe that cancer equals death; however, this is no longer true in many cases, especially with early diagnosis. For cervical cancer that is diagnosed at an early stage, the 5-year survival rate is 92%. If the disease is in situ, the rate is nearly 100% (Department of Health, 2009).

- Explain that 92% of all women with cervical cancer survive for 5 years or more and that the earlier the cancer is detected, the better the prognosis. *This gives the woman hope, an essential ingredient in recovery.*
- Allow adequate time for the woman and her family to express their concerns and ask questions. *Unexpressed feelings and fears and lack of understanding may cause the woman to view the situation as worse than it is.*
- Refer to cancer counsellor or support groups for additional information. *Cancer survivors who visit people in the hospital provide proof that people can survive the diagnosis and treatment of cancer and lead normal, productive lives.*

Impaired tissue integrity

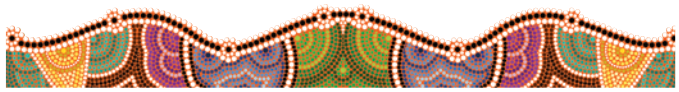
Surgery interrupts the integrity of the skin surface, providing a potential portal of invasion for bacteria. Radiation therapy causes an inflammatory response in the skin and mucous membranes within the field of radiation, creating further risk of tissue reaction and breakdown.

- Provide health education on wound and skin care, particularly if pelvic exenteration is performed. Irrigations with saline or other prescribed solutions can be performed at intervals. *Open and damaged tissue increases the risk of infection. Meticulous skin and wound care is necessary to prevent infection and further tissue destruction.*
- If appropriate, provide education on stoma care and care for the skin surrounding the stoma. (These procedures are discussed in Chapter 23.) *Urine and stool are irritating to the skin. Without proper care, the skin surrounding the stoma can become excoriated.*
- Apply non-oil-based lotions to skin to help minimise itching and maintain integrity. *Oil-based lotions are not recommended for tissue undergoing radiation.*
- Educate the woman about the importance of the markings used to localise the radiation beam to the target area and not to remove them. *Markings are used in future radiation treatments.*
- Monitor for evidence of fistula formation and teach the woman to do the same. *Fistula formation is a potential complication of radiation to the pelvic or abdominal cavities.*

Community-based care

Health education varies according to the stage of the cancer and the treatment selected. Provide information concerning radiation, chemotherapy or surgery, as indicated. Preoperative health education focuses on postoperative expectations, including management of urinary or faecal diversion, if indicated (see Chapters 23 and 26) and psychological impacts of the diagnosis and surgery. Help the woman and family recognise signs of infection and understand the importance of follow-up care. In addition, suggest the following resources:

- ABC Health & Wellbeing: www.abc.net.au/health/conditions/cancer/default.htm
- Cancer Council Australia Support: www.cancer.org.au/about-cancer/patient-support/



THE WOMAN WITH ENDOMETRIAL CANCER

Endometrial cancer is the most common invasive gynaecological cancer in Australia. The incidence rate of endometrial cancer is increasing due to the increased rate of obesity and the aging population. Presently, one in 69 women are diagnosed prior to being 75 years of age (Cancer Council Australia, 2012). When diagnosed and treated early in the disease, the 5-year survival rate is about 82.5% (Cancer Australia, 2015b).

Risk factors

A significant risk factor for endometrial cancer is prolonged oestrogen stimulation. Other factors that increase risk are obesity, anovulatory menstrual cycles, decreasing ovarian function (as from menopause), oestrogen-secreting tumours and unopposed oestrogen (e.g. oestrogen therapy without progesterone). Medical conditions that may alter oestrogen metabolism and increase the risk of endometrial cancer are diabetes mellitus, hypertension and polycystic ovarian syndrome (Porth & Matfin, 2014). Tamoxifen, a medication that blocks oestrogen receptor sites and is used to treat breast cancer, has a weak oestrogenic effect on the endometrium and is also a risk factor.

Endometrial cancer is the most commonly inherited gynaecological cancer. A family history of hereditary non-polyposis colon cancer (HNPCC) may mean that a woman has an inherited mutation that is a mismatch of repair genes and has a 60% risk of endometrial cancer.

Pathophysiology

Most endometrial malignancies are adenocarcinomas that are slow to grow and metastasise. These cancers develop in the glandular cells or endometrial lining of the uterus (the same tissue that is shed each month during a normal menstrual period). Endometrial hyperplasia (excessive growth) is a precursor of endometrial cancer. These tumours tend to grow slowly in the early stages.

Tumour growth usually begins in the fundus, invades the vascular myometrium and spreads throughout the female reproductive tract. Metastasis occurs by means of the lymphatic system, through the fallopian tubes to the peritoneal cavity and to the rest of the body via the bloodstream. Target areas for metastasis include the lungs, liver and bone. The International Federation of Gynecology and Obstetrics (FIGO) classification of endometrial cancer is presented in Table 48.3.

TABLE 48.3 FIGO staging classification for endometrial cancer

STAGE	DESCRIPTION
I	Tumour limited to endometrium or myometrium
II	Endocervical glandular involvement or invasion of cervical stroma
III	Metastasis or invasion of serosa, adnexae, vagina and pelvic or para-aortic lymph nodes
IV	Tumour invasion of bladder or bowel mucosa; distant metastases

Manifestations

The main manifestation of endometrial hyperplasia or overt endometrial cancer is abnormal, painless vaginal bleeding. In menstruating women, this bleeding is manifested as menorrhagia or metrorrhagia. In postmenopausal women, any bleeding is abnormal. Later symptoms include pelvic cramping, bleeding after intercourse and lower abdominal pressure. In advanced disease, lymph node enlargement, pleural effusion, abdominal masses and ascites may be present.

INTERPROFESSIONAL CARE

The goals of care for the woman with endometrial cancer are to eradicate the cancer and minimise complications and metastasis.

Diagnosis

Tests used to diagnose cancer of the endometrium include a vaginal or transvaginal ultrasound to determine endometrial thickening, which may indicate hypertrophy or malignant changes, or an endometrial biopsy or a dilation and curettage (D&C) to provide a definitive diagnosis (see Chapter 46 for further information and nursing care). Other tests to determine the extent of the disease include chest x-ray, intravenous urography, cystoscopy, barium enema, sigmoidoscopy, MRI and bone scans.

Medications

Although the treatment of choice for primary endometrial carcinoma is surgery, progesterone therapy may be used for recurrent disease. About one-third of women respond favourably, primarily those with well-differentiated tumours. Chemotherapy is less effective than other forms of therapy, although cisplatin or combination chemotherapy may be used for women with disseminated disease.

Surgery

After the diagnosis is confirmed, a total abdominal hysterectomy and bilateral salpingo-oophorectomy is performed for stage I cancer. A radical hysterectomy with node dissection is performed if the disease is stage II or beyond.

Radiation therapy

Treatment with external and internal radiation may be performed as a preoperative measure or as adjuvant treatment in advanced cases.

Nursing care

Health promotion

All women, including perimenopausal and postmenopausal women, need regular pelvic examinations. At the time of menopause all women should be informed of the risks and symptoms of endometrial cancer and strongly encouraged to report any unexpected bleeding or spotting to their healthcare provider. Those in high-risk groups are advised to have endometrial biopsies every 2 years, beginning at age 35. In addition, control of diseases such as diabetes mellitus and hypertension decreases the risk of endometrial hyperplasia.

Assessment

Undertake a health history and physical examination (see Chapter 46):

- *Health history:* abnormal vaginal bleeding, menstrual history, use of oestrogen (without progesterone) to treat menopausal symptoms, breast cancer treated with tamoxifen, childbearing status, presence of chronic illnesses, family history of hereditary non-polyposis colon cancer.
- *Physical assessment:* height and weight, pelvic examination, abdomen, lymph glands.
- *Mental health assessment:* anxiety, coping strategies, emotional wellbeing.

Nursing diagnoses and interventions

Nursing care involves helping the woman deal with the physical and psychological effects of a potentially life-threatening illness, make informed decisions and minimise the adverse effects of therapy. Pain relief is a key component of care, as is counselling for the woman and family. Encourage the woman to perform self-care and resume normal activities of daily living.

Acute pain

Total abdominal hysterectomy can involve severe and prolonged pain, not only from the surgical incision but also from the manipulation of internal organs during surgery. Abdominal viscera are highly vascular and are easily bruised by handling.

- Encourage the woman to report her pain. *This will allow a nursing assessment to be undertaken and effective pain relief to be administered.*
- Administer analgesics. *Analgesics provide pain relief and promote early ambulation.*
- Encourage ambulation. *Ambulation facilitates the expulsion of flatus, which can cause distension as well as discomfort.*

Disturbed body image

For many women, the side effects of cancer treatment can be almost as difficult and painful as the disease itself. Although side effects of the different therapies vary between individuals, the woman's body image and quality of life are always

affected. Such side effects as alopecia (hair loss), nausea, vomiting, fatigue, diarrhoea, stomatitis and surgical scarring disturb body image.

- Encourage the woman to verbalise her feelings. *This allows the nurse to work with the woman on her emotional wellbeing.*
- Review the side effects of the proposed treatment regimen and assist the woman to develop a plan to deal with these effects. *This promotes a sense of control.*
- Suggest to the woman and family that side effects are usually manageable and may be temporary. *Over-the-counter agents can be used to alleviate stomatitis. Frequent rest periods can relieve fatigue. Medications can be prescribed for nausea, vomiting and diarrhoea.*

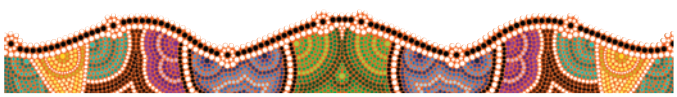
Ineffective sexuality pattern

Altered sexuality may result from a feeling of unattractiveness, fatigue or pain, and discomfort. The woman's partner may fear that sexual activity will be harmful.

- Encourage expression of feelings about the effect of cancer on their lives and sexual relationship. *Verbalising feelings helps relieve stress and maximises relaxation.*
- Suggest that the couple explore alternative sexual positions and coordinate sexual activity with rest periods and times that are relatively free from pain. *This creates a more favourable environment for satisfying sexual activity.*

Community-based care

Provide information about the specific treatment and prognosis for the cancer. Explain the expected side effects of radiation implant therapy (see Chapter 13). Pain control measures are also an essential part of the health education plan (see Chapter 8). The resources listed for the woman with cervical cancer are also appropriate for the woman with endometrial cancer.



THE WOMAN WITH OVARIAN CANCER

Ovarian cancer is the ninth most common cancer diagnosed in women in Australia. There is a one in 78 chance of being diagnosed with ovarian cancer before the age of 85. More than 1200 women are diagnosed each year (Cancer Council Australia, 2013).

Risk factors

Family history is a significant risk factor, with a 50% risk of developing the disease if two or more first- or second-degree relatives have site-specific ovarian cancer. Other types of inherited risk are breast–ovarian cancer syndrome (first- and second-degree relatives have both breast and ovarian cancer) and family cancer syndrome (Lynch syndrome II), in which male or female relatives have a history of colorectal, endometrial, ovarian, pancreatic or other types of cancer. The breast cancer susceptibility genes BRAC1 and BRAC2 are implicated in 5–10% of hereditary ovarian cancers (Cancer Council Australia, 2013).

Risk factors also include having no children or giving birth after age 30, exposure to talc powder prior to 1973 or asbestos, endometriosis, pelvic inflammatory disease and living in a Western industrialised country (Cancer Council Western Australia, 2013). Protective factors include long-term contraceptive use, having a child before the age of 25, tubal ligation, breastfeeding and hysterectomy.

Pathophysiology

There are several types of ovarian cancers: epithelial tumours, germ-cell tumours and gonadal stromal tumours. Most ovarian cancers are epithelial tumours, originating from the surface epithelium of the ovary. Ovarian cancer usually spreads by local shedding of cancer cells into the peritoneal cavity and direct invasion of the bowel and bladder. Cancer cells in peritoneal fluid can implant in the intestines, bladder and mesentery. Tumour cells also spread through the lymph and blood to such organs as the liver and across the diaphragm to involve the lungs. Both pelvic and para-aortic lymph nodes may be involved and tumour cells can block lymphatic drainage from the abdomen, resulting in ascites. Staging for ovarian cancer is based on surgical and histological evaluation (see Table 48.4).

Manifestations

In early stages, ovarian cancer generally causes no warning signs or symptoms. When symptoms do develop, they are often vague and mild, such as indigestion, urinary frequency, abdominal bloating and constipation. Abnormal vaginal bleeding may occur if the endometrium is stimulated by a hormone-secreting tumour or if the tumour erodes the vaginal wall. Pelvic pain sometimes occurs. An enlarged abdomen with ascites signals later-stage disease.

Complications

The complications of advanced ovarian cancer, with related nursing assessments and treatment, are outlined in Table 48.5.

TABLE 48.4 FIGO staging classification for ovarian cancer

STAGE	DESCRIPTION
I	Growth limited to the ovaries
II	Growth involving one or both ovaries with pelvic extension
III	Tumour involving one or both ovaries, with peritoneal implants outside the pelvis or positive retroperitoneal or inguinal nodes
IV	Growth involving one or both ovaries with distant metastasis

TABLE 48.5 Complications of advanced ovarian cancer

COMPLICATION	ASSESSMENTS	TREATMENT
Ascites (accumulation of fluid in the abdominal cavity; a form of third spacing)	• Abdominal distension • Shiny abdominal skin • Dullness on percussion of dependent areas • Dyspnoea, constipation • Abdominal pain	Paracentesis (removing fluid from the abdomen)
Intestinal obstruction	• Abdominal distension • Abdominal pain • Projectile vomiting • Constipation • Hyperactive bowel sounds	Nasogastric tube insertion, NBM
Deep venous thrombosis	• Leg oedema • Leg pain • Redness, warmth	Anticoagulants
Lymphoedema (leg)	• Oedema of leg • Decreased range of motion • Tight, shiny skin on leg	Skin care, range-of-motion (ROM) exercises, massage or physical therapy, compression bandaging

INTERPROFESSIONAL CARE

As with other malignancies, care of the woman with ovarian cancer is focused on surgery to determine the stage of the tumour and to remove as much of the tumour as possible. Unfortunately, because there are no early symptoms, the disease is often well advanced prior to diagnosis. In younger women an ovarian mass may be monitored for several menstrual cycles, but any ovarian mass must immediately be investigated in a postmenopausal woman.

Diagnosis

Tests used in the diagnosis of ovarian cancer may include transvaginal or abdominal ultrasound and a CT scan of the abdomen and pelvis. (See Chapter 46 for further information about diagnostic tests.)

The blood test most useful is a CA-125 antigen level. CA-125 is a tumour marker that is highly specific to epithelial ovarian cancer. Transvaginal or transabdominal ultrasonography is used to measure ovarian size and detect small masses. These tests, however, are not appropriate screening measures because they cannot differentiate between cystic or benign ovarian masses and malignancy.

Medications

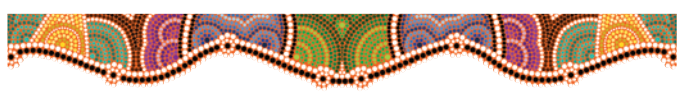
While surgery is the treatment of choice for ovarian cancer, chemotherapy may be used to achieve remission of the disease. Chemotherapy is not curative for ovarian cancer. Combination chemotherapy regimens using cyclophosphamide and cisplatin or other agents may be employed. Combination therapy with a platinum compound (cisplatin or carboplatin) is superior to treatment with a single medication, with paclitaxel/carboplatin the preferred regimen (Martin, 2005). Chemotherapy with paclitaxel (Taxol) may prolong survival. Close monitoring of bone marrow and renal function is vital while the woman is on chemotherapy because these medications have significant toxic effects.

Surgery

In young women with stage I disease who wish to have children, treatment may be limited to removal of one ovary. Usually, however, total hysterectomy with bilateral salpingo-oophorectomy (removal of the ovaries and fallopian tubes) and removal of the omentum are performed.

Radiation therapy

Radiation therapy using external-beam or intracavitary implants is performed for palliative purposes only and is directed at shrinking the tumour at selected sites.



Nursing care

Nursing care for the woman with ovarian cancer is similar to the nursing care for women with other gynaecological cancers. The side effects of treatment of cancer and generally poor prognosis diminish the woman's quality of life and involve major psychosocial implications (see Chapter 13).

Community-based care

Address the following topics in preparing the woman and her family for self-care:

- If a positive family history of the disease or previous breast cancer exists, stress the importance of obtaining regular pelvic examinations. Inform women in this risk group that annual screening with transvaginal ultrasound and CA-125 measurements may be recommended.

- Long-term use of oral contraceptives may reduce the risk of developing ovarian cancer.
- It is crucial not to ignore symptoms such as indigestion, nausea or urinary frequency, because these seemingly unrelated symptoms may be early signs of ovarian tumours. Emphasise, however, that ovarian cancer usually is asymptomatic in early stages.
- Discuss treatment options and their side effects and provide information on ways to minimise or manage side effects.
- Refer to hospice services when appropriate. The resources suggested for the woman with cervical cancer are also appropriate for the woman with ovarian cancer.

THE WOMAN WITH CANCER OF THE VULVA

Cancer of the vulva is rare, occurring in two in 100 000 women in Australia. It usually occurs in postmenopausal women. However, there has been an increase of vulvar cancer in women under 50 years of age. It has been identified that for Indigenous women living in remote rural areas it is 50 times more common than it is for the non-Indigenous population (Condon, 2010). The prognosis of vulvar carcinoma depends on the degree of invasion, general health status of the woman, presence of chronic diseases and ability to withstand treatment.

Pathophysiology

The cause of vulvar cancer is unknown, but there is evidence to associate it with STIs, particularly HPV. Nearly 85% of malignant and premalignant cervical and vulvar lesions have been found to contain HPV DNA, HPV structural antigens or both. Herpes simplex type 2 (HSV2) infection has also been associated with vulvar cancer. Other risk factors include advanced age, diabetes and a history of leucoplakia (a precancerous lesion on the vulvar mucous membranes characterised by raised white patches).

Most vulvar cancers are epidermoid or squamous cell carcinomas. The primary site is usually the labia majora, but vulvar cancer is also found on the labia minora, clitoris, vestibule and occasionally in multiple locations. Metastasis occurs by direct extension into the vagina, perineal skin, anus and urethra. The cancer also spreads through the lymphatic system via the superficial and deep inguinal and femoral nodes and to the pelvic lymph nodes.

Manifestations

The woman with vulvar cancer is often asymptomatic and lesions are discovered on routine examination or self-examination. Discolouration can vary from white macular patches to red painless sores. Lesions may be *exophytic* (proliferating outwardly), *endophytic* (proliferating inwardly), *ulcerative* or *verrucous* (resembling a wart).

Pruritus (itching) is the most common manifestation and the woman often has had a history of prolonged vulvar irritation. Perineal pain and bleeding indicate large tumours and advanced disease. In very advanced disease, dysuria related to urethral involvement may be the presenting symptom.

INTERPROFESSIONAL CARE

The report of itching, burning or a sore on the vulva merits careful investigation and biopsy of any lesions found. Inguinal lymph nodes may be enlarged. The goal of care is to eradicate the lesion and reduce the risk of recurrence. Surgical resection is the preferred treatment. If lymph nodes are involved, radiation therapy is used postoperatively. Chemotherapy is reserved for distant metastases.

Diagnosis is based on the results of an excisional biopsy of the lesion. Metastasis, if suspected, can be evaluated by chest x-ray examination, barium enema, intravenous pyelogram, cystoscopy, CT and MRI scans, and proctoscopy. Lymphangiography can also be used.

Surgery is the most common treatment for vulvar cancer. The specific procedure depends on the stage of the cancer. Early, non-invasive lesions may be treated with laser surgery, cryosurgery or electrocautery. For more advanced disease, vulvectomy may be performed (see Figure 48.6). A simple vulvectomy involves the removal of the vulva, labia majora and minora, clitoris and prepuce. A radical vulvectomy is performed if invasion is suspected. This procedure involves removal of all the tissue in a simple vulvectomy, as well as the subcutaneous tissue and regional lymph nodes.

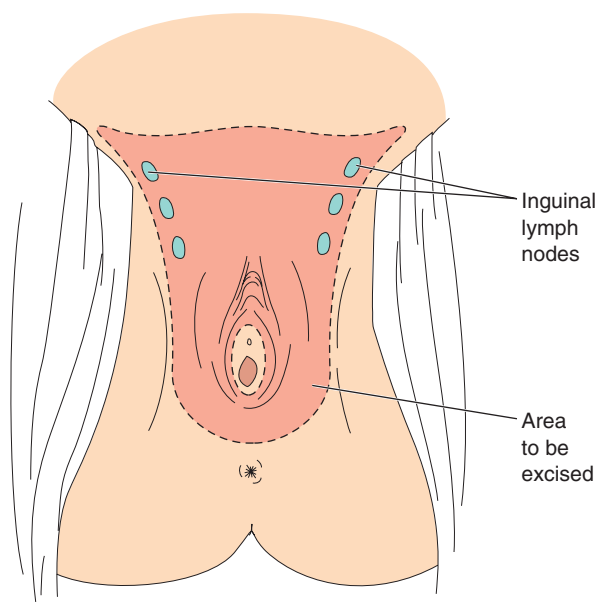


FIGURE 48.6 ■ Vulvectomy for vulvar carcinoma. A radical vulvectomy involves removal of the vulva, labia majora, labia minora, clitoris, prepuce, subcutaneous tissue and regional lymph nodes

Nursing care

Nursing care is similar to that for the woman with endometrial cancer. The woman fears death as the ultimate outcome, as well as the possible pain and suffering that surgery and other treatments may cause. Radical surgery represents a great emotional loss to women of all ages.

Nursing diagnoses and interventions

- Women who have been diagnosed with cancer of the vulva and are undergoing treatment will need to be supported. A mental health assessment for anxiety, coping strategies and emotional wellbeing will need to be undertaken. The disruption of perineal tissues is a priority issue for these women. Pain, discomfort and altered body image would also impact on the woman's wellbeing.

Impaired tissue integrity

The woman who has undergone a vulvectomy is at high risk of infection and impaired healing because of the proximity of the surgical site to urinary and anal orifices. In addition, the women are often older and may have age-related changes in healing and immune function.

- Educate the woman and/or her partner or other family member on the procedure for irrigation of the vulvectomy. *If neither is able to perform this procedure, arrange for home health nursing. Irrigation helps prevent skin breakdown and infection.*
- After irrigation, dry the area; a hairdryer on low heat may be used (Cancer Council NSW, 2014). *Dry heat helps promote healing and comfort.*
- Provide information on maintaining a diet high in protein, iron and vitamin C. *These nutrients promote collagen formation and wound healing.*

Community-based care

Health education for the woman undergoing a vulvectomy should emphasise the potential for skin breakdown, particularly with radiation therapy. Explain that removal of lymph nodes leads to lymphoedema and that recurrent cellulitis and sexual dysfunction are common complications of vulvar cancer.

THE PERIMENOPAUSAL WOMAN

MENOPAUSE

Menopause is the permanent cessation of menses. The *climacteric*, or *perimenopausal*, period denotes the time during which reproductive function gradually ceases. For most women, the perimenopausal period lasts several years. It begins with a decline in the production of the hormone oestrogen, includes the permanent cessation of menstruation due to loss of ovarian function, and extends for 1 year after the final menstrual period, at which time a woman is said to be *postmenopausal*. On average, women live one-third of their lives after menopause.

Menopause is a normal physiological process. It is not a disease or a disorder. It is included here because it does increase the risk of physical disorders, as well as affecting various aspects of women's health. Many women welcome the freedom from monthly menstrual periods and have relatively minor physical effects from the reduction in oestrogen. However, the hormonal changes that occur can be accompanied by side effects. There is wide variation in how individual women experience these side effects. In Australia, most women cease menstruating at between 48 and 55 years of age, with the average being about 50 or 51 years. Early menopause is when a woman stops menstruating before 45 years of age. In 50% of cases of early menopause there are no known causes. However, early menopause is associated with surgical removal of the ovaries, chemotherapy and radiotherapy (Jean Hailes Foundation, 2014). After menopause certain health risks increase, including heart disease, osteoporosis, macular degeneration, cognitive changes and breast cancer.

The physiology of menopause

The menopausal period marks the natural biological end of reproductive ability. *Surgical menopause* occurs when the ovaries are removed in premenopausal women, dramatically reducing the production of oestrogen and progestins. *Chemical menopause* often occurs during cancer chemotherapy, when cytotoxic medications arrest ovarian function.

As ovarian function decreases, the production of oestradiol (E2) decreases, and is ultimately replaced by oestrone as the main ovarian oestrogen. Oestrone is produced in small amounts and has only about one-tenth the biological activity of oestradiol. With decreased ovarian function, the second ovarian hormone, progesterone, is also markedly reduced.

Manifestations

As oestrogen decreases, various tissues are affected, and breast tissue, body hair, skin elasticity and subcutaneous fat decrease. The ovaries and uterus become smaller and the cervix and vagina also decrease in size and become pale in colour. These changes may result in problems with vaginal dryness, dyspareunia, urinary stress incontinence, urinary tract infections (UTIs) and vaginitis. Hot flushes, palpitations, dizziness and headaches are often caused by vasomotor instability. Other problems resulting from vasomotor instability include insomnia, frequent awakening and perspiration (night sweats). The woman may experience irritability, anxiety and depression as a result of these events.

MANIFESTATIONS The perimenopausal period

- Menstrual cycles become unpredictable. Menstrual flow varies widely in amount and duration and eventually ceases.
- Vaginal, vulval and urethral tissues begin to atrophy.
- Vaginal pH rises, predisposing the woman to bacterial infections.
- Vaginal lubrication decreases and vaginal rugae decrease in number. This may result in dyspareunia, injury and fungal infections.
- Vasomotor instability due to a decrease in oestrogen may result in hot flushes and night sweats. A hot flush starts in the chest and moves upwards towards the face, and may last from seconds to several minutes.
- Psychological symptoms may include moodiness, nervousness, insomnia, headaches, irritability, anxiety, inability to concentrate and depression.

Long-term oestrogen deprivation results in an imbalance in bone remodelling and osteoporosis, leading to fractures and kyphosis. The risk of cardiovascular diseases increases in response to an increase in atherosclerosis (from an increase in the LDL-to-HDL cholesterol ratio). Symptoms of the perimenopausal period are listed in the following box. These symptoms vary widely. Some women experience few or no symptoms, others experience moderate symptoms and some women experience severe symptoms.

INTERPROFESSIONAL CARE

Care of the woman experiencing menopausal symptoms focuses on relieving symptoms and minimising postmenopausal health risks.

Diagnosis

As oestrogen secretion diminishes, levels of FSH and LH rise and remain elevated. A woman who has not menstruated for 1 full year or who has an increased FSH blood level is considered menopausal.

Medications

Hormone replacement therapy may be prescribed to alleviate severe symptoms of menopause, but only for a limited amount of time and only after a woman has been provided with information about known risks. HRT may include oestrogen alone for women who have had a hysterectomy, or a combination of oestrogen and progestin for women who still have their uterus. The addition of progestin stimulates monthly shedding of the interuterine lining, decreasing the risk of uterine cancer. HRT relieves hot flushes and night sweats, and decreases problems of vaginal dryness and urogenital tissue atrophy, which can lead to painful intercourse and urinary incontinence. Long-term HRT may increase the risk of breast cancer, ovarian cancer, stroke and venous thrombosis (Mayo Foundation for Medical Education and Research, 2015). However, women who have had a hysterectomy and take oestrogen alone do not have an increased risk of breast cancer (Lancet Oncology, 2012).

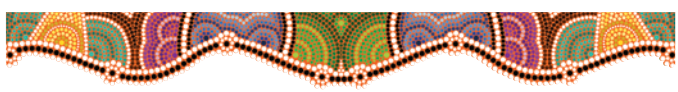
Selective oestrogen receptor modulators (SERMs), such as raloxifene (Evista) and tamoxifen, bind to oestrogen receptors and exert site-specific effects in different target tissues. Tamoxifen and toremifene (a derivative of tamoxifen) have a beneficial effect on bone mineral density, and serum lipids and decrease the risk of invasive breast cancer in women at high risk. They also provide an alternative to HRT for preventing osteoporosis.

Alternative and complementary therapies

Non-traditional or alternative therapies have become popular as a result of the controversy surrounding the use of HRT. The following complementary therapies are examples of those used by menopausal women to reduce associated discomfort:

- acupuncture
- biofeedback
- massage
- herbs such as *Cimcifuga racemosa* (black cohosh), *Vitex agnus castii* (chasteberry), *Rehmannia*, ginseng, the Chinese tonics he shou wu and dong quai, golden seal, flaxseed and evening primrose
- supplements such as vitamin E and soy protein (soy is high in plant oestrogens)
- meditation and yoga.

However, there is little reliable research available on the effect of soy, primrose oil, black cohosh or other herbs on decreasing hot flushes or sleep disturbances. However, exercise such as yoga or walking will assist women to maintain a healthy lifestyle and may combat some of the side effects of menopause (Women's Health Queensland Wide Inc., 2013).



Nursing care

Nursing care focuses on educating the woman about implementing lifestyle changes that are important to her health and wellbeing. These will assist women to minimise the symptoms associated with hormonal changes, reducing the risk of cardiovascular disease, cancer and osteoporosis.

Health promotion

National screening programs are available in Australia for various cancers, such as breast, bowel and cervical (Department of Health, 2015). It is a good idea, especially as people age, to have regular health assessments. A health assessment includes examination for cancers of the thyroid, ovaries, lymph nodes, oral cavity and skin. Other important health assessments include screening for cervical, breast and colorectal cancer. Health counselling should also include information about alcohol and tobacco use, sun exposure, diet and nutrition, exercise, risk factors, sexual practices, mental and emotional wellbeing, and environmental and occupational exposures. It is important to discuss the benefits of rest and exercise, as well as a diet that includes fruit, vegetables and

fibre. In addition, suggest the following resources for further information:

- Women's Health Australia: www.alswh.org.au

  - *Alternatives to HRT fact sheet:* www.womhealth.org.au/conditions-and-treatments/alternatives-hrt-fact-sheet
  - Women's Health Queensland Wide Inc. (middle years): www.womhealth.org.au/resources/book-library/30-middle-years

Assessment

Undertake a thorough health history and physical examination. When assessing the older woman, be aware of normal changes with ageing, as outlined in Chapter 46.

- *Health history:* problems with urinary frequency, urgency or incontinence; menstrual history; sexual history; dyspareunia; use of alcohol, nicotine and illicit drugs; medications, sleep patterns, hot flushes, night sweats, changes in emotional responses.
- *Physical assessment:* height and weight; posture; vital signs; abdominal assessment; with verbal consent, breast examination and pelvic examination.

Nursing diagnoses and interventions

Although each nursing care plan must be individualised, interventions often focus on physical problems. There is often a lack of information on sexuality, self-esteem, emotional well-being and body image.

Deficient knowledge

Menopausal symptoms vary widely. However, the well-informed woman is better prepared to deal with whatever symptoms she experiences.

Discuss physiological symptoms, such as hot flushes and night sweats. The underlying cause of hot flushes is not known. As previously discussed, many physiological effects of menopause are responsive to non-pharmacological methods of relief, such as lifestyle changes.

CONSIDERATION FOR PRACTICE

When hot flushes occur at night and are accompanied by perspiration, they are called night sweats. Night sweats often interfere with normal sleep patterns, leading to increased tiredness and irritability.

- Provide information to the woman about dietary recommendations. The recommended daily intake of calcium for women over 50 is 1200 mg. *Some women need to use calcium supplements or calcium-containing antacid tablets to meet this requirement.*
- Emphasise the importance of weight-bearing exercise. *Weight-bearing exercise reduces the rate of bone loss, helps maintain optimum weight and reduces cardiovascular risk.*
- Provide information about the benefits and risks of HRT. Not every woman will need or want it. *Every woman needs to understand both the risks and the benefits before deciding whether to use HRT.* To assist health professionals and individuals to whom they provide care to make informed choices regarding HRT, there are various web-based resources available.
- Encourage the woman to perform monthly breast self-examination (BSE) on the same day each month, and to have a mammogram and a cervical screening every 2 years (Department of Health, 2015). In May 2017, a new cervical screening program will be introduced in Australia. A primary human papillomavirus (HPV) test will replace the Pap smear test for cervical screening. It is recommended that a HPV test be performed every 5 years on women between the ages of 25 and 74 years of age (Department of Health, 2015).

Ineffective sexuality pattern

Vaginal dryness and atrophy, together with the emotional effects of menopause, can interfere with sexual expression and satisfaction. Suggesting measures to help the woman and her partner cope with these changes can enable them to continue or resume a mutually satisfying sexual relationship.

- Encourage expression of feelings and concerns about how menopause is changing the woman's sex life. *The woman may not be comfortable in discussing their intimate sexual behaviour.*
- Suggest ways to increase vaginal lubrication, such as spending more time in foreplay and/or using water-soluble gels (e.g. K-Y jelly) for vaginal lubrication. A more leisurely approach to sexual activity can be mutually gratifying for both the woman and her partner. *Use of water-soluble gels can prevent vaginal pain and irritation, and improve the quality of the sexual experience.*
- Explain that as women age, it may take longer for vaginal lubrication and orgasm to occur. *This information is important to prevent the woman from believing something is wrong with her, or her partner believing she is no longer interested or sexually exciting.*
- Inform about changes in the sexual responsiveness of male partners. Difficulty in achieving an erection or maintaining an erection occurs in one in five Australian men over the age of 40 (Andrology Australia, 2015).

Situational low self-esteem

Each woman responds to the ageing process in her own way. Most women have coping skills that adequately equip them to deal with the gradual changes associated with ageing. Factors that may provoke a lowered self-esteem are the loss of youth, a sense of emptiness as children leave home and the need to redefine one's self-concept and roles as parenting becomes less important. Women who place a high value on their physical attractiveness may experience a painful psychological response to the physical changes of menopause.

- Encourage expression of fears and concerns related to changes in interpersonal and family functions. *Many women associate ageing with 'uselessness' and unattractiveness.*
- Suggest volunteer activities or employment for the woman who has extra time. *This enables the woman to feel that she is still a contributing member of society.*
- Discuss the importance of a healthy lifestyle in maintaining physical attractiveness. Identify risk factors and high-risk behaviours. *Lifestyle habits and behaviours affect many body systems and physical appearance. For example, cigarette smoking and overexposure to the sun make the skin age faster, contributing to wrinkles.*

Disturbed body image

As a woman progresses through the perimenopausal period, changes in her appearance and the loss of childbearing ability may combine to make her feel vulnerable to community stereotyping of the 'older woman' as less attractive and unproductive. Although this is far from the truth, with women living at least one-third of their lives after menopause in productive careers and activities, it nevertheless is the perception of women as well as society. The physical changes the woman often experiences include growth of facial hair, excessive perspiration and flushing of the face, and weight gain.

- Encourage the woman to describe her perceptions of her own body. *This information is necessary to obtain data to establish an individualised plan of care.*
- Encourage verbalisation of feelings of concern, anger, anxiety, loss and fear over body changes. *Expressing these emotions can facilitate the grieving process and acceptance of change.*
- Stress that certain physical characteristics of a person cannot be changed; emphasise the importance of learning to recognise and appreciate one's own special strengths. *These help the woman gain acceptance and have a realistic appraisal of self.*
- Refer, as appropriate, for dietary management, exercise, sleep studies, stress management and cosmetic assistance (e.g. for aggravating facial hair). *These actions increase wellness and a positive sense of self.*

DISORDERS OF THE BREAST

Breast disorders are common conditions that primarily affect women. (Disorders of the male breast are discussed in Chapter 47.) When a woman discovers a breast lump, her first response is often fear: of breast cancer, of losing her breast and perhaps of losing her life. As many societies view the breast as a significant component of feminine sexuality, any problem that threatens the breast often strikes at the core of a woman's self-image.

Nurses play a critical role in the care of women experiencing breast disorders by providing education, support and advocacy. Part of the nurse's role is educating women about normal breast tissue, common benign breast disorders, available screening techniques and risk factors for breast cancer, and breast self-examination (BSE).

THE WOMAN WITH A BENIGN BREAST DISORDER

Benign breast disorders occur frequently in women and may be a source of anxiety. Changes in a woman's breast tissue often correspond to hormonal changes of the menstrual cycle. Most women notice increased tenderness and lumpiness prior to menses. (For this reason, it is best to perform BSE 7 to 10 days after the beginning of the menstrual period.) Breast tissue changes in response to hormonal, nutritional, physical and environmental stimuli. Benign breast disorders include fibrocystic breast changes, fibroadenomas, intraductal papillomas, duct ectasia, fat necrosis and mastitis (see Table 48.6).

Pathophysiology and manifestations

Fibrocystic changes

Fibrocystic changes (FCC) (*fibrocystic breast disease*) are the physiological nodularity and breast tenderness that increase and decrease with the menstrual cycle. An estimated 60% of all women experience some of these changes, which include fibrosis, epithelial proliferation and cyst formation. FCC is most common in women 30 to 50 years of age (Centre of Health, 2015) and is rare in postmenopausal women who are not taking HRT.

FCC includes many different lesions and breast changes. The more common non-proliferative form does not increase the risk of breast cancer. The proliferative form, accompanied by giant cysts and proliferative epithelial lesions, does increase the risk of breast cancer.

Non-proliferative changes may be cystic or fibrous. Cystic change refers to the dilation of ducts in the subareolar, lobular or lobe areas. Cysts often go unnoticed unless pain and tenderness is associated with menses. Fibrous changes are infrequent but can occur during the menstrual years. A firm, palpable mass, 2–3 cm in size, is typically located in the upper outer breast quadrant following an inflammatory response to ductal irritation.

Women with fibrocystic changes experience bilateral or unilateral pain or tenderness in the upper, outer quadrants of their breasts and report that their breasts feel particularly thick and lumpy the week prior to menses. Nipple discharge may be present. Pain is due to oedema of the connective tissue of the

TABLE 48.6 Summary of common breast disorders

CONDITION	AGE	PAIN	NIPPLE DISCHARGE	LOCATION	CONSISTENCY AND MOBILITY	DIAGNOSIS AND TREATMENT
Duct ectasia	35 to 55 years; median age 40	Burning around nipple	Sticky; multicoloured; usually bilateral	No specific location	Retroareolar mass with advanced disease	Open biopsy; local excision of diseased portion of breast
Fibroadenoma	15 to 39 years; median age 20	No	No	No specific location	Mobile, firm, smooth, well-delineated mass	Mammography; surgical or needle biopsy; excision of the tumour
Fibrocystic changes (FCC)	20 to 49 years; median age 30 (may subside with menopause)	Yes	May occur	Upper outer quadrant	Bilateral multiple lumps influenced by the menstrual cycle	Needle aspiration; observation; biopsy if there is an unresolved mass or mammographic changes
Intraductal papilloma	35 to 55 years; median age 40	Yes	Serous or sanguineous; usually unilateral from one duct	No specific location	Usually soft, poorly delineated mass	Pap smear of nipple discharge; biopsy; wedge resection
Mastitis, acute	Childbearing years	Tenderness; pain	No	No specific location	Generalised redness of overlying skin	Antibiotic therapy; incision and drainage if mastitis progresses to an abscess
Mastitis, chronic	Any age	Tenderness, pain; headache; high fever	No	No specific location	Generalised redness and swelling	Antibiotics, usually penicillin
Fat necrosis	Any age	Tenderness	No	No specific location	Firm; irregular; palpable	Surgical biopsy to rule out cancer

breast, dilation of the ducts and some inflammatory response; some women report an increase in breast size. Multiple, mobile cysts may form, usually in both breasts (see Figure 48.7). Fluid aspirated from these cysts ranges in colour from milky white to yellow, brown or green. If the fluid is tinged with blood, there is reason to suspect malignancy.

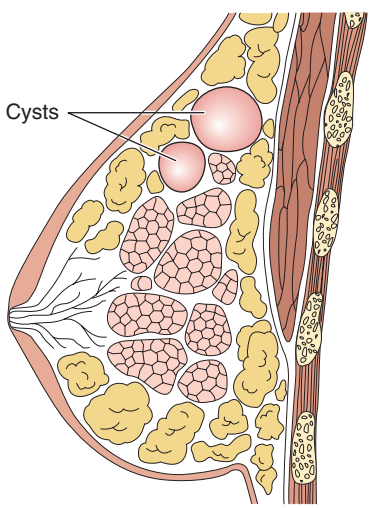

FIGURE 48.7 ■ Fibrocystic breast changes

Intraductal disorders

An *intraductal papilloma* is a tiny, wart-like growth on the inside of the peripheral mammary duct that causes discharge from the nipple. The discharge may be clear and sticky or bloody. When more than one of these growths is present, the condition is called *intraductal papillomatosis*. This condition is most common in women in their 40s (Breast Cancer Care, 2015). The lesion must be investigated to rule out malignancy.

Mammary duct ectasia (*plasma cell mastitis*) is a palpable lumpiness found beneath the areola. Duct ectasia involves periductal inflammation, dilation of the ductal system and accumulation of fluid and dead cells that block the involved ducts. The condition usually occurs in perimenopausal women and is difficult to differentiate from cancer.

Symptoms of mammary duct ectasia include sticky, thick nipple discharge with burning and itching around the nipple and inflammation. The discharge may be green, greenish brown or bloody. Nipple retraction often is associated with duct ectasia in postmenopausal women.

INTERPROFESSIONAL CARE

Diagnosis of FCC is based on complete history, physical examination and imaging studies. A biopsy may be required for diagnosis.

Analysis of nipple discharge, mammography and possibly ductography may be used to diagnose ductal disorders. The affected duct is excised in an open biopsy procedure. Nursing care for the woman is similar to that for any person with an open biopsy. It also is important to reassure the woman that these disorders are not breast cancer.

The treatment is usually symptomatic. Cyst aspiration may relieve pain and also allows examination of fluid to confirm the cystic nature of the disease. A well-fitting bra, often one without underwire, that provides good support worn day and night helps relieve discomfort. Some women report that eliminating xanthines (found in coffee, tea, cola and chocolate) from the diet decreases symptoms. Aspirin, mild analgesics, local heat or cold, and vitamin E may help relieve breast pain. Hormone therapy is controversial because of the benign nature of the disease and potential adverse effects of therapy. Danazol, a synthetic androgen, may be prescribed for women with severe pain.

Nursing care

When a woman presents with a breast mass, nursing responsibilities include taking a careful physical and mental health history and facilitating follow-up care. If a palpable mass is present, it is important to ask how long the lesion has been present and whether the woman has noticed any pain associated with the mass, any change in its size and any changes in association with the menstrual cycle.

In many cases, definitive diagnosis of the breast disorder requires surgical biopsy to rule out cancer. During the diagnostic process, the nurse should provide emotional support and health education about diagnostic and therapeutic procedures, self-care and comfort measures, and resources to help the woman discuss her feelings and cope with the experience.

THE WOMAN WITH BREAST CANCER

Breast cancer is the unregulated growth of abnormal cells in breast tissue. Breast cancer is the third most common invasive cancer in Australia. The Australian Government estimated that more than 15 740 new cases would be diagnosed in 2015, consisting of 145 males and 15 600 women. One in eight women and one in 719 men under the age of 85 are at risk of being diagnosed with breast cancer (Cancer Australia, 2015c). There are racial differences in the incidence and mortality of breast cancer (see the 'Focus on cultural diversity' box).

FOCUS ON CULTURAL DIVERSITY Incidence and mortality for breast cancer in women

- Breast cancer is more prevalent in non-Indigenous Australian women than Indigenous Australian women.
- Breast cancer is more prevalent in Caucasian women over the age of 40 years.
- Indigenous Australian women are more likely to die from breast cancer because they are often diagnosed at an advanced stage as they are less likely to participate in breast screening (Cancer Australia, 2015d).

Risk factors

Of the various kinds of risk factors for breast cancer, some can be changed and some cannot. Those that cannot be changed are:

- *Age and gender.* Women are 100 times more likely to have breast cancer than men, with the risk increasing with age. See the 'Nursing care of the older woman' box below.
- *Genetic risk factors* (discussed below).
- *Family history of breast cancer*. Relatives from either the maternal or the paternal side of the family. The risk is greater if two or more relatives have been diagnosed with breast cancer. Although women who have a first-degree relative who has experienced breast cancer are at an increased risk, most do not develop breast cancer. If these women do develop breast cancer, they are likely to be aged over 50. Having a male family member with breast cancer also poses an increased risk.
- *Personal history of breast cancer.* A woman with cancer in one breast has a three- to five-fold increase in risk of developing a new cancer in the other breast or in a different part of the same breast.
- *Previous breast biopsy.* If earlier breast biopsies were diagnosed as proliferative, then breast disease without atypical hyperplasia increases risk by 1.5 to 2 times. A previous biopsy of atypical hyperplasia increases risk by 4 to 5 times.
- *Previous chest irradiation.* Radiation of the chest as a child or young woman for other cancer (such as Hodgkin's disease) significantly increases the risk.
- *Menstrual history.* Women who begin menstruating before the age of 12 or who have menopause after the age of 50 are at a slightly higher risk.

Lifestyle-related factors and breast cancer risk include using oral contraceptives, not having children or having them after the age of 30, using HRT for more than 5 years, not breastfeeding, drinking alcohol (especially two to five drinks daily), obesity, high-fat diets, physical inactivity and (possibly) environmental pollution. Lower risk factors for breast cancer include breastfeeding, moderate or vigorous physical activity, and maintaining a healthy body weight.

Pathophysiology

Possible causes of breast cancer include environmental, hormonal, reproductive and hereditary factors. Two breast cancer susceptibility genes have been identified: BRCA1 on chromosome 17 and BRCA2 on chromosome 13. These genes may be responsible for the approximately 10% of women with hereditary breast cancer,

NURSING CARE OF THE OLDER WOMAN with breast cancer

- Although the incidence of breast cancer is increasing in premenopausal women, it is still primarily a disease of older women. However, the needs of older women with breast cancer have been inadequately addressed in the professional literature and in the popular media.
- Women between the ages of 50 and 65 are the group most likely to benefit from screening mammography, yet many women in this age group have never had a mammogram. Failure of health professionals to refer older women for mammography is the reason most frequently cited for this statistic; nurse practitioners and female medical officers are more likely to refer women for mammography.
- For too long, mastectomy was perceived as the only treatment option open to most older women with breast cancer, even those with early-stage disease. Slowly that perception is changing as breast-conservation treatment gains greater acceptance. The choice of surgical treatment, particularly for older women, is highly individual. Many older women wish to preserve their breasts.
- Although older women with breast cancer may experience coexisting chronic illnesses and impaired physical function, research suggests that they show lower levels of emotional distress than younger women. Obviously the need for services such as personal care, shopping, housekeeping and transportation increases as the ages of the woman and the caregiver increase.

with genetic mutations causing up to 80% of breast cancer in women younger than 50 years of age. A woman with identified mutations in BRCA1 (known to be involved in tumour suppression) has a lifetime risk of 56–85% for breast cancer and also has an increased risk of ovarian cancer. Mutations of a tumour suppressor gene are also linked to increased risk of breast cancer.

Cancer of the breast begins as a single transformed cell and is hormone dependent. Cancers of the breast are classified as non-invasive (in situ) or invasive, depending on the penetration of the tumour into surrounding tissue. Breast cancer may remain a non-invasive disease or an invasive disease without metastasis for long periods of time.

Breast cancer may be categorised as carcinoma of the mammary ducts, carcinoma of mammary lobules or sarcoma of the breast. Most breast cancers are adenocarcinomas and appear to arise in the terminal section of the breast ductal tissue. There are many histological types of breast cancer and only examples are described here. The most common type is *infiltrating ductal carcinoma*. Two atypical types of breast cancer are inflammatory carcinoma and Paget's disease. Inflammatory carcinoma of the breast, a systemic disease, is the most malignant form of breast cancer. Oedema with dimpling of the skin that results in the skin looking like the peel of an orange (*peau d'orange*) is usually present. *Paget's disease* is a rare type of breast cancer involving infiltration of the nipple epithelium.

Breast cancer can metastasise to other sites through the bloodstream or lymphatic system. The common sites of metastasis of breast cancer are bone, brain, lung, liver, skin and lymph nodes. Staging is a system of classifying cancer according to the size of the tumour, involvement of lymph nodes and metastasis to distant sites, and the presence/absence of distant metastasis (see Table 48.7). The staging of

TABLE 48.7 Staging of breast cancer

STAGE	TUMOUR	NODE INVOLVEMENT	METASTASIS
0	Tis—Carcinoma in situ or Paget's disease of the nipple	N0—No regional lymph node metastasis	M0—No evidence of distant metastasis
I	T1—Tumour no larger than 2 cm	N0	M0
IIA	T0—No evidence of primary tumour T1 T2—Tumour no larger than 5 cm	N1—Metastasis to movable ipsilateral axillary nodes N0	M0 M0
IIB	T2 T3—Tumour larger than 5 cm	N1 N0	M0 M0
IIIA	T0 T1 T2 T3	N2—Metastasis to ipsilateral fixed axillary nodes N1 N2	M0 M0 M0
IIIB	T4—Tumour of any size with direct extension to chest wall or skin	Any N	M0
	Any T	N3—Metastasis to ipsilateral internal mammary lymph nodes	M0
IV	Any T	N0 and N1	M1—Distant metastasis

the breast cancer provides important information for making decisions about treatment options and is also used as a basis for prognosis.

Manifestations

The symptoms of breast cancer may include a non-tender lump in the breast (most often in the upper outer quadrant, the area with the most glandular tissue), abnormal nipple discharge, a rash around the nipple area, nipple retraction, dimpling of the skin or a change in the position of the nipple (see the box below). There may also be nipple pain, scaliness, ulceration, skin irritation or discharge. Breast cancer is usually painless, but some women report a burning or stinging sensation. Many women with breast cancer have no symptoms and their tumours are detected by mammography. However, most breast cancers are found by the women themselves (during BSE or a shower) or by their partners during sexual activity.

MANIFESTATIONS Breast cancer

- Breast mass or thickening
- Unusual lump in the underarm or above the collarbone
- Persistent skin rash near the nipple area
- Flaking or eruption near the nipple
- Dimpling, pulling or retraction in an area of the breast
- Nipple discharge
- Change in nipple position
- Burning, stinging or pricking sensation

INTERPROFESSIONAL CARE

Diagnosis of breast cancer begins with detection, either detection of asymptomatic lesions discovered through screening or of symptomatic lesions discovered by the woman. Any palpable mass requires evaluation. Once the diagnosis is made, a number of treatment options are available. The choice of treatment depends on several factors, such as the stage of the cancer, the age of the woman, geographical location of the woman and related health services and the woman's preferences.

Diagnosis

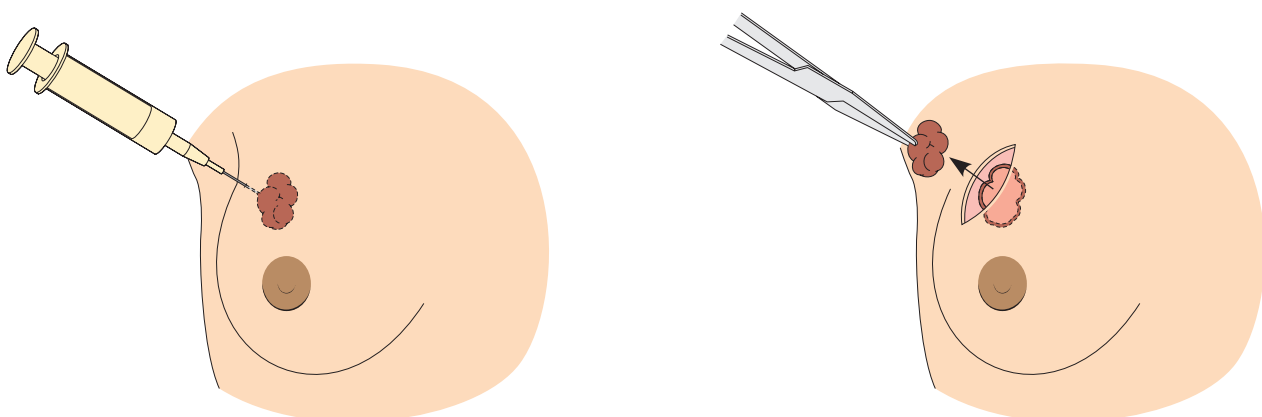
Early detection of breast cancer is possible with clinical breast examination (CBE) and mammogram (see Chapter 46 for further information). Mammography can detect breast tumours 2 years before they reach palpable size; most of these tumours have been present for 8 to 10 years. Cancer Council Australia recommends mammograms every two years for women aged between 50 and 69 years of age, although women from 40 years of age onwards can have free mammograms (Cancer Council Australia, 2015b). Magnetic resonance imaging (MRI) is used for young women who are at risk of breast cancer (Cancer Council Australia, 2015b).

Other diagnostic tests include a percutaneous needle biopsy to define a cystic mass or fibrocystic changes and provide specimens for cytological examination and a breast biopsy. In aspiration biopsy or fine-needle aspiration biopsy, a needle is used to remove cells or fluid from the breast lesion (see Figures 48.8A and 48.8B). The types of breast biopsy and related nursing care are described in Chapter 46. In many facilities, fine-needle aspiration biopsies are performed using a stereotactic biopsy device; mammography and a computer are used to guide the needle.

Medications

Tamoxifen citrate (Nolvadex) is an oral medication that interferes with oestrogen activity. It is used to treat advanced breast cancer, as an adjuvant for early-stage breast cancer and as a preventive treatment for women at high risk of developing breast cancer. Nursing implications for tamoxifen are presented in the 'Medication administration' box below.

Immunotherapy, using trastuzumab (Herceptin), is used to stop the growth of breast tumours that express the HER2/neu



A Aspiration biopsy

B Excisional biopsy

FIGURE 48.8 ■ Types of breast biopsy. *A*, In an aspiration biopsy, a needle is used to aspirate fluid or tissue from the breast. *B*, In an excisional biopsy, tissue from the breast lesion is removed surgically

MEDICATION ADMINISTRATION Tamoxifen

TAMOXIFEN (NOLVADEX)

Tamoxifen is the most widely prescribed breast cancer medication, commonly given to prevent recurrence of oestrogen-positive breast cancer in postmenopausal women. It inhibits tumour growth by blocking the oestrogen receptor sites of cancer cells. Tamoxifen increases a woman's risk of developing endometrial cancer, deep venous thrombosis (DVT) and pulmonary embolism.

Nursing responsibilities

- Assess for potential contraindications to therapy.
- Assess liver function tests; tamoxifen may interfere with liver function.

Health education for the woman and family

- If in childbearing years, use a non-hormonal, barrier form of contraception; tamoxifen has adverse effects on the developing foetus.
- Take the medication as prescribed until the doctor indicates otherwise.
- Side effects such as hot flushes, vaginal dryness, irregular periods and weight gain are commonly experienced by women taking tamoxifen.
- If you are a smoker, stop. Smoking further increases the risk of DVT and is linked to the development of cancer.
- Promptly report any abnormal vaginal bleeding (non-menstrual bleeding, bleeding after menopause) to your primary care provider.

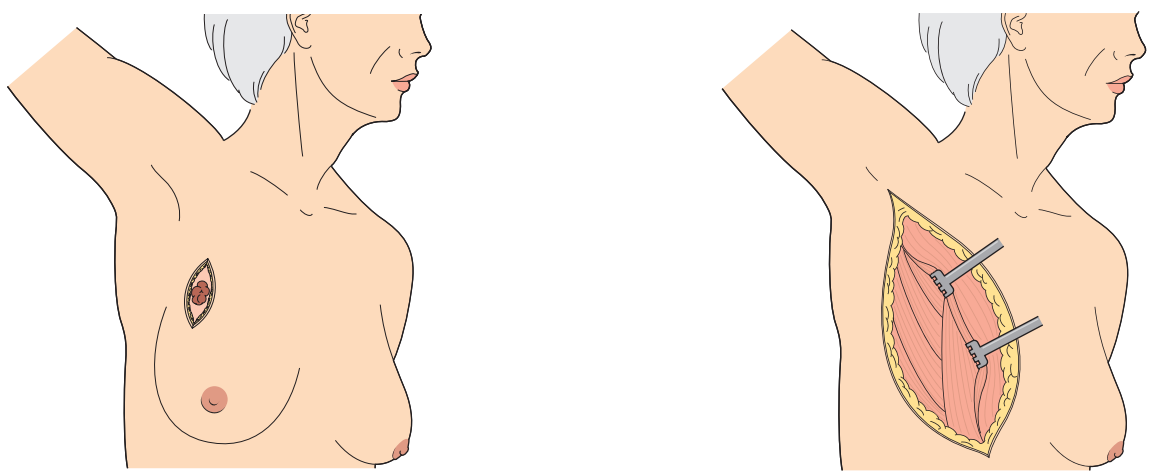
receptor (which binds an epidermal growth factor that contributes to cancer cell growth) on their cell surface. This medication is a recombinant DNA-derived monoclonal antibody that binds to the receptor, inhibiting tumour cell proliferation.

Chemotherapy has become the standard of care for the majority of breast cancer cases with axillary node involvement. In late metastatic disease, chemotherapy becomes the primary treatment to prolong the woman's life. Chemotherapy is discussed in Chapter 13. Adjuvant (additional) systemic therapy following primary treatment for early-stage breast cancer refers to the administration of chemotherapy and other pharmacological agents. This type of therapy has been widely studied; its use reduces the rates of recurrence and death from breast cancer. For example, bevacizumab (Avastin), when combined with chemotherapy to treat metastatic breast cancer, has extended cancer-free survival; and letrozole (Femara) (an aromatase inhibitor) has reduced the risk of recurrence after surgery (in some cases, more effectively than tamoxifen).

Surgery

Until recently, the treatment of choice for breast cancer was a radical mastectomy. The trend now is towards more conservative surgery combined with chemotherapy, hormone therapy or radiation, depending on the stage of the tumour and the age of the woman.

MASTECTOMY There are various types of mastectomy for breast cancer. *Radical mastectomy* is the removal of the entire affected breast, the underlying chest muscles and the lymph nodes under the arms. *Simple mastectomy* is the removal of the complete breast only. *Segmental mastectomy* or *lumpectomy* (see Figure 48.9A) is the removal of the tumour and the surrounding margin of breast tissues. *Modified radical mastectomy*



A Lumpectomy

B Modified radical mastectomy

FIGURE 48.9 ■ Types of mastectomy. *A*, In a lumpectomy, only the tumour and a small margin of surrounding tissue are removed. *B*, In a modified radical mastectomy, all breast tissue and the underarm lymph nodes are removed, but the underlying muscles remain

is the removal of the breast tissue and lymph nodes under the arm (axillary node dissection), leaving the chest wall muscles intact (see Figure 48.9B). See below for the nursing care of a woman having a mastectomy.

Axillary node dissection is generally performed during surgery for all invasive breast carcinoma to stage the tumour. This surgery can cause lymphoedema (accumulation of fluid in the soft tissues of the arm caused by removal of lymph channels), nerve damage and adhesions, and because of the role of the lymph nodes in immune system function, non-surgical methods of detecting lymph node involvement are used. Sentinel node biopsy prior to a node dissection is conducted by injecting a radioactive substance or dye into the region of the tumour. The dye is carried to the first (sentinel) lymph node to receive lymph from the tumour and would therefore be the node most likely to contain cancer cells if the cancer had metastasised. If the sentinel node is positive, more nodes are removed. If it is negative, further node evaluation is usually not indicated.

LUMPECTOMY Breast conservation surgery (*lumpectomy*) may be defined as excision of the primary tumour and adjacent breast tissue followed by radiation therapy. Many women are candidates for this procedure; however, women who have multicentric breast neoplasms and those who have large tumours in relation to their breast size are examples of unsuitable candidates. Selection of women for this procedure is guided by the need for local control of the lesion, cosmetic results and personal preference.

BREAST RECONSTRUCTION After a mastectomy, some women may choose to have their breast reconstructed. They report that surgical reconstruction of the breast simplifies their lives and restores a sense of body integrity. Other women choose to use a removable breast prosthesis and some women are comfortable without reconstruction or a prosthesis.

Breast reconstruction may be performed at the time of the mastectomy or at any time thereafter, depending on the woman's preference. A number of procedures may be used for the breast reconstruction (see Figure 48.10). These include placement of a submuscular implant, the use of a tissue expander followed by an implant, the transposition of muscle and blood supply from the abdomen or back, or using (most often) the transverse rectus abdominis myocutaneous (TRAM) free-tissue flap. Nursing implications for the care of women undergoing breast reconstruction surgery are summarised in the box below.

Radiation therapy

Radiation therapy is typically used following breast cancer surgery to destroy any remaining cancer cells that could cause recurrence or metastasis. If a tumour is unusually large, radiation may be used to shrink the tumour prior to surgery. Radiation therapy is most commonly used in combination with lumpectomy for early stage (I or II) breast cancer. Palliative radiation therapy is also used to treat chest wall recurrences and some bone metastases to help

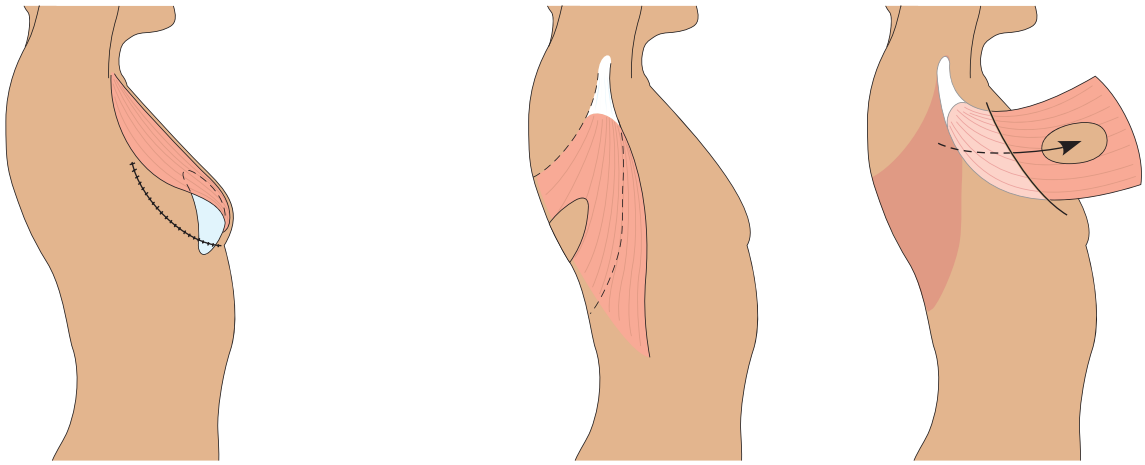
NURSING CARE OF THE WOMAN having a mastectomy

PREOPERATIVE CARE

- Ensure that the woman or family member signs an informed consent form.
- See Chapter 3 for preoperative preparation.

POSTOPERATIVE CARE

- Deep-breathing exercises are important because after general anaesthesia it is difficult for air to reach the lungs, particularly with the restrictive surgical dressing that decreases chest expansion.
- A suction apparatus will be placed in the wound to allow drainage of excess body fluids that accumulate when the lymph nodes are removed. This device is usually removed 3 to 5 days after surgery.
- An IV line may be in place for fluid replacement and antibiotics to reduce the risk of postoperative infection.
- Control pain by using the patient-controlled analgesia device or requesting analgesics before pain becomes severe. Take analgesics as needed before performing recommended exercises to facilitate full movement.
- Note any signs of bleeding on the dressing or on the bedding.
- Numbness or feelings of 'pins and needles' in the axillary area are common.
- Lying on one's back or on the side not operated on helps fluid drain from the site.
- Moving the arm on the operated side helps regain mobility; specific exercises will be prescribed for increasing mobility after the incisions have healed.
- If fluid builds up after the drains have been removed, it can be aspirated by the surgeon.
- Use caution if lifting heavy objects with the arm on the operated side.
- Be careful about injury and infection on the affected side; wear rubber gloves when washing dishes, garden gloves when working outside. Request that caregivers not perform blood pressures or venipunctures on the operative side to reduce the risk of injury and infection.
- Feelings of anxiety, sadness and fear of looking at the incision are normal; mastectomy means abrupt change in body image. It is normal to mourn the loss of a breast and to fear the loss of one's life after a cancer diagnosis.
- Sexual intimacy can be affected by mastectomy; it often helps to be able to discuss potential sexual problems with one's partner, a counsellor or a breast cancer support group.



A Implant **B** Latissimus dorsi musculocutaneous flap

FIGURE 48.10 ■ Types of breast reconstruction surgeries. *A*, A breast implant is inserted under the pectoris muscle. *B*, Autogenous procedures transfer a flap of skin, muscle and fat from the donor site on the woman's body to the mastectomy site. The most frequently used donor muscle sites are the latissimus dorsi and the rectus abdominis (the TRAM flap)

control pain and prevent fractures. Radiation therapy is administered by means of an external beam or tissue implants.

A new radiation treatment (*intraoperative radiotherapy*) is provided by a single, concentrated dose of radiation. During surgery, a probe is inserted into the cavity created by the lumpectomy and radiation equivalent to 6 weeks of doses is emitted for about 25 minutes. If this proves successful, the treatment could make lumpectomy available to more women and prevent the woman from having 6 weeks of daily radiation treatments following surgery.

Nursing care

Breast cancer is not one disease entity, but many, depending on the affected breast tissue, the tissue's oestrogen dependency and the age of the person at onset. The psychological and social impact of breast cancer extends beyond the fear and threat of death. The diagnosis may transform the woman's sense of self and lead to reintegration or negotiation of family relationships. A nursing care plan for a woman with breast cancer is found below.

NURSING CARE OF THE WOMAN having breast reconstruction

HEALTH EDUCATION FOR THE WOMAN AND FAMILY

- Controversy exists about the health effects of silicone. While there is no conclusive evidence that silicone implants induce cancer or autoimmune disease, they are associated with hardening and pain due to contracture of the capsule around the implant. The implant may rupture, releasing silicone gel, or infection may occur. Saline-filled breast implants may be an alternative.
- Reconstruction can be done immediately after a mastectomy or at any time later on. Some surgeons believe that delayed reconstruction offers better cosmetic results.
- Reconstructive surgery can create a natural-looking breast that makes clothes fit better. Since it has no nerve endings, however, the reconstructed breast has no feeling or sensations.
- If a simple mastectomy is done, an implant approximately the same size as the other breast is placed under the pectoral muscle on the operative side. This creates a breast mound that closely resembles the natural breast in shape and softness. If the implant is placed over the pectoral muscle, a high degree of firmness may occur.
- With a simple mastectomy or modified radical mastectomy, a tissue expander may be used to replace the breast. The tissue expander is placed under the pectoral muscle and gradually expanded with saline injections every 2 to 3 weeks to stretch the overlying skin and create a pocket. After a period of time, usually 1 to 2 months, the tissue expander is exchanged for a saline implant.
- With more extensive surgery such as radical mastectomy, a flap of skin, fat or muscle is transferred from a donor site to the operative area. A new nipple may be created by using tissue from the opposite nipple or from the inner thigh.
- Reconstructive surgery may require multiple surgeries, including all the risks associated with anaesthesia. As the complexity of the procedures increases, so does the risk of complications such as infection.
- To decrease the risk of a fibrous capsule forming around the implant, it is important to perform breast massage as instructed.

NURSING CARE PLAN A woman with breast cancer

Vanessa Cole is a 46-year-old mother of three—Sarah, aged 20, Rory, aged 18, and Jennifer, aged 16. Due to a family history of breast cancer, she has been closely monitored (annual mammograms and clinical breast examination, monthly BSE, a needle aspiration biopsy with negative findings) for 4 years prior to her diagnosis. Vanessa discovers a lump in her left breast during her monthly BSE. An incisional biopsy reveals invasive lobular carcinoma in the left breast. Vanessa is debating whether to have reconstructive breast surgery. One of her greatest concerns is how her illness will affect her ability to support and care for her family. The breast cancer diagnosis seems part of the family legacy. She wonders, 'When will it happen to Jennifer? To Sarah?'

ASSESSMENT

During the history, Marc Acut, RN, the admitting nurse, learns from Vanessa that her mother, two of her aunts and one sister had been diagnosed with breast cancer. Her mother and one of the aunts died before age 45. Physical assessment findings include T 37.0°C, BP 110/62, P 65, R 14. Her weight is 54 kg; she is 168 cm tall. Modified radical mastectomy is performed; histological examination shows a 3 cm tumour; axillary node dissection shows that 4 of 16 lymph nodes are positive.

DIAGNOSES

- *Infection risk* related to surgical incision.
- *Acute pain* related to surgery and postoperative recovery.
- *Body image altered* in response to loss of her breast.
- *Personal conflict* about treatment options, related to concerns about risks and benefits.
- *Personal fear* related to current and future wellbeing related to the disease process/prognosis.
- *Anxiety.*

PLANNING

- Educate Vanessa about handwashing and wound care.
- Assess her pain tolerance and administer analgesics as prescribed.
- Educate her to use caution when moving the arm on the operated side, to avoid lifting heavy objects and to wear gloves when gardening.
- Encourage her to discuss her thoughts and feelings about her body changes.
- The Breast Cancer Network www.bcna.org.au or her state/territory Cancer Council can also be a good source of support; also social work or community health referral to assist with care of her children while undergoing treatment. If Vanessa lives in a rural or remote rural area of Australia, her family may need to be temporarily relocated to be with her.
- Assess her interest in spiritual/religious support and refer if appropriate.
- Discuss the use of a temporary prosthesis and later the fitting of a permanent prosthesis (6 to 8 weeks after surgery), the need to be fitted by an experienced person and health insurance reimbursement for the prosthesis.
- Discuss the possibility of attending a breast cancer support group where she can draw on the experiences of other women who have undergone mastectomy, chemotherapy or radiation.
- Encourage her to verbalise her fears about her own prognosis and about her daughters' future risk of breast cancer; assess the need/interest for referral to psychological counselling in the future. However, these services may not readily available in some geographical regions of Australia. Registered Nurses as health professionals can provide information, education and reassurance.

Expected outcomes

- Remain free of infection.
- Experience minimal pain or discomfort during her recovery.
- Maintain a positive body image, regardless of her decision about reconstruction.
- Evaluate the treatment options in relation to personal values and decide on a course of action.
- Identify the sources of her fear and demonstrate behaviours that may reduce fears.

IMPLEMENTATION

- Initiate each of the steps outlined in the planning section detailed above.
- Monitor the effectiveness of the plan by monitoring Vanessa's response to:
  - surgery
  - pain management.
- Engage in ongoing discussion with Vanessa about the implementation of the plan and her psychosocial wellbeing.

EVALUATION

At discharge, Vanessa has no signs of physical complications and is looking forward to being at home with her daughters as temporary caregivers. Vanessa contacted a Breast Cancer Network volunteer, who sent her a temporary prosthesis and booklets about postmastectomy exercises, chemotherapy and breast reconstruction. The volunteer also referred her to a local cancer support group. Vanessa has talked about her concerns related to breast reconstruction. 'I want to avoid anything that would increase the risk of complications. The possibility of recurrence and my fear for my daughters' future health are more than enough to worry about.'

CRITICAL THINKING IN THE NURSING PROCESS

1. What role could genetic counselling play in helping Vanessa and her daughters better understand the daughters' risk of breast cancer?
2. Describe the types of mastectomies and their implications for nursing care.
3. Which medications might help minimise the side effects of chemotherapy?
4. Develop a plan of care for Vanessa for her *Disturbed sleep pattern*.

REFLECTION ON THE NURSING PROCESS

1. Outline what you have learned from Vanessa's case study. How would you incorporate this into your future nursing practice?
2. Which strategies would you use in your future nursing practice to assist women who are undergoing treatment for breast cancer?

Health promotion

All women should be taught to perform BSE monthly (see Box 48.1). Premenopausal women should perform BSE between 7 and 10 days from the first day of their menstrual period, because hormonal changes increase breast tenderness and lumpiness prior to menses. Postmenopausal women should choose one date of the month (e.g. the first day of the month) for BSE.

Educational messages about breast cancer screening need to be culturally and age sensitive to the intended audience. Media campaigns promoting mammography often show young white women, an approach that has proved ineffective for Aboriginal and Torres Strait Islander women (see the 'Translation to practice' box below). By working with women from culturally and linguistically diverse (CALD) backgrounds, nurses can help make breast cancer education more meaningful to women in these groups.

Assessment

Undertake a through health history and physical examination (see Chapter 46). Further focused assessments are described with nursing interventions.

- *Health history:* family history of breast cancer, breast changes, nipple discharge, use of HRT, personal history of breast cancer, previous diagnostic tests and treatment for cancer, menstrual history, pregnancies, alcohol intake, physical activity, dietary history.
- *Physical assessment:* height and weight, breasts, lymph glands.
- *Mental health assessment:* anxiety, coping strategies, emotional wellbeing.

BOX 48.1 Breast self-examination (BSE)

- Observe your breasts for any visual changes.
- Lie down on your back and place your right arm behind your head. (BSE should be done while lying down because this position spreads breast tissue evenly over the chest wall, making it easier to feel all the breast tissue.)
- Use the finger pads of the middle fingers on your left hand to feel for lumps in the right breast. Use overlapping 20-cent-sized circular motions of the finger pads to feel the breast tissue.
- Use three different levels of pressure to feel all the breast tissue. Light pressure is needed to feel the tissue closest to the skin; medium pressure to feel a little deeper; and firm pressure to feel the tissue closest to the chest and ribs. A firm ridge in the lower curve of each breast is normal. Use each pressure level to feel the breast tissue before moving on to the next spot.
- Move around the breast in an up and down pattern starting at an imaginary line drawn straight down your side from the underarm and moving across the breast to the middle of the chest bone (sternum, breastbone). Be sure to check the entire breast area before going down until you feel only ribs and up to the neck or collar bone.
- Repeat the exam on your left breast, using the finger pads of your right hand.
- Stand in front of the mirror with your hands pressing firmly down on your hips. Look at your breasts for any changes in size, shape, contour or dimpling.
- Examine your underarm while sitting or standing and with your arm only slightly raised.
- If you find any changes, see your healthcare provider as soon as possible.

Nursing diagnoses and interventions

Although each woman has individual needs, nursing priorities prior to surgery are concerned with *Anxiety*, *Decisional conflict*, *Grief*, *Risk of infection*, *Risk of injury* and *Disturbed body image* over the loss of a breast. As the typical hospital stay is short, usually 2 to 3 days, preoperative education is often done on an outpatient basis.

Anxiety

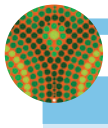
The woman with breast cancer is often anxious about the diagnosis, the surgery, the outcome of surgery if nodal involvement is found and the possible changes in sexual and family relationships. Studies show that young women with breast cancer, a growing population, are particularly vulnerable to anxiety and other psychosocial effects, as are their spouses and their children.

- Provide opportunities to express thoughts and feelings. In this process, the woman can name her fears. *Once the fears are named, the nurse may simply listen, educate or dispel fears that stem from lack of understanding.*
- Discuss with the woman her knowledge of breast cancer. *Assessing the woman's knowledge of breast cancer helps the nurse plan more effective health education.*
- Encourage discussion relating to immediate concerns about resuming her life at home and the changes she must make. *Anticipatory guidance can help plan for and cope with changes in her life and relationships.*
- Explain the surgical procedure, including information about preoperative medications, anaesthesia and recovery. *Knowing what to expect helps to decrease anxiety.*
- Explain that it is normal to have decreased sensation in the surgical area. *Severed or damaged nerves reduce sensation.*

Decisional conflict

The woman with breast cancer must make life-changing decisions about treatment within a relatively brief and highly stressful time. Her age, menopausal status, relationships and stage of cancer are only some of the factors that affect her decisions. Culture, values, lifestyle, socioeconomic status and self-esteem also are considered.

- Provide an opportunity for the woman to ask questions; answer them as simply and directly as possible. Make eye contact as appropriate and pay attention to body language. *During this time, the woman can process information and make informed decisions.*
- Focus on immediate concerns and provide up-to-date written material for the woman to review. *Written material provides easy reference to information not processed immediately because of anxiety and stress.*
- Listen to the woman in a non-judgmental and respectful manner during her decision-making process.



TRANSLATION TO PRACTICE Evidence-based practice: breast and cervical cancer in Aboriginal and Torres Strait Islander women

Despite efforts to improve both the diagnosis and treatment of women with breast and cervical cancer, Aboriginal and Torres Strait Islander women experience a higher incidence of cervical cancer, and have poorer outcomes for breast and cervical cancer than non-Aboriginal and Torres Strait Islander women (Shannon et al., 2011). Data show that Aboriginal and Torres Strait Islander women experience less incidence of breast cancer than non-Aboriginal and Torres Strait Islander women, yet the survival outcome is poorer. It is believed that this statistic is the result of Aboriginal and Torres Strait Islander women's advanced stage of disease at diagnosis, primarily due to a delay in seeking treatment. Seeking treatment is difficult in rural and remote areas of Australia where health services are few or non-existent (Sabesan et al., 2012).

Reath and Carey (2008) conducted a study that explored whether improved service coordination and access to healthcare, general practitioner knowledge of cultural issues and health promotion and a recall system improved detection of cervical and breast cancer in Aboriginal and Torres Strait Islander women. The researchers found that partnership with the Aboriginal and Torres Strait Islander community and Aboriginal and Torres Strait Islander health workers when planning and delivering healthcare services was the key to improving Aboriginal and Torres Strait Islander women's participation in cervical and breast screening processes. In addition, these researchers found that the availability of a female general practitioner also enhanced Aboriginal and Torres Strait Islander women's attendance at healthcare clinics.

IMPLICATIONS FOR NURSING

Nurses must consider multiple factors when considering what may or may not influence Aboriginal and Torres Strait Islander women to delay diagnosis and treatment for cervical and breast cancer, including intra- and intercultural differences and similarities, as well as perceptions and health beliefs. Nurses need to conduct accurate assessments and design interventions based on considerations of both individual and group cultural differences. Culturally safe and appropriate healthcare is paramount.

CRITICAL THINKING IN PERSON-CENTRED CARE

1. Which barriers to cervical and breast cancer screening in women of all cultures and ethnicities can you identify? Do you think these barriers differ based on culture, race or socioeconomic level? Why or why not?
2. Are there barriers to cervical or breast cancer screening that might be unique to Aboriginal and Torres Strait Islander women?
3. What type of questions would you include in a health assessment to identify if an Aboriginal and Torres Strait Islander woman may be worried about cervical or breast cancer, but has not sought diagnosis?

Non-judgmental, empathic listening helps the woman process information and make informed decisions. Only she knows the context of her life.

- If the woman wishes, provide opportunities for her to meet with other women who have had breast cancer surgery. *Not all women are ready to meet others in their situation, but opening the door to this resource is appropriate. The woman may choose to talk with these women after the surgery.*
- Facilitate a team approach with the surgeon, anaesthetist, oncologist, plastic surgeon and other health professionals. *Being the woman's advocate during this time of anxiety and decision making reduces the stress of coordinating multiple healthcare provider schedules.*

Anticipatory grieving

Breast surgery, even lumpectomy, alters the appearance of the breast. This loss is expressed through grief and anger.

- Listen attentively to expressions of grief and watch for nonverbal cues (failure to make eye contact, crying, silence, anger, bargaining). *Not all women will express grief clearly; sometimes unspoken grief is the most painful. Grief is best relieved only when expressed in a non-threatening environment.*
- Allow time to interact and do not rush interactions. *Taking time to be with the woman communicates caring.*
- Explain that it is normal to have periods of depression, anger and denial after breast surgery. *All these feelings are appropriate expressions of grief.*
- If the woman wishes to do so, involve the partner in helping her cope with her grief. Remember that the partner may also be grieving. *Not all women want to share their grief and not all partners are interested and supportive.*

Risk of infection

Like any person undergoing surgery, the woman who has breast surgery is at risk of infection. Removal of lymph nodes and the presence of a draining wound increase the risk.

- Assess the surgical dressings for bleeding, drainage, colour and odour every 4 hours for 24 hours and document your findings. Circle any visible bleeding and drainage on the dressing as a baseline for subsequent assessment. *Excessive bleeding or drainage signals postoperative complications that may require emergency attention.*
- Observe the incision and IV sites for pain, redness, swelling and drainage. Assess the drainage system for patency and adequate suction; note the colour and amount of drainage. *Careful observation for any signs of infection is essential because the woman's immune system is compromised. IV catheters should be placed on the uninvolved side only.*
- Change dressings and IV tubing using aseptic technique. Moist dressings and intravenous tubing provide sites for bacterial growth. *Routine dressing and IV tubing changes using aseptic technique reduce the risk of infection.*
- Encourage a protein-rich diet. Discuss the woman's nutritional status with the dietitian and request a

consultation for the woman. *Adequate nutrition promotes healing and boosts the immune system.*
- Teach the woman how to care for the drainage system, if present. (Clean the site, empty the device and record the amount, colour and type of drainage.) *The woman is often discharged prior to removal of the drainage system and dressings, and needs health education to provide self-care.*
- At discharge, educate the woman how to recognise and report to her healthcare provider the symptoms of infection: fever, redness or hardness at the surgical site or purulent drainage. Any of these symptoms should be reported to the physician/surgeon. *Knowing the signs and symptoms of infection prepares the woman to seek prompt treatment if infection occurs.*
- Explain that she may experience scaling, flaking, dryness, itching, rash or dry desquamation of the skin, particularly after radiation therapy. *Impaired skin integrity increases the risk of infection.*
- Tell the woman to avoid deodorants and talcum powder on the affected side until the incision is completely healed. *These substances may irritate the skin and impede healing.*

Risk of injury

Removal of the lymph nodes puts the woman at risk of injury and long-term complications such as lymphoedema and infection.
- When obtaining blood pressure and starting IVs, use the non-surgical side. *Compression of the arm on the surgical side may cause lymphoedema.*
- Elevate the affected arm higher than the shoulder on a pillow, but do not abduct it; the hand should be higher than the elbow. *Elevating the arm permits drainage, prevents swelling and promotes circulation.*
- Encourage ROM exercises in the affected arm. *Exercise helps develop collateral drainage.*
- Explain that lymphoedema massage and an elastic compression bandage may help control the swelling after she has recovered from surgery. *It is important that women know about the resources available after recovery.*

Disturbed body image

Breast surgery can change the woman's body image. The surgical changes may be compounded by weight gain and other side effects of chemotherapy or hormone therapy. Self-esteem also affects adjustment to a changed body image.
- Assess how the woman views her body. Discuss with the woman what image of herself she had prior to surgery. *Self-image is related to self-esteem. Discuss whether her self-image has changed.*
- Explain that redness and swelling in the scar will fade with time. *The knowledge that the scar will fade may give the woman a more realistic view of the changes.*
- Include the partner and family if possible when discussing the plan of care and activities of daily living (ADLs). Request consultation with a mental health professional if the woman is interested. *Discussion with the partner and family can facilitate the woman's emotional healing process.*
- Offer pamphlets and suggest books and DVDs and appropriate websites that might increase knowledge about what lies ahead. *Knowing what to expect can help the woman cope.*
- Encourage the woman to look at her incision when she feels ready; often the reality is not as frightening as she had imagined. Explain that it is normal to be afraid to look. *Reassurance that her behaviour is normal decreases anxiety.*
- If the woman is interested in breast reconstruction, provide written material and encourage her to talk (in person, telephone or online) with a plastic surgeon and with women who have had reconstruction. *It is important for the woman to be fully informed about available options to make an informed decision.*

CONSIDERATION FOR PRACTICE

Offer referral to support groups with women experiencing similar problems. Some women may prefer one-on-one counselling. However, these services may not readily available in some geographical regions of Australia. Registered Nurses as health professionals can provide information, education and reassurance.

Community-based care

The woman with breast cancer and her family have much to learn to provide self-care at home. Address the following topics in preparation for home care:
- Symptoms of infection and the need to report any that occur to her healthcare provider.
- The importance of ADLs, such as eating properly, combing her hair and washing her face.
- Postmastectomy exercises and lymphoedema care (see Figure 48.11), as discussed with physicians and physical therapists.
- The need for adequate rest and emotional support.
- Participation in a breast cancer support group and online information services and bulletin boards for sources of education and support.
- Prosthesis management, if this option is chosen. (A temporary lightweight prosthesis may be worn immediately after the drains and sutures have been removed from the surgical site. Due to prostheses being expensive, a permanent one should not be purchased until the wound has completely healed. Prostheses are available at medical stores and many larger department stores. Most health insurance policies pay for the first prosthesis.)
- Helpful resources:

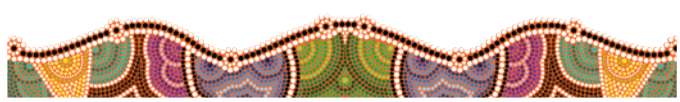
  - Cancer Council Australia—*After a diagnosis*: www.cancer.org.au/about-cancer/after-a-diagnosis/
  - Cancer Council NSW—*Understanding breast cancer*: www.cancercouncil.com.au/wp-content/uploads/2014/09/Breast-Booklet_-NSW-lversion.pdf



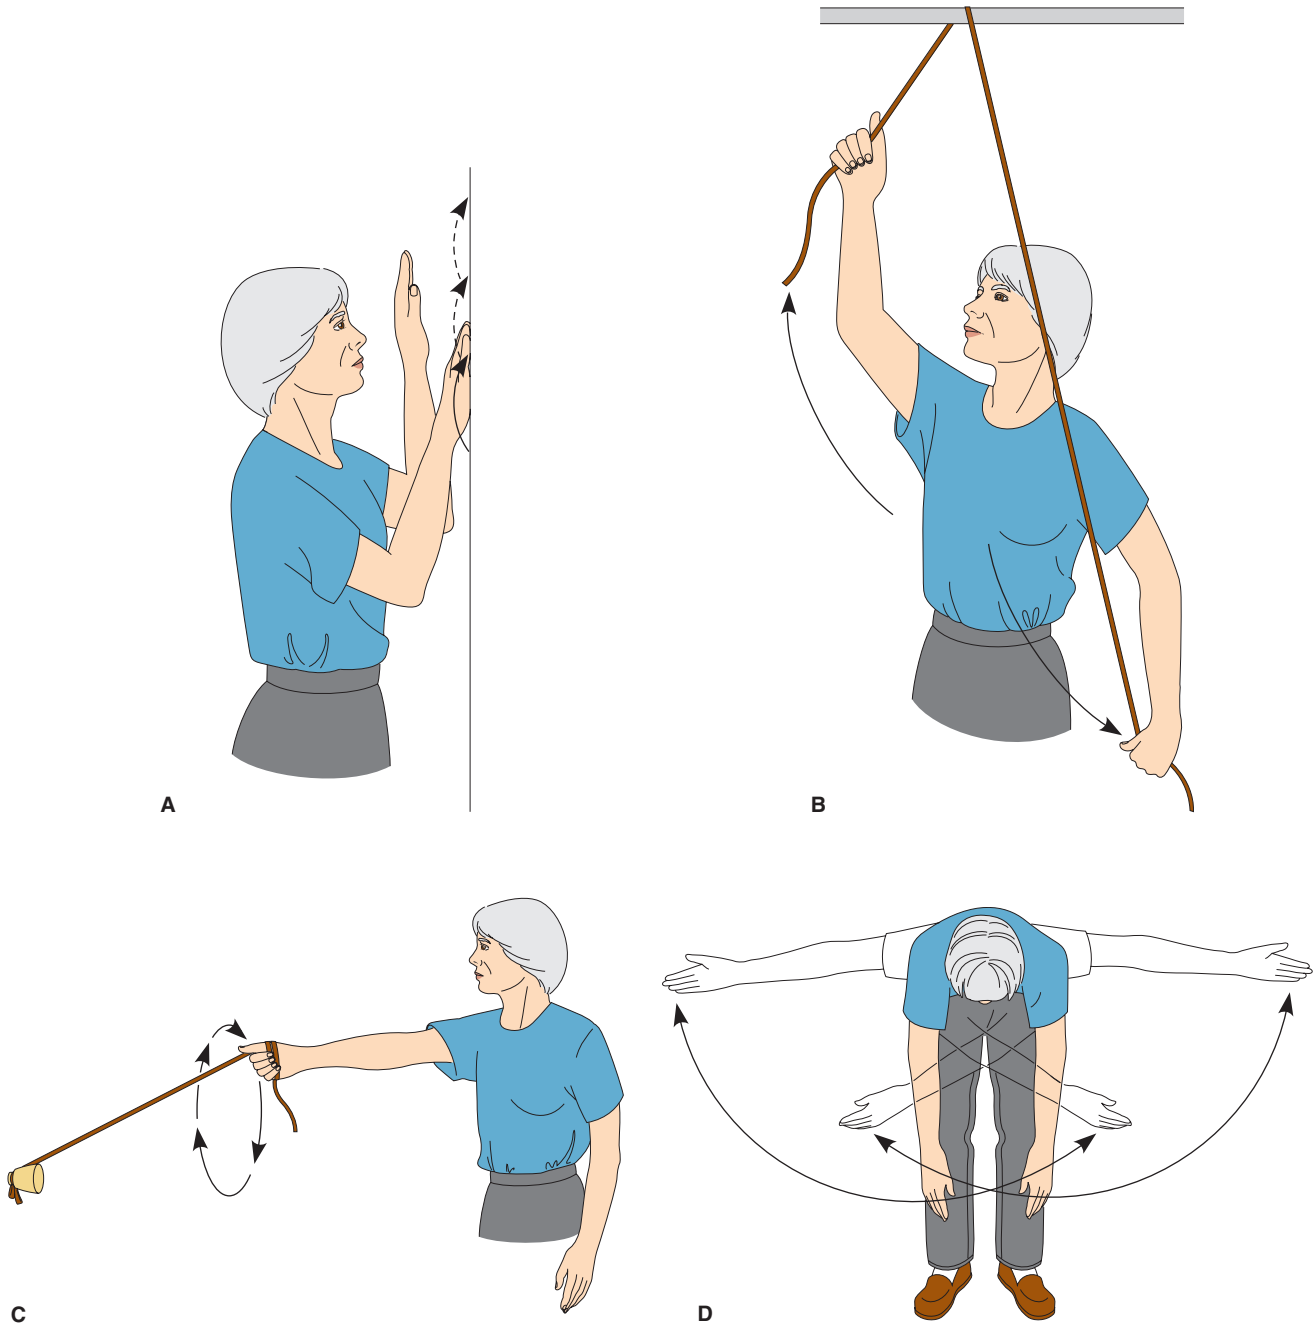


FIGURE 48.11 ■ Postmastectomy exercises. *A*, Wall climbing: stand facing wall with toes 15 to 30 cm from wall. Bend elbows and place palms against wall at shoulder level. Gradually move both hands up the wall parallel to each other until incisional pulling or pain occurs. (Mark that spot on wall to measure progress.) Work hands down to shoulder level. Move closer to wall as height of reach improves. *B*, Overhead pulley: using operated arm, toss 1.8 metre rope over shower curtain rod (or over top of a door that has a nail in the top to hold the rope in place for the exercise). Grasp one end of rope in each hand. Slowly raise operated arm as far as comfortable by pulling down on the rope on opposite side. Keep raised arm close to your head. Reverse to raise unoperated arm by lowering the operated arm. Repeat. *C*, Rope turning: tie rope to door handle. Hold rope in hand of operated side. Back away from door until arm is extended away from body, parallel to floor. Swing rope in as wide a circle as possible. Increase size of circle as mobility returns. *D*, Arm swings: stand with feet 20 cm apart. Bend forwards from waist, allowing arms to hang towards floor. Swing both arms up to sides to reach shoulder level. Swing back to centre, then cross arms at centre. Do not bend elbows. If possible, do this and other exercises in front of a mirror to ensure even posture and correct motion

CHAPTER HIGHLIGHTS

- Disorders of female sexual function include dyspareunia, inhibited sexual desire and orgasmic dysfunction. Nurses should be able to obtain a sexual history, discuss sexual concerns and make appropriate referrals without embarrassment.
- Menopause, a normal physiological event in the lifespan of a woman, is the permanent cessation of menses. Loss of oestrogen results in widespread tissue changes and increases the risk of osteoporosis, fractures and cardiovascular disease.
- Menstrual disorders encompass PMS, dysmenorrhoea and abnormal uterine bleeding. Nursing interventions are focused on providing health education about good health practices and interventions to relieve symptoms. Interprofessional care includes a therapeutic D&C and hysterectomy.
- Uterine displacement and vaginal fistulas are structural disorders. Uterine displacements may be treated surgically or with a pessary and may include education about Kegel exercises to minimise urinary leakage. Fistulas may spontaneously resolve if small or may be surgically repaired.
- There are both benign and malignant disorders of female reproductive tissue, including cysts or polyps, leiomyomas, endometriosis and cancers of the cervix, endometrium, ovaries and vulva.
- Leiomyomas (fibroid tumours) are benign tumours that originate from smooth muscle of the uterus. Treatment depends on the size and location of the tumours. Both leiomyomas and endometrial implants (benign implants of endometrial tissue in the pelvic cavity) may interfere with the ability to have a child and are reduced in size after menopause.
- Cervical cancer is a common female reproductive system cancer, but the incidence and mortality has been greatly reduced by the Pap smear for early diagnosis.
- Endometrial cancer is the most common invasive gynaecological cancer in Australia, with one in 69 women being affected by the age of 75 years. The main manifestation is abnormal, painless vaginal bleeding (menorrhagia or metrorrhagia in menstruating women). Postmenopausal women should have annual pelvic examinations and report any unexpected vaginal bleeding to their healthcare provider.
- Ovarian cancer increases in incidence with ageing; one in 78 women will be diagnosed prior to the age of 85. In early stages, there are generally no warning signs.
- Benign breast disorders in women include fibrocystic changes and intraductal disorders. Both treatment and nursing care are primarily symptomatic.
- Breast cancer is the most commonly invasive cancer in Australian women. A strong genetic link has been identified, as have a large number of risk factors. Early diagnosis is possible with BSE, clinical breast examination and mammograms. Treatment includes surgery (one of several types of mastectomy, lumpectomy), radiation therapy and chemotherapy. Both combination therapies and immunotherapy are proving to be effective in suppressing tumour growth and facilitating longer life. Along with other problems, mastectomy and radiation therapy interfere with lymph drainage on the affected side, leading to lymphoedema of the arm.
- Appropriate preoperative nursing diagnoses for the woman with breast cancer include anxiety and fear, decisional conflict and anticipatory grieving. Following surgery, interventions focus on risk of infection, risk of injury, pain and disturbed body image.

CONCEPT CHECK

1 During a health assessment, a woman in her fifties tells you that she is having some pain with intercourse. You are uncomfortable discussing this topic with her. What would you say?
1. 'I know this can be a problem; please discuss it with your doctor.'
2. 'I don't know anything about that; you'll have to ask someone else.'
3. 'Do you normally enjoy sexual activity?'
4. 'What do you think is causing your problem?'

2 Long-term oestrogen deprivation results in an increased risk of physical disorders. What are these? (Select all that apply.)
1. colon cancer
2. osteoporosis
3. cardiovascular disease
4. fractures
5. cervical cancer

3 You are conducting a health education seminar for postmenopausal women. When discussing calcium intake, you recommend _____ mg per day.

4 An intervention for the woman with a uterine displacement disorder is to teach Kegel exercises. These exercises may help reduce:
1. stress incontinence
2. menorrhagia
3. vaginal discharge
4. retroversion

5 Which of the following topics would you include in a health-promotion seminar to reduce the risk of cervical cancer?
1. weight loss
2. safer-sex methods
3. yearly mammograms
4. a diet high in iron

6 When discussing dietary guidelines with a woman with PMS, you recommend she reduce her sodium intake. What is the rationale for this recommendation?
1. Sodium increases reactive hypoglycaemia, increasing physical symptoms.
2. Sodium increases thirst, thereby facilitating increased oral fluid intake.
3. In and of itself, sodium is not harmful, but it may increase cancer risk.
4. Sodium restriction helps minimise fluid retention.

7 What happens to endometrial implantations after menopause?
1. They tend to become malignant.
2. They tend to atrophy and disappear.
3. The number of implants increases.
4. Each implant enlarges.

8 You are designing an education plan for home care for a woman who had an abdominal hysterectomy. Which interventions should be included? (Select all that apply.)
1. Restrict heavy lifting for 4 to 6 weeks.
2. Take tub baths until bleeding has stopped.
3. Report an increase in temperature or severe pain.

4 Take regular rest periods.
5 Avoid coughing and deep breathing at home.

9 Of the following women, which one would be most at risk of breast cancer?
1 age 23, two children
2 age 33, never pregnant
3 age 45, very thin
4 age 64, positive family history

10 You are caring for a woman who is scheduled to have a mastectomy for breast cancer. She is crying. Why might this be so?
1 *Disturbed body image*
2 *Fatigue*
3 *Anticipatory grieving*
4 *Risk of injury*

CHAPTER 49

NURSING CARE OF PEOPLE WHO HAVE SEXUALLY TRANSMITTED INFECTIONS

LORRAINE FIELDS & LORNA MOXHAM

KEY TERMS

LEARNING OUTCOMES

- Explain the incidence, prevalence, characteristics and prevention/control of sexually transmitted infections (STIs).
- Compare and contrast the pathophysiology, manifestations, interprofessional care and nursing care of genital herpes, genital warts, vaginitis, chlamydia, gonorrhoea, syphilis and pelvic inflammatory disease.
- Explain the risk factors for and complications of STIs.
- Discuss the effects and nursing implications of medications and treatments used to treat STIs.

CLINICAL COMPETENCIES

- Assess the functional health status of people living with an STI and monitor, document and report clinical indicators.
- Determine nursing priorities and select and implement individualised nursing interventions for people living with an STI.
- Administer treatment, including medications, knowledgeably and safely.
- Integrate interprofessional care for people living with an STI.
- Provide education appropriate for prevention, management and self-care of STIs.
- Revise plans of care as needed to provide effective interventions to promote, maintain or restore functional health status for people living with an STI.

Infections transmitted by vaginal, oral and anal intimate contact and intercourse are referred to as **sexually transmitted infections (STIs)**. Infections transmitted by sexual intercourse are also sometimes known as *sexually transmitted diseases (STDs)* or *venereal diseases.* The most contemporary and acceptable term is STI. A person can have an STI before having symptoms of the disease. STIs also include systemic diseases (such as tuberculosis, hepatitis and HIV/AIDS) that can be transmitted from one infected person to another. This chapter discusses STIs that involve the urogenital system, as well as vaginal infections.

OVERVIEW OF SEXUALLY TRANSMITTED INFECTIONS

Sexually transmitted infections include those caused by bacteria, *Chlamydiae*, viruses, fungi, protozoa and parasites. Portals of entry for these agents of transmission include the mouth, genitalia, urinary meatus, anus, rectum and skin. STIs have many consequences and nurses have the responsibility to provide health education to people on how to prevent STIs, regardless of their gender, age or sexual orientation. Nurses have a critical role in the prevention of STIs by providing accurate information about these diseases, their prevention, treatment and potential complications. Nurses should be aware of policies, protocols and strategies. Australia (Department of Health, 2014a) has guidelines within the *Third National Sexually Transmissible Infections Strategy 2014–2017* available at www.health.gov.au/internet/main/publishing.nsf/Content/ohp-bbvs-sti. The World Health Organization (WHO) (2007) has a publication called *Global strategy for the prevention and control of sexually transmitted infections: 2006–2015. Breaking the chain of transmission.* This book is available from www.who.int/reproductivehealth/publications/rtis/9789241563475/en/.

Incidence and prevalence

Sexually transmitted infections are a major public health issue. STIs have reached epidemic proportions in many countries and are on the increase worldwide. The WHO estimates that 500 million new infections of curable sexually transmitted infections (syphilis, gonorrhoea, chlamydia and trichomoniasis) occur globally each year (WHO, 2013).

Accurate information about infection rates is difficult to obtain, especially for many developing countries, and the available information is often at least 3 to 4 years old. There is no one organisation that regularly collates all global STI statistics, although the WHO does try. To complicate matters further, different countries have different types and levels of reporting. It is thought that many reports substantially underestimate the number of new STI cases because of social stigma and other factors, such as poverty, that prevent people seeking healthcare.

Women and infants are disproportionately affected by STIs. Many STIs are more easily transmitted from a man to a woman than they are from a woman to a man. Women often experience few early manifestations of the infection, delaying diagnosis and treatment. Furthermore, women are at greater risk of complications of STIs such as pelvic inflammatory disease (PID) and genital cancers.

Several factors may help explain the escalating incidence of STIs. The 'sexual revolution' of the 1960s and 1970s, fuelled by 'the pill' and the freedom this gave women from unplanned pregnancy, led to more permissive attitudes about sexual freedom and increases in sexual activity and the number of sexual partners. When hormonal contraceptives became available in Australia in the 1960s, they replaced the condom as the predominant means of birth control. However, unlike condoms, oral contraceptives do not protect against STIs, a fact of increasing public health importance.

STIs affect men and women of all ages, backgrounds and socioeconomic levels. Individual factors related to the contraction of STIs are risky behaviours such as drug abuse, sex with multiple or new partners, sex with high-risk partners, unprotected sex, sex while intoxicated and sex in exchange for money. A further factor contributing to the increasing incidence of STIs is that people are becoming sexually active at an earlier age and committing to one partner later. As a result, sexually active people today are more likely to have multiple sex partners in their lifetime and are potentially at higher risk of STIs.

The emergence of HIV/AIDS has created a kind of 'epidemiological synergy' between all STIs. Other STIs, such as syphilis, herpes simplex virus (HSV) and chancroid, facilitate the transmission of HIV/AIDS, and the immunosuppression caused by HIV potentiates the infectious process of other STIs. People who are infected with STIs are at greater risk of acquiring HIV if they are exposed to the virus. This is the result of genital ulcers creating a portal of entry for HIV, non-ulcerative STIs increasing the concentration of cells in genital secretions that can be targets for HIV and infection with both an STI and HIV resulting in an increased likelihood of having HIV in genital secretions and semen.

Pathophysiology, manifestations and nursing care

Although STIs are caused by various organisms, they have several common characteristics:

- Most can be prevented by the use of latex condoms.
- They can be transmitted during sexual activities, including non-penetrating intimate exposure.
- For treatment to be effective, sexual partners of the infected person must also be treated.
- Two or more STIs frequently coexist in the same person.

FAST FACTS

- The majority of STIs are present without symptoms.
- More than 1 million people acquire an STI every day.
- Each year, an estimated 500 million people become ill with one of four STIs: chlamydia, gonorrhoea, syphilis and trichomoniasis.
- More than 530 million people have the virus that causes genital herpes (HSV2).
- More than 290 million women have a human papillomavirus (HPV) infection. HPV causes 530 000 cases of cervical cancer and 275 000 cervical cancer deaths each year.
- Some STIs can increase the risk of HIV acquisition three-fold or more.
- STIs can have serious consequences beyond the immediate impact of the infection itself, through mother-to-child transmission of infections and chronic diseases.
- Drug resistance, especially for gonorrhoea, is a major threat to reducing the impact of STIs worldwide.
- In developing countries, STIs and their complications rank in the top five disease categories for which adults seek healthcare.
- In women of childbearing age, STIs, excluding HIV, are second only to maternal factors as causes of disease, death and healthy life lost.
- According to estimates from the WHO (2015a), around 36.9 million people were living with HIV in 2014. The number of people newly infected with HIV in 2014 was 2 million.
- AIDS deaths globally in 2013 accounted for 1.5 million people.
- AIDS incidence in Australia (0.9 per 100 000 population) is similar to that in the UK and Canada (1.4 and 0.8, respectively) but much lower than in the US (12.8).
- As of December 2011, an estimated 24 731 people were living with an HIV diagnosis in Australia.
- From the start of the epidemic until the end of 2011, there have been 31 645 diagnoses of HIV and 10 796 diagnoses of AIDS. Australia has recorded 6843 AIDS deaths.
- New South Wales had the highest incidence of AIDS diagnosis followed by Victoria, Queensland, Western Australia, South Australia, the Australian Capital Territory, Tasmania and the Northern Territory.
- Chlamydia was the most common STI notification in Australia, with 82 707 new cases in 2012.
- Indigenous Australians are over-represented in STI notification data.
- One in two sexually active people will contract an STI by age 25.

(2012). *Education programs for Indigenous Australians about sexually transmitted infections and bloodborne viruses*. Resource sheet no. 14. Produced for the Closing the Gap Clearinghouse. Canberra: Closing the Gap Clearinghouse; Department of Health (2014b). *Sexually transmissible infections.* Retrieved from www.sti.health.gov.au/internet/sti/publishing.nsf.

The complications of STIs in women include pelvic inflammatory disease, ectopic pregnancy, infertility, chronic pelvic pain, neonatal illness and death, and genital cancer. Some bacterial STIs can be treated through appropriate early intervention with antibiotics. Others, like genital herpes, are chronic conditions that can be managed but not cured because they are caused by viruses. The most serious STI is AIDS, which currently does not have a cure. HIV/AIDS is discussed in Chapter 12. Treatment guidelines for STIs are updated regularly and are available from the World Health Organization and the Centers for Disease Control and Prevention (CDC) websites.

Prevention and control

Prevention and control of STIs are based on the principles of education, early detection, diagnosis and treatment of infected people, and evaluation, treatment and counselling of sexual partners of people who are infected. The skill of the healthcare provider to be able to obtain an accurate sexual history is essential to prevention and control efforts. One approach to collecting accurate information about key areas has been summarised by the CDC (2015). It includes the '5 Ps' partners, prevention of pregnancy, protection from STIs, practice and past history of STIs. Suggested questions to use are found on the CDC website: www.cdc.gov/std/tg2015/clinical.htm.

The most effective way to prevent STIs is to avoid sexual intercourse with an infected partner. It is recommended that both partners be tested for STIs, including HIV, before beginning to have sexual intercourse. If a person chooses to have intercourse with an infected partner or one whose infection status is unknown, a new condom should be used for each act of intercourse (CDC, 2015). See Table 49.1 for STI barrier guidelines.

Health education for the person who is an injecting-drug user includes:

- Enrol or continue in a drug treatment program.
- Do not use injection equipment that has been used by another person. If equipment is shared, first clean the syringe and needle with bleach and water (to reduce the rate of transmission).
- If needles can be legally obtained, use clean needles.
- Dispose of used needles safely and appropriately.

Syringe disposal containers are located in many public places including shopping centres, public toilets, airports, cinemas and universities.

Eliminating further transmission and reinfection of STIs is critical for control. For treatable STIs, this means that referral of sexual partners for diagnosis, treatment and counselling is essential. HIV/AIDS is a reportable disease in every state and territory in Australia. When an infected person is referred, every effort is made to identify and contact sexual partners. Reports of STI and HIV infections are maintained in the strictest confidence and are protected by law from subpoena. Suggested resources for people with STIs are listed in Box 49.1.

TABLE 49.1 STI barrier guidelines

BARRIER PROTECTION	HEALTH EDUCATION
Male condoms	• Use a new condom for each act of sexual intercourse. • Handle carefully to avoid damaging the condom. Condoms are affected adversely by heat—keep them in a cool place. • Be sure no air is trapped in the end of the condom. • Put the condom on when the penis is erect and before genital contact with partner. • Ensure adequate lubrication exists during intercourse, using only water-based lubricants (e.g. K-Y® jelly) and latex condoms. Oil-based lubricants, such as petroleum jelly, massage oil, mineral oil or body lotions can weaken latex and should not be used. • Ensure adequate lubrication during vaginal and anal sex. • Withdraw while the penis is erect and hold the condom firmly against the base of the penis during withdrawal.
Female condoms	• The female condom is a lubricated polyurethane sheath with a ring on each end that is inserted into the vagina. It is an effective mechanical barrier to viruses.
Vaginal spermicides, sponges, diaphragms	• Spermicides used alone without condoms do not reduce the risk of cervical gonorrhoea, chlamydia or HIV infection. • Diaphragms protect against cervical gonorrhoea, chlamydia and trichomoniasis, but not HIV.

THE PERSON WITH GENITAL HERPES

Genital herpes is caused by the herpes simplex viruses HSV1 and HSV2. Like most STIs, genital herpes is most commonly found in young, sexually active people and is associated with early onset of sexual activity and multiple sexual partners. In Australia, one in eight adults have genital herpes. It is twice as common in adult women (one in six) as in adult men (one in 12) and is most prevalent in women aged 35–44 (Sexual Health Australia, 2013). Currently there is no cure and the treatments are primarily symptomatic.

Pathophysiology

Both HSV1 and HSV2 are transmissible via direct contact. HSV1 is associated with cold sores, but may be transmitted to the genital area by oral intercourse or by self-inoculation through poor handwashing practices. HSV2 is the virus that causes genital herpes and is transmitted by sexual activity or during childbirth. HSV infections begin with exposure to the virus by contact with infectious lesions or secretions. The virus then moves into the stratified squamous epithelium, stimulating the replication of the epithelium and infecting the neurons that innervate the area. HSVs are neurotropic viruses, meaning that they grow in neurons and can maintain their disease potential even when there are no manifestations. The virus ascends through the peripheral nerves to the dorsal root ganglia, where it can remain dormant. For unknown reasons, the virus may reactivate and return to the nerve root of the skin, causing lesions. During dormancy, the virus is impervious to treatment. The incubation period ranges from 6 weeks to 8 months. Genital HSV2 infection is more common in women (approximately one in four women) than in men (almost one in five) (CDC, 2015).

Manifestations

Within 2 to 10 days after exposure to the herpes virus, painful red papules appear in the genital area. In men, the lesions generally occur on the glans or shaft of the penis. In women, the lesions commonly occur on the labia, vagina and cervix. Anal intercourse or oral–anal sex may also result in lesions in and around the anus.

Soon after the papules appear, they form small painful blisters filled with clear fluid containing virus particles (see Figure 49.1). The blisters break, shedding the highly infectious virus and creating patches of painful ulcers that last approximately 6 weeks (or longer if they become infected). Touching these blisters and then rubbing or scratching in another place can spread the infection to other areas of the body (*autoinoculation*).

The first outbreak of herpes lesions is called *first-episode infection*, with an average duration of 12 days. Subsequent occurrences, usually less severe, are termed *recurrent infections* (average duration of 4–5 days). The period between episodes is

FIGURE 49.1 ■ Genital herpes blisters as they appear on the labia

Source: © Biophoto Associates/Science Source.

called *latency*, during which time the person remains infectious even though no symptoms are present. During latency, the virus withdraws into the nerve fibres that lead from the infected site to the lower spine, remaining dormant until recurrence, at which time it retraces its path to the genital area.

The manifestations of genital herpes are presented below. Prodromal symptoms of recurrent outbreaks of genital herpes can include burning, itching, tingling or throbbing at the sites where lesions commonly appear. These sensations may be accompanied by pain in the legs, groin or buttocks. Some research suggests that prodromal symptoms signal increased levels of infectiousness, during which sexual contact should be avoided.

MANIFESTATIONS Genital herpes

- Herpetic lesions
- Regional lymphadenopathy
- Headache
- Fever
- General malaise
- Dysuria
- Urinary retention
- Vaginal discharge
- Urethral discharge (men)

INTERPROFESSIONAL CARE

Presumptive diagnosis of genital herpes is based on history and physical examination of the person, including lesions and patterns of recurrence. Because there is no cure for genital herpes, treatment focuses on relieving symptoms and preventing the spread of the infection. Health education is essential to prevent further transmission of the disease and to help the person integrate chronic disease management into their life.

Diagnosis

Definitive diagnosis requires isolation of the virus in tissue culture. Ideally, tissue specimens should be obtained within 48 hours of the appearance of the blisters. Diagnostic tests are described in Chapter 46.

Medications

Aciclovir is an antiviral drug. It slows the growth and spread of the herpes virus so that the body can fight off the infection. Aciclovir will not cure herpes, but it can help reduce the length and severity of the first episode and lessen the symptoms of the infection. The oral form is considered most effective for first-episode infections as well as for recurrent infections and is given for 7 to 10 days or until lesions heal. It may also be administered intravenously. Some strains of HSV are becoming resistant to aciclovir, particularly in HIV-positive people. In those cases, foscarnet is used. Other antivirals used for treatment and prevention are valaciclovir and famciclovir.

Nursing care

Planning and implementing nursing care for the person who has genital herpes requires consideration of short- and long-term implications. Although the immediate priority is symptom relief and prevention of further transmission, the person will need help to formulate strategies to deal with the life-changing diagnosis of living with a chronic disease. Stigma is also an important consideration; therefore, nurses need to be aware of the person's psychological, as well as physical, needs.

Nursing diagnoses and interventions

Nursing interventions in this section focus on pain and sexual dysfunction.

Acute pain

Herpetic lesions are very painful and can become infected. Because the virus resides in the nerve ganglia, pain may also occur in the legs, thighs, groin or buttocks. Although aciclovir diminishes the pain of herpes and accelerates the healing process, additional measures can relieve the discomfort further.

- Educate the person on how to keep herpes blisters clean and dry. A solution of warm water, soap and hydrogen peroxide (if lesions are not open) can be used to cleanse the lesions two to three times daily. Burow's solution (a liquid containing aluminium sulfate, acetic acid, precipitated calcium carbonate and water) can also be used. Lesions can be dried using a hair dryer turned to a cool setting. It is important to wear loose cotton clothing that will not trap moisture and avoid wearing items such as lycra, pantyhose and tight jeans. *Keeping the lesions clean and dry reduces the possibility of secondary infection and speeds the healing process.*
- For dysuria, suggest the person pours water over their genitals while urinating. Drinking additional fluids

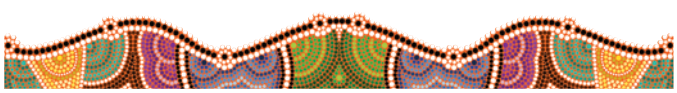
(particularly water) also helps dilute the acidity of the urine. Fluids that increase acidity, such as cranberry juice, should be avoided. *These measures dilute the acid content of urine and thereby reduce the burning sensation.*
- Suggest the person has sitz baths (with tepid water) for 15–30 minutes several times a day. *The warm water is soothing and decreases pain from ulcers and an irritated urethral meatus. It also facilitates wound healing.*

Sexual dysfunction

Some people who learn that they are infected with an incurable STI may believe they can no longer have a normal sex life. Fortunately, many people have learned to live with and manage genital herpes without infecting their partners and/or children.
- Provide a supportive, non-judgmental environment so feelings can be discussed and questions asked freely about what this diagnosis means for future sexual relations. *Feelings of guilt, shame and anger are natural responses and can lead to a total avoidance of sexual intimacy.*
- Provide information about support groups and other resources for people with herpes. *Information about how others cope with this disease can offset feelings of shame and hopelessness.*

Community-based care

Health education for people who are living with genital herpes involves supporting them to manage this chronic disease with the least possible disruption to their lifestyle and relationships. Understanding the disease process and factors that affect it helps the person regain a sense of control and see the potential for future sexual intimacy without transmission of infection. The following topics should be discussed:
- how to recognise prodromal symptoms of recurrence and factors that seem to trigger recurrences (e.g. emotional stress, acidic food, sun exposure)
- the need for abstinence from sexual contact from the time prodromal symptoms appear until 10 days after all lesions have healed
- if lesions become infected, use of topical aciclovir (painful lesions can be protected with sterile petroleum jelly or aloe vera gel)
- use of latex condoms, due to viral shedding at any time, and careful hygiene practices (such as not sharing towels or other personal items) even during latency periods.



THE PERSON WITH GENITAL WARTS

Genital warts (*condylomata acuminata*), caused by the human papillomavirus (HPV), are one of the most common transmissible genital infections and are considered epidemic. Genital warts are chronic and, in many people, largely asymptomatic. Currently, they are incurable.

Genital warts are often described as fleshy growths or bumps seen mostly in areas around the genitals and anus. HPV is spread through direct skin-to-skin contact with a person infected with HPV. This occurs most commonly through sexual contact. HPV may be passed from person to person where there is skin-to-skin contact of the genital area. This can occur even when there are no visible warts, explaining why genital HPV infection spreads easily. HPV may also be passed from mother to baby during childbirth. The virus can live on the skin for many years and during that time can be passed on through sexual contact.

Warts that occur elsewhere on the body are caused by different types of HPV. Contact with these warts is not known to cause genital warts.

Prevention

Some types of HPV infection can be prevented by new vaccines which have been registered for use in Australia. One of the vaccines licensed for use can prevent HPV infection that causes genital warts. The use of male and female condoms for all sexual contact can reduce the transmission of HPV.

Women are at greater risk of HPV genital infections because they have a larger mucosal surface area exposed in the genital area. Most HPV infections are asymptomatic or unrecognised.

HPV infection rates vary greatly between geographical regions and population groups. Almost all cervical cancer is caused by HPV. HPV 16 and 18 are the two most common forms and are known to cause over 70% of cervical cancers. Two vaccines are available that prevent infection from both HPV 16 and 18; however, these vaccines do not treat HPV and it is recommended they are administered prior to first sexual contact (WHO, 2015).

HPV and cervical cancer

All women who have ever had sexual contact should commence having Pap smears from 2 years after first sexual contact. This includes male-to-female and female-to-female contact. Thereafter, Pap smears are routinely done every 2 years, or more frequently if abnormalities are detected. The Gardasil® vaccine, developed by a team led by Australian scientist Professor Ian Frazer, protects against four HPV strains: HPV genital types 6, 11, 16 and 18. HPV types 16 and 18 are linked to 70% of cervical cancers in Australia; types 6 and 11 are linked to approximately 90% of genital warts cases. The National HPV Vaccination Program is ongoing for 12- to 13-year-old girls and boys and provides free vaccination through a school-based

FAST FACTS

- One of the most common STIs is HPV.
- Almost all sexually active people in the US acquire genital HPV infection at some point in their lives.
- Most people with a genital HPV infection do not know they are infected; most women are diagnosed by abnormal Pap tests.

Source: CDC (2015).

program. For information about the program, see the Cancer Council Victoria website www.hpvvaccine.org.au.

The vaccine will not prevent all types of HPV that cause cervical cancer, nor can it 'cure' an HPV infection if it has been acquired previously. There are many different types of the HPV virus that can affect various parts of the body.

Although the majority of infected people are asymptomatic, some experience frequent recurrences. Other than recurrences, men are not likely to experience serious physical complications from genital warts. Women, however, have an increased risk of cervical cancer, with HPV DNA having been identified in almost all cervical cancers worldwide, and in approximately 50–80% of vaginal, vulvar and anogenital cancers.

Pathophysiology

Genital warts, sometimes called venereal warts, are caused by HPV and are transmitted by vaginal, anal or oral–genital/anal contact. The incubation period is between 3 weeks and 8 months (Sexual Health Australia, 2012).

Manifestations

Although some people with HPV may not have manifestations, others exhibit characteristic lesions: single or multiple painless, soft, moist, pink or flesh-coloured swellings in the vulvovaginal area, perineum, penis, urethra, anus, groin or thigh (see Figure 49.2). In women, the growths may be in the vagina or on the cervix and be apparent only during a pelvic examination.

The four types of genital warts are:

1. *Condyloma acuminata:* cauliflower-shaped lesions that appear on moist skin surfaces such as the vagina or anus.
2. *Keratotic warts:* thick, hard lesions that develop on keratinised skin such as the labia major, penis or scrotum.
3. *Papular warts:* smooth lesions that also develop on keratinised skin.
4. *Flat warts:* slightly raised lesions, often invisible to the naked eye, that also develop on keratinised skin.

INTERPROFESSIONAL CARE

Treatment is directed at removal of warts, relief of symptoms and health education to reduce the risk of recurrence and future transmission. Infection with HPV is considered chronic. Research has shown that for about 90% of women, cervical HPV becomes undetectable within 2 years (CDC, 2015).

A B

FIGURE 49.2 ■ Genital warts (*condyloma acuminata*) on the *A*, vulva and *B*, penis

Sources: A, CDC/Richard Deitrick; *B*, CDC/Dr M. F. Rein.

Genital and anal warts are diagnosed primarily by clinical appearance. An HPV DNA test is specific for diagnosis in women. There are currently no HPV tests for men.

Medications

Topical agents can be used to treat genital warts and include podofilox and imiquimod (both can be applied by the person), or podophyllin and trichloroacetic acid (which is administered by health professionals). Podophyllin is contraindicated during pregnancy and can have side effects ranging from nausea, diarrhoea and lethargy, to paralysis and coma (see the following 'Medication administration' box). As already mentioned, Gardasil® is a vaccine developed to prevent genital warts, precancerous genital lesions and cervical cancer due to HPV. It is administered by three intramuscular injections given over a 6-month period. As HPV is so closely associated with cervical cancer, an Australian federal advisory panel recommended that the vaccine be targeted at females aged 9 to 26.

Other treatments

Genital warts may also be removed by cryotherapy, electrocautery, laser vaporisation or surgical excision. Carbon dioxide laser surgery is becoming increasingly common for removal of extensive warts.

Nursing care

Health promotion activities should include information about the causes, treatments and prevention of HPV infections.

Nursing diagnosis and interventions

Nursing interventions primarily involve health education, and discussions on stigma, fear and anxiety. People are often acutely embarrassed.

Knowledge deficits

HPV is spread by contact with infectious lesions or secretions. Up to 70% of genital warts are spread by people who do not know they have the infection. Although there is currently no known cure, it is essential to prevent secondary infections.

- Discuss the need for prompt treatment, and the necessity for sexual abstinence until lesions have healed or using a condom while lesions are present. *This reduces the risk of reinfection and further transmission of the disease. Using condoms promotes the regression of HPV lesions in both men and women.*
- Discuss the increased risk of cervical cancer and the importance of having a Pap smear. *Understanding the risk, the person will be more motivated to seek screening.*
- Stress the importance of thorough handwashing. *Handwashing is essential to prevent the spread of HPV.*

Fear

Surgery engenders some degree of fear in most people: fear of the procedure itself and/or of pain and possible complications. Surgery or cryotherapy in the genital area involves all of these fears plus fear of possible impaired sexual function, as well as stigma.

- Provide opportunities for the person to express their fears and feelings about the procedure. Explain the procedure, approximate recovery time, possible complications and ways to avoid them, and ways to cope with complications that do occur. *Knowing what to expect reduces the person's fear and helps them feel a greater sense of control.*

MEDICATION ADMINISTRATION The person who has genital warts

TOPICAL APPLICATIONS

Podophyllin
Trichloroacetic acid

Although cryotherapy using liquid nitrogen or a cryoprobe is commonly used to treat genital warts, podophyllin preparations are sometimes used. Podophyllin is applied topically to the warts once a week for 3–5 weeks.

Podophyllin is contraindicated during pregnancy; the alternative is cryotherapy. Podophyllin is also contraindicated in cervical, urethral, oral or anorectal warts. It is important to avoid contact of podophyllin resin with the eyes. Wear appropriate personal protective equipment (PPE) when applying podophyllin.

Adverse effects of podophyllin include local irritation, severe ulceration of surrounding tissue, nausea, diarrhoea, lethargy, paralysis and coma.

Nursing responsibilities

- Establish baseline data, including mental status, vital signs and weight.
- Document and report any existing lesions (genital, anal or oral).
- Cover the tissue surrounding the warts with a protective barrier cream or a paste of baking soda and water to protect the tissue from the caustic treatment solution.

Health education for the infected person and their significant others

- Wash off the treated area thoroughly within 1–4 hours after the first application; gradually increase this period to 6–8 hours after the second and subsequent applications.
- Return for regular treatment until warts are gone.
- Refer partners for examination and any necessary treatment.
- Report any adverse effects (nausea, diarrhoea, local irritation, lethargy, numbness).
- Avoid sexual activity until the person and their partners have been free of disease for 1 month.
- Use condoms to prevent future infections.
- Return for an annual Pap smear.

- Explain that the procedure is performed with a local anaesthesia. *Being awake during surgery gives the person a greater sense of partnership in the treatment process.*

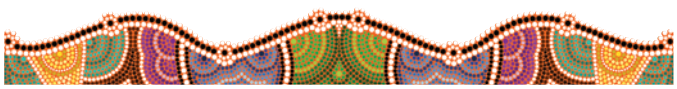
Anxiety

The woman with an HPV infection faces an increased risk of infection of her neonate during delivery. The neonatal infection can range from asymptomatic to widely disseminated fatal disease. Transmission occurs during passage through the birth canal. The risk is highest during the first episode of infection.

- Discuss with women of childbearing age that caesarean delivery can prevent transmission of infection to the neonate. In women without manifestations of recurrence, vaginal delivery is possible. *Understanding that infection of the neonate can be prevented helps relieve anxiety.*

Community-based care

Health education emphasises the need for the infected person and their infected sexual partners to return for regular treatment until lesions have resolved and to use condoms to prevent reinfection. Because of the increased risk of cervical cancer, annual Pap smears are essential for infected women and girls.



THE PERSON WITH A VAGINAL INFECTION

The vagina may be infected by yeasts, protozoa or bacteria. These infections can be sexually transmitted, but the male partner does not usually have manifestations of the infection. Risk factors include the use of hormonal contraceptives or broad-spectrum antibiotics, obesity, diabetes, pregnancy, unprotected sexual activity and multiple sexual partners, particularly if unprotected sex has been practised. Manifestations of vaginal infections are outlined in Table 49.2.

Preventive measures include education about the necessity of high standards of personal hygiene and safe sex practices. Women need to avoid frequent douching and wearing nylon underwear, lycra and/or tight jeans or trousers. Unprotected sexual activity, particularly with multiple partners, increases the risk of vaginal infections.

Pathophysiology and manifestations

Alterations in pH, changes in the normal flora and low oestrogen levels are conducive to the development of vaginal infections. When conditions are favourable, microorganisms invade the vulva and vagina.

Bacterial vaginosis

Bacterial vaginosis (non-specific vaginitis) is the most common cause of vaginal infection in women of reproductive age. *Gardnerella vaginalis* is one of the causative organisms, but others are also implicated. The relationship of sexual activity to this infection is not clear. The primary manifestation is a vaginal discharge that is thin and greyish-white, and has a foul, fishy odour. Complications include pelvic inflammatory disease, preterm labour, premature rupture of the membranes and postpartum endometritis. The infection is treated with oral or intravaginal antibacterial agents.

Candidiasis

Candidiasis (moniliasis or yeast infection) is caused by the organism *Candida albicans*, which has several strains of different virulence. Candida organisms are part of the normal vaginal environment in up to 50% of women, causing problems only when they multiply rapidly. When increased oestrogen levels, antibiotics, diabetes mellitus, faecal contamination or other factors alter the normal vaginal flora, the organism proliferates, resulting in a yeast infection. The manifestations include an odourless, thick, cheesy vaginal discharge

TABLE 49.2 Vaginal infections

INFECTION	TYPE OF DISCHARGE	TYPICAL MANIFESTATIONS	NURSING CARE
Candidiasis (*Monilia*, yeast)	Thick white patches adhering to cervix and vaginal wall, resembling cottage cheese; little odour	Itching of vulva and vaginal area, redness, painful intercourse	Teach perineal hygiene and proper use of vaginal applicators. Instruct the person to complete the entire treatment.
Simple vaginalis (bacterial vaginosis, *Gardnerella vaginosis*)	Thin, white, 'milk-like', or grey with fishy odour, especially when mixed with potassium hydroxide	None to mild itching or burning in vulvar area; clue cells on microscopic examination	Educate the person about proper perineal hygiene. Instruct the person to complete treatment. Inform the person about the relationship of infection to pelvic inflammatory disease.
Trichomoniasis	Frothy, yellow or white, foul odour	Burning and itching of vulva	Provide health education about perineal hygiene.
Atrophic vaginitis (senile vaginitis)	Thin, opaque discharge, occasionally blood tinged, odourless; pale, smooth, thin, dry vaginal walls	Painful intercourse, itching, vaginal dryness	Inform the person about symptoms of menopause and sexual techniques to minimise trauma.

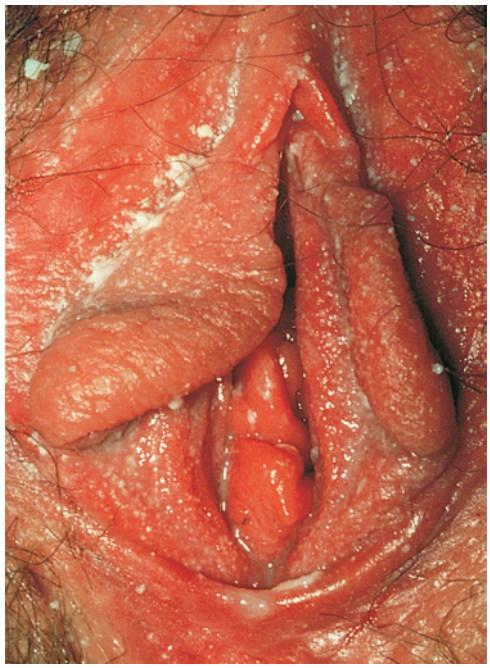


FIGURE 49.3 ■ Yeast infection on female genitalia

Source: Custom Medical Stock Photo, Inc.

(see Figure 49.3). This is often accompanied by itching and irritation of the vulva and vagina, dysuria and dyspareunia. Uncircumcised men may develop a yeast infection over the glans penis, manifested by itching and dysuria. The infection is treated with oral medications or, for women, intravaginal antifungal agents.

Trichomoniasis

Trichomoniasis is caused by *Trichomonas vaginalis*, a protozoan parasite. It is the most common STI worldwide, but is curable. It affects mostly women and is common in Australia. Women who have unprotected sex with multiple partners are at higher risk. Rates of trichomoniasis are increasing in some Aboriginal communities (Australian Sexual Health Alliance (ASHA), 2015). Symptoms usually appear within 5 to 28 days of exposure. It most commonly infects the vagina in women and the urethra in men. Most men are asymptomatic, but when symptomatic may complain of dysuria and urethral discomfort. Women have a frothy, green-yellow vaginal discharge with a strong fishy odour, often accompanied by itching and irritation of the genitalia. A woman with HIV who becomes infected has an increased risk of transmitting HIV to her sexual partner.

Trichomoniasis is treated with a single oral dose of metronidazole or tinidazole. These antibiotics are effective against anaerobic bacteria and certain parasites. Anaerobic bacteria are single-celled, living organisms that thrive in environments in which there is little oxygen (anaerobic environments). They selectively block some of the functions within the bacterial cells and the parasites, resulting in their death.

INTERPROFESSIONAL CARE

Interprofessional care focuses on identifying and eliminating the infection and preventing recurrence.

Diagnosis

Diagnostic tests vary with the suspected organism. Cervical cultures are used to diagnose the causative organism. *Trichomonas* is identified by microscopically examining a specimen of vaginal discharge in saline. Ten per cent potassium hydroxide is used to identify spores and filaments of candida. Diagnostic tests are described in Chapter 46.

Medications

Pharmacological treatments vary with the organism. Sexual partner/s of a woman who has a *Trichomonas* infection must also be treated to prevent reinfection. Some antifungal agents are available without prescription, which can sometimes lead to self-medication with the incorrect agent, or allow repeated infections to go unreported.

Nursing care

Engaging the infected woman in health education and, if necessary, her sexual partner/s to comply with the treatment regimen and using safer sex practices, can prevent future transmission of the infection. Careful history taking may also reveal high-risk sexual practices that require intervention, particularly if the woman has had repeated infections. The initial presenting symptom for many HIV-positive women is vaginal candidiasis which may not respond to over-the-counter treatments. Treatment with some antibiotics destroys normal vaginal flora, also resulting in superinfection with yeast.

Nursing interventions

Although each care plan must be individualised, priorities for care that often apply to women with vaginal infections are *Health education* and *Acute pain*.

Health education

Health education focuses on eradicating the infection, preventing further disease transmission and relieving discomfort associated with the condition. Educating the woman and her partner/s about safe sex and improved genital hygiene practices can reduce the incidence of recurrence.

Many women are unaware of the causes of vaginal infections and the self-care measures to prevent and treat these infections. If possible, both the woman and her sexual partner/s should be provided with information.

- Explain the transmission of the infection and check that you are understood. Many infections are transmitted most easily during menstruation; some can also be transmitted by towels or other inanimate objects, or by certain types of

BOX 49.2 Self-care comfort measures

- Do not wear pantyhose, nylon or lycra; wear loose-fitting trousers, shorts, skirts or dresses.
- Double-rinse underwear; do not use fabric softener.
- Do not use bubble bath, perfumed soaps or perfumed feminine hygiene products.
- Use 100% cotton menstrual pads and/or tampons.
- Use unscented toilet paper.
- Use a water-soluble lubricant for intercourse.
- Apply ice or a frozen gel pack wrapped in a towel to the vulva after intercourse to relieve burning. Ensure the towel is cleansed properly or disposed of.
- Rinse vulva with cool water after voiding and intercourse.

sexual activity. *An open discussion of disease transmission and prevention with the woman and her partner/s can reduce the risk of reinfection.*

- Explain the need to complete the entire course of treatment. *Many infections are asymptomatic in one partner. Incomplete treatment allows for recurrence of the infection and reinfection of the partner.*

Acute pain

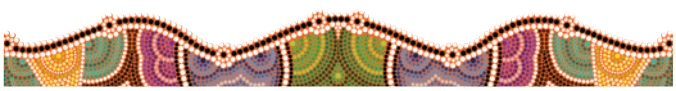
The symptoms of vaginitis can include dysuria, painful excoriation or ulceration of tissue, and painful intercourse (dyspareunia). Often these symptoms can be relieved by relatively simple self-care measures. See Box 49.2 for additional comfort measures.

- Suggest the use of cool compresses. *Cool compresses relieve itching.*
- Recommend warm, not hot, sitz baths to alleviate discomfort. *Sitz baths cleanse the perineal area and the warmth is soothing to inflamed, irritated skin and membranes.*
- Wear cotton underwear. *Cotton absorbs moisture and allows better air circulation than other types of material.*
- If infected with *Trichomonas*, avoid sexual contact until treatment is completed. *Treatment of the infected woman and her partner/s, as well as sexual abstinence, are necessary to facilitate healing and to prevent reinfection.*

Community-based care

Health education

Health education focuses on eradicating the infection, preventing further disease transmission and relieving discomfort associated with the condition. Educating the woman and her partner/s about safe sex and improved genital hygiene practices can reduce the incidence of recurrence.



THE PERSON WITH CHLAMYDIA

Chlamydia is a group of STIs caused by *Chlamydia trachomatis*, a bacterium that behaves like a virus, reproducing only within the host cell. The bacterium is spread by any sexual contact and to the neonate by passage through the birth canal of an infected mother. The infections caused by chlamydia include acute urethral syndrome, non-gonococcal urethritis, mucopurulent cervicitis and pelvic inflammatory disease.

Chlamydia is the most commonly reported bacterial STI in Australia, with 355 cases per every 100 000 people each year (Department of Health, 2014c). Of that number, 81% of reported cases occur in people aged between 15 and 24. Risk factors for chlamydia are listed in Box 49.3.

Because chlamydia is asymptomatic in most women until the uterus and fallopian tubes have been invaded, treatment may be delayed, resulting in devastating long-term complications. Nearly one-third of men with urethral chlamydia are also asymptomatic. Chlamydia is a leading cause of preventable blindness in the newborn.

Pathophysiology

C. trachomatis is an intracellular bacterial pathogen that resembles both a virus and a bacteria. The organism enters the body as an elementary body, a form in which it is capable of entering uninfected cells. The infection begins when the organism enters a cell and changes into a reticulate body. The reticulate body divides within the cell, bursting the cell and infecting adjoining cells.

Manifestations

The incubation period is from 1 to 3 weeks. Chlamydia may be present for months or years without producing noticeable symptoms in women. Chlamydia typically invades the same target organs as gonorrhoea (cervix and male urethra) and results in similar manifestations (dysuria, urinary frequency and discharge). People with the infection may be asymptomatic. However, they are still potentially infectious.

Complications

If a chlamydial infection in women is not treated, it ascends into the upper reproductive tract, causing such complications as pelvic inflammatory disease, which includes endometritis and salpingitis. Chronic pelvic pain may result. These infections are

BOX 49.3 Higher risk factors for chlamydial infection

- Young sexually active poeple
- Previous history of STI
- Homosexually active men and men who have sex with men (MSM)
- Indigenous Australian people
- Oral contraceptive use
- Unprotected sexual activity
- Multiple sexual partners

a major cause of infertility and ectopic pregnancy, which are potentially life threatening. Complications of chlamydial infections in men include pelvic inflammatory disease, epididymitis, prostatitis, sterility and Reiter's syndrome. Reiter's syndrome is a form of reactive arthritis; it is relatively uncommon but can be a debilitating syndrome that follows a gastrointestinal or genitourinary infection. Routine screening for sexually active adolescents and young adults has been suggested by the CDC to minimise these serious complications in asymptomatic people.

INTERPROFESSIONAL CARE

C. trachomatis is treated with medications to eradicate the infection. Its prevalence, particularly in younger populations, makes widespread screening necessary if the disease is to be controlled. Because chlamydia is often asymptomatic, treatment is often begun on a presumptive basis.

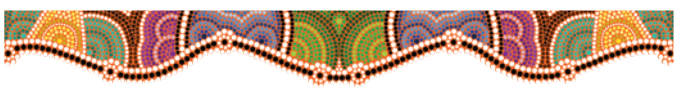
Diagnosis

The diagnostic tests that may be ordered include Gram stain of discharge from the female endocervix and urethra or from the male urethra to look for polymorphonuclear leucocytes (considered evidence of infection).

Tests for antibodies to chlamydia, such as the direct fluorescent antibody (DFA) test and an enzyme-linked immunosorbent assay (ELISA), as well as polymerase chain reaction (PCR) or ligase chain reaction (LCR) tests, are highly sensitive and specific tests performed on cervical and urethral swab specimens. Nucleic acid amplification tests (NAATs), also performed on cervical and urethral swab specimens, are currently the diagnostic method of choice.

Medications

The antibiotic recommended by the CDC for chlamydial infections in men and non-pregnant women is azithromycin, orally in a single dose, or doxycycline, orally for 7 days. All sexual partners must be treated simultaneously or prior to resuming sexual intercourse.

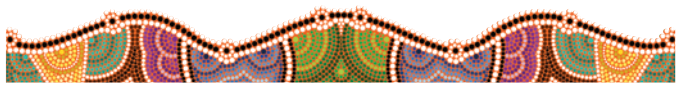


Nursing care

Nursing care of the person who has chlamydia focuses on eradication of the infection, prevention of future infections and management of any chronic complications. Nursing priorities and care for the person who has chlamydia are the same as for anyone with any STI. Interventions are similar to those discussed later in the chapter for gonorrhoea and previously for genital herpes.

Community-based care

Health education for the person who has chlamydia centres on the need to comply with the treatment regimen, to refer partners for examination and necessary treatment, and the use of condoms to avoid reinfection. If the infection has progressed to pelvic inflammatory disease (discussed later), the person will require additional information on self-care and health promotion. The CDC recommends annual screening for chlamydia for people who are young, sexually active and do not use condoms correctly with every act of sexual intercourse.



THE PERSON WITH GONORRHOEA

Gonorrhoea, also known as 'GC' or 'the clap', is caused by *Neisseria gonorrhoeae*, a Gram-negative diplococcus. In Australia, gonorrhoea is the second most commonly reported STI. Global estimated incidence of gonorrhoea is 62 million infected people annually (WHO, 2013).

In Australia in 2010, more than one-third (36%) of all gonorrhoea diagnoses were in Aboriginal and Torres Strait Islander people. The rate of diagnosis was more than 26 times that for the non-Indigenous population (University of New South Wales (UNSW), 2013). Other risk factors include residing in large urban areas, being transient, early onset of sexual activity, multiple serial or consecutive sexual partners, illicit drug use, alcohol misuse, prostitution and previous gonorrhoeal or concurrent STIs.

Pathophysiology

The causative organism of gonorrhoea is a pyogenic (pus-forming) bacterium that causes inflammation characterised by purulent exudate. Humans are the only host for the organism. Gonorrhoea is transmitted by direct sexual intercourse and during delivery as the neonate passes through the birth canal. The portal of entry can be the genitourinary tract, eyes, oropharynx, anorectum or skin. The incubation period is 2 to 7 days after exposure. The organism initially targets the female cervix and the male urethra. Without treatment, the disease ultimately spreads widely to other organs. In men, gonorrhoea can cause acute, painful inflammation of the prostate, epididymis and periurethral glands, and can lead to sterility. In women, it can cause pelvic inflammatory disease, endometritis, salpingitis and pelvic peritonitis.

Manifestations

Manifestations of gonorrhoea in men include dysuria and serous, milky or purulent discharge from the penis. Some men also experience regional lymphadenopathy. About 20% of men and 80% of women remain asymptomatic until the disease is advanced. Women with symptoms experience dysuria, urinary frequency, abnormal menses (increased flow or dysmenorrhoea), increased vaginal discharge and dyspareunia (difficult or painful sexual intercourse).

Anorectal gonorrhoea is seen most often in people who practise anal sex. The manifestations include pruritus,

mucopurulent rectal discharge, rectal bleeding and pain, and constipation. Gonococcal pharyngitis occurs primarily in people after oral sex (fellatio) with an infected partner. The manifestations include fever, sore throat and enlarged lymph glands.

Complications

The complications of untreated gonorrhoea in both men and women may be permanent and serious. They include:

- pelvic inflammatory disease in women, leading to internal abscesses, chronic pain, ectopic pregnancy and infertility
- blindness, infection of joints and potentially lethal infections of the blood in the newborn, contracted during delivery
- epididymitis and prostatitis in men, resulting in infertility and dysuria
- spread of the infection to the blood and joints
- increased susceptibility to and transmission of HIV.

INTERPROFESSIONAL CARE

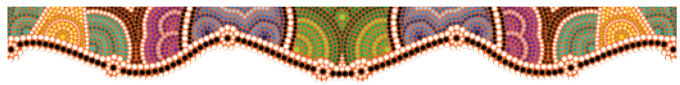
The goals of treatment for the person who has gonorrhoea include eradication of the organism and any coexisting disease, and prevention of reinfection or transmission. It is important to emphasise the importance of taking all medications as prescribed and abstaining from sexual contact until the infection is cured in both the person and their partner/s. Condom use to prevent future infections is essential, particularly for pregnant women whose partner/s may be infected.

Diagnosis

Diagnosis of gonorrhoea is based on cultures from the infected mucous membranes (cervix, urethra, rectum or throat), examination of urine from an infected person and a Gram stain to visualise the bacteria under the microscope. Testing for other STIs (especially chlamydia and syphilis) at the same time is recommended. Pregnant women are routinely screened during their first prenatal visit. Diagnostic tests are described in Chapter 46.

Medications

Because of the many penicillin-resistant strains of *N. gonorrhoeae*, alternative antibiotics, such as ciprofloxacin (Cipro) or ofloxacin (Floxin) are used to treat gonorrhoea. Fluoroquinolone therapy (such as with ciprofloxacin or levofloxacin) is often prescribed because it is inexpensive, oral and single dose. Because of increased prevalence of fluoroquinolone-resistant *N. gonorrhoeae* in Asia, the Pacific Islands and California in the US, this therapy is no longer recommended for use in treating gonorrhoea in those areas. A single dose of oral azithromycin (Zithromax) or a 7-day course of oral doxycycline (Vibramycin, Vivox) is usually added to treat any coexisting chlamydial infection. All sexual partners also need to be treated within 60 days of diagnosis of the infection.



Nursing care

In planning and implementing care for the person who has gonorrhoea, the nurse considers the possible coexistence of other STIs such as syphilis and HIV, the impact of the disease and its treatment on the person's lifestyle, and the likelihood of noncompliance. A nursing care plan for the person who has gonorrhoea is included below.

Nursing interventions

Nursing priorities discussed in this section focus on noncompliance with treatment and social isolation.

Noncompliance

Although one-time treatment with the recommended antibiotic is highly effective in curing gonorrhoea, noncompliance with the doxycycline regimen may leave any coexisting chlamydial infection unresolved. Noncompliance with recommendations for abstinence, follow up or condom use fosters a high rate of reinfection. Failure to refer partners for examination and treatment also leads to reinfection.

- Reinforce the need to take all medications as directed and to keep follow-up appointments to be sure no reinfection has occurred. Discuss the prevalence of gonorrhoea and the potential complications if it is not cured. *The person who understands the complications of incomplete or failed treatment is more likely to comply with the medication regimen.*
- Discuss the importance of sexual abstinence until the infection is cured, referral of partners and condom use to prevent reinfection. *Understanding that cure is possible and reinfection is avoidable helps the person cope with the disease and its treatment, and is likely to increase compliance.*
- Explain to women that condoms must be used during treatment, even if other methods of birth control are used. *Oral contraceptives increase the alkalinity of the vaginal pH, facilitating the growth of the gonococcal bacteria, and intrauterine devices alter the endometrial barrier, favouring persistent gonococcal infections.*

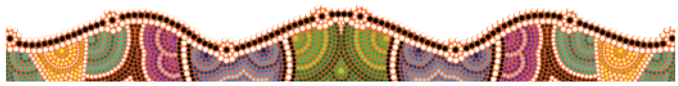
Social isolation

Diagnosis of any STI can make people feel 'dirty', ashamed and guilty about their sexual behaviours, and unworthy of being with others.

- Provide privacy, confidentiality and a safe, non-judgmental environment for expression of concerns. Support the person to gain an understanding that gonorrhoea is a consequence of sexual behaviour, not a punishment, and that it can be avoided in the future. *Being treated with respect and privacy helps the person realise that the disease does not change an individual's worth as a person. This knowledge enhances the person's ability to relate to others.*

Community-based care

Health education focuses on supporting people to understand the importance of (1) taking any and all prescribed medication, (2) referring sexual partners for evaluation and treatment, (3) abstaining from all sexual contact until the person and their partners are cured, and (4) using a condom to avoid transmitting or contracting infections in the future. Individuals also need to understand the need for a follow-up visit 4 to 7 days after treatment is completed.



NURSING CARE PLAN The person with gonorrhoea

Joaddie Deall is a single 26-year-old Assistant in Nursing who lives in a high-density metropolitan apartment. Ms Deall is currently dating Angus Penting, who lives nearby. Ms Deall visits her gynaecologist because her periods have become irregular and she is experiencing pelvic pain. She also complains of an abnormal amount of vaginal discharge. Recently she has developed a sore throat. The pelvic pain has begun to disrupt her sleeping pattern and she is concerned that she might have cancer because her mother recently died of ovarian cancer.

ASSESSMENT

When Ms Deall arrives for her appointment at the gynaecologist's office, Bradley Terr, the Nurse Practitioner (NP), respectfully and non-judgmentally interviews her. Mr Terr undertakes a thorough medical and sexual history, including gathering information about Ms Deall's menstrual periods, pain associated with urination or sexual intercourse, urinary frequency, most recent Pap smear, birth control method, history of STI and drug use, and types of sexual activity. Ms Deall tells the NP her symptoms and her concerns about possible ovarian cancer. She also indicates that she is taking oral contraceptives and therefore sees no need for Angus to use a condom. She believes their relationship to be monogamous.

Physical examination reveals both pharyngeal and cervical inflammation and lower abdominal tenderness. Her temperature is 37.2°C. There are no signs or symptoms of pregnancy.

A Pap smear is ordered and cultures of the cervix, urethra and pharynx to evaluate for gonorrhoea and chlamydial infection. Mr Terr, the NP, takes blood for a white cell count. Test results are positive for gonorrhoea and negative for chlamydia. The white cell count is slightly elevated, indicating possible salpingitis. Because Angus has been Ms Deall's only sexual partner, it is clear that he is the source of infection and also requires treatment.

DIAGNOSES

- *Acute pain* related to the infectious process.
- *Anxiety* related to fear about possible cancer.
- *Low self-esteem* related to shame and guilt because of having an STI.
- *Altered sexuality patterns* related to the impaired relationship and fear of reinfection.

PLANNING

- Establish a therapeutic relationship that is respectful and non-judgmental.
- Discuss with Ms Deall which tests and investigations will be ordered and why.
- In collaboration with Ms Deall, set goals and priorities for care and treatment.

Expected outcomes

- A therapeutic relationship is established and Ms Deall feels as though she was treated with respect and dignity.
- Ms Deall receives education regarding tests and investigations and understands why they have been ordered.
- A care plan is jointly established and agreed upon.
- Ms Deall experiences relief of pain, indicating that the infection has been eradicated.
- Ms Deall understands that she has nothing to be ashamed of and that she was wise to seek treatment as soon as her symptoms occurred.
- Ms Deall understands her diagnosis and the implications of the illness.
- Ms Deall understands the need for her and her partner to use condoms during future sexual activity.

IMPLEMENTATION

- Administer ceftriaxone IM.
- Emphasise the need for regular Pap smears and pelvic examinations because of the family history of ovarian cancer.
- Discuss feelings and concerns about the diagnosis of gonorrhoea. Stress that such a diagnosis is not a reflection on her worth as a person.
- Educate how to talk with sexual partner/s about condom use.

EVALUATION

A week later, during her follow-up visit, Ms Deall states that she is feeling much better and sleeping well at night since the pain has ended. She has terminated her relationship with Mr Penting and is considering joining a health club in the hope of increasing her level of fitness and perhaps meeting someone new.

CRITICAL THINKING IN THE NURSING PROCESS

1. In what ways are Ms Deall's manifestations related to the infectious process of gonorrhoea?
2. Should the nurse have suggested that Ms Deall also be tested for HIV? Why or why not?
3. Develop a care plan for Ms Deall related to *Social isolation*.

REFLECTION ON THE NURSING PROCESS

1. Why is it so important that a therapeutic relationship be established and that the nurse is non-judgmental and respectful?
2. Which aspects of health education should the nurse focus on?

THE PERSON WITH SYPHILIS

Syphilis is a complex systemic STI caused by the spirochaete *Treponema pallidum*. It can infect almost any body tissue or organ and is transmitted from open lesions during any sexual contact (genital, oral–genital, oral–anal, or anal–genital). The organism is highly susceptible to heat and drying, but can survive for days in fluids; thus, it may also be transmitted by infected blood or other body fluid such as saliva. The incubation period ranges from 10 to 90 days, averaging 21 days. If not treated appropriately, syphilis can lead to blindness, paralysis, cardiovascular damage and death. Syphilis often occurs with one or more other STIs, such as HIV/AIDS or chlamydial infection.

Famous people suspected of having syphilis include Charles VIII of France, Adolph Hitler, Mussolini and Leo Tolstoy. Those suspected of dying from the disease include Christopher Columbus, George Washington, Napoleon Bonaparte and Franz Schubert. It is posited that 'the pox', as syphilis is sometimes called, was spread worldwide by Christopher Columbus and his men.

Although the rate of syphilis infection has reduced, it remains a significant problem in certain geographical regions and specific populations. Rates remain high in many urban centres, with higher infection rates found in illicit drug users, people who are transient and people who are homeless. The incidence of primary and secondary syphilis is highest in people 20 to 39 years of age, with the incidence in women decreasing. However, the rate of syphilis in men having sex with men (MSM) is increasing (CDC, 2015).

In 2012, syphilis notifications were approximately four times higher in Aboriginal and Torres Strait Islander people than in the non-Indigenous population. The number of people diagnosed with syphilis was 27 per 100 000 Aboriginal and Torres Strait Islander people, while the number of people diagnosed in the non-Indigenous population was 7 per 100 000 (UNSW, 2013).

Pathophysiology

Any break in the skin or mucous membrane is vulnerable to invasion by the spirochaete. Once it has entered the system, the spirochaete is spread through the blood and lymphatic system. Congenital syphilis is transferred to the foetus through the placental circulation.

Manifestations

Syphilis is generally characterised by three clinical stages: primary, secondary and tertiary. Each stage has characteristic manifestations (see Table 49.3). The person who has syphilis also may experience a latency period when no signs of the disease are evident.

TABLE 49.3 Manifestations of syphilis

SYSTEM	PRIMARY	SECONDARY	TERTIARY
Reproductive	Genital chancre (may be internal in female)	Condyloma lata	
Integumentary		Rash on palms of hands and soles of feet	Granulomatous lesions involving mucous membranes and skin
Gastrointestinal	Loss of appetite Oral mucous patches		
Neurological		Asymptomatic Meningitis Headache Cranial neuropathies	Asymptomatic Tabes dorsalis Neurosyphilis Seizures, hemiparesis, hemiplegia Personality changes, hyperactive reflexes, Argyll Robertson pupil, decreased memory, slurred speech, optic atrophy
Musculoskeletal		Arthralgia Myalgia Bone and joint arthritis Periostitis	Gummas
Cardiovascular			Aortic insufficiency Aortic aneurysm Stenosis of openings to coronary arteries
Renal		Glomerulonephritis Nephrotic syndrome	
Other	Regional lymphadenopathy	Generalised lymphadenopathy Fever Hepatitis Malaise Alopecia	

FIGURE 49.4 ■ Chancre of primary syphilis on the penis

Source: CDC/M. Rein.

Primary syphilis

The primary stage of syphilis is characterised by the appearance of a **chancre** (see Figure 49.4) and by regional enlargement of lymph nodes; little or no pain accompanies these warning signs. The chancre appears at the site of inoculation (such as the genitals, anus, mouth, breast, fingers) 3 to 4 weeks after the infectious contact. In women, a genital chancre may go unnoticed, disappearing within 4 to 6 weeks. In both primary and secondary stages, syphilis remains highly infectious, even if no symptoms are evident.

Secondary syphilis

Manifestations of secondary syphilis may appear any time from 2 weeks to 6 months after the initial chancre disappears. Symptoms can include a skin rash, especially on the palms of the hands or soles of the feet; mucous patches in the oral cavity; sore throat; generalised lymphadenopathy; condyloma lata (flat, broad-based papules, unlike the pedunculated structure of genital warts) on the labia, anus or corner of the mouth; flu-like symptoms; and alopecia. These manifestations generally disappear within 2 to 6 weeks and an asymptomatic latency period begins.

Latent and tertiary syphilis

The latent stage of syphilis begins 2 or more years after the initial infection and can last up to 50 years. During this stage, no symptoms of syphilis are apparent and the disease is not transmissible by sexual contact. It can be transmitted by infected blood. Therefore, all prospective blood donors are screened for syphilis. In two-thirds of all cases, the latent stage persists without further complications. Unless treated, the remaining one-third of infected people progress to late-stage or tertiary syphilis. In the presence of HIV infection, disease progression seems to be more rapid.

Two types of late-stage syphilis occur. Benign late syphilis, of rapid onset, is characterised by localised development of infiltrating tumours (*gummas*) in skin, bones and liver, generally responding promptly to treatment. A more insidious onset involves a diffuse inflammatory response that involves the central nervous and cardiovascular system. Though the disease can still be treated at this stage, much of the cardiovascular and central nervous system damage is irreversible.

INTERPROFESSIONAL CARE

The goals of treatment are to inactivate the spirochaete and provide health education about how to prevent reinfection or further transmission. Treatment includes antibiotic therapy and identification and referral of partners for testing and treatment if necessary, follow-up testing and education about condom use to prevent reinfection of self and transmission of disease to partners. In addition, people with syphilis should also be screened for chlamydial infection and advised to have an HIV test.

Diagnosis

Diagnosis of syphilis is complex because it mimics many other diseases. A careful history and physical examination are obtained, as well as laboratory evaluations of lesions and blood. Diagnostic tests are described in Chapter 46.

People with syphilis become positive about 4 to 6 weeks after infection. However, these tests are not specific for syphilis and other diseases may also cause positive results. Additional tests are required for a definitive diagnosis.

The FTA-ABS (fluorescent treponemal antibody absorption) test is specific for *T. pallidum* and can be used to confirm findings. It may be used for people whose clinical picture indicates syphilis but who have negative venereal disease results. In immunofluorescent staining, a specimen is obtained from early lesions or aspiration of lymph nodes and is specially treated and examined microscopically for the presence of *T. pallidum*. Dark-field microscopy involves examining a specimen from the chancre for the presence of *T. pallidum* using a dark-field microscope.

Medications

The treatment of choice for all stages of syphilis is penicillin G, given intramuscularly (IM) in a single dose. People who are allergic to penicillin are given oral doxycycline or tetracycline for 28 days.

Treatment of syphilis may result in a severe reaction called the *Jarisch–Herxheimer reaction*, involving fever, musculoskeletal pain, tachycardia and sometimes hypotension. This is not a reaction to the penicillin itself, but to the sudden and massive destruction of spirochaetes by the penicillin and the resulting release of toxins into the bloodstream. The Jarisch–Herxheimer reaction generally begins within 24 hours of treatment and subsides in another 24 hours. Treatment should not be discontinued unless symptoms become life threatening.

Nursing care

In planning and implementing nursing care for the person who has syphilis, the nurse needs to consider the person's age, their lifestyle, access to healthcare and their educational

level. A nursing care plan for a person who has syphilis is included below.

Nursing diagnoses and interventions

Nursing priorities discussed in this section focus on the *Risk of injury*, *Anxiety* and *Low self-esteem*.

Risk of injury

If syphilis is not diagnosed and treated promptly and effectively, it can have devastating effects on all body systems, particularly the neurological and cardiovascular systems, eventually leading to a painful death.

- Educate the person about the importance of taking any prescribed medication. *Taking the prescribed antibiotic is important to ensure eradication of the infecting organism.*
- Encourage referral of any sexual partners for evaluation and any necessary treatment. *Without treatment of all partners, reinfection can occur or the disease may be transmitted to other people through sexual activity.*
- Educate about why the person needs to abstain from sexual contact until they and their partner/s are cured, and why they should use condoms to prevent future infections. *Abstinence until the organism is eradicated prevents reinfection. Condoms provide barrier protection, reducing the risk of infection during sexual activity.*
- Emphasise the importance of returning for follow-up testing at 3- and 6-month intervals for early syphilis and at 6- and 12-month intervals for late latent syphilis. *Follow-up testing is performed to ensure eradication of the disease.*
- Provide information about manifestations of reinfection. *Successful treatment of the disease does not prevent possible subsequent infections.*

Anxiety

The diagnosis of syphilis understandably causes the person significant levels of anxiety, not only about personal wellbeing but also about the wellbeing of partners and, in the expectant woman, her foetus.

- Emphasise that syphilis can be effectively treated, preventing the serious complications of late-stage disease. *This information provides a sense of control and can help decrease anxiety.*
- Educate the pregnant woman about taking medications as directed and that returning each month for follow-up testing will help ensure the wellbeing of her baby. *Knowing that treatment can reduce the risk to her baby relieves anxiety and possibly increases compliance.*

Low self-esteem

Living with any chronic disease can be damaging to someone's self-esteem. However, the person who has syphilis needs additional support to cope with the stigma of this kind of disease. Unfortunately, people who are most affected by STIs often lack family and other social support networks.

- Create an environment where the person feels respected and safe to discuss questions and concerns about the disease and its effect on their life. *Being treated with respect helps enhance self-esteem.*
- Provide privacy and confidentiality. *People are often embarrassed to discuss the intimate details of their sex lives.*
- Let the person know that the nurse and other healthcare providers care about them and the successful treatment of their disease. *Feeling valued enhances self-esteem.*

NURSING CARE PLAN A person who has syphilis

Nate Elgmisson, aged 24, works as a butcher at a local supermarket. For the past year he has shared a house with Callie Lincoln, who is 5 months pregnant with his child. Although he intends to marry Callie before the baby is born, he has continued to have a sexual relationship with a previous partner named Joshua Sorronsoin. His sexual activities with Joshua have increased in frequency as Ms Lincoln's pregnancy has advanced. Recently, Mr Elgmisson has noticed a swelling in his groin and a sore on his penis.

ASSESSMENT

When Mr Elgmisson comes to the community health centre, he is interviewed by the Nurse Practitioner (NP), Mary Pertolloti. Mary establishes a therapeutic relationship and gathers a thorough medical and sexual history, including gaining information about drug use, allergies, difficulty with urination, urinary frequency, itching or discharge from the penis, recent sexual activities, precautions taken against infection, history of STIs and sexual function. Mary determines that Mr Elgmisson has been having unprotected sex with both Ms Lincoln and Mr Sorronsoin. Nate thinks that Joshua is not having sex with anyone except him but he is not sure.

Physical assessment reveals a classic syphilitic chancre on the shaft of the penis and regional lymphadenopathy. A specimen of exudates from the chancre is sent for dark-field examination. Ms Pertolotti discusses with Mr Elgmisson the likelihood that he has syphilis and the need to tell both Ms Lincoln and Mr Sorronsoin so that they can be tested and, if necessary, treated. Ms Pertolotti also suggests that Mr Elgmisson be tested for HIV since he has been having unprotected sex with two people, at least one of whom may be sexually active with other partners. He agrees and blood is drawn for an ELISA test. Dark-field analysis of the chancre exudate confirms the diagnosis of syphilis; the ELISA results are negative for HIV.

DIAGNOSES

- *Risk of injury* to the person, his partners and the infant, related to the disease process.
- *Lack of knowledge* about the disease process, its transmission and the need for treatment.
- *Anxiety* related to the effects of the infection on the unborn child and discussing the diagnosis with partners.
- *Possible relationship breakdown* related to diagnosis of syphilis and non-monogamous sexual activity.

NURSING CARE PLAN A person who has syphilis (continued)

PLANNING

- Establish a therapeutic relationship based on respect and a non-judgmental attitude.
- Explain the diagnosis and what having this illness means for the person.
- Establish a collaborative care and treatment plan.
- Explain tests and interventions (e.g. the ELISA test).
- Collaboratively identify coping strategies.

Expected outcomes

- Therapeutic relationship and rapport established.
- Prompt treatment will cure the syphilis.
- The person understands the need to abstain from sexual contact during treatment, complete all medications, return for follow-up visits and use condoms to prevent reinfection.
- The person can identify strategies to cope with the effect of diagnosis and treatment on their relationship/s.
- Decreased anxiety following health and psychosocial education and treatment.
- Penicillin administered.
- Follow-up appointments made.
- Health education material provided and any questions and concerns answered and clarified.
- Sexual partners notified that they need to attend the clinic for testing.

IMPLEMENTATION

- Administer IM injection of penicillin G.
- Discuss the importance of abstaining from sexual activity until Mr Elgmission and his partners are cured, and of using condoms to prevent reinfection.
- Explain the need to return for follow-up testing in 3 months and again at 6 months. Provide a copy of the STI prevention checklist, and document that reminders need to be sent at 3- and 6-month intervals.
- Notify sexual partners that they need to be tested.
- Provide counselling about the effect of the disease on relationships.
- Provide health education regarding the importance of treatment to the health of the infant.

EVALUATION

At the 3-month follow-up visit, the chancre on Mr Elgmisson's penis has healed and he reports that he is using a condom whenever he has sex. Ms Lincoln also tested positive for syphilis and negative for HIV, so she, too, is given penicillin G and verbal and written follow-up instructions, including follow up until the infant is born. The couple is meeting every second week with a relationship counsellor and say that, although strained, the relationship is improving. Mr Sorronsoin has received similar test results and is given a prescription for doxycycline because he is allergic to penicillin.

CRITICAL THINKING IN THE NURSING PROCESS

1. Which manifestations might a person with early syphilis experience?
2. List some appropriate questions for taking a sexual history when you suspect the presence of one or more STIs.
3. How might you support Mr Elgmisson to help him break the news of his diagnosis to his sexual partners, especially Ms Lincoln?

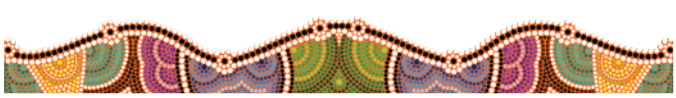
REFLECTION ON THE NURSING PROCESS

1. Which relationship issues will the couple have to deal with?
2. Would your thoughts about Mr Elgmisson's behaviour affect the way you interact with him?

Community-based care

Health and psychosocial education is an essential part of nursing care for someone who has an STI, and syphilis is no exception. The nurse emphasises that syphilis is a chronic disease that can be spread to others even though no symptoms are evident. The following topics need to be discussed:

- taking all prescribed medication
- referring sexual partners for evaluation and treatment
- abstaining from all sexual contact as recommended by CDC guidelines
- using a condom to avoid transmitting or contracting infections in the future
- the need for follow-up testing (at 3 and 6 months for people with primary or secondary syphilis, and at 6 and 12 months for those with late-stage disease). If the person is also HIV positive, follow-up visits are recommended 1, 2, 3, 6, 9 and 12 months after treatment.



THE PERSON WITH PELVIC INFLAMMATORY DISEASE

Pelvic inflammatory disease (PID) is a term used to describe infection of the pelvic organs, including the fallopian tubes (*salpingitis*), ovaries (*oophoritis*), cervix (*cervicitis*), endometrium (*endometritis*), pelvic peritoneum and the pelvic vascular system. PID can be caused by one or more infectious agents, including *N. gonorrhoeae*, *C. trachomatis*, *Escherichia coli* and *Mycoplasma hominis*. *N. gonorrhoeae* and *C. trachomatis* are responsible for as much as 80% of PID; dual infection with both agents is common.

Pelvic inflammatory disease is not a reportable disease in Australia. It is estimated that 1 million women experience PID each year. As a result of the infection, more than 100 000 women become infertile, and a large proportion of the ectopic pregnancies occurring each year are the result of PID (CDC, 2015). The disease may also cause pelvic abscesses and chronic abdominal pain.

Sexually active women aged 16 to 24 years are most at risk. Risk factors include a history of sexually transmitted infection (especially gonorrhoea and chlamydia), bacterial vaginosis, multiple sexual partners, douching and previous PID. Barrier contraceptive devices such as condoms reduce the risk of PID.

Prognosis depends on the number of episodes, promptness of treatment and modification of risk-taking behaviours. Prevention includes health education, especially for young women, regarding the causes and transmission of infection and methods of self-protection, such as avoiding unprotected sexual activity.

Pathophysiology

Pelvic inflammatory disease is usually polymicrobial (caused by more than one microbe) in origin, with *N. gonorrhoeae* and *C. trachomatis* being common causative organisms. Pathogenic microorganisms enter the vagina and travel to the uterus during intercourse or other sexual activity. They can also gain direct access to the uterus during childbirth, insertion of intrauterine devices (IUD), termination of pregnancy or surgery of the reproductive tract. The organisms ascend from the endocervical canal to the fallopian tubes and ovaries.

Manifestations

Manifestations of pelvic inflammatory disease include fever, purulent vaginal discharge, severe lower abdominal pain and painful cervical movement. However, the manifestations may be so mild that the infection is not recognised.

Complications

Complications include pelvic abscess, infertility, ectopic pregnancy, chronic pelvic pain, pelvic adhesions, dyspareunia and chronic pelvic pain. Abscess formation is common.

INTERPROFESSIONAL CARE

The goals of treatment are to eliminate the infection and prevent complications and recurrence. The physical examination may reveal abdominal, adnexal and cervical pain.

Diagnosis

Tests used in the diagnosis of PID may include a full blood count with differential, which will show a markedly elevated white blood cell count and an increased sedimentation rate. If a laparoscopy or laparotomy is done, it may reveal inflammation, oedema or hyperaemia of the fallopian tubes or tubal discharge and, possibly, generalised pelvic involvement, abscesses and scarring.

Medications

Combination antibiotic therapy with at least two broad-spectrum antibiotics, administered IV or orally, is the typical treatment for PID. If PID is not acute, outpatient antibiotic therapy is prescribed. In acute cases, the person may be hospitalised. Analgesics are given, and antibiotics and fluids are administered intravenously. Commonly prescribed antibiotics include parental ceftriaxone, cefoxitin or clindamycin, plus gentamicin or doxycycline. Nursing implications for antibiotics are discussed in Chapter 11.

Surgery

A drain may be inserted into an abscess, if present, and any adhesions may be removed. If the person does not respond to conservative therapy, surgical removal of the uterus, fallopian tubes and ovaries may be necessary.

Nursing care

The goals of nursing care are to treat the infection and to prevent complications, such as scarring and infertility. The person who is hospitalised maintains bed rest in the semi-Fowler's position to promote drainage and to localise the infectious process in the pelvic cavity.

Nursing interventions

Nursing priorities that apply to the person with PID include: *Risk of injury* and *Health education*.

Risk of injury

Pelvic inflammatory disease can have severe, even life-threatening, complications. Scarring of fallopian tubes can lead to ectopic pregnancy or pelvic abscess. Infertility is a common complication, as are recurrent or chronic PID, chronic abdominal pain, pelvic adhesions, premature hysterectomy and depression. The woman who has severe infection and manifestations may be hospitalised for treatment.

- Administer antibiotic therapy and monitor closely for adverse effects. *Antibiotics used in acute PID are potent agents; some can have serious side effects.*
- Practise thorough handwashing and strict adherence to universal precautions when handling perineal pads and linen. Appropriate disinfection of bedpans, toilet seats, linen and utensils is also important. *These practices help avoid transmitting the infection to others.*

Health education

Pelvic inflammatory disease is most common in young women, who often do not understand their own anatomy and physiology or sexually transmitted infections. Diagnosis and treatment of PID provides an opportunity to increase that understanding, thereby preventing complications and recurrent infection.

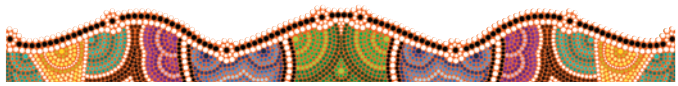
- Explain how infection is spread and which measures to take to prevent future infection. *Understanding can improve compliance with treatment regimens and perhaps change high-risk behaviour.*
- Explain the need to complete the treatment regimen and the importance of follow-up visits. If the person or their partner/s fail to take all of the medication as prescribed, the infection may not be completely cured. *Noncompliance and recurrence are common, particularly if follow-up appointments are not kept.*
- Provide education about proper perineal care, especially wiping from front to back. *This reduces transmission of faecal organisms to reproductive tissues and reduces the incidence of urinary tract infections.*
- Caution the person about using tampons. Educate the person about why it is important to change tampons or pads at least every 4 hours. *Menstrual flow and other discharges provide a favourable environment for microorganisms to multiply.*
- Provide information about safe sex practices and family planning. Support the person to understand that they need

to remove diaphragms within 6 hours after use. IUDs are contraindicated. Latex condoms offer the most effective protection against infection. *These measures help prevent recurrence of infection.*

- Educate the person to recognise and report any unusual vaginal discharge or odour to the healthcare provider. *Treatment is most effective early in the disease process.*

Community-based care

Provide general information related to STIs. Discuss ways to eradicate the infection and prevent recurrence, and support the person to identify strategies to deal with the physical and psychosocial implications of treatment, including possible infertility. Inform the person that the patency of the fallopian tubes can be evaluated after several menstrual cycles; this delay allows for complete resolution of the inflammatory process.



CHAPTER HIGHLIGHTS

- Sexually transmitted infections (STIs) are infections transmitted by sexual contact, including vaginal, oral and anal intercourse. STIs affect women and infants more than men, and are more common in people who have multiple sex partners, abuse drugs or are of a lower socioeconomic status.
- STIs can coexist in the same person and are transmitted by sexual contact. Effective treatment mandates that all sex partners be treated. Most STIs can be prevented by using latex condoms.
- Genital herpes, caused by an infection with an HSV virus, is a commonly occurring STI in teens and young adults. There is currently no cure and treatment is primarily symptomatic. Nursing care is directed towards relieving the pain of the lesions, mitigating sexual dysfunction and relieving anxiety.
- Genital warts, caused by the human papillomavirus (HPV), are a chronic, incurable STI. They are manifested by warts of various forms or may be present without manifestations. Infection with HPV poses a major risk of cervical cancer. A vaccine against the virus has been developed and is recommended.
- Urogenital infections include vaginal infections (bacterial vaginosis, candidiasis and trichomoniasis), chlamydia, gonorrhoea, syphilis and pelvic inflammatory disease (PID).
- Chlamydia, occurring most in young adults under age 25, is a bacterial infection that can spread to the uterus and fallopian tubes in women, causing pelvic inflammatory disease, infertility and ectopic pregnancy. Untreated chlamydia in men may result in epididymitis, prostatitis, sterility and Reiter's syndrome.
- Gonorrhoea (caused by a bacteria) and syphilis (caused by a spirochaete) affect both men and women and may infect the newborn as it moves through the birth canal in an untreated woman. Syphilis, if untreated, exists in the body in three stages, with the third stage lasting up to 50 years. Both of these STIs are treated with antibiotics. Nursing care focuses on education, preventing injury from complications, relieving anxiety and supporting self-esteem.
- Pelvic inflammatory disease is an infection of the female pelvic organs and may be caused by one or more infectious agents. Sexually active young women between the ages of 16 and 24 are most at risk. The prognosis depends on the number of episodes, promptness of treatment and modification of risk-taking behaviours. The goals of nursing care are to treat the infection and prevent complications.

CONCEPT CHECK

1 Which population is most often affected by STIs?
1. men
2. women and infants
3. adolescent males
4. older adults

2 Which of the following statements indicates that a person understands how they should treat an STI?
1. 'My sex partner and I must both take medications.'
2. 'I know I can never have sex again.'
3. 'I will douche after every sexual encounter with my partner.'
4. 'My sex partner does not have an infection, so won't need medications.'

3 When providing a man with information about using condoms to prevent STI, which topics should be included? (Select all that apply.)
1. Use a new condom with each sex act.
2. Ensure a small amount of air is in the tip.
3. Use oil-based lubricants, such as petroleum jelly.
4. Handle carefully to ensure no damage.
5. Withdraw when the penis is erect.

4 You are assessing a young male. He has both blisters and ulcerations on the shaft of his penis. What is he most likely to have contracted?
1. chlamydia
2. gonorrhoea
3. genital warts
4. genital herpes

5 Of the following statements about genital warts, which one is not true?
1. The infection is caused by a yeast organism.
2. The infection can be spread by any type of intercourse.
3. The infection may be transmitted to the foetus.
4. The infection cannot be cured.

6 You are counselling a young woman with an HPV genital infection. Which screening test would you recommend she have every year?
1. breast exam and mammogram
2. stool for occult blood
3. full blood count (FBC) to detect anaemia and infection
4. pelvic exam and Pap smear

7 Which of the following symptoms would most commonly be elicited as part of a health assessment for a woman who has a vaginal infection?
1 pain
2 itching
3 nausea
4 diarrhoea

8 When providing health education to a woman with an STI who has severe genital discomfort, what is one simple recommendation that may relieve her discomfort?
1 Wear nylon pantyhose.
2 Cut fingernails short.
3 Wear cotton underwear.
4 Don't have sex anymore.

9 The infective organism responsible for gonorrhoea initially targets which body parts?
1 male urethra and female cervix
2 female vulva and vagina
3 male prostate
4 male and female external genitalia

10 When providing health education to a person with syphilis, what would you say?
1 Syphilis is caused by a virus.
2 Syphilis is a local genital infection.
3 Syphilis is a systemic infection.
4 Syphilis has no effect on the developing foetus.

UNIT 13 BUILDING CLINICAL COMPETENCE

Responses to altered reproductive function

CLINICAL SCENARIO

- You have been assigned to work with the following four people for the 0700 shift on a medical–surgical hospital unit. Significant data obtained during handover are as follows:
- David Young, a 24 year old, is admitted with a diagnosis of sickle cell crisis. Vital signs are T 37.6°C, P 86, R 10 and shallow, BP 142/84. He is complaining of chest pain, back pain and priapism. He has a PCA with morphine sulfate for pain.
- Victor Windsor, a 77 year old, is 3 days postoperative for transurethral resection of the prostate (TURP). Vital signs are T 37.2°C, P 84, R 16, BP 155/86. His urinary catheter was removed at 0600. He is complaining of dribbling of urine after attempting to void.
- Tina Morriss is 19 years old and newly admitted from the emergency department with complaints of severe lower abdominal pain, purulent vaginal discharge and cervical pain on pelvic exam. Her vital signs are T 39.3°C, P 86, R 22, BP 115/70. She is to be started on ceftriaxone and gentamicin IVI as soon as possible.
- Rose Getz, a 36 year old, has a history of uterine fibroids. She had a uterine fibroid embolisation yesterday. Her vital signs have remained stable throughout the night. Her discharge is written and she is in a hurry to go home so that her husband can get to work.

Critical thinking questions

1 In which order would you visit these people?

1. _____
2. _____
3. _____
4. _____

2 Which top two nursing priorities would you choose for each of the people presented above? Explain the rationale for your choices.

	Nursing Priority #1	Nursing Priority #2
David Young		
Victor Windsor		
Tina Morris		
Rose Getz		

3 Mr Young asks the nurse about complications due to priapism because he often has this problem with sickle cell crises. Which complication does the nurse discuss with him?

1. severe phimosis
2. erectile dysfunction
3. penile cancer
4. urinary retention

4 Mr Windsor suddenly develops nausea and vomiting. His BP is 170/100, P is 58 and he is confused. What is the probable cause of these manifestations?

1. allergic reaction to the bladder irrigating fluid solution
2. anxiety reaction to having prostate surgery
3. absorption of isotonic bladder irrigating fluids
4. hypovolaemic shock complication of the surgery

5 Which of the following is *most* important to educate Ms Morriss about pelvic inflammatory disease?

1. Take all medication as prescribed.
2. Wipe from front to back after urinating.
3. Use latex condoms when having sex.
4. Change tampons or pads every 4 hours.

6 Prior to surgery, Mrs Getz's haematocrit was 34% and haemoglobin was 10 g/dL. She was instructed to increase iron foods in her diet. Which foods are high in iron?

1. beef, eggs, brown rice
2. green, leafy vegetables, chicken
3. fish, broccoli, kidney beans
4. liver, cheese, asparagus

7 Which is a priority nursing *intervention* for a young woman with endometriosis?

1. *Acute pain* as manifested by severe abdominal cramping
2. *Knowledge deficit*: lack of understanding about endometriosis
3. Treatment for partners
4. *Risk of anxiety* related to loss of reproductive function

8 A prescription for tadalafil is ordered for a man with erectile dysfunction. The man indicates he understands about the medication when he says:

1. 'I will take tadalafil just before intercourse to increase my sex drive.'
2. 'I will consult with the doctor before taking other medications.'
3. 'I can take a second tablet the same day if the first one doesn't work.'
4. 'This tablet will relieve all of my sex problems.'

9 Which laboratory studies would you expect to be conducted to diagnose syphilis? (Select all that apply).

1. VDRL
2. Gram stain
3. RPR
4. DFA
5. tissue culture
6. FTA-ABS

10 Which should you say to someone who is receiving radiation therapy for prostate cancer?

1. Eat more red meat to maintain protein for healing.
2. Avoid close contact with pregnant women, infants and children.
3. Avoid sexual contact to prevent stress from dysfunction.
4. Sleep alone for the first night after radiation therapy.

11 Which symptom would be most significant when assessing someone with possible cervical cancer?

1. vaginal discharge
2. weight loss
3. pain in back and thighs
4. vaginal bleeding

12 A sexually active woman is being treated for gonorrhoea. Which method of birth control do you advise is safest to use?

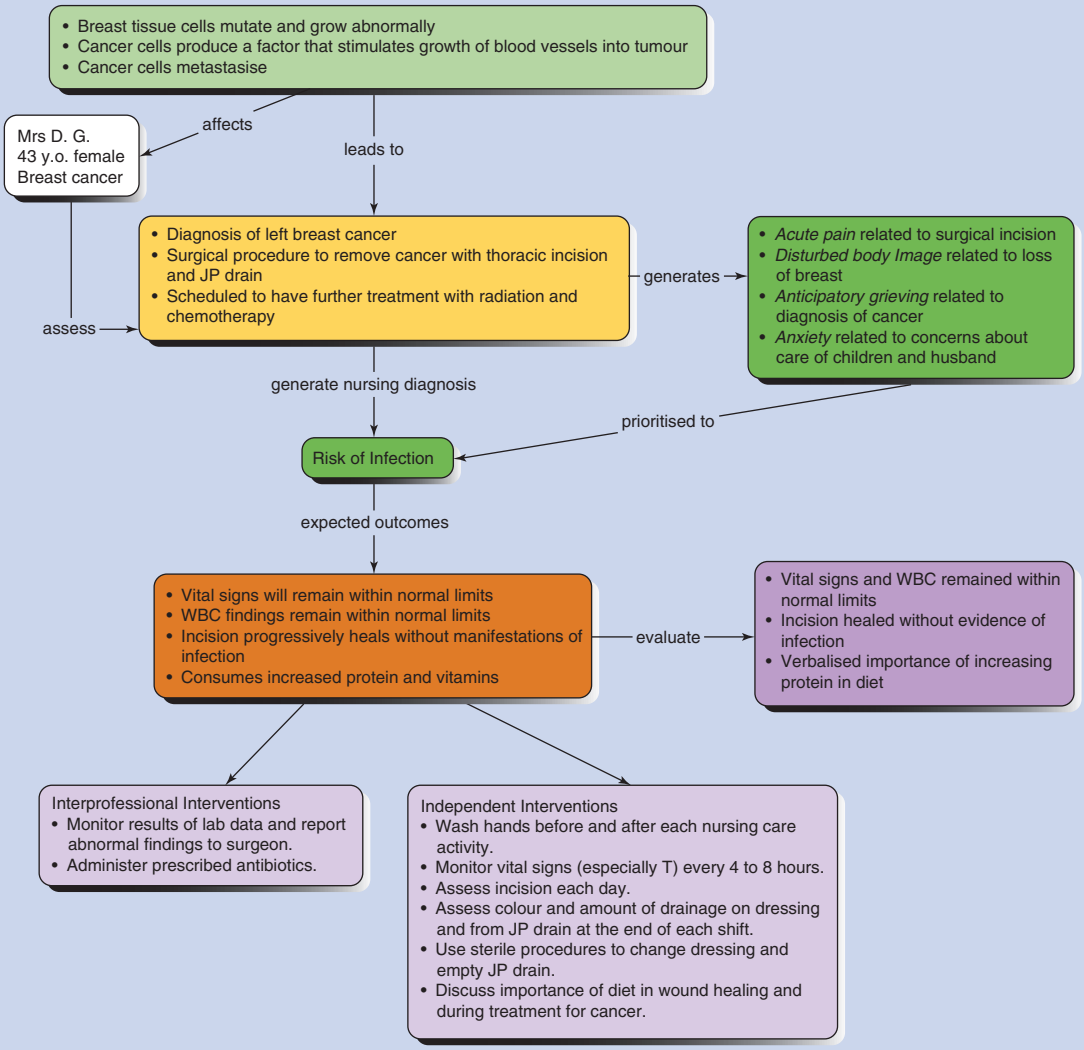
1. oral contraceptives
2. intrauterine device
3. condom
4. oestrogen patch

CASE STUDY

Delaine Grivstasis, a 43-year-old married housewife with two children, had a routine annual mammogram that revealed a mass in the left breast. She has a family history of breast cancer, with her mother and a maternal aunt having breast cancer. She was admitted to outpatient surgery for an incisional biopsy, with results of invasive lobular carcinoma. An MRI was performed, which indicated that four axillary glands have been infiltrated with cancer. She was admitted to the hospital and a modified radical mastectomy on the left side is performed. Postoperatively, she is admitted to the chemotherapy unit. Vital signs are T 36.9°C, P 65, R 14, BP 110/68. She has a dressing on the left chest that is dry and intact, and the Jackson–Pratt drain is intact for suction. Her left arm is elevated on two pillows. The decision has been made to start radiation and chemotherapy treatments as soon as possible.

The pathophysiology of breast cancer is a mutation of breast tissue cells related to hormones and mutations of tumour suppressor genes. Abnormal cell growth occurs. Cancer cells create a factor that stimulates blood vessels to grow into the tumour. Cancer cells invade the blood vessels and travel through the bloodstream or through the lymphatic system to other sites. Manifestations of breast cancer include non-tender lump in the breast, abnormal nipple discharge, rash around the nipple area, nipple retraction, oedema, dimpling of the skin or change in position of the nipple. Some women report a burning or stinging sensation in the breast or nipple pain. Complications of breast cancer are metastasis to bone, brain, lung, liver, skin and lymph nodes, and death.

Based on the surgery of modified radical mastectomy and treatment with radiation and chemotherapy, the nursing diagnosis of *Risk of infection* is an appropriate consideration for planning care for Mrs Grivstasis.



UNIT 14

SPECIAL TOPICS IN MEDICAL–SURGICAL NURSING

CHAPTER 50

MENTAL HEALTHCARE IN THE AUSTRALIAN CONTEXT

LORNA MOXHAM, PAUL ROBSON, SHANE PEGG

KEY TERMS

LEARNING OUTCOMES

- Understand the complexity of definitions related to mental health and mental illness.
- Understand the specialised role of the mental health nurse.
- Appreciate the importance of the Recovery approach within mental healthcare.
- Identify legislation pertaining to the provision of care for people who have a mental illness.
- Understand the symptoms and signs of psychotic and non-psychotic disorders.

CLINICAL COMPETENCIES

- Conduct a mental state assessment (MSA) on a person who is thought to have a mental health issue.
- Use an evidence-based approach to design interventions which promote Recovery.
- Determine priority nursing care, based on assessed data, to select and implement individualised nursing interventions for people who have a mental health issue.
- Provide skilled mental health nursing care for people who live with a mental illness.
- Integrate mental health nursing care into an interprofessional focus for people who live with a mental illness.
- Provide education to decrease the stigma associated with mental illness.

In Australia, and internationally, mental health problems are becoming increasingly common—as many as one in five people are now thought to have a mental health issue in Australia. Internationally, using the United Kingdom as an exemplar, the Mental Health Foundation suggests that up to one in four people will experience some kind of mental health problem in the course of a year.

As a consequence, mental health knowledge and skills, sometimes referred to as mental health literacy, are necessary for nurses working in all areas of nursing practice. Nurses may meet and nurse people as well as their families in a variety of environments such as the emergency department, drug and alcohol services, surgical and medical units, critical care units (CCUs), maternity, outpatients, day surgery, baby health clinics, schools, GP surgeries, paediatrics, intensive care units (ICUs), community health, sexual health clinics, pathology, x-ray departments and rural health.

HOLISTIC CARE

Even though nurses may not be undertaking practice within a specialised mental health setting, it is highly likely that they will provide nursing care for a person who is living with a mental health issue. It may not be the actual person who is the recipient of direct care, but it may be their partner, aunt, uncle, wife, husband, brother, sister, daughter, son, mother, father, grandfather or grandmother. Nurses are beholden to provide the best care they can to all the people they interact with in their practice. This often includes family members and significant others. In the mental health setting, the involvement of carers and family is very important and significant others should be involved in all steps of the nursing process wherever possible. Nurses provide holistic care, across the entire lifespan, which means people are cared for in all aspects of their life and body, and without judgment. Nurses should not 'split' people into physical, social, spiritual or mental health parts—nursing does not compartmentalise. Nurses are there to provide holistic healthcare, to all people in all circumstances, in the safest and best way possible. This is not always easy and nurses cannot be expected to be experts in every nursing specialty. Importantly though, nor do they need to be.

Nurses do, however, need to have an understanding of many areas of nursing. In order to have a balanced understanding of mental illness/mental health, it is important to be aware that there are a number of different types of knowledge bases that contribute to such an understanding. Figure 50.1 demonstrates where our **knowledge resource base** comes from. In the mental health context, the knowledge resource base is founded on a recognition of diversity, mental health literacy, an enriched range of services and supports, and social acceptance and inclusion.

As you can see from the figure, there are a number of different ways that nurses can acquire knowledge about mental health issues. Despite the recognition of multiple ways of knowing and doing, mental health service provision in Australia is still largely based on the medical model. However, with more consumers and their carers gaining a legitimately stronger voice, a social position is being strengthened as nurses continue to advocate for a more holistic approach. As Figure 50.1 suggests, nurses need to appreciate that a balanced understanding of a person's mental health is not only attained through medical or clinical knowledge. This is important as mental healthcare needs to be seen through many different lenses and treatment for people who are living with a mental illness should not be restricted to the administration of medication/s.

Because of the widespread nature of mental health issues, it is necessary to identify some trends around mental health and illness across Australia (see the 'Fast facts' box below).

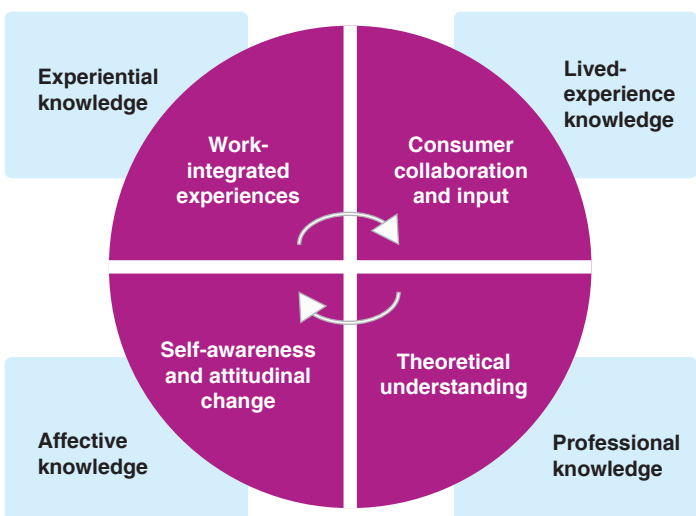


FIGURE 50.1 ■ Knowledge resource base

FAST FACTS

- One in five Australians (20%) will experience some form of mental illness each year. Of these, three out of every 10 will be seriously affected.
- In their lifetime, approximately 45% of Australians aged 16 to 85 years will experience a common mental-health-related condition such as depression, anxiety or a substance use disorder.
- In Australia, approximately 13% of the total burden of disease in Australia is associated with mental and behavioural disorders, placing it third behind only cancer and cardiovascular disease.
- Approximately 31% of Australians receiving a disability support pension were assessed as having a primary medical condition under the category of 'psychological or psychiatric'.
- Depression and anxiety are the most prevalent mental disorders experienced by Australians with over 14% reporting having some form of anxiety disorder. Significantly, depression is predicated to be one of the world's largest health problems by 2020.
- Mental illness affects young people. Around 14% of 12–17 year olds and 27% of 18–25 year olds experience a mental illness in any given year. At least one-third of young people have had an episode of mental illness by the age of 25 years.
- Around 1 million Australian adults and approximately 100 000 young people live with anxiety and depression each year. On average, one in five people will experience depression in their lives—one in four females and one in six males—while many younger people (200 000) are now presenting with aggressive behaviours.
- The majority of mental illnesses begin between the ages of 15 and 25 years. This poses a significant threat to our nation's workforce capacity and economic prosperity.
- The 2007 National Survey of Mental Health and Wellbeing revealed that 11.7% of Australians who had a long-term mental disorder also reported having a physical condition.
- Approximately two-thirds of people with a mental illness do not receive any treatment in a 12-month period.
- Estimates suggest that up to 75% of people presenting with alcohol and drug problems also have additional mental health problems.
- Reports indicate that up to 85% of homeless people have a mental illness.

MENTAL HEALTH AND MENTAL ILLNESS

Mental health and mental illness are difficult terms to define; in fact, there are no universally agreed definitions. While such ambiguity can be frustrating, there are many reasons for this. One key reason arises from the impossibility of separating mind from body; another results from the many unique and individual ways that humans express themselves. Mental illness, as an expression, is also culturally linked and determined, so what might be deemed mental illness in one culture certainly might not be in another.

While it is difficult to arrive at succinct, yet meaningful, definitions of mental illness and mental health, many attempts have been made to conceptualise them. These include:

- the medical model (which emphasises processes of diagnosis and treatment and is based on traditional reductionist models of science)
- the psychoanalytical or psychodynamic approach
- neurobiological theories
- cognitive behavioural perspectives
- lay views
- the legal framework
- lived experience perspectives
- sociological stances (including social causation, social reaction (labelling theory), holism and the social model of disability).

Just as the definitions of mental health and mental illness are ambiguous, so too are the causes and associated nursing care and medical treatments. This makes mental health nursing both complicated and challenging. Modern multidisciplinary mental health practice synthesises the application of understandings that are derived from the various conceptual approaches listed above. Despite this, treatment and management approaches remain heavily dominated by medical models and medical discourse. This is because psychiatrists, as specialist medical practitioners, are trained to identify sick individuals (diagnose), predict the future course of their illness (provide a prognosis), speculate about the cause (identify aetiology), then prescribe a response to the condition, either to cure it or ameliorate its symptoms (medicate).

Diagnosis

The diagnosis of mental illness in Australia occurs as a result of an assessment process. The American Psychiatric Association (APA) established a set of diagnostic criteria, known as the **DSM (*Diagnostic and Statistical Manual of Mental Disorders*)**. The DSM is used in Australia to diagnose a person with signs of mental illness. The DSM 5 was released in May 2013.

There is also another set of diagnostic criteria in use. This is the **International Classification of Diseases (ICD)**, which is the global standard to report and categorise diseases, health-related conditions and external causes of disease and injury. The ICD that specifically relates to mental healthcare is the ICD-10—Classification of Mental and Behavioural Disorders. Classification systems are constantly revised. The current version is the ICD-10: Version 2010. The eleventh revision of the ICD is underway and it is expected to be presented to the World Health Assembly some time in 2017. The current version, ICD-10, is available in the six official languages of the World Health Organization (WHO),

which are Arabic, Chinese, English, French, Russian and Spanish, as well as in 36 other languages (WHO, 2012a).

The Australian version, the ICD-10-AM or, more accurately, the *International Statistical Classification of Diseases and Related Health Problems, Tenth Revision, Australian Modification*, serves Australia's particular needs and supports the national collection of data relevant to its population health.

Psychiatrists are in powerful and dominant positions within mental health settings (they are often the directors of services at local, state, territory and national levels). As such, medical opinion remains at the fore of any debate about mental health problems. As a result of these powerful influences, psychiatrists principally view people through an illness lens when they encounter variations in conduct or when they have to assess someone who is 'different'. The concept of illness—and its associated language, symptoms, therapies and the people who are living with the illness, who are invariably known as 'patients'—legitimises and perpetuates the prevailing public perceptions and attitudes, often at the expense of other possible frameworks.

It is therefore fair to say that significant debate still exists about what constitutes mental health or mental illness. One of the places where discourse occurs is the **Australian College of Mental Health Nurses (ACMHN)**. This college is the peak professional body for mental health nurses in Australia and is overseen by a Board of Directors that is elected by college members every 2 years. The ACMHN is recognised as representing the specific interests of mental health nurses in Australia. The ACMHN hosts an annual international conference at which issues such as mental health, mental illness, treatment, policy and particularly mental health nursing practice are discussed and debated.

Definitions

Although there is no specific universal definition, mental health can be described as a positive state in which the person is responsible, self-directive, displays self-awareness and is generally accepted within a group. Numerous factors impact on mental health and include inherited characteristics, childhood nurturing and life circumstances. The nature/nurture debate continues in the field of mental health.

Nature refers to inherited genes and characteristics that are totally out of one's control. Nurture refers to parent–child interactions, sibling interactions and early communication patterns. Positive childhood nurturing refers to the child feeling loved, secure and accepted.

Life circumstances from birth also influence one's mental health. These include socioeconomic status, quality of relationships, physical health, housing and educational success or failure. If influencing factors are positive, a person is more likely to experience positive mental health and a sense of wellbeing.

Mental health is generally defined by essential characteristics rather than a set of statements about a state of health. In order to define mental health, comparisons are often made between mental health and mental illness. This is done in an attempt to distinguish the 'normal' from the 'abnormal'. There is therefore a lot of confusion about what mental health and mental illness are, and how they differ. In the absence of a universal definition, Figure 50.2 describes the factors that influence a person's mental health, while Table 50.1 offers a set of indicators for mental health.

Stigma

Stigma is the single most difficult issue that people with a mental illness face. When society or communities consistently stigmatise people with a mental illness, such attitudes become internalised. Internalised stigma is a process whereby people with a mental illness endorse stereotypes, anticipate social rejection, consider stereotypes to be self-relevant and believe they are devalued members of society. Sensationalist media headlines lead to a perpetuation of such stigma (see Box 50.1).

As the scenario in Box 50.1 demonstrates, *reactions* as a result of this event were considered over the top. Thanks to sensationalist media reporting, which still persists, common public perception remains that innocent individuals may become the victim of random acts of violence perpetuated by people with mental health issues.

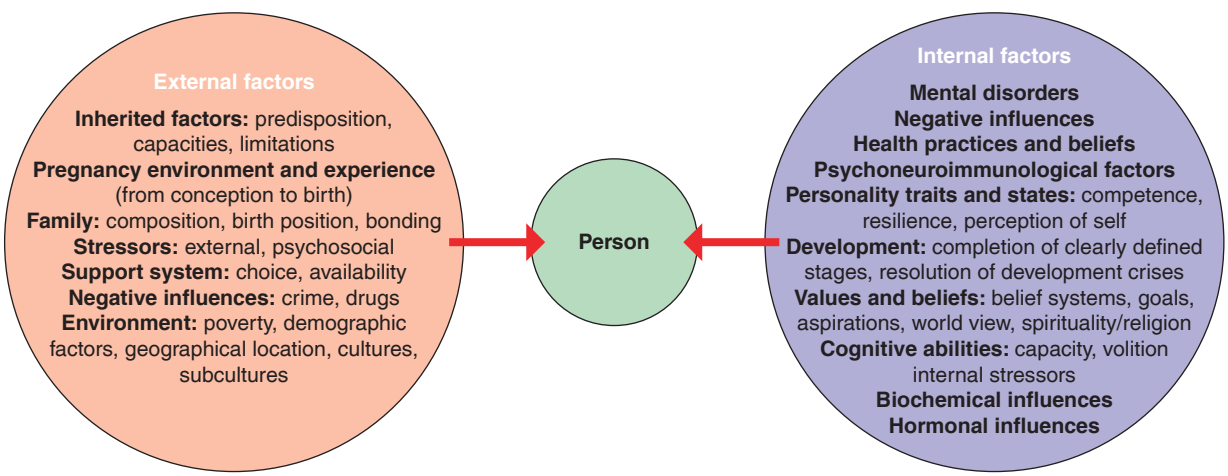

FIGURE 50.2 ■ Influencing factors for mental health or illness

Table 50.1 Components of mental health

SELF-AWARENESS AND DEVELOPMENT	ENGAGEMENT WITH AND RESPECT FOR OTHERS	ADAPTABILITY AND RESILIENCE	CLARITY AND INSIGHT
Attain and maintain positive self-esteem: • Self-concept • Self-image • Self-esteem Involve self in purposeful, meaningful life work Maintain reasonable expectations concerning self and others Seek self-actualisation Learn from experiences Use talents to fullest Maintain wholesome values and belief system Develop and demonstrate appropriate sense of humour Attain self-defined spirituality	Respect societal rules and sanctions Accept self and others as uniquely different but humanly similar Engage in play Relate to others: • Form relationships • Maintain close, meaningful, loving, adaptive relationships • Work and play well with others • Be intimate, appropriately and selectively • Respond to others in need • Feel and exhibit compassion and empathy towards others • Demonstrate culturally and socially acceptable interpersonal interactions • Manage interpersonal conflict constructively • Give and receive gracefully • Learn from and teach others • Function interdependently	Adapt to social environment Function interdependently Return to usual or higher function after crises Be optimistic Be resilient Find beauty, joy and goodness in self, others and the environment Appreciate life Negotiate each development stage Cope with internal and external stressors in constructive and adaptive ways	Ability to: • Demonstrate mental and physical competence and skills • Perceive self, others and events correctly • Recognise own strengths, weaknesses, capabilities and limitations • Separate fantasy from reality Think clearly: • Problem solve • Use good judgment • Reason logically • Reach insightful conclusions
SELF-CONTROL	**INDEPENDENCE**	**SELF-EXPRESSION**	**PHYSICAL HEALTH**
Control impulses and behaviour Delay gratification	Accept responsibility for actions Function independently	Be creative Express emotions Exhibit congruent thoughts, feelings and behaviours	Presence of anatomical and physiological components necessary to function in the world Absence of signs and symptoms of mental disorder Freedom from excessive mental and emotional disability and pain

There is a general belief that people who have a mental illness are dangerous. This perception underpins some of the most destructive stereotypes. Research has demonstrated that people with a mental illness are no more violent than members of society who do not have a mental illness. They are often frightened and are among the most vulnerable members of society. That is not to say, though, that they do not get frustrated and angry with things that happen as part of everyday life (as we all do). The media, however, have promulgated negative stereotypes. Public perception is largely influenced by media sources and negative portrayals have negative impacts on people who live with a mental illness and their family.

Most people who have a mental illness do not need inpatient treatment. If they do, admissions to mental health inpatient units are often brief. Effective treatments, mostly developed in the 1950s and early 1960s, have removed the need for isolation and confinement in asylums—a common occurrence in the past (see Figure 50.3). The attitude of family, friends and the community towards people who have a mental illness plays a critical part in determining their quality of life. Attitudes that people, including nurses, hold have a major effect on how the people feel about themselves and on their recovery. Many people with a mental illness face isolation and discrimination simply for having an illness. This is often not so for people who have a physical illness. People who have cancer, diabetes, asthma, multiple sclerosis, Alzheimer's disease, Parkinson's disease and heart diseases such as cardiomyopathy are often met with sympathy, but people who are living with a mental illnesses are often the butt of jokes, innuendos and scaremongering.

Who would get your donation? An organisation that works with people who have cancer, or one that works with people who have a mental illness? Why is it that people donate more for physical conditions when mental health problems affect at least 25% of the population?

The role of the mental health nurse

The role of the mental health nurse is multifaceted, specialised and dynamic. Mental health nurses' skills, and the roles that they perform, vary according to the context of practice and the level of education, training and experience of the individual nurse. Fundamentally, mental health nurses provide nursing care for people whose lives are affected by mental illness (see Figure 50.4). Nursing care includes the promotion of mental health, the prevention of mental illness and the minimisation of the problems associated with mental illness on individuals, their families and the community. The ACMHN describes mental health nursing as a specialised field of nursing which focuses on meeting the mental health needs of the person in partnership with family, significant others and the community in any setting.

BOX 50.1 The story of a person with a mental illness

Consider the case of a person in Queensland, Australia. The person, who was described on the front page of the *Courier-Mail* (a Queensland newspaper) as 'a paranoid schizophrenic who hacked off his clergyman father's head' (*Courier-Mail*, 23 January 2002) left his ward, which was within the grounds of a psychiatric rehabilitation facility, without permission. Eighty-four hours later, a tired, hungry and thirsty man quietly returned to his ward after having spent the entire time under a cricket shed in the grounds of the facility.

In the meantime, following what was reported as 'extensive searching', a maelstrom erupted; the resultant media coverage could be described as nothing less than a feeding frenzy. The man appeared to represent everything that society feared about mental illness—namely, that all people with mental illness are dangerous. In a sense, this man became stigma personified and for weeks people in Queensland were bombarded with news of other mentally ill people on the run. 'Dangerous', 'violent', 'criminal', 'escapees' and 'killer' were all used to describe people who had a mental illness but were currently, and for numerous valid reasons, not being detained in psychiatric hospitals at all. The relentless media barrage, particularly the insinuation that members of the general public were in danger from these 'killers at large', resulted in a reaction few would have expected. First, an inquiry was held to quantify how many 'patients' who were deemed to be criminally insane were absent without leave (AWOL) from mental health facilities. Recommendations from this inquiry included the 'capture' of these so-called AWOL patients. Surprisingly and controversially, given the ethical nature of the issue, the then state premier ordered the release of photographs of 15 'patients' who were described as AWOL; these pictures were published in the *Courier-Mail*. Second, any patient then under a forensic order who was living in the community, despite the fact that their leave had been granted by the treating psychiatrist and the then Patient Review Tribunal (now the Mental Health Review Tribunal), were taken back to hospital under an involuntary treatment order (ITO). Many people who were well and residing in the community were returned to hospital as a result of this unprecedented over-reaction. Others feared that they, too, would soon be 'taken back to hospital'. Would anyone contemplate doing this to people who have a physical illness?

The tragedy of this 'escape' and its aftermath reached far beyond the city where it occurred. It was acutely felt by people living with mental health issues across the country. The stigma extended to families and their friends, many of whom have also struggled with the discrimination that having a family member with mental health issues brings.

See also 'Risky news, madness and public crisis: A case study of the reporting and portrayal of mental health and illness in the Australian press' by W. Blood & K. Holland (2004). *Journalism*, *5*, 323–342, http://jou.sagepub.com/cgi/reprint/5/3/323.pdf, for an excellent analysis of the reporting of this event.

Mental health nursing has long been recognised as one of the three specialist nursing areas. Psychiatric nurses had separate registration or endorsement in Australia until recently. Previously in Australia, students could enter directly into a 3-year hospital-based mental health nursing course, graduating with a certificate in

psychiatric nursing and registering as a Registered Psychiatric Nurse (RPN). This changed when nursing education moved en masse to the higher education sector in 1985. Today, baccalaureate programs (BN) prepare the nurse for 'beginning level' in all health settings, but many BN students have only limited clinical placements in mental health settings and some get no placements at all in mental health. Some education providers have a 'major' in mental health nursing, where the student nurse can start to specialise, usually in the second year of their BN. For the most part, specialist mental health nursing is now a postgraduate area where students can undertake a graduate certificate (GradCert), graduate diploma (GradDip), master's, professional doctorate or PhD.

Mental health nursing in practice

Mental health nurses can aptly be described as the eyes and ears of the multidisciplinary team. Nurses interact with people on a continual basis, observing ADLs and social functioning, monitoring effects (positive and negative) of medication and treatment, and working closely with people and their significant others in a therapeutic manner towards Recovery. Such a therapeutic relationship places nurses in an excellent position to work in collaboration with the person and their family to provide care, such as:

- planning, implementing and evaluating interactions to help the person achieve the highest possible quality of life using a Recovery focus (see below)
- monitoring the person's response to nursing and other interventions, including medication efficacy
- the establishment and maintenance of the therapeutic relationship.

Mental health nursing is founded upon a **therapeutic relationship**, a rapport based on empathy and trust, with the person and family. There is increasing evidence suggesting that a positive therapeutic relationship contributes significantly to recovery. Mental health nurses, who are central in forming and maintaining the therapeutic relationship, therefore play a pivotal role in the *recovery* of a person who is living with a mental illness. The essence of mental health nursing is therefore not in the tasks that are performed, but in the positive relationships the nurse develops with the person and their family. Nursing focus should not be on the illness (the diagnosis that has been given) but on how the person manages on a daily basis. People living with a mental illness are more focused on day-to-day living than the label they have been given.

AREAS OF PRACTICE Within an inpatient unit in many Australian settings there are high-dependency units (for people who are even more acutely unwell). These can be equated to critical or intensive care units in general hospitals. **Acute inpatient units** could be described as the mental health services equivalent of high-dependency nursing. Mental health nurses in these settings need highly developed expertise and skills in observation, assessment, negotiation, de-escalation and milieu management.

Intake team or *acute care team nurses* are often considered the gatekeepers to mental health services. This is also acute care nursing. In these settings the mental health nurse provides short-term interventions and requires highly specialised skills in assessment, psychopharmocology and monitoring. Mental health nurses on these teams often do their 'work' via the telephone, when people call mental health services in crisis. It takes special expertise to be able to conduct an accurate assessment without face-to-face interaction. The role of mental health nurses in this setting is also to be aware of and to liaise with other services and agencies.

Community care coordinators are mental health nurses who undertake their craft by providing continuing care and follow up of people in the community. They used to be called 'case managers', but consumers say, and rightly so, they are not 'cases' to be 'managed'. Care coordinators often have many people to work with and undertake duties such as medication administration, management and monitoring. Assisting people by finding accommodation and employment options, as well as linking people in with therapeutic leisure and recreation activities, are also part of the role. **Community mental health nurses** also provide family support and work with the broader community in mental health promotion and education.

Forensic mental health nurses practise in a range of settings that include courts, police custody centres, prisons, secure hospitals and the community. Practice standards for forensic mental health nurses can be viewed in the *Forensic Mental Health Nursing: Standards of Practice 2012*, which can be accessed at <www.forensicare.vic.gov.au>.

Consultation liaison (CL) nurses have different approaches depending on the setting in which they are practising. This area of mental healthcare is rapidly expanding as a result of the number of people within generalist care settings who also have a mental illness. One approach is having CL nurses in the emergency department (ED) who provide specialist care for someone in the ED with a mental health problem. Another CL approach is where the CL nurse provides care to people who are admitted to a general hospital for a non-psychiatric condition. The CL nurse in this instance usually gets a referral from their general nursing or medical colleagues and provides direct consultation with the person or indirect consultation through support, education and advice for colleagues. CL nurses have high-level assessment and interpersonal skills and broad nursing knowledge that enable them to rule out physical causes and work with complex health issues.

STIGMA AND THE ROLE OF THE NURSE As Box 50.1 shows, the general public continues to receive a very distorted and one-sided picture of people with mental health problems. Sensationalist reporting exacerbates discriminatory attitudes and stigmatising attitudes that society in general holds towards people with mental health problems. Public stigma robs people who live with a mental illness of many opportunities. Nurses need to discuss mental illness openly with family, friends and colleagues. When nurses think about and describe mental illness in similar terms to other illnesses or conditions, this helps educate the community to overcome discrimination and negative attitudes based on misconceptions and stereotypes. Box 50.2 responds to some common misconceptions about mental illness.

Because it is common for individuals to accept and internalise negative stereotypes it is a prime responsibility of nurses to advocate for people who have a mental illness. This means dispelling myths and challenging discrimination. We need to tell people that

BOX 50.2 The facts about mental illness and violence

Are people with a mental illness violent?

Having a mental illness does not mean someone will be violent. People receiving treatment for a mental illness are no more violent or dangerous than anyone else. To make this clear, it has been calculated that the lifetime risk of someone with an illness such as schizophrenia seriously harming or killing another person is just 0.005%. It is much more likely that someone with a mental illness will hurt themselves or be hurt by someone else.

Is there a link between mental illness and violence?

The great majority of people with a mental illness are not violent at all. Research suggests they are more likely to be victims of violence. Violent behaviour is slightly more likely among people with a psychotic illness, especially in the first episode of illness. It may also be associated with other factors, including the type of person they were before the illness and if they have been violent in the past. It is also associated with drug use such as ice.

Does having an illness such as schizophrenia mean someone will be violent?

Violence is not a symptom of psychotic illnesses, such as bipolar disorder and schizophrenia.

There is a slightly increased possibility someone with a psychotic illness may be violent if they are not receiving treatment, have a previous history of violence or are abusing alcohol or drugs.

Symptoms of psychotic illnesses may include frightening hallucinations and delusions, as well as paranoia. This means there is a small chance someone who is experiencing them may become violent when they are scared and misinterpret what is happening around them. If a person is being effectively treated for psychotic illness and is not abusing alcohol or drugs, there is no more risk they will be violent than anyone else.

Who is most likely to be violent in our society?

Research by the Australian Institute of Criminology shows that the vast majority of violence is committed by males aged 18 to 30 years. This is more likely when someone has exhibited highly aggressive behaviours in the past and has some history of alcohol or drug abuse. People in this group are far more likely to be violent than someone with a mental illness.

Where do people learn about mental illness?

The media plays a big part in the way we think about mental illness. Sadly, media often make the link between mental illness and violence appear much stronger than it is. There is actually a weak link between mental illness and violence, but many people wrongly believe all people who have a mental illness are violent.

What can be done to help?

Mental health workers, people with a mental illness and their families all agree the most important step is making sure people receive effective treatment. Mental health workers need to know who is most at risk of being violent or of being a victim of violence. Making sure people receive the right treatment as quickly as possible requires early intervention, especially in the first episode of illness, and ongoing treatment for as long as required. It is also important for everyone to understand that mental illness is not a choice and could happen to anybody.

jokes about mental illness are not funny, names that are negative are not acceptable and that perpetuating myths is harmful.

On 21 January 2009, one of the largest ever programs to reduce stigma and discrimination against people with mental health disorders was launched. It was called 'Time to Change' and was UK based. The initiative was funded with £18 million and was run by three charities: Mental Health Media, MIND and Rethink. While the initial campaign concluded in September 2011, two of the charities involved, MIND & Rethink Mental Illness, have continued to evolve the campaign. Importantly, the campaign continues to advocate for changes in community and individual behaviour and not just attitudes towards people with mental illness. Equality and respect incorporate tolerance, active listening, empathy, compassion, safety, trust, diversity and cultural competence. Nurses should develop these virtues and practise them every day, both in and out of the work environment.

MENTAL HEALTH PROMOTION AND THE ROLE OF THE NURSE Nurses play an important part in promoting mental health. This can be achieved by nurturing healthy attitudes and coping mechanisms through early childhood and adult life. Nurses can empower people by helping them develop appropriate and effective ways to deal with trauma in relationships, situations and events. All nurses, no matter what their discipline area, should provide high-quality support and treatment services that enable people with a mental illness to participate fully in all aspects of their life (Recovery-focused care). Even when not on duty, nurses can encourage and assist friends and relatives who may have a mental illness to seek care and obtain treatment. The nurse can then follow up by encouraging engagement and compliance with the treatment regimen, just as they would with a person who has a physical illness, disease or injury that requires nursing and medical care.

Nurses can also encourage, support and undertake research related to mental health. This evidence base will assist the community to understand causes of mental illness; how these illnesses affect people, their families and the community as a whole; and how they can be prevented.

Mental health legislation

In 1901 Australia became a federation: a country with local, state, territory and federal governments. Australia has many state and territory differences and these occur in school curricula and holidays, number plates, pension entitlements and laws. Often terminology is also different between jurisdictions. Definitions about mental health and mental illness also differ between jurisdictions. These definitions are outlined in the

various **Mental Health Acts** (see Box 50.3) and further demonstrate the complex nature of mental illness and mental healthcare and treatment. Why is it that the states and territories do not differ in their approach to broken legs, appendicitis or aneurysms? Why is mental healthcare different?

Why is mental illness treated so differently?

The various definitions indicate that what *is not* a mental illness is just as important as what *is* a mental illness. This is indicative of the complexity of defining a mental illness; in fact, some of the mental health legislation does not actually define mental illness.

Although mental health legislation across various Australian jurisdictions has similar intent, the differences create major challenges for mobile populations, including nurses. Mental health nurses need to understand and implement different Mental Health Acts as they move across borders when changing jobs (now made easier with a single point of national registration). Subtle differences also make it more complicated for people who are managing their own journey of recovery, particularly if they also wish to travel interstate and are subject to an order set down within a Mental Health Act.

The concept of **Recovery** is a recognised and accepted paradigm that has significant implications for people who have mental health problems, their carers, mental health professionals and mental health services. Traditional models of mental health service delivery were not focused on Recovery; rather, they focused on containment and control of the individual. The notion of Recovery is embedded in the very personal journey of the individual, which is, of course, highly unique. Research has shown that people with a mental illness can and do recover but Recovery does not necessarily mean a cure; nor does it necessarily mean a return to a pre-illness state. Hope energises the Recovery process and lays the groundwork for the healing process to begin.

Recovery

Mental healthcare in Australia and many countries internationally now incorporates Recovery models of care in practice. The Australian Government is committed to the notion of Recovery as a process not an end point. The following information about the Recovery model was sourced from the excellent booklet *Sharing responsibility for recovery: Creating and sustaining recovery oriented systems of care for mental health,* www.health.qld.gov.au/mentalhealth/docs/recovery.pdf.

Recovery, as it is used in mental health, is the journey towards a new and valued sense of identity, role and purpose outside the parameters of mental illness. Recovery is about living well despite the limitations resulting from the illness, its treatment and personal and environmental conditions. Mental health services that are Recovery focused are underpinned by a fundamental shift in power, attitude and beliefs regarding the prognosis for a person who has been diagnosed with a mental illness. A Recovery approach emphasises mutual respect and collaboration between providers and service users as opposed to individual dependency on the system and a profound loss of personal autonomy. Recovery-focused service providers focus their attention on creating environments that nurture recovery and then on facilitating the process of recovery, rather than determining its direction. Recovery is considered a journey not an outcome.

Recovery is viewed as a journey that is a unique and personal experience for each individual (see Figure 50.5). It has often been said to be about gaining and retaining hope, understanding of one's abilities and limitations, engagement in an active life, personal autonomy, social identity, meaning and purpose in life, and a positive sense of self. Essentially, the personal view of Recovery is about a life journey of living a meaningful and satisfying life (NSW Consumer Advisory Group, 2012).

Helen Glover's 2012 model reflects the efforts that people undertake in their personal Recovery journeys through a set of five processes:

1. *from passive to active sense of self:* moving from the passive position of being a recipient of services to reclaiming one's strengths, attributes and abilities to restore recovery
2. *from hopelessness and despair to hope:* moving from a position of hopelessness and despair to one of hope
3. *from others' control to personal control and responsibility:* moving from others taking responsibility for recovery to the person taking, holding and retaining responsibility

FIGURE 50.5 ■ The concept of Recovery

Source: A national framework for recovery-oriented mental health services: Guide for practitioners and providers, Figure 2, p. 12 © 2013 Commonwealth of Australia.

4. *from alienation to discovery:* 'finding meaning and purpose in the journey; doing more of what works and less of what does not work; learning from experiences and incorporating those lessons into the present; acknowledging that journeys always have something to teach us and contribute to our sense of discovery'
5. *from disconnectedness to connectedness:* moving from an identity of illness or disability to an appreciation of personal roles and responsibilities and to 'participating in life as a full citizen and not through the powerlessness of illness' (NSW Consumer Advisory Group, 2012).

HOPE **Hope** is the foundation or guiding principle of Recovery. Hope is the belief that things do not have to remain the same and that change for the better can and does happen. Hope instils the belief that it is possible for someone to have a meaningful life, despite living with a mental illness. An approach based on hope concentrates on a person's strengths, with a focus on the future. Nurturing hope celebrates all successes rather than expecting and insisting on large and rapid change. Setting smaller goals means they are realistic and much more likely to be achieved. Positive reinforcement occurs because change has happened. This in turn provides future hope. Hope is about being positive and is important for the person to hold on to, but is equally important for others to have for the person. The positive impact that the hope of others can have on an individual with mental illness, when all seems bleak, cannot be underestimated. What do we have if we have no hope?

CONSIDERATION FOR PRACTICE

Mental health nurses are the holders of hope. When a person expresses little or no hope, offer to hold their hope in your hands. Tell them you will care for it and nurture it and when they are ready, you will hand it back.

Source: © S. Dashkevych/Shutterstock.com.

ACTIVE SENSE OF SELF For people who are living with a mental illness, sometimes their sense of self can become lost and their identity can revolve around their illness. It is very important that mental health nurses do not perpetuate this. This can happen when they refer to the person as 'the schizophrenic' or 'the depressive'. This kind of language is easy to fall into, but what it does is put the illness first, in front of the person. It is very disempowering language and serves to help destroy an already fragile sense of self. It is also stigmatising.

Nurses need to remember that having an illness is only one part of a person. Having a positive self-image comes from being treated as a whole person instead of just a part—this is called an **active sense of self**. Imagine if you were to be compartmentalised by only being referred to as a nurse or as a student. There is far more to you than simply being a nurse or a student and it devalues the complex person you are if only a single component of you is referred to. Recovery, then, goes beyond just merely functioning. It is the development of meaningful existence and a sense of purpose. We all need a reason to get up in the morning and our sense of purpose is developed through things such as relationships and work. Renowned psychiatrist Victor Frankl's premise is that 'man's search for meaning' is the primary motivation of his life.

DISCOVERY In mental health, **discovery** means that people with a mental illness deserve equality and respect. People who are living with a mental illness struggle every day with stereotypes that are perpetuated in the media (see Mindframe: <www.mindframe-media.info>). They are the most stigmatised and discriminated group in society. Unconditional positive regard is what nurses should afford people.

CONNECTEDNESS Recovery is a social process and correlates to the strength of people's social networks. It involves being with other people and reconnecting with the world. There are very few human beings who really enjoy being alone. Of course, there are times when we enjoy solitude, but by and large humans are social creatures and want the company of others. Indeed, humans actually need human company (interpersonal relationships) in order to be mentally healthy. To make social connections, social roles must be established. This is often very hard for the person who has a mental illness as society is not very accepting of '**differentness**' and, as we have already discussed, subscribes to myths and stereotypes that are simply untrue.

In fostering social connectedness, issues relating to community integration and full community participation need to be considered. Community integration is a concept drawn from the larger disability and civil rights movements and is founded upon the belief that all people have a right to full community participation and full community membership. This includes jobs, relationships with people who don't have a mental illness and appropriate and affordable housing.

PERSONAL RESPONSIBILITY It is the people who are affected by the mental health problem who hold the key to their own recovery, not service providers. Service providers such as mental health nurses need to ensure that people with mental health problems are recognised as whole people who are self-determining, able to make their own choices and able to take **personal responsibility** and live with the consequences of their decisions. Service providers, who are often risk averse, can find handing responsibility to the person a challenge. Recovery occurs when people are empowered to take ownership and when they can take an active role in their own recovery process. **Empowerment** is vital for correcting the learned helplessness that many people experience as a result of long-term interactions with a mental health system. The importance of people participating in their own healthcare has long been recognised as an essential element of effective service provision. This right is included in the World Health Organization Declaration of Alma-Ata (1978). It is also consistent with the principles stated in the *National Standards for Mental Health Services* and the former *National Action Plan on Mental Health 2006–2011*. These documents each served to highlight the need for care to be focused on the needs of the individual, rather than the service. The National Action Plan aimed to improve mental health and facilitate recovery from illness through a greater focus on promotion, prevention and early intervention; improved access to mental health services, including in Indigenous and rural communities; more stable accommodation and support; and meaningful participation in recreational, social, employment and other activities in the community. Improving the care system would also involve a focus on better coordinated care and building workforce capacity.

In 2012, The Council of Australian Governments (COAG) released the *Roadmap for National Mental Health Reform*. This document, now commonly referred to as simply 'The Roadmap', reaffirmed a commitment by state and territory governments to support the federal initiatives with a shared vision for mental health reform for the next 10 years. The creation of a COAG Working Group on Mental Health Reform, to oversee the implementation of new governance and accountability arrangements, has also been charged with development of the next version of the National Mental Health Plan (House of Representatives Standing Committee on Health and Ageing (HRSCHA), 2013). The current National Action Plan seeks to improve mental health and facilitate recovery from illness through a greater focus on promotion, prevention and early intervention strategies and related services. As part and parcel of this ongoing process, particular effort has been made to improve access to mental health services, inclusive of Indigenous and rural communities; provide more stable accommodation and support services; and facilitate the opportunity to access a more meaningful range of recreational, social, and employment-related activities in the community. In early 2014, the Australian Government requested the National Mental Health Commission to undertake a wide-ranging review of existing mental health programs and services across the government, non-government and private sectors nationally with a view to identifying ways to deliver services more efficiently and effectively. Concurrently, the Independent Hospital Pricing Authority was charged with the development of a new classification for mental health, to be known as the Australian Mental Health Care Classification (AMHCC). The development of the AMHCC is intended to improve the clinical meaningfulness of the way that mental healthcare services can be classified, leading to improvements in cost prediction, and support the implementation of new models. This has engendered a greater consideration of the best means for building greater workforce capacity. Of course, while much of the attention has been placed on national

initiatives in recent years, it should be equally evident that individual state and territory governments have also implemented their own suite of state/territory-specific mental health action plans and initiatives. Mental health is, and will remain for many years to come, a national health priority area.

The Commonwealth Government, having acknowledged the full significance of the growing national mental health issues, committed to a raft of new and expanded mental health reforms for the period 2011–2016. This represented increased expenditure, most of which was set aside exclusively for early intervention and prevention programs for youth at risk (HRSCHA, 2013). The AIHW estimates that nearly $7.5 billion is now spent annually in Australia on mental-health-related services. While a considerable sum by any standards, it is, however, a lot less than the amount spent on physical illnesses, despite the fact that mental illness affects one in five people. Perhaps we need to ask why governments continue to concentrate their funding on physical illnesses while acknowledging that mental health is a national priority.

Recovery versus rehabilitation

The following sums up the difference between rehabilitation and Recovery:

> *Rehabilitation refers to the services and technologies that are made available to disabled persons so that they may learn to adapt to their world. Recovery refers to the lived or real-life experience of persons as they accept and overcome the challenge of the disability. (Deegan, 1988)*

The aim of rehabilitation is the restoration of function and the minimisation of psychiatric disability. Rehabilitation does this through the development of strengths, restoration of hope, environmental modifications, enhancement of vocational potential and maximisation of social and recreational networks.

Recovery therefore forms the basis upon which rehabilitation services can be developed, but rehabilitation services should not be considered the only vehicle for Recovery. Rather, rehabilitation services are just one component in a framework that ensures hope, respect and pathways to community participation within a comprehensive service system that collectively works towards the individualised goal of Recovery.

Assisting Recovery

People who are recovering have described specific ways others have helped them. These include:

- *ventilation:* being able to converse with others; sharing concerns
- *reality testing:* having people assist in maintaining clear distinctions between reality and distortions of thought
- *material support:* helping with financial, housing and transport problems
- *social approval and integration:* receiving reassurance when people accept them and provide a sense of belonging
- *constancy:* associating with people they knew before they became unwell, connecting current identity with pre-hospital identity and giving roots to existence
- *motivation:* receiving encouragement to achieve higher levels of occupational and social functioning
- *modelling:* observing the behaviour of others and incorporating appropriate behaviour into their own lifestyle
- *symptom monitoring:* having others alert them to manifestations of symptoms
- *problem solving:* discussing problems and getting concrete, solution-focused feedback
- *empathic understanding:* being understood by people important to them
- *reciprocal relating:* becoming an equal partner, able to share and be of assistance to others
- ***insight**:* acquiring more complete and accurate understanding of themselves.

(Glover, 2012)

One of the initial processes that all nurses need to appreciate is the importance of gathering sound data and undertaking an assessment that provides enough information to establish a beginning path of action. Probably the most common of these, and one that all nurses should have a good understanding of and be competent in, is the mental state assessment.

ASSESSING PEOPLE FOR SIGNS OF MENTAL ILLNESS

MENTAL STATE ASSESSMENT

A **mental state assessment (MSA)** or examination (MSE) is a systematic clinical assessment that provides a picture of what a nurse observes during an interaction or interview with a person (see Box 50.4). The MSA is for that particular interaction only—a person's mental state is subject to change. Do you have the same thoughts, feelings and behaviours every day?

An MSA is not only undertaken by specialist mental health nurses or psychiatrists. Nurses use their skills to conduct an MSA in many healthcare settings. In fact, you are probably applying some of the elements of a mental state assessment already. When you first meet someone you 'assess' them, when you decide who to sit next to on the bus or train or in the movie theatre; when you see an old friend after a time apart, you check out what they are wearing, how they are behaving, what sort of things they are talking about, how their mood seems. All of these things are elements of a mental state assessment.

The MSA is just one part of the bigger picture. A more complete, holistic (biopsychosocial) assessment needs to be undertaken while being mindful of the context of the person's presentation and their history. Think of someone's life as a jigsaw—it is made up of many pieces. A full mental health or psychiatric assessment will include information about why a person is being seen, any significant mental health or medical history, current medications, drug or alcohol use, family history and current family circumstances, developmental history,

BOX 50.4 Components of a mental state assessment

Identifying information
Name
Age
Gender
Occupation
Cultural affiliation
Religion
Next of kin

Presenting problem
Why has the person presented?
What do they see as the problem?

Appearance
Hygiene
Grooming and dress
Posture
Eye contact
Scars/marks/tattoos/piercing/needle sites
Appearance versus stated age
Overall appearance

Behaviour
Tics/tremors
Calm
Agitated
Hyperactive
Rigidity
Facial movements
Unusual movements or gestures
Catatonia

Speech (assessment of the person's ability to communicate vocally)
Tone
Rapid/slow
Pressured
Loud/soft
Fluency (hesitant, mute)
Repetition

Attitude to interview
Cooperative
Hostile
Friendly
Combative
Aloof
Suspicious
Guarded
Apathetic
Distant

Thought processes
Blocking
Flight of ideas
Clang associations
Tangentiality
Loose associations
Circumstantiality
Echolalia
Word salad
Concrete thinking

Thought content
Delusions
Paranoia
Phobias
Magical thinking
Poverty of speech
Obsessions
Risk
- Self-harm
- To others
- To reputation
- Of dependence/ institutionalisation

Mood (Objective—the person's own view) = What does the person say?
Describe how the person identifies what they feel is happening in their own words; for example:
- Sad
- Elated
- Fearful
- Worried
- Angry
- Guilty
- Happy
- Hopeless
- Irritable
- Mixed (anxious and depressed)

Affect (subjective—the clinician's view) = What do you observe?
Is the person:
- Flat
- Blunted
- Diminished
- Appropriate
- Inappropriate

Perceptual disturbances
Hallucinations
- Visual
- Auditory
  - Command
  - Loud/soft
  - Commenting
  - Discussing
- Tactile
- Olfactory
- Gustatory

Illusions
Depersonalisation

Memory/cognition
Orientation (time, place and person)

Memory (ability to store, retain and recall information, both recent and remote)
General: alertness and cooperation
Attention: WORLD backwards and serial sevens
Language: naming and repetition
Calculation: division and subtraction
Abstraction: proverbs and similarities

Insight and judgment
Awareness of illness
- Do you consider that you are ill in any way?
- Why have you come into hospital?
- Do you have a physical or a mental illness?
- Are you suffering from a mental health problem? What is it?

Correct labelling of abnormality:
- You described several symptoms, namely . . .
- What is your explanation of these experiences?

Willingness to take treatment:
- How do you feel about being in hospital . . . coming to the clinic . . .?
- How do you feel about taking medication?
- Has the medication been helpful?
- Have any other treatments been helpful?
- What helps you remain well?

What supports do you have?

Impulse control
Can the person control urges of anger, laughter, self-harm?

their social situation and current level of functioning, including sleep, self-care, spirituality, diet and sexual health.

People often present for help as a result of the impact that their symptoms are having on their level of functioning. This frequently includes situations where things feel overwhelming such as when a person's mood is so low they wish they could die, or their **anxiety**—excessive worry about everyday life events with no obvious reasons for this worry—has become so great they cannot leave home without having a panic attack. Health practitioners, however, are often focused on the need for a diagnosis. While diagnosis can be important, the 'label' is not what the person is concerned with. People with a mental illness, like all of us,

generally just want their life to improve. The focus is different, but hopefully everyone is aiming for the same thing. The needs of the person seeking help should be at the forefront of all nursing care.

The process of assessment is in itself an intervention. This is because the nurse is spending time engaging with the person. Within an MSA there are formal terms and processes that we will now examine. A framework for conducting the assessment is also outlined. There are many assessment tools in use throughout Australia and New Zealand. The following outlines the main components. It is beholden upon the nurse conducting an MSA to make the person feel comfortable about expressing their thoughts and feelings without fear of negative judgment. A conversational approach, rather than a set of formal closed questions, is likely to make the person feel calmer and less anxious. This will result in greater rapport with the nurse and therefore better information. Nurses should use open-ended questions and be conscious of their own non-verbal responses and body language. People can tell if you have a genuine interest in them or are just 'going through the motions', and people with a mental illness are no less sensitive to this. Validating feelings is always helpful. Where possible, sit with the person and/or their family.

The assessment process cannot be rushed. Often people who have a mental illness feel anxious, afraid and vulnerable, and may fear that nurses will judge them negatively. The more patience and respect the nurse shows to the person and their family, the quicker the nurse will gather the information and the more accurate it will be. Accurate information is needed to form the basis of a comprehensive and holistic assessment.

TYPES OF MENTAL ILLNESS

The brevity of this chapter does not allow for an in-depth examination of the various types of mental illness. Broadly speaking, mental illness falls into two large groups—psychotic disorders and non-psychotic disorders.

Psychotic disorders

Psychosis describes a state in which a person's reasoning and thinking (**cognition**) are distorted, leading to a loss of contact with reality. Psychosis, like most mental illnesses, is episodic in nature. People who experience psychotic disorders are not out of touch with reality all the time. Instead, when someone is experiencing psychosis, they are having what is known as a psychotic episode. Such an occurrence describes the state of mind that the person is currently in.

A psychotic episode can occur as part of a number of different disorders—for example, schizophrenia; as part a drug-induced state; in affective illnesses such as depression or mania; and where there is an established physically defined brain disease or impairment, including brain tumours or even epilepsy.

A psychotic episode is a frightening and confusing event for the person experiencing it, and for their carers and friends. Approximately three in every 100 people will experience a psychotic episode at some time, and a psychotic episode usually first occurs between the ages of 15 and 35 years. Of this group, fewer than 4.5 people per 1000 will seek contact with specialised public mental health services. Sometimes a psychotic episode has a rapid onset (a few days), but often the onset of a psychotic episode is more gradual, over a period of weeks or months. When the onset is more gradual, individuals and their families will often report that things 'weren't quite right' for some time before the psychotic episode. A psychotic episode always requires treatment, and studies have shown that the earlier that treatment is obtained, the better the outcome for the person (healthdirect Australia, 2016).

The main distinguishing feature of a psychotic disorder is the person's loss of contact with reality. The person may not be aware of this, however. Two of the key symptoms that a nurse might observe in a person who is experiencing a psychotic disorder are delusions and hallucinations.

Delusions

Delusions are fixed false beliefs that are not a normal part of the person's cultural or religious environment and that cannot be altered by logic. A person who has a delusion is absolutely convinced that what they think is true. It cannot be argued with. A nurse who tries to dispel the delusion and argues with the person runs the risk of becoming incorporated into the delusion and being perceived as combative. Delusions are often complex and can be difficult to comprehend, especially when they incorporate very unusual beliefs. The authors have seen people with delusions who believe that they have chips inserted into their brains to track their thoughts and feelings, or that they were attached to a genetic line of descendants from gangsters located in spy organisations, or that they are working for prime ministers, ASIO or presidents. Delusions that involve the belief that the person is being followed, controlled or watched are common. Such beliefs can be very distressing and cause the person to act in ways they would not normally act. There are many different types of delusions. Some include:

- *delusions of grandeur:* beliefs of great importance or extraordinary powers or abilities (e.g. the person believes they are royalty, the president or Superwoman)
- *somatic delusions:* beliefs that something odd is happening to their body, that they have a disease or that part of their body is missing or has been changed in some way, despite medical evidence to the contrary (e.g. the person believes they have no stomach)
- *delusions of reference:* beliefs that the behaviour of others, events, objects or information such as television, songs or newspapers contain messages that are specifically meant for them (e.g. the person believes that car number plates send special messages)
- *delusions of persecution/paranoia:* beliefs of being pursued, watched, tracked or followed (e.g. the person believes that a government agency is following them).

Hallucinations

A **hallucination** is an alteration in perception. It occurs when a person experiences a sensation of something that is not objectively present. A person can experience hallucinations in any of the senses—auditory (hearing), visual (sight), olfactory (smell), tactile (touch) and gustatory (taste).

- *Auditory:* the most common type of hallucination is auditory and relates to hearing something that others cannot. The sounds (voices, music, tapping etc) can be 'inside' or outside their head. They are real to the person and should never be dismissed as a joke. What the person hears can be of any nature. Hearing voices can be pleasant but can also

be frightening, threatening or critical. The commentary may be about what the person is doing; voices that are telling them they are wrong or that they should be doing something else, or that they are worthless. On the other hand, the voices may be kind, comforting or neutral. Sometimes voices command a person to do something. The name given to this is *command hallucination*s and, depending on what the voices are commanding the person to do, they can pose a threat to the safety of the person or to others. It is very important that the nurse establishes what it is these particular voices are commanding the person to do. Refer back to the MSA and note that when assessing perceptual disturbances, nurses are encouraged to ascertain the content of the voices. Yet other voices may repeat the person's thoughts. Sometimes the person may hear two or more voices having a conversation about them, or several voices at once shouting or yelling at them. Sometimes it may not be a voice/s. People have described hearing an orchestra, birds, animals, drums and all manner of sounds. As with voices, these sounds are not imagined and brain-imaging studies suggest that voices arise from parts of the brain that are ordinarily involved in perceiving spoken speech.

- *Visual:* things or people are seen that cannot be seen by others. Hallucinations are not illusions. An accurate assessment (MSA) will ascertain the difference. (An **illusion** is a distortion of sensory perception and, therefore, reality. It is a misinterpretation of a true sensation and is shared by most people.)
- *Olfactory:* if a person experiences olfactory hallucinations, they smell things that others cannot. These smells may be good or bad and can have an effect on what the person eats.
- *Gustatory:* if a person experiences gustatory hallucinations, food may taste as if it is bad, contaminated or poisoned. If this is the case, the nurse has to be very skilful in order to get the person to have enough sustenance.
- *Tactile:* with this type of hallucination, sensations are experienced that have not actually occurred or are sensed differently from the way they usually are—for example, the person may feel as though spiders, bugs or ants are crawling over their skin, or that they are being touched by someone. Tactile hallucinations are said to be common in people who use the methamphetamine ice.

Types of psychotic disorders

DRUG-INDUCED PSYCHOSIS Using drugs, coming down from them, or withdrawing from certain drugs can precipitate psychotic symptoms. In particular, it is common to see people who have a drug-induced psychosis present with delusions and hallucinations. Sometimes these symptoms wane within a few days as the effects of the substances wear off, and the person may not experience another episode unless they continue to use drugs. However, for some people the effects can last for a long time, even after abstinence. If someone has an underlying vulnerability to a psychotic disorder such as schizophrenia, the psychotic episode can last much longer, and may be triggered by the initial substance use. Drugs such as amphetamines and ice are often linked to psychotic episodes. The link between cannabis (THC) and mental illness is becoming increasingly obvious.

ORGANIC PSYCHOSIS The importance of a medical clearance for possible physical causes of what may appear to be a mental health issue cannot be underestimated. Sometimes a physical injury or an illness that affects the brain can be the cause of an organic psychosis. Such conditions include brain tumours and infections, Alzheimer's disease, delirium, cardiovascular accident and some vitamin deficiencies. Treating the underlying physical problem is the main treatment.

BRIEF REACTIVE PSYCHOSIS A traumatic or very stressful event in someone's life, such as the death of a loved one, a physical or sexual assault, or a natural disaster, can cause a psychotic episode. During a brief reactive psychosis the symptoms can be severe and appear quickly. Symptoms can also rapidly abate.

DELUSIONAL DISORDER In a delusional disorder the main sign is a strong belief in something that is not true, with few if any hallucinations (see above for examples of delusions). People who have a delusional disorder may not experience any other symptoms of mental illness. If the delusions do not affect their lives as such, they can usually continue to manage their responsibilities, and their behaviour may not be very different from usual. Some delusions may not interfere with life as much as others. For example, a delusion that all women who have purple hair, wear green Versace jeans and are very tall are dangerous is not likely to cause alarm because meeting a person who fits this description is not very likely. However, if a person believes that men under 25 who drive white cars are following them, this is likely to have an impact on the person's life because it is highly probable they will encounter this scenario. The effect is dependent on the nature and content of the delusion.

SCHIZOPHRENIA **Schizophrenia** is a mental illness that affects approximately one person in every 100. People who live with this psychotic disorder often experience hallucinations, delusions and thought disorder (see Figure 50.6). The onset of schizophrenia may be rapid, with acute symptoms developing very quickly, or it may be slow and develop over many months or even years. Some people experience only one episode but for others it is a lifelong condition. First onset is usually in adolescence, but it can also occur for the first time in older people. Schizophrenia refers to a change in a person's mental function. A person who has schizophrenia does not have a 'split personality' although this is how this condition is often described, especially in the media. People with schizophrenia may however experience changes to their own personality as a result of disturbed perceptions and thoughts.

There are different types of schizophrenia but it normally has three phases:

1. *Prodromal phase:* early warning signs are present; something is 'not quite right'.
2. *Acute phase:* symptoms of a psychosis are observed, such as hallucinations and/or delusions and/or thought disorder.
3. *Recovery phase:* people return to their day-to-day lives, with the help of treatment.

FIGURE 50.6 ■ Some people with schizophrenia experience hallucinations and delusions

BIPOLAR AFFECTIVE DISORDER Bipolar affective disorder is the name given to what was previously known as manic depressive psychosis. Bipolar affective disorder aptly describes the recurrent episodes of 'up and down' mood swings. These can range from elation and excitement to sadness and depression. When people experience such extremes in mood it can be difficult for them to manage day-to-day responsibilities such as work, finances and family commitments. Episodes of mania (see Box 50.5) and episodes of depression (see Box 50.6) can last for a short time (days) or for a longer time (months). There are different types of bipolar disorder.

People who have bipolar disorder often experience psychotic episodes. The symptoms experienced usually match the person's current mood. If a person is depressed they might hear voices that tell them that they are horrible or no good, or direct the person to hurt themselves. A person who is manic, however, might believe that they are very special and can do remarkable things (delusions of grandeur).

Some of the famous people said to live/have lived with bipolar disorder include Adam Ant, Mark Twain, Catherine Zeta-Jones, Patty Duke, Andrew Johns, Vivien Leigh, Edgar Allen Poe, Nina Simone, Jean-Claude Van Damme, Sidney Sheldon, Sinéad O'Connor, Mel Gibson and Richard Dreyfuss.

BOX 50.5 Symptoms of mania

- An elated, happy mood or an angry, irritated mood
- Increased energy or activity levels
- Decreased sleep/less need for sleep/difficulty getting to sleep
- Increased talking, and talking louder and faster than usual
- More thoughts, and faster thinking than usual
- Overly ambitious plans and reckless behaviour (e.g. spending too much money or engaging in careless or potentially dangerous behaviour)
- Grandiose delusions

BOX 50.6 Symptoms of depression

- Sadness or depressed mood
- Lack of motivation and energy
- Changes in sleep patterns—sleeping more or less than usual
- Changes in appetite—eating more or less than usual
- Hopeless and helpless feelings
- Less interest in and less enjoyment from usually enjoyed activities
- Feelings of guilt and worthlessness
- Depressive delusions

PSYCHOTIC DEPRESSION People who are experiencing psychotic depression may have many of the same symptoms that people with bipolar disorder experience when they are depressed (see Figure 50.7). People who have psychotic depression, though, do not experience periods of elation or mania. When people have psychotic depression they tend to experience symptoms that match their mood; for example, they might hear voices that tell them to kill themselves, or voices that make fun of them, or they may experience delusions.

Non-psychotic disorders

Throughout life we have all experienced strong feelings of sadness, tension or fear. For some people, though, these feelings can become so troubling and overpowering that they have difficulty coping with everyday activities, even those that they have been successfully managing and coping with for years. The processes of going to work, enjoying leisure time and maintaining relationships become so intense that they are unable to carry them out.

FIGURE 50.7 ■ Highly successful individuals, like Andrew Johns the former NRL player, are not immune from depression. It is beholden upon the nurse conducting an MSA to make the person feel comfortable expressing their thoughts and feelings without fear of negative judgment

Source: © Jonathan Carroll/Australian Associated Press Pty Ltd.

Such all-consuming feelings are not often evident to others. For the person who is experiencing them, though, they can cause considerable personal distress and anguish. Such mental illnesses are labelled as non-psychotic illnesses. They are a common experience for many people and the list below demonstrates how widespread and prevalent these illnesses are. It is highly likely that someone with one of these illnesses will require care within the general nursing setting. Nurses themselves can also live with these types of illnesses every day. Remember, if mental illness affects one in five Australians, it is highly likely that someone you know, are related to, study with or work with has a mental health issue.

- Adjustment disorder
- Anxiety disorders
- Post-traumatic stress disorder
- Phobias
- Obsessive compulsive disorder
- Dissociative disorders
- Eating disorders:
  - Bulimia
  - Anorexia nervosa
- **Impulse control** disorders:
  - Pyromania
  - Kleptomania
  - Pathological gambling
- Mood disorders
- Sexual disorders:
  - Paedophilia
  - Necrophilia
  - Fetishism
- Sleep disorders:
  - Night terror disorder
  - Insomnia
  - Narcolepsy
- Sexual dysfunctions:
  - Gender identity disorder
  - Sexual aversion disorder
  - Premature ejaculation
- Somatoform disorders:
  - Hypochondriasis disorder
  - Pain disorder
- Substance disorders:
  - Substance abuse
  - Substance dependency
- Personality disorders:
  - Antisocial personality disorder
  - Narcissistic personality disorder
  - Borderline personality disorder.

Most non-psychotic illnesses can be effectively treated, usually with a combination of medication and psychotherapies. Treatment helps the person understand their illness and gain insight into what exacerbates their symptoms. It also assists with illness management and recovery.

The most common type of non-psychotic disorder is depression. Depression is so commonplace that the WHO (2012b) predicts that by the year 2020 it will be the second main contributor to the world's disease burden.

Depression

We have all felt sad or 'blue' at some time in our lives. This experience of having a low mood can result from something we have experienced: a loss, relationship difficulties, trauma or an event to which we can attribute feeling down. Sometimes, though, people experience low moods for no apparent reason at all. Such feelings are normal and are not cause for concern. However, feeling down can become an illness. Indications that a person may have a depressive illness include when a low mood becomes very severe and lasts for 2 weeks or more and when the low mood interferes with the person's ability to function.

Depression affects nearly all physical and psychological functions. A person with depression may have difficulty getting out of bed, not care for their ADLs, experience loss of appetite, have difficulty coping at work, have constipation (related to not eating; lack of mobility), have difficulty in concentrating and sleeping and suffer with memory loss. Many famous people are said to live/have lived with depression: Schumann, Virginia Woolf, Rachmaninov, Tchaikovsky, Adam Duritz, Billy Joel, Buzz Aldrin, Drew Carey, Kurt Cobain, Vincent van Gogh, Rodney Dangerfield, Winston Churchill, Sheryl Crow, Jeff Kennett and Rosie O'Donnell, to name but a few.

Signs of a depressed mood include:

- apathy and indifference
- lowered energy levels
- reduced motivation
- feelings of dejection and despondency
- lowered pain tolerance and new aches and pains
- reduced libido
- changes in appetite or weight
- reduced ability to control emotions (labile crying, anger outbursts)
- poor concentration and memory
- changes in sleep patterns
- reduced capacity to enjoy life—nothing is pleasurable
- suicidal thoughts.

The above list is not exhaustive and having one or two symptoms is not necessarily indicative of a depressive illness. The nurse needs to ascertain thoughts of self-harm which then need to be further explored so that risk can be properly assessed.

Treatments in mental health

Treatments for mental illness are as varied and diverse as the illnesses themselves but largely fall into two categories: physical treatments and psychological therapies.

Physical treatments

There are a number of types of physical treatments, the most common of which is medications.

MEDICATIONS One of the roles of a mental health nurse is to administer, monitor and evaluate drug therapy. Medications are used widely for many different types of mental health issues. Medications fall broadly into a number of categories, including antidepressants, anxiolytics, antipsychotics and

FIGURE 50.8 ■ Types of medications: *A*, an antidepressant, *B*, an antipsychotic

Sources: A, © Najlah Feanny/Corbis; *B*, © Chris Gallagher/Getty Images.

mood stabilisers (see Figure 50.8). The mental health nurse needs to engage with the person regarding their pharmacological treatment and provide psychoeducation with the aim of medication management.

BRAIN STIMULATION THERAPIES Brain stimulation therapies involve activating or touching the brain directly with electricity, magnets or implants. These therapies are usually focused on mood and anxiety-type disorders. Brain stimulation therapies include vagus nerve stimulation, repetitive transcranial magnetic stimulation, magnetic seizure therapy and deep brain stimulation. Some of these are relatively new and are currently considered experimental methods.

ELECTROCONVULSIVE THERAPY (ECT) is a type of brain stimulation therapy that is worthy of particular discussion because of its controversial past. It is considered particularly useful for someone who is suffering with severe depression or life-threatening mania. Before ECT is administered, the person is sedated with a general anaesthetic and given a muscle relaxant. This prevents jerking and movement during the procedure. As with all general anaesthetics the person's breathing, heart rate and blood pressure are closely monitored throughout the procedure.

Electrodes are placed on the person's temples, either bilaterally or unilaterally, and an electric current is applied through the brain. The person under anaesthesia does not feel this impulse, although a convulsion is induced. In contemporary practice, this convulsion is barely visible and lasts from a few seconds to usually less than 1 minute. This is in stark contrast to the early days of such treatment where the person often thrashed about violently on the procedure table. The most common side effects associated with ECT are headache, upset stomach and muscle aches. Some people may also experience memory problems, especially around the time of the treatment. People may also have trouble remembering information learned shortly after the procedure, but this difficulty usually disappears over the days and weeks following the end of an ECT course. It is possible that a person may have gaps in memory over the weeks during which he or she receives treatment. ECT is usually done in a course of treatments that are individualised for the person.

Psychological therapies

Psychological therapies can also contribute to the Recovery journey of a person who has a mental illness. The most important of these is the development and maintenance of a therapeutic relationship with the care coordinator. The importance of this relationship is the subject of many research papers written by mental health service users, their carers and clinicians.

COGNITIVE BEHAVIOURAL THERAPY (CBT) Along with a therapeutic relationship, CBT can also be useful. CBT aims to work closely with the person in order for them to see the links between their moods and their thinking. The objective is therefore to get the person to think in ways that are more positive.

INTERPERSONAL THERAPY (IPT) IPT aims to help the person identify current life factors that are leading them to experience a mental illness. IPT is founded upon the assumption that a person's vulnerabilities lead them to an illness. The aim is to strengthen the vulnerable parts of the person's personality.

NARRATIVE THERAPY (NT) NT places its main emphasis on a person's strengths. Narrative therapists listen closely to the person's life story and help them recognise times when they have solved problems with a positive outcome. Past situations and circumstances are thus learned from and built upon, ready to be used in future situations.

All therapies and treatments work best when the person is accepting of and seeking treatment for their mental health issues. See Box 50.7 for the SANE checklist to determine whether someone should see a mental health practitioner. Psychological therapies in particular will not work if the person does not trust the therapist. Once again, the importance of developing and maintaining a therapeutic relationship is at the fore.

BOX 50.7 A SANE checklist

Are you worried about someone whose behaviour has changed? If someone you know has become confused, avoids people or has developed strange ideas that are not shared by others, it is important they talk to a mental health nurse or doctor to get help. The reason for this change may be that they have an illness.

Checklist

Encourage someone to seek help if anything on this checklist describes how they feel or act:

- They stop talking to family and friends.
- They become afraid or suspicious for no reason.
- They sleep poorly or often are awake all night.
- They develop strange ideas.
- They hear voices no one else can hear.
- They feel they have special powers.
- They have difficulty concentrating.
- They say or write things that don't make sense.
- They abuse drugs or alcohol.

How to get help

- Encourage the person to see a doctor.
- Offer to go with them, as a support.
- Ask for a longer appointment so there is sufficient time to explain concerns.
- Suggest you write some notes together to help explain things to the doctor.
- If the person is reluctant to seek help, visit the doctor yourself to ask for advice.

CHAPTER HIGHLIGHTS

- Mental disorders account for an estimated 11% of the disease burden worldwide and this is projected to rise to 15% by the year 2020.
- In Australia, mental disorders are the third leading cause of overall disease burden, accounting for 13% of total burden and 27% of years lost due to disability.
- Mental illness represents the largest single cause of disability, accounting for almost 25% of the burden of non-fatal disease.
- It is imperative that all nurses have the skills and knowledge to provide safe and effective care for the large number of people affected by mental illness.
- The care that people who have a mental illness receive should be no less evidence based than the care that is provided to people who have a physical illness or injury.
- Nurses' attitudes towards people who have a mental illness should be respectful and non-judgmental; the nurse should show positive regard and be professional at all times.

CONCEPT CHECK

1 There are two main diagnostic criteria used internationally:
   1 DSN and ICD
   2 DSM and ICC
   3 DSM and ICD
   4 DMM and ICD

2 The American Psychiatric Association *Diagnostic and Statistical Manual of Mental Disorders:*
   1 assists with diagnosis
   2 sets nursing priorities
   3 establishes appropriate treatment regimes
   4 ensures accurate epidemiological data is collected

3 Antonio has altered thought processes. An appropriate nursing response would be to:
   1 explore his delusions with him
   2 redirect his attention back to the here and now
   3 point out gently the way in which his thinking is altered by giving examples
   4 ensure you speak loudly enough so that he can hear you above his hallucinations

4 Bipolar disorder is:
   1 a non-reactive set of depressive symptoms
   2 a common disorder in young males
   3 a psychotic disorder
   4 a hereditary mental illness

5 People with bipolar disorder have:
   1 delusions and spatial disruption
   2 positive and negative symptoms
   3 mood swings
   4 hallucinations and thought blocking

6 Bipolar disorder is often written as:
   1 BD
   2 BPD
   3 BiPD
   4 BAD

7 Manic symptoms associated with bipolar disorder include:
   1 little eye contact
   2 speaking one's mind
   3 no time for conversations
   4 feeling really good

8 The following is not an example of a perceptual disturbance:
   1 delusion
   2 seeing things
   3 hearing voices
   4 feeling things on your skin

CHAPTER 51

COMMUNITY CARE

JENNY DAY, ANN TAYLOR, SHARYN HUNTER, SARAH JEONG, ISABEL HIGGINS

KEY TERMS

biomedical model of health 1878
biopsychosocial model of health 1878
community 1873
consumer-directed care 1875
distal determinants 1881
health determinants 1878
health education 1884
health promotion 1884
intermediate determinants 1881
intersectorial 1875
primary care 1882
primary healthcare 1882
proximal determinants 1881
social determinants of health 1878
social model of health 1878
transdisciplinary 1882

LEARNING OUTCOMES

- Describe the background and contemporary context of community care in Australia.
- Differentiate the health models underpinning and influencing community care services in Australia.
- Compare individualist and structuralist–collectivist approaches to health promotion.
- Discuss the evidence for social determinants of health as factors that affect the health of communities.
- Differentiate between primary healthcare and primary care and identify their relationships to community care approaches. Explain the role and contribution of nurses in community care, including intersectorial partnerships.

CLINICAL COMPETENCIES

- Understand the health of communities in conjunction with the health of individuals.
- Apply the social determinants of health in relation to the health of individuals and communities.
- Collaborate with health and non-health professionals intersectorially to promote health, prevent illness/injury and restore health for individuals and communities.
- Utilise culturally safe approaches to care within primary healthcare and primary care services.
- Utilise partnership approaches to facilitate consumer-directed care.

In Australia, community care, or primary care, and public health are terms that are used to refer to organisations which provide health-related services in the community. These organisations aim to support and improve the health of communities by providing a universal point of access to the health system, promoting health and preventing illness, providing high-quality healthcare across the lifespan and ensuring continuity of care (Australian Productivity Commission, 2015). The roles nurses play in these organisations are complex and diverse, ranging from early childhood clinics, occupational health services, chronic disease management and palliative care to providing education on healthy lifestyle and prevention of disease or injury. Also important is the role of nurses in identifying and addressing social, environmental and political factors that impact on the health of individuals and communities as a whole (Schofield et al., 2011). The integral role of nurses in achieving the aim of community care is well acknowledged, as is the importance of nursing's future role in health care (Adrian, 2009; Department of Health and Ageing, 2009a; 2010).

This chapter provides an introduction to the concepts that are important to understanding community care services in Australia, as well as exemplars which illustrate nursing practice in this sector. While reading this chapter, it will be important to appreciate the interrelated nature of each concept in order to understand the contribution community care organisations make to the health of people and populations, and how community care services articulate with, but differ from, those provided by the acute care sector. Also important is remembering that community care organisations are characterised by their diversity, ranging from state- and federal-government-funded health services to church organisations, private businesses and volunteer organisations. Many of these organisations are not recognised as formal healthcare organisations but nevertheless play a vital role in developing and supporting community health in Australia (Australian Productivity Commission, 2015). In addition, key nursing concepts, such as culturally safe care and critical thinking, apply equally to nursing practice in community and hospital contexts.

To begin to understand how community care organisations work and the concepts that guide nurses working in this sector, we first need to clarify what is meant by the term community.

WHAT IS A COMMUNITY?

When considering communities and their health it is helpful to reflect on what is meant by the term **community** (see Figure 51.1). While this term has different meanings, two common meanings used in relation to health are 'community as locality' and 'community as relationships' (Taylor, Wilkinson & Cheers, 2008). Community as locality refers to the

FIGURE 51.1 ■ Community: places where people live and relate

Source: Jenny Day.

geographical location that people share with others (e.g. town, city or suburb), reflecting the role of people's environment and its resources on health (Heller cited in Taylor et al., 2008). Community as relationships refers to the human interactions and social connections that unite people (Heller cited in Taylor et al., 2008). Different communities of people therefore have different attributes, making it important not to assume communities are the same, perhaps thinking they have close-knit relationships or shared values and interests (Talbot & Verrinder, 2013). Also important is acknowledging that each community is likely to have subcommunities, such as school communities and inner- and outer-town communities, based on relationships, interests or localities, creating a complex and dynamic whole. Based on these meanings, the health of a community is a synthesis of people interacting or relating within their locality (McMurray, 2011).

Communities show qualities that indicate their health, many of which are detailed in Box 51.1. These qualities provide a guide for nurses who work in community organisations and reveal an orientation that considers health for the community rather than for each individual.

COMMUNITY CARE IN AUSTRALIA

Since 1973, when a formalised program to address the health of communities was established (McDonald & Smith, 2001; Coombs, 1985), seven goals have guided community health services: prevention, self-help, participation, integration, area responsibility, accountability and teamwork (Division of Health Services Research, 1975, cited in Owen et al., 2008). These goals continue to guide services; however, the current National Primary Health Care Strategic Framework (Department of Health and Ageing, 2013) promotes a stronger emphasis on the empowerment of individuals and communities to improve health literacy and healthy lifestyle choices. Also advocated is flexibility of health services to meet the needs and preferences of individuals and communities (Department of Health and Ageing, 2009b).

Community groups of interest to community services and the focus of their service activities are shown in Table 51.1. These groups and activities describe how different people within communities might need different community services.

To achieve the goals of community health and to meet the needs of groups within the population, community care services are provided in a variety of settings, by a range of people and organisations, and are funded through a range of different sources (Department of Health and Ageing, 2008). Complex networks of organisations, which together support the health of the community and its people, are therefore evident. This network involves interaction between community care organisations and those of the acute or hospital system, as well as interaction between formal health services and other organisations which address the social determinants of health or public health and safety. Figure 51.2 describes service network connections between general and specialist community services and acute care services.

The complex funding structure and areas of responsibility of Australia's health system is illustrated in Figure 51.3. This figure shows the web of health system services, including community and public health services. Note that health services comprise a mix of public and private sector involvement, with funding from the Australian Government, the state and territory governments and private funders. The total government expenditure on community and public health in 2011–2012 was $140.2 billion (Australian Institute of Health and Welfare (AIHW), 2014a, p. 47). This represents 9.5% of

BOX 51.1 Community alert: qualities of healthy communities

- Clean and safe physical environment
- Peace, equity and social justice
- Adequate access to food, water, shelter, income, safety, work and recreation for all
- Adequate access to healthcare services
- Opportunities for learning and skill development
- Strong, mutually supportive relationships and networks
- Workplaces that are supportive of individual and family wellbeing
- Wide participation of residents in decision making
- Strong local cultural and spiritual heritage
- Diverse and vital economy
- Protection of the natural environment
- Responsible use of resources to ensure long-term sustainability

Source: Ontario Healthy Communities Coalition (n.d.). *What makes a healthy community?* Retrieved from www.ohcc-ccso.ca/en/what-makes-a-healthy-community.

These principles have been adapted from the work of Trevor Hancock and Leonard Duhl. They are discussed in more detail, with references to earlier documents, in a report Dr Hancock prepared for the Senate Subcommittee on Population Health in March 2009 entitled *Act locally: Community-based population health promotion.*

TABLE 51.1 Community groups: needs and services

COMMUNITY GROUP	SERVICE ACTIVITY
Community members not at risk of ill health/injury	Health promotion
Community members at risk of developing a health problem	Prevention and early detection
Community members who present with a health problem	Assessment and investigation that does not require access to special technology
Community members with a confirmed problem	Community treatment
Community members with chronic consequences arising from a health problem	Continuing care

Source: K. Eagar et al. (2008). *Community health at the crossroads: Which way now? Final report of the NSW Community Health Review.* Wollongong: Centre for Health Service Development, University of Wollongong.

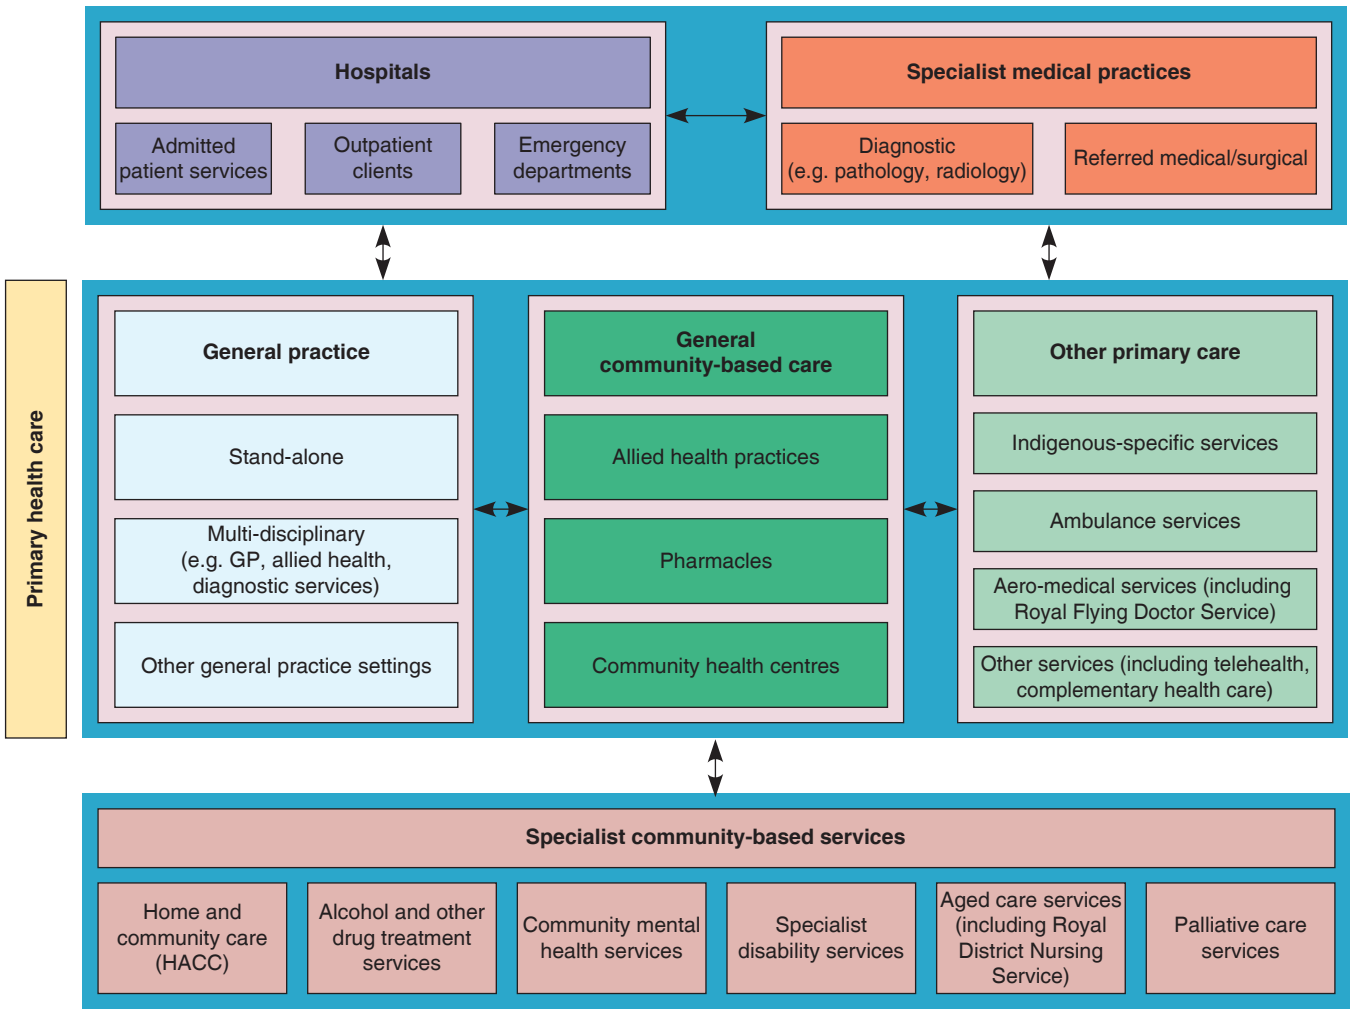

FIGURE 51.2 ■ Community health service network connections

Source: Australian Institute of Health and Welfare (AIHW) (2014a). *Australia's health 2014.* Chapter 8: Treating and preventing ill health. Retrieved from http://www.aihw.gov.au/australias-health/2014/preventing-ill-health/#t3. © Australian Institute of Health and Welfare.

gross domestic product (GDP). It is concerning that the cost of health has grown faster than the population has grown. It must be remembered, however, that formal health services are only one component of the network of organisations within communities which aim to promote health.

To be effective, community health services need to work in partnership with health and other services within the community to ensure the health of the population. They therefore work with many government and non-government organisations and services which are funded outside the health system, yet which make significant contributions to the health of the population, particularly disadvantaged groups (e.g. people who are homeless). This is known as **intersectorial** collaboration. Examples of these organisations include religious organisations; specific interest groups such as Diabetes Australia, Australian Breastfeeding Association and SIDS and Kids; and income-support organisations. Some other partners that are needed to develop and sustain healthy communities are listed in Box 51.2. Importantly, however, there is increasing emphasis on working in partnership with the people, or consumers, who use community services. This shift responds to consumers' calls for models of care which are consumer driven and oriented and is reflected in the introduction of services underpinned by **consumer-directed care** (CDC) philosophies. These CDC services aim to increase consumer power/control over care, increase consumer satisfaction with care and improve consumer health outcomes—both functional and social (Low et al., 2012). In Australia, community aged care CDC refers to enhancing service users' autonomy by enabling and optimising consumer goal setting and control over the care they receive and the providers who deliver their services; the opposite of agency directed or controlled care which has operated in the past (Low et al., 2012).

Community-based programs based on the CDC model have been available in the Australian disability sector for some time. These have stemmed from disability self-advocacy and empowerment movements. They have developed considerable support from consumers with a disability (Low et al., 2012; Aged and

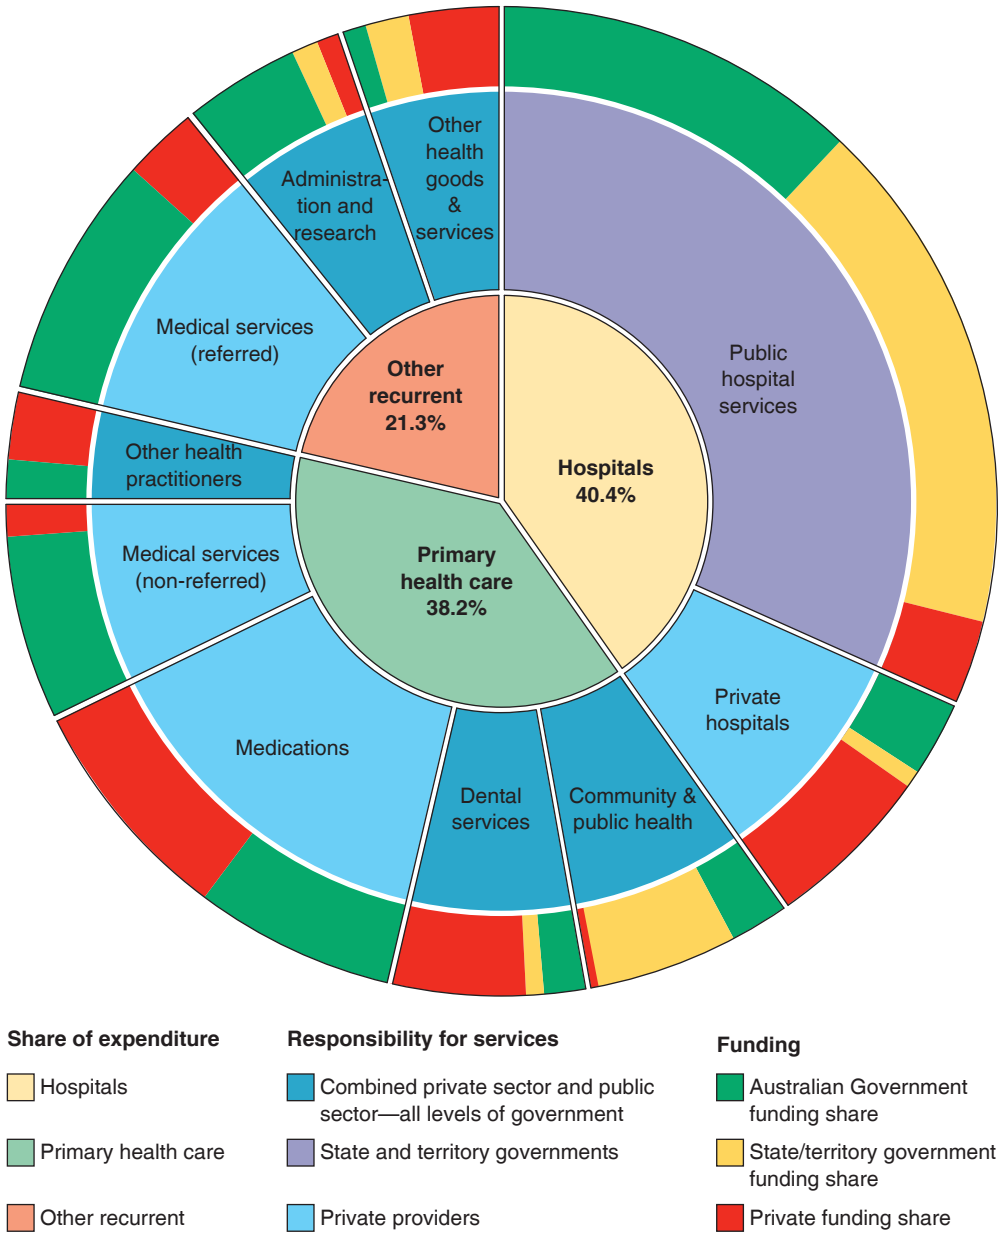

FIGURE 51.3 ■ Australian health services—funding and responsibility

Source: Australian Institute of Health and Welfare (AIHW) (2014a). *Australia's health 2014*. Australia's health series no 14. Cat no. AUS 178. Canberra: AIHW, p. 34. Reproduced with permission.

Community Services Australia (ACSA), 2008). More recently, CDC has been introduced to some community-based services for older people, aiming to deliver increased consumer engagement, power over the design of care packages and the direction of service arrangements (with a corresponding increase in consumer choice), responsibility for making decisions and managing the outcome of service provision (Low et al., 2012). The change that this approach can make is illustrated by Anna's story in Box 51.3.

Community care initiatives based on CDC have similarities with acute health care initiatives based on Standard 2: Partnering with Consumers, as detailed in the Australian National Safety and Quality Health Service Standards (Australian Commission on Safety and Quality in Health Care (ACSQHC), 2012), depending on where consumer involvement fits along the continuum of participation. However, community-based aged care and disability service CDC extend consumer choice, control and responsibility further, placing care outcomes in the hands of consumers by enabling consumer decision making regarding care goals, which services are provided, who provides them and how each consumer's individual service budget is spent (Low et al., 2012).

The role and contribution of non-health organisations and the services they provide are important. Many of the major

BOX 51.2 Possible partners in the healthcare continuum

Community health partners include, but are not limited to, the following:

Health promotion
Public health units, local government, schools, other state government departments, non-government organisations (NGOs), community groups and consumers.

Prevention and early detection
Schools, GPs, Nurse Practitioners, other state government departments, NGOs, community groups and consumers.

Assessment and investigation
GPs, Nurse Practitioners, allied health professionals, community nurses (general, child and family, and mental health), schools, other state government departments, Commonwealth-funded services such as aged care assessment teams (ACATs), NGOs and consumers.

Community treatment
GPs, practice nurses, Nurse Practitioners, allied health professionals, community nurses (general, child and family, and mental health), pharmacies, NGOs and consumers.

Continuing care
GPs, practice nurses, Nurse Practitioners, hospitals, other state government departments (particularly ageing, disability and home care, community services, housing and police), home and community care (HACC) services and Commonwealth-funded services such as community aged care packages (CACPs), NGOs/charities and consumers.

Source: Adapted from *Community health at the crossroads: Which way now? Final report of the NSW Community Health Review* by K. Eagar et al. (2008). Centre for Health Service Development, University of Wollongong, p. 7.

issues for the future attainment of community health involve strategies that promote effective links within and beyond the services of the health system, so that a reorientation of health services and expenditure to primary health can be achieved (Adrian, 2009; Eagar, et al., 2008). Also important is recognition that people within communities will move between community organisations and acute care services at some time in their life, further highlighting the need for partnerships between services in each setting and the contribution each makes to the health of individuals and communities across the lifespan. While community organisations and the services they deliver are important, they cannot function without each other to achieve health for people and communities.

The complex nature of the community health system is also characterised by a tension between providing a comprehensive, participatory and health-promoting approach, and a need to provide within a community direct care and medical interventions that are efficient and sustainable (Nesbit & Allen, 2011). Compounding this complexity is a view that community care services should provide the full range of services from prevention to palliation where people live, and at the same time cater to the needs of hospitals under stress from the impact of factors such as the increasing incidence of chronic diseases and their complications (e.g. diabetes and respiratory diseases) (Eagar et al., 2008).

The model of health embraced by community organisations is reflected in the types of services they provide. The following section discusses different models of health and raises implications for how health is addressed, with a particular focus on community health.

MODELS OF HEALTH AND COMMUNITY CARE

Each community organisation is based on a model of health which influences how healthcare is defined and provided. It also affects when and how the factors that affect health are addressed. In the following sections three models of health are

BOX 51.3 Consumer-directed care in practice

When Anna accessed a CDC-based home care package the focus of her services changed. She was able to identify her own needs and goals, including social isolation. Together with her case manager, Anna decided that involvement in a Lifebook project—a short biography and digital photo book—while receiving community visits from community volunteers might be a good option to increase her social interaction.

Initially, Anna was reluctant to have her private life story divulged to anyone. However, over the course of the project she developed a rapport with and trusted the volunteers who visited. When her completed Lifebook was given to her, Anna decided she would present her Lifebook. She spoke with clarity, expressing for the first time without tears that she did not wish her husband back to suffer more; he would have been 92. She had cared for him at home and done all she could. It seemed to those present that Anna was not just telling her life story, but engaging in a process that enabled her to name and share her grief.

Through the support she receives with her CDC package, Anna has not only reduced her social isolation but also her inner isolation. Anna is now ready to engage more fully with the life she is living.

discussed and presented sequentially, representing a continuum which illustrates a move from medical to social orientations to health, and individual to population health concerns. While there are many other models of health, those presented here are a useful introduction to community organisations and the services they provide. The use of different models across health organisations does, however, mean that there can be tensions around the focus of healthcare for individuals, the interventions used and how care is ultimately delivered. In community care, the biomedical and social models of health are often integrated (Talbot & Verrinder, 2013).

The biomedical model of health

The **biomedical model of health**, also known as the medical model, defines health as the absence of disease (Germov, 2014). In this model there is a focus on 'objective specific findings that are interpreted as causal factors of a disease or disorder that needs to be eliminated by medical interventions to cure the patient' (Lundstrom, 2008, p. 393). Health is primarily considered to be an individual responsibility determined by biology and poor lifestyle choices (Engel, 1977; George, 1998). In services that prioritise this model, the psychological and social dimensions of health are not priority concerns for organisations or practitioners and may be overlooked. In contrast, in community and primary care settings the psychological and social dimensions of health are always important considerations.

This model of health is most evident in Australian acute care services, and those community care services which provide primary care (see discussion of primary care and primary healthcare later in this chapter), and is usually the main model used in general medical practice (Adrian, 2009). It is argued that community care services need to move beyond this model and embrace psychological and social dimensions of health as important considerations (Adrian, 2009; Keleher, Parker et al., 2007; World Health Organization (WHO), 2012).

As a reaction to the dominance of biomedicine and its orientation to health, a biopsychosocial movement has developed (Engel, 1977). This is a modification of the biomedical model which incorporates the concept of holistic wellbeing. It can be seen as an intermediate or middle-of-the-road model which lies between the biomedical and social models of health.

The biopsychosocial model of health

The **biopsychosocial model** defines health as holistic wellbeing within an individual (Taylor, 2011). It argues that a focus on disease is too narrow, and that health services need to include psychological and social functioning and social and personal resources, as well as physical capacities (Engel, 1977; Taylor, 2011). In this model, health is a dynamic concept influenced by multiple interacting factors that change over time. It reasserts a connection between mind and body, seeing the individual's mental state as influencing biological processes and thus susceptibility to disease (Engel, 1977; Taylor, 2011). However, it shares many key assumptions and characteristics of the biomedical model, including the focus on individual diagnosis and treatment, so that it is individualistic even if it includes emotional and social factors.

The social model of health

The **social model of health**, also referred to as new public health or the social ecological model (Richmond & Germov, 2014), sees health as multifaceted, with a focus on social rather than biological determinants of health. This model emphasises health equity and prevention of illness or injury, as well as collaboration and empowerment (Talbot & Verrinder, 2013).

> *The social model locates people in social contexts, conceptualises the physical environment as socially organised, and understands ill health as a process of interaction between people and their environments. (Broom cited in Germov, 2014, p. 16)*

The social model focuses on the interrelationship between human interaction, social organisation and natural environment and sees health as a resource within individuals, communities and the population as a whole. It underpins many health policies on a national and global scale. For instance the World Health Organization (WHO) Commission on Social Determinants of Health's 2008 report 'Closing the gap in a generation: Health equity through action on the social determinants of health' (2008b), argues that the 'high burden of illness . . . arises in large part because of the conditions in which people are born, grow, live, work and age—conditions that together provide the freedom people need to live lives they value' (WHO, 2008b). In the Commission's view the biomedical approach, while important, downplays the significance of influences on health that lie beyond the health sector—otherwise known as social determinants of health (AIHW, 2014a; Keleher & Murphy, 2004). Also ignored in the biomedical approach are values, vested interests, politics and context (Baum, 2008a; Sax, 1990).

The social model of health makes a link between 'private troubles', such as obesity, diabetes or unemployment, and 'public issues', such as transport options, food availability, government policy and globalisation (Mills, 1959 cited in Germov, 2014, p. 7). This alerts us to the fact that individuals often share problems, including health problems. Problems then may have a common cause, which may be solved through collective action. Health and illness, in this view, are not simply an individual concern.

In the following section the social determinants of health (those that align with health viewed through the social model of health) are discussed.

SOCIAL DETERMINANTS AND COMMUNITY HEALTH

The AIHW (2014a) calls the factors that affect the health of people '**health determinants**'. There is a growing body of evidence which shows that health determinants are the key to understanding the health of a community, promoting health and providing healthcare (Baum, 2008b; Wilkinson & Marmot, 2003). In particular, the **social determinants of health** are central to understanding the health of a community and community organisations which embrace the social model of health, discussed earlier in the chapter. In the social model, the focus is on social rather than biological health determinants.

Social determinants of health '. . . are the conditions in which people are born, grow, live, work and age, and include the health system. These circumstances are shaped by the distribution of money, power and resources at global, national and local levels' (WHO, 2012). The social determinants are increasingly recognised as the key to the health of people and communities because of the evidence that social conditions, specifically where people are born, live and work, determine people's chances of good health and a long life (WHO, 2012). It is interesting to note that despite the increasing levels of affluence in modern communities, people who have less still have poorer health (Wilkinson & Marmot, 2003). Figure 51.4 shows that in most age groups Australians with the lowest socioeconomic status die at a higher rate than Australians with fewer disadvantages. These differences are explained by the social determinants approach.

There are several ways of thinking about social determinants of health (Cannon, 2008). For instance, Wilkinson and Marmot (2003) refer to a list of 10 social determinants (see Box 51.4), whereas others have developed models to describe the social processes and elements that influence health. An example of one of these models is shown in Figure 51.5. All such models attempt to map a number of common and interconnected dimensions which operate as an intricate web of influence on people and their lives, acting on individuals and the population as a whole (Hetzel et al., 2004).

Early life factors

Early life factors influence a person's experience of health. For example, an adult's health is adversely influenced by physiological or emotional deprivation in early childhood and/or before birth (Wilkinson & Marmot, 2003). When a child is emotionally deprived, brain development can be adversely affected which in turn can lead to low levels of educational attainment, problem behaviour and social exclusion in later life (Cannon, 2008). Physical deprivation such as lack of nourishment in a child is associated with decreased development and function of major organs, which increases the risk of ill health in later life (Wilkinson & Marmot, 2003).

Some models include genetics as a social determinant of health because social factors interact with each other and with the individual's genetic composition. Others exclude genetics on the grounds that even though a person's genetic susceptibility to disease produces ill health, this health change is not a product of the social environment.

Income and socioeconomic conditions

Income and socioeconomic conditions are one of the key social determinants of health (Hetzel et al., 2004). People with higher incomes are often healthier and live longer lives than people who have middle and lower incomes (AIHW, 2014a; Marmot, 2002; Wilkinson & Marmot, 2003). Health and wellbeing

therefore improve as people's income and social position move upwards—a concept known as the social gradient (Hetzel et al., 2004). The more people live in difficult financial and social circumstances, the greater the ongoing wear and tear they endure, and the less chance they have of continuing to healthy older age (Wilkinson & Marmot, 2003). Income and social conditions act in relation to one another and, at times, it is not only a lack of material resources that affects health but also the social (dis)advantages associated with these conditions (Hetzel et al., 2004).

Living conditions

Living conditions have a significant impact on the experience of health by individuals and communities. The following are important aspects of people's living conditions:

- affordability of housing
- degree of overcrowding in housing
- design of cities
- liveability of communities outside major metropolitan areas
- degree of pollution—air and noise
- availability of transport options
- availability and pricing of nutritious food
- exposure to marketing of nutrient-poor foods
- affordability of utilities (e.g. electricity and water) (Cannon, 2008; Wilkinson & Marmot, 2003).

The cost of living is increasing in Australia, particularly for housing, food and utilities (Cannon, 2008). As a result, people reliant on government benefits and on low incomes are finding their living conditions being eroded and are at an increased risk of ill health.

Other factors

Levels of education, health literacy, behaviours and lifestyle factors are intrinsically linked to health. Education provides the basis for employment and generating an income. Education also enables the person to engage with information about health and to take the appropriate actions to maintain their health (Cannon, 2008). This engagement is referred to as health literacy. When a person does not have a sound level of education they are more likely to be health illiterate. Education and health literacy also influence a person's behaviours and lifestyle. With good levels of education and health literacy there is an increased likelihood that behaviours or lifestyle factors that adversely impact on health are not disregarded (Cannon, 2008). A person's low social position has also been shown to be associated with unhealthy behaviour. Regular tobacco use, poor food choices and low exercise levels are significantly greater in the lowest socioeconomic groups in Australia (AIHW, 2014a; Friel, 2009, p. 3).

The equitable distribution of resources, such as health services, is another key social determinant of health (WHO, 2008a). Access to and use of health services influences the

health of a person and a community. Comprehensive accessible healthcare should be available to everyone in the Australian community on the basis of need, not the ability to pay. However, access to health services is affected by many factors including socioeconomic status, geographical location, cultural background and intellectual or other disabilities. While most Australians benefit from our universal healthcare system, equity of access to healthcare remains an issue for immigrants, asylum seekers, refugees and Indigenous Australians (Adrian, 2009; Cannon, 2008). For example, access to health services is lower for Indigenous people than non-Indigenous people because of proximity, availability, cultural appropriateness, transport availability, health insurance, health services affordability and proficiency in English (AIHW, 2014a; Thomson, 2004). The relationship between socioeconomic status and access to health services, and ultimately to health, is well established. Indigenous Australians who have low socioeconomic status have reduced access to nutritious food, education and healthcare (AIHW, 2014a). They also live in risky environments and participate in unhealthy behaviours. All these social factors interact and contribute to poor health.

Racism, discrimination and culture are also known factors that affect the health of people and communities, as these influence basic levels of security, safety, hygiene, housing, nourishment, knowledge, employment, medical care, community support and social participation (Paradies, Harris & Anderson, 2008). Henry, Houston & Mooney (2004) reported that racism is present in the Australian healthcare system; for example, differences in treatment regimens, inadequate funding to reduce language barriers and a lack of understanding about the different constructs of health for Indigenous people. It is important to note that Australians from culturally and linguistically diverse (CALD) backgrounds also experience racism and discrimination, which contributes to their ill health. Racism and discrimination place significant pressure on people by creating barriers to education, employment and culturally appropriate and specific healthcare (Cannon, 2008; Hetzel et al., 2004). Many people are culturally, socially and economically disadvantaged simply because of cultural difference. Cultural difference may place people at increased risk of disease for a range of reasons including identity, misunderstanding and perceived threats to personal safety.

The concept of cultural safety (see Chapter 1) is an attempt to respond to many of these factors. Cultural safety is concerned with developing ways of addressing the 'social, [economic], political, historical and [often] emotional reasons' for illness and disease in marginalised and Indigenous cultural communities (Papps & Ramsden, 1996, p. 492). Practising cultural safety means ensuring quality in healthcare through culturally appropriate communication and ensuring equity and access to health services. It implores us to reflect on our attitudes and values, respect difference, recognise power differentials in relationships and act upon these. The idea of cultural safety 'assumes that each healthcare relationship between a professional and a consumer is unique, power-laden and culturally dyadic' (Kearns & Dyck in Papps & Ramsden, 1996, p. 494). The tenets of cultural safety help people to feel safe; there is no 'assault, challenge or denial of . . . identity' (Williams, 1999, p. 213). Cultural safety is about respect, shared meaning, knowledge and experience.

Social interaction and support at an individual and community level increase a sense of belonging and social connectedness that has been linked to positive physical and psychological health (Cannon, 2008; Labonte, 1997). Social exclusion leads to loss or lack of connection to the community in which a person lives. This exclusion is linked to psychological stress, depression, smoking, use of illicit drugs, and alcohol misuse and dependence (AIHW, 2010). Therefore, when engagement and interaction between individuals and communities is lacking, people experience ill health (Cannon, 2008; Hetzel et al., 2004). To facilitate interaction and engagement, health services need to embrace body, mind, spirit, land, environment, culture, customs and socioeconomic status, and be accessible to all individuals and communities as close as possible to where they live (Adrian, 2009).

Levels of determinants and interventions

Some social determinants of health have a more direct effect on health than others and hence they can be viewed on a continuum from proximal to distal (Keleher & MacDougall, 2015). **Distal determinants** of health tend to be stable and concern historical, national, institutional, political, legal and cultural factors; for example, anti-discrimination law, changes in taxation or changes to the provisions of government income support. The influence of distal determinants is often mediated through more proximal determinants (Keleher & MacDougall, 2015). **Intermediate determinants** concern community infrastructure, personal wealth or access to resources, and natural, physical and built environments. This level also includes access to healthcare and health systems (Keleher & MacDougall, 2015). **Proximal determinants** have a more direct impact on health, and include lifestyle and behavioural factors as well as underlying health conditions (Keleher & MacDougall, 2015).

Different community organisations address the determinants of health in different ways. Health promotion based on the social model of health focuses on distal or upstream factors and seeks to address working conditions or the effects of rapid social change. Examples of this include campaigns for legislation on food labelling, changes in environmental legislation such as those that have banned smoking from public places or, on a smaller scale, the introduction of harm-reduction strategies, such as needle-exchange programs and early intervention programs for families. Health promotion based on the biomedical model concentrates on proximal or downstream factors such as screening for high cholesterol levels and treating people with lifestyle changes or drugs. Organisations using the biopsychosocial model, the middle-of-the-road model of health that includes psychological and social factors, often focus prevention on intermediate factors or midstream factors.

PRIMARY HEALTHCARE AND PRIMARY CARE

Community organisations use approaches to care which complement the model and definition of health and orientation

to social determinants that has been embraced. Two common approaches to community care in Australia are **primary healthcare** and **primary care**. Each of these approaches describes in more detail how health is achieved for individuals and communities through the activities of community organisations. It is important to note, however, that while the terms 'primary care' and 'primary healthcare' are used widely and are at times interchangeable, primary care and primary healthcare approaches reflect different views of health and service provision (Adrian, 2009; Keleher, 2001). Calling 'primary care' 'primary healthcare' is therefore like calling an apple an orange and can understate the contribution services outside those of the health system (e.g. local councils and churches) make to the health of individuals and communities (Adrian, 2009). It is also important to remember that the underpinning beliefs about health that guide community services may be different from those that underpin medical and surgical or acute hospital services.

Primary healthcare

The philosophy of primary healthcare originates from the WHO. As an agency of the United Nations, the WHO was established to address international health issues and aims to achieve worldwide health (Talbot & Verrinder, 2013). In 1978, 134 nations attended the WHO International Conference on Primary Health Care as a response to growing concern about the world's health in terms of its people and healthcare systems (Talbot & Verrinder, 2013; WHO, 2008a). This conference was marked by the Declaration of Alma-Ata, a declaration that articulates primary healthcare as the guiding philosophy for health development across the world and as a vision for the future (Nesbit & Allen, 2011; Talbot & Verrinder, 2013; WHO, 2008a). Improved health outcomes, reduced costs and a reduction in inequalities have all been associated with having a strong primary healthcare system (Macinko, Starfield & Shi, 2003).

Primary healthcare is intended to be a comprehensive approach to health which forms the nucleus of the health system and the social and economic development of the community (WHO, 1978). This approach to health challenges the prevailing focus on finding a cure, a focus characteristic of current health systems, and calls for a focus on anticipating and preventing health problems (Nesbit & Allen, 2011). It reaffirms that health and wellbeing are dependent on a broad range of interrelated social factors (e.g. socioeconomic, cultural and political environment) and that health is a fundamental human right (Talbot & Verrinder, 2013; WHO, 2008a).

Primary healthcare is based on the social model of health and an understanding of the social determinants of health, both discussed previously (Keleher, 2001). It is defined by the WHO as:

> *essential health care based on practical, scientifically sound and socially acceptable methods and technology . . . made universally accessible to individuals and families in the community through their full participation and at a cost that the community and country can afford to maintain at every stage of their development in the spirit of self-reliance and self-determination. (WHO, 1978, p. 1)*

The goal of primary healthcare, underpinned by the principles of social justice, empowerment/community participation and equity, is 'Health for All' (Talbot & Verrinder, 2013; WHO, 1978). It advocates community services that promote community participation, and ensures access to health-related services for all people and the provision of services at a cost that is affordable and as close as possible to where people live (WHO, 1978). The philosophy of primary healthcare is also underpinned by the tenets of cultural safety. Guided by a primary healthcare philosophy, community organisations work in partnership with people and communities to enable and empower change that is local, affordable and sustainable (Talbot & Verrinder, 2013). The focus is on addressing the root cause of health problems or the social determinants of health experienced by people and communities, reducing the effects of disadvantage and health inequality (Keleher, 2001; Talbot & Verrinder, 2013). The focus of primary healthcare is broad and is therefore at times also referred to as comprehensive primary healthcare. The characteristics of primary care and primary healthcare are listed in Table 51.2.

To practise in a way consistent with primary healthcare, community organisations need to focus on addressing social determinants of health (Adrian, 2009) and to encompass strategies that address the underpinning principles noted previously, including cultural safety. The minimum activities for primary healthcare described by the WHO (1978) are listed in Box 51.5. Intersectorality, a strategy to address social determinants of health and structural barriers to health, refers to collaborative **transdisciplinary** partnerships, with the needs of the community dictating which are the most appropriate services and service relationships (Adrian, 2009). Transdisciplinary care goes beyond past models of multidisciplinary or interprofessional care and facilitates intersectorial relationships which value expertise in areas beyond those addressed by traditional health disciplines. This might include partnerships with services that provide education, transport or income support, reflecting an understanding of the social determinants of health. These approaches are central to primary healthcare and have been identified as key processes for closing the gap between the health of Indigenous and non-Indigenous people in Australia (Adrian, 2009). An exemplar of an Australian community service based on the philosophy of primary healthcare is detailed later in this chapter.

Primary care

While primary healthcare has been advocated by the WHO (1978) as a way to restore the health of communities across the world, another approach has evolved in developed countries such as Australia. This alternative approach returns the focus of health services to the absence of disease (Awofeso, 2004; Cueto, 2004) and to the provision of a first point of contact and entry into the health system (Cueto, 2005; Keleher, 2001). It is known as primary care or selective primary healthcare, reflecting a more selective view of health and service orientation than primary healthcare as advocated by the WHO (Nesbit & Allen, 2011). Although there has been considerable focus on primary care services provided by general medical practitioners in Australia (Australian Productivity Commission, 2015), primary care is also practised in Australian communities by other health professionals

TABLE 51.2 Characteristics of primary care and primary healthcare

CHARACTERISTIC	PRIMARY CARE	PRIMARY HEALTHCARE
Synonym	Selective primary healthcare	Comprehensive primary healthcare
Main aim	Reduction of specific disease—technical focus	Improvement in overall health of the community and individuals; health for all as overall social and political goal
Model of health	Biomedical	Social
Sectors involved	Strong focus on health sector—very limited involvement from other sectors	Involvement of other sectors is central
Strategies	Focus on curative care, with some attention to prevention and promotion	Comprehensive strategy with curative, rehabilitative, preventive and health promotion that seeks to remove root causes of health
Planning and strategy development	External, often 'global', programs with little tailoring to local circumstances	Local, reflecting that community priorities are professional and 'on tap not on top'
Participation	Limited engagement, based on terms of outside experts and tending to be sporadic	Engaged participation that starts with community strengths and the community's assessment of health issues, is ongoing and aims for community control
Engagement with politics	Professional and claims to be apolitical	Acknowledges that primary healthcare is inevitably political and engages with local political structures
Forms of evidence	Limited to assessment of disease-prevention strategy based on traditional epidemiological methods, usually conducted out of context and extrapolated to situation	Complex and varied research methods including epidemiology and qualitative and participatory methods

BOX 51.5 Minimum activities for primary healthcare

- Education concerning prevailing health problems and the methods of preventing and controlling them.
- Promotion of food supply and proper nutrition.
- Provision of an adequate supply of safe water and basic sanitation.
- Provision of maternal and child healthcare, including family planning.
- Immunisation against major infectious diseases.
- Prevention and control of locally endemic diseases.
- Appropriate treatment of common diseases and injuries.
- Provision of essential drugs.

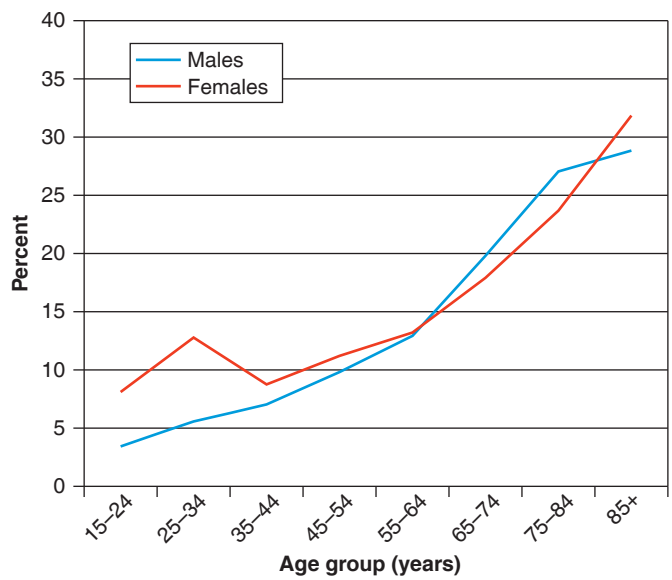

FIGURE 51.6 ■ Proportion of people aged 15 to 85+ years visiting a general practitioner 12 or more times over the previous 12 months

Source: Australian Bureau of Statistics (ABS) (2013). *Patient experiences in Australia: Summary of findings, 2012–13*. Retrieved from www.abs.gov.au/ausstats/abs@.nsf/Lookup/4839.0main+features32012-13. © Commonwealth of Australia.

including Nurse Practitioners, practice nurses, midwives and allied health professionals (Department of Health and Ageing, 2008). Figure 51.6 shows the number of visits made to general practitioners by people aged 15 to over 85 years in a 12-month period. How healthy a person considers themselves to be is related to the number of times they see their GP. Those who considered their health to be 'fair' or 'poor' were more likely to see a GP more often than those who believed their health was 'good', 'very good' or 'excellent'. In addition, the frequency of GP visits was related to the presence of long-term health conditions.

Primary care services are based in communities and focus on a person's specific disease or illness using a disease-management orientation (Nesbit & Allen, 2011). Services

are usually controlled by the healthcare provider (Nesbit & Allen, 2011) rather than developed in partnership with the community, and often use intermittent management or single occasions of service. Visits are often based on appointment times initiated by the consumer (e.g. Medicare short consultation) and providers strategically manage follow-up appointments (e.g. screening or acute diagnostic test results, assisted chronic disease management). Exemplars of Australian community services based on primary care are detailed later in this chapter.

In contrast to primary healthcare, primary care services are usually based on the biomedical model of health (Keleher, 2001), discussed previously, and place minimal emphasis on social determinants, empowerment, partnership or community engagement (Keleher, 2011; Talbot & Verrinder, 2013). However, at times community organisations also display an holistic orientation to individual care within a primary care framework. While not as comprehensive as primary healthcare, this variation addresses some social aspects of heath at an individual rather than a community level.

The characteristics of primary care are listed in Table 51.2 above and can be contrasted with those listed for primary healthcare. The table shows primary care's reliance on medical interventions and professional control, with little local community engagement, minimal involvement across sectors and minimal attention to structural factors affecting health (Baum, 2007). While it is recognised that primary care has led to health gains for some, to improve the health of all members of the community health needs to be contextualised within its social, cultural, economic and environmental context (Adrian, 2009).

HEALTH EDUCATION AND HEALTH PROMOTION

Health promotion, illness/injury prevention and health education are the cornerstones of primary healthcare and community care. **Health promotion**, incorporating illness/injury prevention, is described in the Ottawa Charter for Health Promotion as the process of enabling people to increase control over and improve their health (WHO, 1986). **Health education** is often used interchangeably with health promotion; however, health education refers to an individualist model which focuses on the individual and individual strategies to improve health by increasing knowledge or influencing attitudes to alter behaviours and lifestyle, such as health counselling and health education (WHO, 2012). Primary healthcare, which focuses on the determinants of health, is aligned with population-focused strategies for health promotion, known as structuralist–collectivist health promotion (SCHP), a model that involves community engagement and capacity building.

Individualist health promotion

The individualist model of health promotion focuses on changing individual behaviour and lifestyle, and rests on the assumption that individuals harm their health by engaging in unhealthy living (i.e. smoking, eating fatty foods, not exercising and drinking alcohol). It aims at improving health by focusing on risk factors, particularly those identified as precursors to disease (Duckett, 2004; Richmond & Germov, 2014). In this model, disease and illness are seen as a consequence of failure to comply with healthy lifestyle choices; in an individualist society this is difficult to challenge because it appears to make sense. However, it is a single-cause approach which emphasises individual choices associated with risk factors rather than the underlying social conditions that influence choice and behaviours (Povlsen & Borup, 2011). Most factors affecting illness and health lie outside the control of individuals, and lifestyles are powerfully influenced, if not fully determined, by the social organisation in which they are embedded (Richmond & Germov, 2014; George, 1998; Underwood, Owen & Winkler, 1986).

Individualist health promotion (IHP) is promoted as being successful and cost effective, but adequate evaluation is lacking (Travers, Martin-Khan & Lie, 2009). Few programs succeed for any length of time and many are either unsuccessful or cater only for the well motivated (e.g. weight loss programs). Exaggerated in this case is the ease with which individuals make connections between knowledge and behaviour, when in reality there is a complex interaction between knowledge, attitude and practice/behaviour change (Talbot & Verrinder, 2013). Education alone does not necessarily lead to behaviour change and approaches that rely only on education underestimate the impact of social factors on health and illness or injury.

While IHP is a dominant model and can be useful, it is too narrow when considering health through a social model, as in primary healthcare services. It also risks leading to victim blaming; if an individual is sick, it is because he or she has not complied with health advice. In short, if people took better care of themselves they would not have the health problems they have. The person who develops lung cancer and is also a smoker is an obvious example. IHP programs do nothing to alter the structural causes or determinants of ill health or injury, and can be paternalistic and patronising (Talbot & Verrinder, 2013) (i.e. increased health education, knowledge and/or awareness do not equal structural change). For example, people on low incomes cannot afford more nutritious food, irrespective of their health education. In this example, it is not so much ignorance that is the problem but inadequate employment opportunities and/or welfare allowances. Healthy choices are not easy choices for the disadvantaged; people with little choice about their lives often regard immediate comfort to be more important than end-stage health. All these situations highlight issues and concerns for healthcare which is experienced as culturally safe.

Health promotion should aim to change the social situations framing individual decision making, particularly in terms of income, employment and housing. In particular, attention to the social determinants of health can bridge the disparity between 'knowing' and 'doing' by empowering people to make healthier choices. This can involve small-scale local interventions as well as broader national or global social change. Table 51.3 lists the characteristics of individualist health promotion, including its relationship to models of health and primary healthcare.

TABLE 51.3 individualist and structuralist–collectivist health promotion

	INDIVIDUALIST HEALTH PROMOTION (IHP)	STRUCTURALIST–COLLECTIVIST HEALTH PROMOTION (SCHP)
Model of health	Biomedical or biopsychosocial model	Social model
Target level	Individuals Operates at point of entry, screening, advice Downstream determinants	Community Active care recipients and communities, social change Upstream determinants
Focus of education	Individual focus, expert-led, passive person Lifestyle, risk taking	Participatory, legislation, bureaucratic intervention Community engagement, advocacy, enabling, mediating, organisational development, builds healthy policies
Aim	Persuade individual change Improve physiological risk factors and personal behaviours	Invoke population change Address determinants of health, redress inequities
Examples	Healthy eating campaigns Safe-driving campaigns Brief intervention strategies Quit campaign	Needle exchange Legislation (e.g. banning smoking in public places, compulsory wearing of seat belts) Health services offered by Indigenous health workers working with Indigenous communities
Relationship to primary healthcare	Selective primary healthcare or primary care	Comprehensive primary healthcare or primary care

Structuralist–collectivist health promotion

In accordance with the Ottawa Charter, and in alignment with the WHO primary healthcare approach, health priorities should be community-based, reflect the concern of particular communities and be 'bottom up' (WHO, 1978; 1986). Often, though, structuralist–collectivist health promotion (SCHP) is less about structural change and more about health education in disguise by imposing policies or legislation on communities without adequate consultation. A barrier to SCHP approaches is that some interventions are highly politicised (such as food advertising to children) (Richmond & Germov, 2014).

The Ottawa Charter (WHO, 1986) aims to integrate individualist and SCHP approaches by focusing on 'positive' health, improving the settings for decision making on health and rewarding health professionals for their involvement in health promotion. Figure 51.7 illustrates a continuum of health-promotion approaches and Table 51.3 contrasts characteristics of individualist health promotion and SCHP. The 'Translation to practice' box below describes the development of a community care model, based on CDC, which led to educational resources aimed at supporting implementation of the model in community practice. For health education to be effective, culturally safe approaches are needed.

COMMUNITY CARE EXEMPLARS

To cater for the diverse communities and complex health needs that characterise Australian communities, a broad range of community care services have been needed, many of which are characterised by innovative approaches underpinned by primary care or primary healthcare. The goal is to improve the health of people, families or communities and to provide healthcare from conception to death in a range of community settings. These services care for people and communities within their usual environments, including homes, caravans, rural and outback campsites, schools and workplaces. Detailed below are examples of some Australian community nursing services. Each is located in the community and demonstrates aspects of primary care or primary healthcare. They aim to meet the specific health needs of their population and each contributes to ensuring the health of its community in a different way. Reading each exemplar should promote reflection on the key concepts discussed earlier in this chapter and how these are enacted in practice by community nurses.

Caravan Park Project

The Caravan Park Project (Baker cited in Adrian, 2009) commenced in 2000 and is an example of a nurse-led primary healthcare strategy in rural New South Wales which aims to develop health equality. It exemplifies an innovative and sustained response to the social determinants of health impacting on the health of residents of the caravan park, both children and adults. This example illustrates ways of practising which acknowledge and work with cultural dimensions of the health of a community and demonstrates the remarkable resilience, leadership and commitment of the nurse leading the project.

The community of interest for this project was the residents of a local caravan park (see Figure 51.8). Like similar caravan parks in rural and urban locations, the residents came from diverse and difficult backgrounds, including homelessness or transient low-cost accommodation, prison and juvenile services, mental health facilities or refuges. These backgrounds placed residents at risk of poor health, a situation that was confirmed

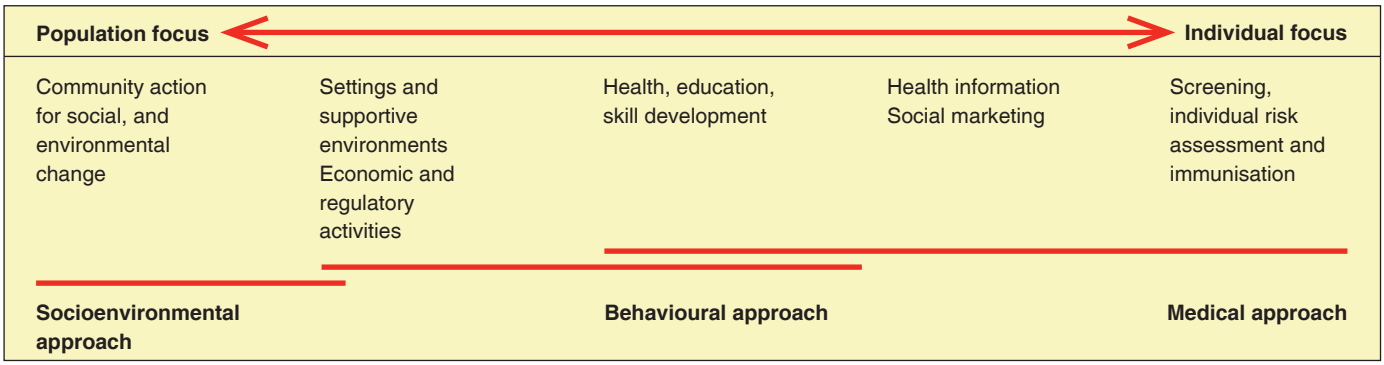

FIGURE 51.7 ■ Continuum of health-promotion approaches

Sources: Figure 1.6 in L. Talbot & G. Verrinder (2010). *Promoting health: The primary health care approach* (4th ed.). Sydney: Elsevier Churchill Livingstone; adapted from R. Labonte (1992). Heart health inequalities in Canada: Models, theory and planning. *Health Promotion International, 7*(2), pp. 119–21.

by a high number of referrals for residents of the park to health professionals—referrals which were difficult to follow up due to factors such as poor or no access to telephones, being away from their caravan when health professionals called to visit and a lack of resident trust in government-based services.

At the outset, a presence of health professionals was established onsite by running a van-based child and family health clinic (Baker cited in Adrian, 2009). This facilitated contact between health staff and residents, allowed an understanding of residents' health issues to be developed and enabled consideration of how social determinants were acting on this community. During this time a picture emerged of a highly disadvantaged community with the following characteristics:

- largely reliant on government benefits for income
- poor functional literacy
- frequent domestic violence
- high levels of substance use and high rates of hepatitis C infection
- social isolation with poor self-esteem
- poor school attendance by the children

TRANSLATION TO PRACTICE Applying evidence about CDC to community aged care practice

Between 2010 and 2012 a major trial of aged care CDC in Australia, the People at Centre Stage (PACS) project, addressed obstacles for successful CDC reported previously by international researchers, and gathered evidence about CDC implementation in Australia (Ottmann & Mohebbi, 2014). In the PACS trial a 'case management led capacity building and restorative health approach' (p. 600) was applied in conversations with older people to set health priorities and goals, and to support three levels of self-direction: level 1, where the older person participated in care planning; level 2, where the older person assumed both care planning and care coordination responsibility; and level 3, where the older person performed the activities of level 2 but also administered and budgeted care using a voucher option with a small cash component. Overall the PACs model resulted in most older people reporting increased satisfaction with care and decision processes, improved health, sense of engagement and community connectedness (Ottmann, Laragy & Allen, 2012, p. 24).

Subsequently the evidence obtained from the PACS trial led to the development of practical resources and tools for community aged care providers delivering CDC-based services to older Australians. These materials, referred to as the 'choices' model of CDC, provide services with materials to address the distinctive needs of older Australians while implementing CDC, including restorative health and capacity building; goal-directed care planning; individualised budgets; self-direction and mentoring; enabling risk; community connectors; and planning ahead. The 'choices' materials can be accessed through the Home Care Today website (www.choicesinagedcare.com.au/training/).

IMPLICATIONS FOR NURSING

- To provide CDC, nurses need to work in partnership with individuals to enable consumer choice and control about all aspects of their care.
- Community care nurses need to work with older individuals to identify their care goals as well as choose care options that match the individual's preferences for community care.

CRITICAL THINKING IN PERSON-CENTRED CARE

1. How might person-centred care be different from consumer-directed care?
2. Why might consumer direction and control be important for community-based individuals?
3. How can nurses enable consumer choice and control of community care?

- a strong history of childhood sexual assault, abuse and/or neglect
- failure to access mainstream health services or general practitioners (Baker cited in Adrian, 2009).

With funding from New South Wales Health and Primary Healthcare and Partnerships, an innovative outreach project involving an early childhood nurse, a project officer (Registered Nurse) and a registered psychiatric nurse was developed based on the social model of health/social determinants of health and advocacy (Baker cited in Adrian, 2009). The main aims were to reorient health services to meet the needs of caravan park residents, to build capacity and partnerships with other health and intersectorial services (e.g. Centrelink, local community businesses, schools, charities and education providers), to strengthen existing partnerships, to increase resident literacy and to strengthen resident capacity for community action. Interventions included advocacy for improved living conditions in the park, particularly as children were over-represented for admission to hospital with respiratory conditions exacerbated by damp and musty van accommodation. An onsite needle and syringe program was also established in the outreach van and disposal bins placed in the communal toilet blocks to reduce the number of childhood presentations at the emergency department due to needle-stick injuries. Also negotiated were the supply of full-size refrigerators to enable better food purchases and safe storage of food. Health and intersectorial services were lobbied to reorient their services to enable resident access, and entrepreneurial partnerships were nurtured with private businesses. These helped to raise funds to enable the resident children to participate in sport, dance classes and school excursions, and also to resolve transportation barriers. Onsite services were then extended further to include paediatric clinics and a volunteer public health physician.

After 6 months the caravan park's culture began to change, developing a sense of community (Baker cited in Adrian, 2009). Residents attended antenatal care, TAFE and school. As confidence felt by residents grew, the project team members linked residents back into mainstream health and social services. The project continues to evolve and has been successful in delivering high-quality health services on minimal funding to highly disadvantaged members of the community. The holistic approach has made changes that remove barriers; barriers which make it impossible for disadvantaged members of this community to live in ways that support health and wellbeing. The approach used during this project demonstrates service development and provision using a primary healthcare approach.

Practice nursing

Practice nurses (see Figure 51.9) deliver primary care in a general medical practice context within communities and are a relatively new area of clinical practice in Australia (Australian Nursing Federation (ANF), 2011b). This role has developed due to a combination of factors including inadequate numbers of general practitioners in the primary care sector, a renewed focus on health promotion and chronic disease management, and population ageing (ANF, 2011b). It recognises the role nurses play in ensuring the health of people in a community. A significant driver for nurse employment in general practice, particularly for the development of the clinical nursing role in the management of chronic disease, has been the Australian Government Practice Nurse Incentive Scheme (Australian General Practice Network (AGPN), 2009). The number of general practices employing practice nurses has risen to 63.3% in 2012, compared with 56.9% in 2009 and 58% in 2007 (Australian Medicare Local Alliance, 2012). The number of practice nurses employed was 10 693 in 2012 (Australian Medicare Local Alliance, 2012), with a clear trend that practices are employing more than one practice nurse (AGPN, 2009).

Practice nursing involves care for a broad range of community members from all stages of life and from backgrounds that reflect the diversity of the community population (ANF, 2011b). While practice nurses work in different relationships

FIGURE 51.9 ■ Nurses work in community-based general practices in Australia

Source: © Life in View/Science Photo Library.

with general medical practitioners, many adopt an approach based on primary care rather than task delegation (Keleher, Joyce et al., 2007). While the role varies according to the profile of people attending the general medical practice, adopting a primary care approach allows the practice nurse to play a key role in health promotion, health maintenance and illness prevention through the provision of information, education and care to community members who attend the practice (ANF, 2011b). Also important is working collaboratively with others in the practice and the wider community (ANF, 2011b). The roles that nurses undertake in Australian general medical practices are listed in Table 51.4. Although these mainly illustrate a biomedical orientation to service provision and, hence, an approach consistent with primary care rather than primary healthcare, some practice nurses provide care in ways that also reflect a biopsychosocial understanding of health.

Managing acute illness at home

Community nurses work in a range of contexts, including people's homes, and can be called domiciliary or generalist community nurses. For the community nurse, contact with people is initiated for many reasons. In the following exemplar, nursing assistance has been sought as a consequence of an acute illness and demonstrates a nursing focus beyond the individual to the family, and to health beyond the immediate health issue. Assessing the needs of the person in their own environment and within their normal family relationships highlights the importance of being holistic in the way health is considered. The following narrative provides an example of primary care which extends beyond the biomedical model.

Jodi, a community nurse working in a new local multipurpose centre, has been asked to see Mr Louis Spelt, aged 72 years. The reason given for the referral from a hospital ward is care of a wound with a vacuum-assisted closure (VAC) system and continuous IV antibiotic therapy administered via a Baxter pump into a peripheral intravenous catheter (PIC) line. Mr Spelt has returned home from the local private hospital following revision surgery of his tibia. He originally had a benign tumour removed near his knee but an infection developed and required further removal of bone, and debridement of the original wound.

Jodi arrives at Mr Spelt's cottage and notices it has four steps at the entry. Mr Spelt's wife answers the door and invites her into their home. Jodi finds Mr Spelt dressed in his dressing gown and waiting in the living room. The room is very comfortable but is

TABLE 51.4 Roles of nurses in general practice

ROLE	ACTIVITIES
Clinical nursing services	Triage and individual assessment Clinical care (e.g. wound care) Diagnostic services Clinical data management
Health promotion and chronic disease management	Health screening Immunisation Health check reminders (e.g. Pap smear) Individual health education Outreach services (e.g. visiting elderly people unable to visit the practice) Acute and chronic disease management (e.g. diabetes and asthma management)
Coordinating person services	Working with GPs to plan and manage individual care Liaising with allied health and community care services Coordinating delivery of healthcare services Ensuring continuity of care Facilitating effective communication between individuals and healthcare providers Individual advocacy
Promoting person, carer and community wellbeing	Providing education and health information Delivering specific programs Engaging in community development Educating about self-care
Managing clinical standards and legislative requirements	Infection control and sterilisation Monitoring incidence of infectious disease Records management Occupational health and safety Participating in accreditation processes Maintaining medical supplies
Management of human and material resources	Optimising the use of professional resources Building the practice base Building practice capacity to adapt to change Maximising financial efficiency

Source: Adapted from Australian Nursing Federation (2011b). *A snapshot of general practice nurses in Australia: Fact sheet no. 7.* Retrieved from www.anf.org.au/pdf/Fact_Sheet_Snap_Shot_General_Practice_Nurses.

cluttered. Jodi proceeds to complete her assessments and, in consultation with Mr Spelt and his wife, identifies that Mr Spelt will need nursing care every morning to renew the Baxter infusion and to monitor the VAC dressing, also allowing time for carer support for Mrs Spelt and health education as their situation changes.

During the holistic assessment Mrs Spelt assists, describing herself as 'Louis's full-time carer at the moment. He really can't do much for himself.' Before Jodi completes the consultation she is able to discuss with Mr Spelt some of his other needs and what support Mrs Spelt needs in her caring role. Jodi discusses pain management and completion of activities of daily living. Mr Spelt is mobilising with a single crutch and has an exercise program that he doesn't think is important. Jodi and the Spelts review the program and work out an achievable action plan for them to follow. Jodi also discusses ways of reducing the risk of falls, including the removal of some occasional tables in the living room. She further expresses a concern about the entry steps but Mrs Spelt assures her that Louis would only use them when she was there to assist.

One week passes and Jodi arrives to change the VAC dressing for the second time. Jodi no longer changes the Baxter unit daily as she has been able to educate Mr and Mrs Spelt to attend to this independently; every morning after his shower they do this together. Mrs Spelt is proud that she can help and they are pleased because once the Baxter is changed they are free to continue their day and no longer need to wait for the nurse to arrive. Although there is still the dressing, life is returning to normal for them.

Today while Jodi is changing the VAC dressing, she reflects on the changes that have occurred over the past week. Mr Spelt met her at the door and was dressed in casual clothes ready for a trip to his daughter's house. He was relaxed and chatting about a cruise they were going to book once his leg had healed. The living room was free of clutter and Mrs Spelt was hanging out the washing.

Jodi's narrative shows how individual and family wellbeing are facilitated despite significant illness. Mr Spelt's recovery has been supported by the community nurse's actions, for them as individuals and as a couple. The community nurse's role has been described as one where '. . . you are very much involved in a person's life, not just their condition . . . In this kind of nursing one must consider all of the influences in a client's situation' (Adrian, 2009, p. 43).

THE WAY FORWARD

It has been argued that revision and reorientation of the Australian healthcare system towards a more comprehensive primary healthcare approach is required in response to increasing social and demographic factors, such as health system burdens from chronic conditions, an ageing population and a need to manage increasing healthcare costs (Parker & Keleher, 2008). The complexity and volume of care delivered also continues to increase due to factors such as reduced hospital stay duration, increased focus on ageing in place and care at home, and de-institutionalisation processes (Department of Health and Ageing, 2008). Specific drivers underpinning this reform in NSW are detailed in Box 51.6. Government attention has therefore become focused on the need to develop capacity in the prevention and management of chronic conditions (Parker & Keleher, 2008). Several health reform strategies have ensued, including:

- National Primary Healthcare Strategic Framework
- National Maternity Services Plan
- Nursing and Midwifery Consensus View: Primary Health Care in Australia
- National Health and Hospitals Reform Commission (NHHRC).

The goals of recent health reform have been a reorientation of services towards increased primary healthcare and include increased service access, strengthened prevention and early intervention, improved management of chronic conditions, integrated delivery and cross-disciplinary team-based care (Keleher, Parker et al., 2007). Central to these developments is a desire to shift the emphasis of the system from narrow hospital-based care, treatment and cure of already established disease to the promotion of health across the lifespan; prevention of injury/disease; effective management of chronic disease; and the reduction of health inequalities (Adrian, 2009; Department of Health and Ageing, 2013;

BOX 51.6 Drivers for change for community care

- There is demand for greater provision and variety of primary health services.
- The behaviour and attitudes of people influence their health. Prevention can be encouraged in the community.
- The environment of infancy and childhood influences the development of personality. This should be emphasised in community health and welfare service.
- One-quarter of the total population suffers from chronic disease which will never be cured.
- One person in every 10 is disabled by chronic disease. One-third of those with chronic disease are under the age of 60, and many have psychological and social disabilities. Disability in older people increases with age. Four out of 10 of those aged 75 and over are limited in one or more of their daily activities.
- About 2% of the population have some form of serious mental illness and more than this have a psychological disorder. Many people have coexisting emotional and physical disorders. They require more support, alleviation, special training, rehabilitation and care in the community than is available at present.
- Early discharge programs are moving more people requiring acute and post-acute care into the community.
- There are many problems where the medical and social aspects are so interrelated that they require teams of health and welfare professionals to assist.

Source: Community health: The evidence base. A report for the NSW Community Health Review by A. Owen et al. (2008). Wollongong: Centre for Health Service Development, University of Wollongong, p. 1.

Keleher, Parker & Francis, 2010). This inherently emphasises primary care and illness/injury prevention, making them linchpins of the health system (Keleher et al., 2010). This improvement aims to counteract a natural health system tendency away from primary healthcare (WHO, 2008a) and to increasingly locate care in community settings (Keleher et al., 2010). To achieve this outcome more nurses will be needed, with nurses working in diverse community roles and in ways that harness the benefits of a primary care orientation to health (Adrian, 2009).

Nurses, who are socially mandated to improve population health, hold views complementary to the philosophies of primary care and primary healthcare, and are ideally placed to contribute to this reform and the health of communities (Eagar et al., 2008). While there are already over 29 000 nurses employed in Australian primary healthcare settings (ANF, 2011a), further development of community nursing roles is needed to support the required shift in health system orientation to primary healthcare (Keleher, Parker et al., 2007). Choosing to work as a nurse in a community organisation is an exciting decision and a step towards a challenging and rewarding career. In community care, the community as a whole and the person are both privileged, no matter whether they are a child, a family, a work team or a school. It is important to acknowledge that community members have the potential to make their own decisions about their health and healthcare. The challenge is to work in a sustained way with individuals, groups and organisations to assist community members, their families and community groups to prevent illness and injury, and to lead healthy and rewarding lives. Optimising health for the community is about ensuring a quality of life that is consistent with the individual's and community's needs and values, and is within the WHO's framework for 'Health for All' (WHO, 1978).

CHAPTER HIGHLIGHTS

- The factors that determine the health of a community include societal, environmental and socioeconomic factors, as well as the knowledge, values, beliefs and health behaviours of individuals and the community as a whole.
- Different models of health underpin the way community organisations contribute to the health of individuals and communities.
- In Australia, community services are underpinned by the biomedical, psychosocial and social models of health. Those services underpinned by a social model of health will approach health differently from acute care services based on the biomedical or psychosocial model.
- Community care is delivered in a diverse range of settings, to diverse populations and by a range of different people/services.
- Cultural safety is integral to community care in all settings.
- Community care is provided in partnership with the person and their family, and a range of government and non-government organisations.
- Health promotion and health education are based on different models of health and contribute in different ways to achieving community health. Structural–collectivist approaches to health promotion support primary healthcare.
- Many community organisations in Australia approach community care service provision using a primary care approach rather than a primary healthcare approach.

CONCEPT CHECK

1 Social determinants of health are:
1. all biological and environmental conditions that affect the health of people and communities
2. the conditions in which people are born, grow, live, work and age
3. the biological factors that cause ill health in people
4. none of the above

2 Which factors are considered important social determinants of the health for an individual or group in a community? (Select all that apply.)
1. presence of disease
2. unemployment
3. attitudes
4. genetics
5. life skills

3 Primary healthcare is described by the World Health Organization as essential healthcare based on practical, scientifically sound and socially acceptable methods, which is affordable and is delivered to individuals and families in the community.
1. true
2. false

4 Match the following terms to as many models as needed for each term.

Terms
- a Primary healthcare
- b Primary care

Models
1. Social model of health
2. Biomedical model of health
3. Biopsychosocial model of health

5 What are the principles that underpin a primary healthcare orientation to community health? (Select all that apply.)
1. social justice
2. medical expertise
3. equity
4. responsiveness to need
5. community participation

6 Which of the following are characteristics of primary care? (Select all that apply.)
1. reduction of specific disease and a technical focus
2. based on the biomedical model of health
3. involvement of sectors other than health
4. focus on curative care, with some attention to prevention and promotion
5. limited community engagement

7 Which of the following are characteristics of primary healthcare? (Select all that apply.)
1 improvement in overall health of the community and individuals, and 'Health for All' as overall social and political goal
2 based on the socioecological model of health
3 strong focus on health sector with very limited involvement from other sectors
4 comprehensive strategy with curative, rehabilitative, preventive and health promotion that seeks to remove root causes of health
5 engaged participation that starts with community strengths and the community's assessment of health issues, is ongoing and aims for community control

8 Which of the following are drivers to reorienting community service organisations towards primary healthcare? (Select all that apply.)
1 One-quarter of the total population suffers from chronic disease which will never be cured.
2 Medical and social aspects of health are so interrelated that they require teams of health and welfare professionals to assist.
3 Behaviour and attitudes of people influence their health. Prevention can be encouraged in the community.
4 Demand for greater provision and variety of primary health services.

9 In health, two common ways of understanding what is meant by 'community' are:
1 community as relationships
2 community as politics
3 community as locality
4 community as health

10 On the continuum of interventions using social determinants, which of the following levels of health determinant have a more direct effect on the health of an individual?
1 distal and proximal determinants
2 proximal and intermediate determinants
3 distal and intermediate determinants
4 none of the above

11 Intersectorial refers to:
1 the way health professionals interact within community organisations
2 the way health professionals interact within their own organisation
3 the way health professionals interact with non-health organisations
4 none of the above

CHAPTER 52

NURSING CARE OF PEOPLE IN REGIONAL, RURAL AND REMOTE AREAS OF AUSTRALIA

LEEANNE HEATON

KEY TERMS

LEARNING OUTCOMES

- Discuss the challenges faced in providing nursing care in regional, rural and remote communities.
- Discuss the rewards of nursing in regional, rural and remote areas.
- Identify the determinants of regional, rural and remote classification in Australia.
- Identify the determinants of regional, rural and remote health.
- Describe nursing in remote Indigenous communities with regard to cultural awareness, cultural safety and the rights of people living in these communities.
- Describe the role of the nurse in regional, rural and remote healthcare.
- Discuss the barriers to healthcare as identified by nurses, other health professionals and consumers in regional, rural and remote communities.

CLINICAL COMPETENCIES

- Use evidence-based practice guidelines and clinical assessment skills to inform clinical decision making.
- Provide timely and accurate person-centred assessment.
- Incorporate an understanding of the local determinants of healthcare provision in regional, rural and remote areas into quality nursing care.
- Use evidence-based nursing practice to provide quality nursing care in acute and non-acute situations, including health promotion and prevention strategies.
- Incorporate the principles of primary healthcare into the provision of nursing care in regional, rural and remote settings.
- Provide culturally safe nursing care.
- Use professional communication skills to develop therapeutic relationships and establish professional boundaries when working in regional, rural and remote communities.
- Use assessment findings to determine initial nursing care, referral and transfer as deemed necessary.
- Recognise and work within the interdisciplinary team locally and in distance mode.
- Incorporate all available resources, including technological resources, to maximise health outcomes.
- Recognise the special considerations for people from regional rural and remote areas in the discharge planning process.

Note on clinical competencies

This chapter relates regional, rural and remote nursing in Australia to the Nursing and Midwifery Board of Australia (NMBA, 2016) *National Registered Nurse Standards for Practice (2016).* The competencies of the Registered Nurse practising in regional, rural and remote Australia are directly linked to all of the domains of professional practice, critical thinking and analysis, provision and coordination of care, and collaborative and therapeutic practice. Specifically, regional, rural and remote nursing practice in Australia is clearly aligned with the guidelines of all of the individual elements as identified in the NMBA Standards for Practice.

The terms 'regional', 'rural' and 'remote' invoke impressions of distance but in reality the communities, people and available health services in these areas vary greatly. So, too, do the responsibilities, roles and philosophies employed when providing nursing care for people in these areas. Therefore, any discussion about regional, rural and remote nursing requires acknowledgement of the fact that there is no single definition of 'regional', 'rural' or 'remote', and awareness of the specific areas being discussed to ensure accurate and consistent representation.

Understanding regional, rural and remote nursing is not exclusively the domain of the local workforce, health department officials or government policy advisers. All nurses, including those working in large metropolitan areas, need to possess a sound knowledge of the associated challenges and barriers. Nurses provide a greater percentage of healthcare than any other health-related discipline, and regional, rural and remote nursing encompasses a vast range of nursing skills, including the ability to accurately identify the health needs of people in these communities and to refer and/or transfer people to major centres as appropriate. Nurses working in referral centres also face unique challenges when caring for, and planning discharge for, people who usually reside in a regional, rural or remote area.

This chapter discusses the nursing care of people in regional, rural and remote areas from two perspectives: first, the challenges, opportunities and rewards associated with nursing in regional, rural and remote Australia; and second, the provision of nursing care for people from rural and remote areas in regional or metropolitan areas.

CHALLENGES AND REWARDS

Nurses work in remote areas for a range of reasons, and quite often the reason that brings them to the community may be the reason they leave. This can include employment for their partner, family commitments, end of employment contract and change in life expectations. Leaving small communities can be a distressing time for the nurse, colleagues and the community members. This can be compounded if there is difficulty in filling the vacant nursing position.

Working in regional, rural and remote areas can be extraordinarily challenging while at the same time being immensely rewarding, quite often for the very same reasons. Nursing practice in regional, rural and remote areas is holistic in the truest sense of the term. A nurse who works in a small community for many years may well provide nursing care for several generations of a family, providing holistic care from the cradle to the grave.

THE DIFFERENCES BETWEEN 'REGIONAL', 'RURAL' AND 'REMOTE'

One of the most complex tasks when discussing regional, rural and remote issues relating to any discipline is to identify and apply common definitions. To assist in providing a consistent guide, the Australian Government uses three systems that incorporate many of the factors impacting on an individual's access to health services as a result of their location. These systems are the Accessibility/Remoteness Index of Australia (ARIA+) (University of Adelaide, 2015), the Rural, Remote and Metropolitan Areas (RRMA) Classification (Australian Institute of Health and Welfare (AIHW), 2015a) and the Australian Statistical Geography Standard (ASGS) (Australian Bureau of Statistics (ABS), 2014a).

There is a complex method of determining remoteness areas (RAs) in Australia. In 2011, the remoteness structure of the Australian Statistical Geography Standard (ASGS) was introduced by the ABS to assist in publishing a diverse range of social and demographic statistics (ABS, 2014a). The ASGS divides each state and territory into regions according to the access to services in the localities (ABS, 2014a). The University of Adelaide is responsible for the Accessibility/Remoteness Index of Australia (ARIA+), which measures the remoteness of one point to another based on physical road distance to the nearest urban centre in each of the five size classes: major cities, inner regional, outer regional, remote and very remote (University of Adelaide, 2015). The ARIA+ information is placed into 1 km grids of Australia. These grids are then overlayed onto the ASGS statistical area (SA) levels, determining the remoteness areas (RAs) (ABS, 2014a). Awareness of these classifications is necessary for nurses for a range of reasons. Possibly of greatest importance is the statistical evidence that people who live in remote and very remote Australia have overall poorer mortality (up to 1.4 times higher) and morbidity than those who live in major cities (AIHW, 2014). It is statistically significant that Aboriginal and Torres Strait Islander people make up a higher percentage of the remote area population than of the urban population. Indigenous people in regional, rural and remote areas are also over-represented in poorer health outcomes data overall, which is consistent with the lower life expectancy rates for Indigenous people in Australia (AIHW, 2014). Furthermore, it has been proposed that the lower life expectancy of Indigenous people living in remote areas is more suggestive of their Indigenous status than their locality.

The Council of Remote Area Nurses of Australia (CRANAplus) explained that working in remote areas can present its own set of challenges (CRANAplus, 2015). This can be due to factors such as geography causing difficult access, extreme distance and variations in weather conditions. The population is scattered, with people from different cultures and groups who have challenging health conditions. Lack of resources and a highly itinerant group of health professionals also impact on delivery of quality health services to people in regional, rural and remote areas of Australia (CRANAPlus, 2015).

Regional, rural and remote nursing

In Australia, nursing is one of the most stable and equally distributed healthcare disciplines, with many nurses working in a diverse range of settings within regional, rural and remote areas. However, the nursing workforce in very remote Australia is like the rest of Australia in that it is ageing. Of the remote area nurses (RANs) working in very remote areas, 66.6% are aged 50 years or over, despite the average age of Registered Nurses being 44.2 years, and the national percentage of nurses aged 50 years or over being 39%. Men working in very remote areas account for 15% of the nursing and midwifery workforce (AIHW, 2012).

FAST FACTS

- Approximately 69% of the Australian population resides in major cities (ABS, 2015).
- Approximately 2.3% of the population lives in remote or very remote Australia (ABS, 2015).
- The Northern Territory has the largest percentage of people (57%) living in outer regional areas (including Darwin), and remote (20%) and very remote (22%) areas (ABS, 2015).
- The life expectancy for Aboriginal and Torres Strait Islander men is estimated to be 10.6 years lower than for non-Indigenous men (ABS, 2014b).
- The life expectancy for Aboriginal and Torres Strait Islander women is 9.5 years lower than for non-Indigenous women (ABS, 2014b).
- The mortality rate of Indigenous Australians was nearly twice that of non-Indigenous Australians and five times higher for Indigenous people aged 35 to 44 years (AIHW, 2015b).
- The rate of dying due to a land transport accident was more than four times higher in remote and very remote areas than in major cities (AIHW, 2014).
- Homelessness is an issue related not only to urban living. There are high rates of homelessness in regional and rural areas. The homelessness rate for Indigenous people in 2011 was nearly 14 times the rate for non-Indigenous people and is often due to severely overcrowded dwellings (AIHW, 2015b).
- Of the proportion of people living in remote areas, the Indigenous population is very high, with 45% living in very remote and 16% in remote areas (AIHW, 2015b).
- The nursing workforce in Australia has increased by 13% from 2005.
- In 2013, there were 1111 full-time equivalent nurses per 100 000 people in outer regional areas compared with 1264 nurses working in very remote areas (AIHW, 2015c).

Over 43% of RANs in very remote areas are in working in Indigenous communities in primary healthcare settings (Lenthall et al., 2011). Many remote communities are relying on health professionals who have not trained in Australia, and on locums or fly-in/fly-out healthcare providers who do not have an understanding of cultural awareness, cultural safety and/or the rights of people living in these communities (Ware, 2013).

CRANAplus describes RANs as working in a multitude of settings such as Indigenous communities, outback and isolated towns, farm communities, islands, tourist locations, mines and railways. They must have skills that facilitate a primary healthcare response ranging from covering an emergency to administering a variety of medications to providing health education. The scope of practice required of an RAN can be quite diverse and, depending on a number of factors, can become quite broad when required (CRANAplus, 2015). There is a great deal of information about the health of people living in remote areas, particularly about Indigenous people who have complex medical issues, but who are less able to access equitable health services.

PRIMARY HEALTHCARE AND REGIONAL, RURAL AND REMOTE NURSING

Over recent decades, the World Health Organization (WHO) has outlined global health strategies, from the early primary healthcare models to the current more specific strategies designed to address the underlying factors that affect health outcomes. This is hoped to achieve defined healthcare goals. These healthcare goals, as defined by the WHO, are further supported by the Millennium Development Goals (MDGs) initiated by the United Nations (WHO, 2015).

The delivery of any health service based on **primary healthcare** principles includes acknowledgement of the individual and often specialised needs of the community. This is achieved through consultation, optimising availability of and accessibility to services, and adopting an interdisciplinary approach which addresses all aspects of healthcare, from prevention and early detection to curative, rehabilitative and palliative services. These strategies require a 'whole of government' approach, coordinated and in collaboration with community organisations to ensure that changes in the global provision of healthcare acknowledge the rights of individuals and communities to have equitable access to quality healthcare. The implementation process of primary healthcare models in regional, rural and remote areas in Australia has proven to be more lengthy than anticipated. However, throughout this process the role of the nurse in these areas has evolved to what it is today, becoming increasingly recognised as that of an advanced clinical practitioner.

The Medical Specialist Outreach Assistance Program (MSOAP) was initially established in 2000. In the 2011–2012 Budget, the Australian Government announced it would provide funding to establish the Rural Health Outreach Fund consolidating the MSOAP, MSOAP ophthalmology expansion, MSOAP maternity services expansion, rural women's GP service and National Rural and Remote Health Kimberley Paediatric Outreach Program. This funding is an attempt to improve health outcomes for people living in regional, rural and remote locations by supporting the delivery of outreach health activities (Department of Health, 2014a).

Primary healthcare and social determinants of health

The WHO (2012) has determined that one of the most important ways in which the global community can affect health inequity is to mobilise governments and political bodies to address the inequity from a social determinants perspective. *Social determinants* is a broad term that describes the main factors influencing the quality of preventive and curative healthcare available to all people. As well as the persuasive power of global economics, national, state and local politics and economics influence the access to and quality of healthcare services. To achieve the goals outlined by the WHO (2012), governments, policy advisers and budgetary committees must be prepared to invest in the future health of all of their citizens. The realities of distance impacting on access to more

comprehensive healthcare services cannot be changed—Australia is a vast country—but what can be changed is the ability of people who live and work in regional, rural and remote areas to access healthcare services and the effort it takes to do so. Economic viability and sustainability are immense challenges to implementing higher-level health services in 'the bush', a colloquial term for non-urban areas. The health demands of people in regional, rural and remote areas will never be as great as those in urban centres where a much greater percentage of the population resides. As such, most health services are concentrated in urban areas. This approach not only significantly impacts on people who live in regional, rural and remote areas, but also has significant implications for the clinical practice of health professionals.

The role of the education provider should also not be overlooked. Institutions providing courses for health professionals must address the health issues and concerns inherent in these communities. Graduates need to be encouraged to work in regional, rural and remote areas, and having a clinical placement opportunity in the bush can facilitate this (Hart et al., 2014). There are a number of scholarship or intern schemes for all health disciplines which aim to recruit and retain staff in regional, rural and remote areas. Some examples of these are the opportunities provided by the Australian College of Nursing (ACN) for nurses to participate in a regional, rural or remote placement. Most state health departments also offer such opportunities. Medical students are offered support from the Medical Rural Bonded Scholarship scheme, and the Services for Australian Rural and Remote Allied Health (SARRAH) organisation offers scholarships for allied health professional students to attend placement in rural settings. As with most of the organisations that offer scholarships, these are often funded by the Department of Health. Many education providers also offer courses which incorporate regional, rural and remote health in Australia. Most universities offer placements for regional, rural and remote health. These include Central Queensland University, University of Wollongong, University of New South Wales, Charles Darwin University, Charles Sturt University, Flinders University, Deakin University and Curtin University. The importance being placed on regional, rural and remote considerations is demonstrated by the forming of a number of centres for rural health at various universities throughout Australia. The staff in these centres perform research into issues such as mental health, Indigenous health, aged care, health workforce and health and wellbeing for people living in regional, rural and remote communities.

INDIGENOUS HEALTH CONSIDERATIONS IN REGIONAL, RURAL AND REMOTE AREAS

The Indigenous people of Australia are over-represented in mortality and morbidity statistics (AIHW, 2015b). These poorer health outcomes are an indicator of very complex issues relating to Australia's First Nation peoples, requiring greater consideration than a simple set of health problems. There are a range of strategies in place throughout Australian states and territories which aim to return control to Indigenous communities through approaches that are culturally appropriate. One of these is the Closing the Gap campaign (Council of Australian Governments (COAG), 2008) which highlights many of the social issues impacting on health equity. An agreement was made in 2008 between all tiers of the Australian Government to work with Aboriginal and Torres Strait Islander communities to reduce the disparity in healthcare outcomes with the non-Indigenous Australian population. The first two points agreed to by COAG were to 'close the gap in life expectancy within a generation and halve the gap in mortality rates for Indigenous children under five in a decade' (COAG, 2008, p. 14). The four other points made in this agreement relate to improving the education and employment of Indigenous people (COAG, 2008).

The current estimate of the differences in life expectancy of Aboriginal and Torres Strait Islander people compared with non-Indigenous Australians is 10.6 years for a male and 9.5 years for a female (AIHW, 2015b). Information relating to the indicators that may cause a reduction in life expectancy are the principal reason for admission to hospital, numbers of current daily smokers, average daily alcohol consumption, levels of obesity, levels of physical activity and ability to access healthcare compared with need (COAG, 2008).

The *Closing the gap in a generation* (WHO, 2008) report calls for health equity through action on the **social determinants of health**. The social determinants of health are the circumstances relating to dealing with illness. The WHO (2012) states that regardless of where people are born, live or work, or who the government that rules on the day is, all people are entitled to equality in healthcare services. Low levels of health literacy are also seen as an issue that affects the health and wellness of lower socioeconomic groups, with many of these groups living in regional, rural and remote areas (Australian Commission on Safety and Quality in Health Care (ACSQHC), 2015).

Some of the relevant issues include improving access to health prevention and screening strategies, improving access to quality health services and improving the recruitment and retention of **Indigenous health** workers and professionals. To impact on the disparity requires a multi-level, multifaceted and interdisciplinary approach across many diverse professions, only some of which are formally defined as health professions. Such an inclusionary approach includes government policy and budgetary advisers, strategic planners, community agencies, community liaison workers and community representatives, all of whom are essential members of the decision-making process and can affect change in healthcare services (ACN, 2011).

Working in an Indigenous community

Nurses working in Indigenous communities must earn acceptance and respect. This respect is often earned through listening to, and really understanding (i.e. hearing the words and the feelings) what the community identifies as the issues relating to healthcare, and what it considers appropriate solutions to be. The nursing workforce is a facilitator of community ownership

of health through a consultative process underpinned by the principles of reciprocity, respect, equality, responsibility and integrity (ACN, 2011). This approach goes at least some way to ensuring that the community members are not passive recipients of care and enables the health service provider to address the overarching health issues by actively addressing community-identified needs. It is essential that a consultative, respectful approach be taken to ensure that health strategies are embedded within the community structure in a sustainable manner.

The process of consultation aligns with the principles of respect and acknowledgement of traditional beliefs and practices. It also underpins the development of sustainable healthcare based on prevention of illness through education and compliance through understanding. The long-term effects of implementing a community-driven healthcare service include improved mortality and morbidity statistics, a reduction in the representation of Indigenous people in relation to poor health outcomes and the ongoing world presence of a traditional culture for generations to come. Additionally, active consultation and consistent demonstration of cultural respect are safe cultural practice. All health professionals working in Indigenous communities should complete professional development courses in cultural awareness, cultural safety and cultural security prior to going to the community (SARRAH, 2015).

Aboriginal or Torres Strait Islander Health Workers (ATSIHWs) employed in each Indigenous community are the foundation of the health service (see Figure 52.1). The ATSIHWs, as respected community members, often live within the community and have established links that are invaluable to engaging members of the community in healthcare issues. The professional relationship between the nurses and the health workers is a symbiotic one, in which each role relies upon the other to achieve stated outcomes. In summary, a mutually respectful, collaborative, collegial interdisciplinary team approach underpins the success of health initiatives in Indigenous communities (National Aboriginal & Torres Strait Islander Health Worker Association (NATSIHWA), 2012).

THE REGIONAL, RURAL AND REMOTE NURSING WORKFORCE

The roles of nurses in regional, rural and remote communities differ from the roles of their metropolitan counterparts. However, regional, rural and remote nurses can also find that their practice can vary greatly from location to location, depending on the economic, geographical, social, spiritual, cultural and political identity of the individual community. Regional, rural and remote nurses can experience feelings of isolation and stress related to community demographic, lack of multidisciplinary and interdisciplinary support, resource un/availability and the nurses' in/ability to meet the complex health requirements of the communities in which they work. The specific needs of the community, exacerbated by the degree of isolation that can be felt, require nurses to adopt more flexible and creative approaches to clinical problem solving. Such autonomous practice environments may further contribute to the development of professional skills and support the development of an advanced practice or Nurse Practitioner role.

Globally, the nursing workforce is an ageing workforce. Recent statistics from AIHW (2015c) indicate that the average age of nurses working outside major cities is slightly higher than that of their metropolitan counterparts. Detailed statistics of the **regional, rural and remote health workforce** show that the number of clinicians in remote and very remote areas is increasing, particularly for general practitioners (GPs), whose rate is higher than the national average of 108 per 100 000 population (AIHW, 2015c). However, the number of practising GPs is not sufficient for demand in regional, rural and remote areas and this implies an increased workload for the nurses in those communities (Health Workforce Australia (HWA), 2012). The gap in health service provision is often met by experienced nurses adopting a greater role in local health services. Historically, nurses and GPs in rural and remote areas work collaboratively. The loss of professional support may lead to increased feelings of isolation, scope of practice issues and ethical dilemmas for the nurses. However, the lack of GPs in rural and remote areas and the requirement for nurses to adopt greater roles has contributed to the ongoing demand for an increased scope of practice for rural and remote nurses, advanced practice nurses and suitably qualified Nurse Practitioners (HWA, 2012). These roles are supported by local health workers (NATSIHWAH, 2012). The number of registered Aboriginal and Torres Strait Islander health practitioners in Australia rose from 265 in 2012 to 310 in 2013, with the majority of staff working in remote/very remote areas. These were mainly women aged 55 and over (AIHW, 2015c).

It is a common generalisation that people residing in regional, rural and remote areas are resilient and somewhat hardened: 'making do' and 'getting on'. It is also commonly accepted that these traits extend to the nurse in these areas, who does tend to 'soldier on' and does what has to be done with often limited resources. However, for some nurses, the stressors associated with practising in such difficult circumstances can lead to burnout. This can occur in health professionals due to an overwhelming anxiety resulting from the ongoing

expectations and responsibility to patients (Remote Area Health Corp (RAHC), 2015). While burnout is not specific to rural and remote practice, it is unfortunately common in nurses who try to work harder and longer to fulfil the expectations of what can be sometimes unrelenting community demands. This can lead to increasing job dissatisfaction, increased stress levels, work/life imbalance, professional relationship breakdown, personal relationship breakdown and physical deterioration. Such professional side effects have the further potential to negatively impact on nurses in small communities, exacerbated by their high visibility and the overlap between personal and professional identity (RAHC, 2015) (see Figure 52.2).

Recruiting new nurses to rural and remote areas can be challenging for a number of reasons, such as a lack of connection with the community, a change in lifestyle, worries about physical security and a lack of personal support. New graduates may also not possess the advanced clinical competencies required to practise in a regional/rural/remote setting that has limited resources (Hart et al., 2014; Bennett et al., 2012). See the accompanying 'Translation to practice' box.

TRANSLATION TO PRACTICE New nursing graduates working in rural communities

Bennett et al. (2012) reported that factors such as personal and professional expectations, unusual workloads and varying levels of support available to staff can cause staff to leave regional, rural and remote areas. Anderson (2012) supported this by explaining that issues such as lack of cultural awareness, inadequate resources, role confusion and limited social support make working in regional, rural and remote areas challenging. Although it is recognised that new graduate nurses may find the transition into the workplace challenging, with ongoing support from employers obstacles can be overcome. The researchers found that issues such as understanding expectations, having social support and reviewing workloads should be an integral part of educating and preparing nurses for practice in regional, rural and remote communities. With the current workforce shortages in regional, rural and remote areas, it is imperative that these recommendations are acknowledged and incorporated in education programs and recruiting processes.

IMPLICATIONS FOR NURSING

- Resource planning by health services can incorporate these findings to individualise the health service to meet the specific needs of the communities. This will also have a significant impact on the skill-mix considerations for staffing health facilities.
- These findings should be considered by nursing professional bodies when addressing the professional representation and development needs of the nurses.
- Undergraduate education providers and the providers of ongoing professional development should consider professional requirements, attributes expected of graduates on completion of their undergraduate degree and curriculum and program design.

CRITICAL THINKING IN PERSON-CENTRED CARE

Some critical-thinking skills linked to consideration of working in a regional, rural or remote area relate to the ability of the nurse to self-assess and identify areas of professional strengths and areas requiring further development.

1. What do you identify as the individual strengths that would support your ability to practise in a regional, rural or remote setting?
2. In which areas of your professional practice do you require further enhancement prior to embarking on a nursing career in regional, rural or remote areas?
3. What do you see as the advantages of engaging with the community to identify the attributes of the nurses working within the community?

Competency to practise

Nurses working in regional, rural and remote areas must possess highly developed skills related to physical assessment, especially those related to traumatic injury. This skill level must include the ability to perform the assessment, note and interpret abnormalities, initiate treatment, initiate communication with emergency transport and personnel as required, and refer to other health professionals locally if available. The nurse in this setting will also initiate access to professional guidance from a distant provider as deemed necessary. Great responsibility is placed on nurses in these situations, with the experience of the practitioner performing the assessment a major factor. The accuracy of initial assessment and timing of referral and transfer can make a major difference in the health outcome. Accuracy of initial assessment, timing of referral, and timing of transfer directly affect the prognosis, with the experience of the practitioner performing the initial physical assessment being a major factor in determining outcomes (Centre for Remote Health, 2015).

Regional, rural and remote areas are not all the same, and the individual characteristics of the region, including the main industries, will contribute to the healthcare requirements of that region. For example, some regional, rural and remote areas rely on farming and agriculture for their local economy, while others may have a mixture of agriculture and mining (see Figure 52.3), or tourism and ecotourism.

FIGURE 52.3 ■ Mining is one of the main economic activities for rural and remote communities

The Nursing and Midwifery Board of Australia provides the opportunity for nurses in isolated areas to be endorsed to administer, obtain, possess, prescribe or supply a scheduled medicine as an isolated or rural practice nurse.

ROLE OF THE NURSE IN REGIONAL, RURAL AND REMOTE AUSTRALIA

The role of nurses in regional, rural and remote areas of Australia is as vast and divergent as the country that surrounds them. The following areas of practice demonstrate the diversity of nursing roles which combine to make up the multifaceted approach to healthcare that these nurses engage in.

Health promotion

Health outcomes are the ultimate deciders, but community education and awareness also reflect the success of health promotion strategies. The role of the nurse is extremely valuable in activities such as multimedia campaigns promoting early detection of cancer by means of screening (e.g. for breast, prostate or bowel cancer) which can result in an increased number of people presenting to screening services. Regional, rural and remote nurses liaise with health service providers and the community; advocate for individuals and for the community regarding access, which may include, for example, the arrival of a breast screen bus; coordinate the local application of service provision and accessibility for community members (ramps, signs); actively promote the event; recruit from the targeted population and facilitate follow-up care as necessary. When the initial health promotion strategy has been completed, the nurse, as part of the interdisciplinary team, is required to evaluate the program and ensure that people requiring further investigation or treatment gain referral to the appropriate service.

Regional, rural and remote nurses actively participate in health promotion in individual, small group or community sessions, or by providing education sessions in the hospital or community setting. Furthermore, it is extremely difficult for nurses in small communities not to be identified as a nurse, so often their professional expertise and advice will be sought during their off-duty hours (e.g. at the local shop), extending their ongoing commitment to the provision of accurate health advice.

Governments and health providers organise national and state-wide rollouts of specific health promotion campaigns that include smaller regional/rural/remote communities. Some of these campaigns will be specifically aimed at residents of country areas; for example, the *Close the Gap* campaign directed at Indigenous health inequality, and the Care for Kids' Ears campaign aimed at highlighting the risk of hearing loss associated with ear disease in Aboriginal and Torres Strait Islander people. Nurses in these communities are actively involved in the planning, implementation and evaluation of the programs. This has further implications for practice and ongoing professional development, and also for the workload of nurses, requiring that the nurses have up-to-date knowledge of the campaign content and the health promotion approach.

Screening and prevention strategies

Health screening programs globally are based on the principle of early detection leading to early intervention, which leads to improved health outcomes for individual people and communities. As previously stated, residents in regional, rural and remote areas of Australia have statistically poorer outcomes for many diseases. This may be partially due to a lack of participation in screening programs, which in turn may be due to a lack of awareness or inability to access screening points. There are a number of reasons—not only confined to regional, rural and remote communities—why people do not participate in screening programs. However, when geographical and cultural isolation are factored in, Australia suffers from a 'tyranny of distance', and there is an increased risk of non-participation. In many cases, strategic planning and service development address this through specialised, localised screening and detection programs, bringing the screening points to the community where at all possible. For example, in sparsely populated areas in Australia, mobile women's health nurses ensure that all women have access to regular, timely screening for breast and cervical cancers, among other health screening services. This model of health screening has also been used in other preventive health strategies, some of which are provided by community organisations as a not-for-profit community service.

Acute assessment

Nurses intending to work in regional, remote and rural settings need to be cognisant of their individual scope of practice and seek to address limitations prior to embarking upon this field of nursing. It should be acknowledged that while nursing education provides a basis for generalist nursing, it is untenable for any single program to cover all discipline perspectives in equal depth. For some graduates, this may necessitate gaining additional experience and education in areas such as aged care, paediatrics, people who live with mental health problems, or primary health screening.

Nurses working in small communities, either in health centres or in hospitals, must be competent to practise in emergency situations. In many instances, the nurse will be working alone or with only limited support from other health professionals. Some of the skills required in emergency situations are outlined below.

Unexpected illness or trauma are two of the main reasons why people living in sparsely populated areas seek healthcare. Road trauma, workplace injuries, mental health and farm-related injuries require the nurse on duty to have a high level of competence in acute health assessment, including physical and mental health assessment, and an in-depth understanding of the particular type of injuries and presentations associated with these conditions. Injuries received in motor vehicle accidents can range from minor to life threatening, requiring immediate intervention. In a regional, rural or remote area, the availability and timely response of emergency assistance can be varied at best. Therefore, many regional, rural and remote residences are equipped with emergency medical kits, provided through organisations such as the Royal Flying Doctor Service (RFDS). Medical advice can also be sought through radio or telephone contact: a suitably qualified professional will instruct the person at the site of the emergency what to do. Nurses in regional, rural and particularly remote areas can be called upon to receive the person in the local health service clinic or hospital; or to assist in the **retrieval** process; or they can be called upon in their role as neighbour and community member.

Nurses working in regional, rural and remote areas must be prepared to provide care for people with a broad spectrum of clinical presentations including mental illness. In Australia, in 2007, 45% of the population aged between 16 and 85 years stated that they had been affected by anxiety, mood (affective) or substance

use disorder (ABS, 2012), so the probability that the nurse will be confronted by a person with a mental health issue is very high. While it is not feasible for any one person to know each and every possible clinical presentation, nurses must be able to identify deviations from normal and seek appropriate assistance in a timely manner to ensure optimal outcomes for the person presenting to them for help. In all areas of nursing practice, irrespective of the context, assessment forms the cornerstone of best practice. In regional, rural and remote areas, enhanced assessment skills are the basis upon which management of the person and significant clinical decisions are made. Astute assessment provides the nurse with the requisite decision-making capacity. It is essential to be able to assess, plan, implement and evaluate treatment based on psychological, physiological and pathophysiological knowledge. Nurses are expected to identify and interpret data before responding appropriately. The presenting problem of the person will guide the order and priority of the type of assessment to be undertaken, but will not limit the extent to which the nurse will perform a full physical and psychological assessment. For example, while some individuals will not present with any obvious physical injury or physiological dysfunction, they may exhibit signs of distress, altered mental health state and/or drug and alcohol issues. Acute presentation of injuries or illnesses acquired may be further complicated by co-morbidities or by combinations of two or more problems (e.g. trauma and drug or alcohol problems). In addition to the varied physical and psychological presentations, nurses will be required to provide care to people who come from diverse cultural backgrounds and from across the lifespan.

Emergency nursing care

Triage

In remote communities and health sites across Australia, some degree of emergency care for communities is provided. The health outcomes are influenced in part by the large distances to travel, the time taken for retrieval and emergency stabilisation, and the emergency skills of the local practitioners (HWA, 2011). For **triage in regional, rural and remote areas**, nurses may use the Australasian Triage Scale (ATS, see Table 52.1) but this may be quickly followed by the nurses themselves initiating emergency treatment. In situations such as this, the ATS is applied according to nurse waiting times.

The ATS categories determine the urgency with which the person's presenting problem must be treated. In regional, rural and remote areas, the deterioration of the person's condition must be considered with regard to the response time of appropriate personnel and the needs of the individual to be triaged. Therefore, the triage category may be higher in anticipation of the challenges of assembling qualified personnel and required equipment. The triage categories are based on the presumption of morbidity if treatment is not initiated within the identified time to treatment. The categories also include behavioural or mental health disorders, which pose a threat of danger to self or others.

By nature, triage is necessarily contingent upon context; in such settings the attending nurse will use advanced decision-making processes to determine the person's need for emergency care and put in place the resources available to expedite time-critical interventions.

PRIMARY SURVEY A primary survey is focused on identifying life-threatening conditions and the need for emergency first aid. In the regional, rural and remote context, nurses may be called to a scene to provide assistance or they may be the only staff member in the local healthcare facility. In these situations, having the means by which to summon assistance is also a priority, requiring the nurse to be competent at emergency transmission via the telephone or by radio.

Understanding the principles of Danger, Response, Send for help, Airway, Breathing, Circulation, Disability (neurological) and Exposure is essential in the provision of safe and effective care. To provide appropriate and expedient care the nurse must possess effective assessment skills and be able to interpret findings accurately, in addition to having a working knowledge of all resources available. This includes awareness of where to locate, and how to use, emergency resuscitation equipment.

Some members of the community require special consideration during primary survey and physical assessment. Care of children in emergent situations requires more than merely size modification of adult assessment and management. Children are more susceptible to heat loss, and their fluid and medication requirements are different from adults. During the primary survey, nurses must incorporate knowledge of the physical, cognitive, emotional and behavioural stage of development into the interpretation of findings. Likewise, the older adult has altered states resulting from the normal ageing processes or disease processes which will influence the interpretation of assessment findings. This group is also at higher risk of complications from co-morbidities or as a result of concurrent treatment regimens. The older adult and the child are only two examples that demonstrate the breadth of clinical practice needed by nurses working in regional, rural and remote areas.

SECONDARY SURVEY A secondary survey is not performed until the primary survey has been completed, findings have been interpreted and documented, and the prioritised interventions implemented. It is generally accepted that the secondary survey entails a comprehensive head-to-toe physical assessment. This physical assessment includes inspection, palpation, auscultation and percussion of the body systems.

Physical assessment is not the only form of assessment that nurses working in regional, rural and remote areas must be proficient in performing. Mental health assessment is also frequently performed, and requires the nurse to possess a sound understanding of assessment processes, manifestations of mental illness and treatment strategies. True holistic person-centred care includes acknowledgement of the whole person as well as the lifestyle factors influencing the person's health and wellbeing.

Depression has been recognised as a major health issue in all Australian communities and is a health priority area throughout Australia. Global statistics of suicide in young men living in rural areas show consistently higher rates in this demographic than in the general population (Jones et al., 2015; Kennedy et al., 2014; Hirsch & Cukrowicz, 2014). There are a range of factors that may influence the rates of suicide in young men living in regional, rural and remote areas, including mental illness, physical illness, financial stress, isolated residence, increased

TABLE 52.1 The Australasian Triage Scale

ATS CATEGORY	RESPONSE	DESCRIPTION OF CATEGORY	CLINICAL DESCRIPTORS (INDICATIVE ONLY)
Category 1	Immediate simultaneous assessment and treatment	**Immediately life threatening** Conditions that are threats to life (or imminent risk of deterioration) and require immediate aggressive intervention.	• Cardiac arrest • Respiratory arrest • Immediate risk to airway—impending arrest • Respiratory rate < 10/min • Extreme respiratory distress • BP < 80 (adult) or severely shocked child/infant • Unresponsive or responds to pain only (GCS < 9) • Ongoing/prolonged seizure • IV overdose and unresponsive or hypoventilation • Severe behavioural disorder with immediate threat of dangerous violence
Category 2	Assessment and treatment within 10 minutes (assessment and treatment often simultaneous)	**Imminently life threatening** The individual's condition is serious enough or deteriorating so rapidly that there is the potential of threat to life, or organ system failure, if not treated within 10 minutes of arrival or **Important time-critical treatment** The potential for time-critical treatment (e.g. thrombolysis, antidote) to make a significant effect on clinical outcome depends on treatment commencing within a few minutes of the individual's arrival in the ED or **Very severe pain** Humane practice mandates the relief of very severe pain or distress within 10 minutes	• Airway risk—severe stridor or drooling with distress • Severe respiratory distress • Circulatory compromise — Clammy or mottled skin, poor perfusion — HR < 50 or > 150 (adult) — Hypotension with haemodynamic effects — Severe blood loss • Chest pain of likely cardiac nature • Very severe pain—any cause • BSL < 2 mmol/L • Drowsy, decreased responsiveness any cause (GCS < 13) • Acute hemiparesis/dysphasia • Fever with signs of lethargy (any age) • Suspected meningococcaemia • Acid or alkali splash to eye—requiring irrigation • Major multi-trauma (requiring rapid organised team response) • Severe localised trauma—major fracture, amputation • High-risk history: — Significant sedative or other toxic ingestion — Significant/dangerous envenomation — Severe pain suggesting PE, AAA or ectopic pregnancy • Behavioural/psychiatric: — violent or aggressive — immediate threat to self or others — requires or has required restraint — severe agitation or aggression
Category 3	Assessment and treatment start within 30 minutes	**Potentially life threatening** The patient's condition may progress to life or limb threatening, or may lead to significant morbidity, if assessment and treatment are not commenced within 30 minutes of arrival or **Situational urgency** There is potential for adverse outcome if time-critical treatment is not commenced within 30 minutes or Humane practice mandates the relief of severe discomfort or distress within 30 minutes	• Severe hypertension • Moderately severe blood loss any cause • Moderate shortness of breath • SAO_2 90–95% • BSL > 16 mmol/L • Seizure (now alert) • Any fever if immunosuppressed (e.g. oncology patient, steroid prescription) • Persistent vomiting • Dehydration • Head injury with short LOC—now alert • Moderately severe pain—any cause—requiring analgesia • Chest pain likely non-cardiac and moderate severity • Abdominal pain without high-risk features—moderately severe or patient age > 65 years • Moderate limb injury—deformity, severe laceration, crush • Limb—altered sensation, acutely absent pulse • Trauma—high-risk history with no other high-risk features • Stable neonate • Child at risk of abuse/suspected non-accidental injury

(continued)

TABLE 52.1 The Australasian Triage Scale (continued)

ATS CATEGORY	RESPONSE	DESCRIPTION OF CATEGORY	CLINICAL DESCRIPTORS (INDICATIVE ONLY)
			• Behavioural/psychiatric: — very distressed, risk of self-harm — acutely psychotic or thought disordered — situational crisis, deliberate self-harm — agitated/withdrawn — potentially aggressive
Category 4	Assessment and treatment start within 60 minutes	**Potentially serious** The individual's condition may deteriorate, or adverse outcome may result, if assessment and treatment is not commenced within 1 hour of arrival in ED. Symptoms moderate or prolonged. or **Situational urgency** There is potential for adverse outcome if time-critical treatment is not commenced within 1 hour or **Significant complexity or severity** Likely to require complex work-up and consultation and/or inpatient management or Humane practice mandates the relief of discomfort or distress within 1 hour	• Mild haemorrhage • Foreign body aspiration, no respiratory distress • Chest injury without rib pain or respiratory distress • Difficulty swallowing, no respiratory distress • Minor head injury, no loss of consciousness • Moderate pain, some risk features • Vomiting or diarrhoea without dehydration • Eye inflammation or foreign body—normal vision • Minor limb trauma—sprained ankle, possible fracture, uncomplicated laceration requiring investigation or intervention • Normal vital signs, low/moderate pain • Tight cast, no neurovascular impairment • Swollen 'hot' joint • Non-specific abdominal pain • Behavioural/psychiatric: — Semi-urgent mental health problem — Under observation and/or no immediate risk to self or others
Category 5	Assessment and treatment start within 120 minutes	**Less urgent** The individual's condition is chronic or minor enough that symptoms or clinical outcome will not be significantly affected if assessment and treatment are delayed up to 2 hours from arrival or **Clinico-administrative problems** Results review, medical certificates, prescriptions only	• Minimal pain with no high risk features • Low-risk history and now asymptomatic • Minor symptoms of existing stable illness • Minor symptoms of low-risk conditions • Minor wounds—small abrasions, minor lacerations (not requiring sutures) • Scheduled revisit (e.g. wound review, complex dressings) • Immunisation only • Behavioural/psychiatric: — Known patient with chronic symptoms — Social crisis, clinically well individual

GSC = Glascow Coma Scale; BSL = blood sugar level; PE = pulmonary embolism; AAA = abdominal aortic aneurysm; LOC = level of consciousness

Source: Australasian College for Emergency Medicine (ACEM) (2005). *G24 Guidelines for the Implementation of the Australasian Triage Scale in Emergency Departments.* Revised November 2013. Retrieved from www.acem.org.au/getattachment/d19d5ad3-e1f4-4e4f-bf83-7e09cae27d76/G24-Implementation-of-the-Australasian-Triage-Scal.aspx.

availability of lethal means, male stereotyping and reluctance to seek help. These issues are often exacerbated by variations in mental health services in these areas (Jones et al., 2015; Kennedy et al., 2014; Hirsch & Cukrowicz, 2014).

The *2015 Australian National Drug Strategy Household Survey* (AIHW, 2013) revealed that people living in remote and very remote areas were more likely to smoke, drink at risky levels and use cannabis and methamphetamines. These data provide essential background knowledge for nurses working in these areas, to ensure that they possess the critical-thinking ability to assess each individual situation. The data may be relevant to opportunistic intervention and treatment, early detection and accurate monitoring and management of symptoms.

TYPES OF QUESTIONING In emergency situations, specific closed questioning is often appropriate. For example, when the person is short of breath and complaining of pain, the nurse should use closed questions to extract the relevant information in the shortest time (see Box 52.1 for examples).

Open questions require the person to respond in more than one word, allowing greater depth of information to be obtained (see Box 52.2). Open questions are the style predominantly used for mental health assessments where in-depth information is required in order to gain a comprehensive understanding of the presenting problem or issue. Try not to ask two questions as one, such as 'What car were you driving and was it yours?' These types of questions are confusing and should be asked separately.

BOX 52.1 Closed questions

- Where is the pain?
- On a scale of 1–10, how much does it hurt?
- Does your arm hurt?
- Does it hurt when you breathe in?
- Does it hurt when you breathe out?
- Is the pain any better now?
- Have you had this pain before?

BOX 52.2 Open questions

- Can you describe what the pain is like?
- Tell me what were you doing when this pain started?
- What have you done since the pain started?
- Which types of pain relief have you tried?

In all aspects of nursing care in all settings—metropolitan, regional, rural or remote—nurses must be proficient communicators to gain relevant information for care planning and to establish a supportive relationship with the person, their family and/or their carers. In some cases, if the person or their significant other is distressed, the presence of the nurse to listen and provide support through silent empathy is invaluable.

Establishing boundaries

As previously mentioned, nurses working in small regional, rural and remote communities are less anonymous than their urban counterparts, a consequence of which may be that a more considered commitment to the protection of each person's privacy and confidentiality is required. Personal communication can be either a barrier or a bridge in these communities. One of the most important factors in establishing a professional therapeutic relationship is that of trust. The person must feel comfortable discussing their personal information and health history with the nurse providing care. This can be difficult in small communities where the nurse may know the person through social and community interactions. While it is also possible for this to occur in larger towns or cities, it is far more likely to occur in communities where the population is smaller and the possibility of crossing paths in various roles is greater. For example, the person may be the manager of the local bank which holds the mortgage over the nurse's property. As in all professional interactions, the person requires reassurance that they will be treated with dignity, integrity and professionalism in the course of receiving healthcare—expectations which may be intensified and become challenging in smaller communities. It is thought that some people in small communities have sought healthcare away from their home areas to minimise the chance of knowing their care provider socially. Therefore, it is imperative that the nurse is able to reassure the person by verbal and nonverbal means during any interactions that they will uphold confidentiality at all times.

Subjective data on individuals are obtained through a range of clinical approaches which are each contingent upon the clinical context specific to the person. Both over-familiarity and failure to acknowledge the person may be perceived as equally offensive. The degree of familiarity will depend on each individual and the type of healthcare they require. Nurses will have to use their judgment and exercise it for each individual circumstance. One way to approach this is for the nurse to actually ask the person what degree of familiarity they would like. An example of this would be: 'If I see you in the shops how would you like me to behave? Do you want me to say hello or would you prefer I just went about my business without acknowledging you?' Establishing mutually agreed upon boundaries will prevent uncomfortable future situations.

The type and manner of the interview will depend largely on the information required. If the person is already known to the nurse, the beginning phase may be briefer. In many cases, it may be advisable to approach the interaction as if beginning a new relationship. Gaining the relevant information should not be influenced by previous interactions because each occasion where the person is seeking healthcare is a new and slightly different occasion. Closing the interview may involve reference to seeing the person in the community, but should clearly reinforce the respect for confidentiality.

Teleconsultations/videoconsultations

The *Millennium Development Goals Report 2015* (United Nations, 2015) states that with regard to achieving the millennium goals related to the improvement of mortality and morbidity statistics, the global use of mobile communication services has been growing at a fast rate and is seen to be a major contributor to the success of the initiative. Access to information has the ability to increase the knowledge of individuals and communities, leading to improved, informed decision making and, ultimately, improved health outcomes—empowerment through knowledge. The objectives of these goals continues with 17 new sustainable goals being implemented to be developed by 2030 (United Nations, 2015).

In modern Australia, the availability of telecommunications services and the internet is growing. The introduction of the Australian National Broadband Network (NBN) is assisting to bridge the gap of telecommunication access. However, in many rural and remote areas these services are limited and unreliable. The ability to phone in or dial in to include a specialist in the assessment of, or discussion with, a person in a regional, rural or remote area has the potential to be an immensely valuable tool. Expert opinion remains divided, with some people viewing **telehealth** as a time-efficient, labour-efficient and cost-effective method of delivering health services to the bush, for which long-term investment in the system is extremely worthwhile. The monetary savings can include the cost of a videolink instead of the cost of the person and carer travelling to the service or their appointment, and their accommodation. That said, patient transport schemes do not cover all expenses. They merely subsidise the person's costs and most people who have to travel to access healthcare are financially disadvantaged. The humanitarian savings of a reliable system are immeasurable: the assumption is that the person is not removed from their home area; they remain with family, friends and support networks; and they do

not have the burden of finding someone to care for family, property, animals or business for the period of their absence.

From a nurse's perspective, having access to clinical expertise while geographically isolated is reassuring. An example of this is the access to emergency mental healthcare in rural and remote emergency departments in rural Australia. Staff at rural locations have access to a telepsychiatry program to assist with emergency mental health issues (Saurman, Kirby & Lyle, 2015).

The introduction of telehealth to provide specialist advice to people living in regional, rural or remote areas of Australia has been quite an achievement. This service facilitates specialist care for an individual so that they do not have to leave their local area. A **referral** to a specialist can be from a nurse or medical practitioner, midwife, practice nurse or Aboriginal or Torres Strait Islander Health Worker on behalf of a medical practitioner (Department of Health, 2015). Among other potential benefits, telehealth enhances a sense of professional support for nurses and other health professionals in regional, rural and remote settings.

The provision of professional support not only provides timely guidance but may well impact on the recruitment and retention issues surrounding nursing in regional, rural and remote areas. This is especially so as nurses in these areas report a perception of professional isolation as a contributing factor to leaving these roles (Bennett et al., 2012). The provision of professional support is extended to include online access to professional databases for current publications and best practice guidelines. This access relies heavily on the motivation of the practitioner to access, interpret and adopt current practice standards, which is more difficult for nurses who are already mentally, emotionally and physically fatigued. Many professional groups and colleges now offer online professional development opportunities for nurses in a vast range of specialties. However, the lack of reliability of access and the potential cost associated with such programs may preclude use by some regional, rural and remote nurses.

The uptake of telehealth has been a major boost for people living in regional, rural and remote locations. The ability to access specialist health professionals in metropolitan and city locations is helpful for people suffering health conditions as well as the health professionals situated in those areas. Emergency mental health, rheumatoid arthritis and oncology clinic consultations are just some examples of effective service provision by telemedicine (Saurman, Kirby & Lyle, 2015: Sabesan et al., 2014: Roberts et al., 2012). The Royal Flying Doctor Service (RFDS) also provides medical consultation to people living or travelling in regional, rural and remote Australia (RFDS, 2012a).

Liaison and advocacy

Nurses working in regional, rural and remote areas of Australia must possess a high standard of interpersonal skills and be able to communicate effectively with their community, nursing colleagues, members of the interdisciplinary team, local health service providers, tertiary referral centres, retrieval teams and other organisations involved in the transfer of people in their care (e.g. the RFDS). In remote Indigenous communities, local health workers form the backbone of the health service, integrating community knowledge, cultural knowledge and health knowledge into individualised person-centred care. It is therefore imperative that nurses in these areas work closely with other health workers to ensure that the healthcare provided is culturally safe and acceptable to the community.

Referral and retrieval

Preparing a person for referral to a metropolitan or city health service is a part of the daily routine for regional, rural and remote nurses, especially when dealing with acute illness or trauma.

Public hospitals in central Australia are noticeably absent, but the RFDS is notable for its broad range of services throughout Australia, including the sparsely populated areas. The RFDS began in 1928 when Reverend John Flynn initiated a flying medical service to isolated inland communities (RFDS, 2012a). The service has continued to grow and is funded by the Australian Government to provide aeromedical transport and healthcare services to people living in regional, rural and remote areas of Australia. The RFDS provides a 24-hour medical evacuation service staffed by highly skilled flight nurses and medical practitioners, primary and community healthcare clinics. It also provides remote consultations via phone or radio by medical practitioners or nurses, and supplies medical chests for emergency use (RFDS, 2012b). Although access to services in regional, rural and remote regions is improving due to the National Strategic Framework for Rural and Remote Health, the RFDS can provide invaluable support for practitioners where there are gaps in service provision. In many cases, the RFDS provides essential lifelines for the practitioners and communities (Department of Health, 2012).

Correctly following transfer and retrieval guidelines and policy is extremely important to ensure that the process proceeds smoothly. Such professional actions may not be noticeable until after the transfer is complete. All centres have criteria for transfer, clearly articulated in policies and procedures, often with quick reference guides for use in emergent situations. The process usually follows a flowchart or document with a 'checkbox' format. The accurate handover of relevant information is essential to the provision of appropriate care during the transfer and on arrival at the destination. In some cases, the nurse completing the checklist will be the nurse escorting the person to the referral centre. However, in other instances, the transfer will be by outside organisations such as ambulance services, emergency services or the RFDS. Nurses working in these areas must be fully aware of these transfer procedures prior to an emergency, as it is not the right time to be reading policies when dealing with a critically ill or injured person who requires immediate attention.

Discharge planning and continuum of care

When providing nursing care to a person in any health facility in any community, it is imperative that **discharge planning** is incorporated into all aspects of person-centred care. Commencement of discharge planning at the initial point of contact is a fundamental nursing consideration, whether the person presents with a chronic condition or acute illness, or as a result of trauma. The role of the nurse is to assist the person to return to their home having regained their former level of independence if possible, or having achieved an optimal level of independence or mental health recovery resulting from their altered physical, psychological or cognitive ability.

Therefore, the discharge of a person within a regional, rural or remote community or back to a rural or remote community from an urban setting must be done proficiently and acknowledge the individuality of the person and their needs. It must also take into account the resources and support available in their community. If the discharge process is not performed appropriately, the chance of readmission is increased by limited availability of follow up, limited contact with health professionals and limited access to healthcare facilities.

Provision of care for the person from a regional, rural or remote area

In all hospitals in every metropolitan or city centre in Australia, nurses will be providing care for people who have had to travel, sometimes long distances, for treatment. These people have a unique set of challenges for inpatient treatment, upon discharge and for the **continuum of care**. The following considerations relate to nursing and discharging people who are from regional, rural and remote areas.

Considerations

The person is likely to feel isolated and lonely. Their support systems are often hundreds of kilometres away, which will impact on their mental health and their ability to heal. When the person is from a regional, rural or remote area, discharge planning becomes even more significant in the overall care of the individual. When preparing to transfer a person back to their home area, or to discharge them to travel home, nurses must ensure that they take all aspects of transport into consideration (see Box 52.3).

The financial costs associated with transport must be incorporated into care planning and discharge planning. All states and territories have implemented a state-specific model of patient travel subsidy, identified by different titles according to whichever state or territory is the place of origin. In contemporary healthcare, with the continuous state of reduced bed availability, it is not uncommon for people to be transferred across jurisdictional borders to receive specialised medical care.

In some cases, the person may be required to fund their return home and claim expenses at a later date. Claiming back the costs may be time consuming and exhausting for a person who may still be recuperating from significant illness or injury. Therefore, the cost of transport becomes increasingly important. New South Wales has the Isolated Patients Travel and Accommodation Assistance Scheme (IPTAAS) (NSW Government, 2015a). This scheme is for people who have to travel significant distances to access specialist medical treatment which is not available locally (NSW Government, 2015a). Many people from the Northern Territory are transported to Adelaide for tertiary-level healthcare. The cost of getting back home is supported through the Patient Assistance Travel Scheme (PATS). This scheme or others like it are available to all people living in rural and remote Australia in each state and territory (Department of Health, 2014b). The cost of transport for a carer is often covered by the transport scheme, but this can be variable. If there is more than one support person, individuals may be required to pay the full costs. For example, this may be a problem if the person has a great distance to travel, is required to change modes of transport at some stage during the journey and the carer is not physically able to assist. In these cases, there is an increased need for the assistance of another support person or carer. In the case of the transfer of a child, there may be two parents to accompany the child, one of whom will travel with the child regardless of transport and the remaining parent who will need to organise their own transport and perhaps that of other children returning home. This may also occur when an older parent is travelling with their spouse and an adult child is required to be a further support person. There are support groups or volunteer organisations that can assist with emergency funding in times of financial difficulty for people and their families. Transport for treatment or returning home from treatment is deemed eligible for this purpose in many instances.

The person returning home will also need to have adequate supplies of medications and medical supplies, as access to a supplier may be limited (National Rural Health Alliance Inc., 2014). Contact should also be made with the pharmacy in the person's local area to give sufficient time for ordering and receiving supplies.

BOX 52.3 Considerations when discharging or transferring a person

Transport availability

What type of transport is available?
- Private motor vehicle
- Aircraft (commercial)
- Aircraft (specialist provider)
- Bus
- Train
- Marine transport (some island communities are only accessible by water)

How frequently does this service run?
- Some services run only twice a week or weekly
- On demand

Will this cost money?
- How much?
- Who will pay?

Is the person able to travel via this mode of transport?

Can they spend long periods of time sitting?
Are they able to mobilise as necessary?
Can they board the transport?
Do they require a stretcher/lift to board?
If travelling by air, can the person tolerate the pressure changes?
Can this mode of transport accommodate the person's needs?

Carer support

Can the person travel unaccompanied?
Will the person require a nursing or medical escort?
Can the carer/escort travel with the person?

In many regional, rural and remote areas of Australia, residents and services are quite often restricted by seasonal weather patterns. For example, in the northern areas of Australia, the wet season between November and March can significantly impact on the mobility of the population and access to services. The coming of the rains usually brings great anticipation to the residents of the outback, especially those reliant on the water for crops, stock, replenishing water supplies and rejuvenating the bush flora. However, while the rains are essential to the lifeblood of the community, the associated flooding or limiting of access can range from being mildly frustrating to intensely problematic (see Figure 52.4). The lack of access can affect the ability of the person requiring healthcare to access the relevant services, and it can limit the ability of the health service to discharge the person.

Community care

Hospitals are fast becoming places for people who are treated for acute illnesses and conditions. Many people (under 65 years of age, or Aboriginal and Torres Strait Islander people under 50 years of age) are now treated at home for conditions that restrict their normal daily living or who are living with a disability. There are also services for frail older people with dementia, those who are financially disadvantaged or those in remote or isolated areas still living in their home (NSW Government, 2015b). There are a range of resources available through community care services such as in-home services, community-based services, clinical services, respite, counselling and carer support. People who are having difficulty with their daily activities of living and are at risk of losing their independence are eligible for these services.

FIGURE 52.4 ■ Rain is necessary to survival but it can isolate people and communities. Children often make the most of being restricted to the home area

Source: Adele Baldwin.

In 2010 the Productivity Commission launched a public enquiry regarding long-term disability care and support services. The National Disability Insurance Scheme (NDIS) was established in 2011 when COAG agreed to the need for reform for disability services (Queensland Government, 2015). The service provides referrals and support services for people with a disability so that they can achieve their goals and be in a position to enjoy their lives (NDIS, 2015).

TRANSLATION TO PRACTICE The perceptions of people living in regional, rural and remote areas

The reduced level of services available for residents of regional, rural and remote communities who required cancer treatment was the subject of a study by Moorin et al. (2012). The study highlighted that, unbelievably, some older people who live in remote areas of Western Australia accept that services are not available to them due to isolation, and that cancer is part of growing older. Of particular concern is evidence to support that up to 12% of Indigenous Australians living in regional rural and remote areas have difficulty with transport to cancer services compared with only 4% of non-Indigenous Australian people (Moorin et al., 2012). This discrepancy has also been highlighted for mental health services for older people living in rural areas in South Australia (Henderson et al., 2014). The difficulties associated with travel for medical consultation or for long-term treatment highlight the need for continuity of care across health services and the need for consideration of this to be incorporated into the care received in the referral centre and the support services available.

IMPLICATIONS FOR NURSING PRACTICE

Research projects such as these provide significant evidence of the importance of both physical and psychosocial support to the experience of, and recovery from, serious illness. The provision of support measures adapted for use in regional, rural and remote areas is not insurmountable.

The difficulties associated with living in regional, rural and remote areas are exacerbated in times of extreme vulnerability related to serious illness. The role of the nurse can impact positively and result in improved quality of life for people and their families.

CRITICAL THINKING IN PERSON-CENTRED CARE

1. Using your current knowledge about holistic person-centred care, how can a perceived lack of psychosocial support influence the person's response to treatment?
2. As a nurse working with people in this or similar situations, what are some strategies you could implement to meet the psychosocial needs of the person and their families?
3. People in these situations require significant support from their local community, but confidentiality is often a concern. Can you identify some community-based initiatives that would contribute to the overall wellbeing of these people?

CHAPTER HIGHLIGHTS

- The formal acknowledgement of the specialised nature of regional, rural and remote nursing is driving the adoption of greater clinical responsibility and advanced practitioner roles.
- Community-driven healthcare addressing the needs of the community, as identified by the community, is a key feature of healthcare provision in regional, rural and remote areas.
- Equity in access to quality healthcare in a timely manner is the foundation for improving health status in regional, rural and remote communities.
- Health promotion, including early detection and prevention strategies, is a vital component in regional, rural and remote healthcare provision.
- Incorporating rurality into the provision of nursing care is not the sole domain of the regional, rural and remote nursing workforce.
- Factors impacting on the continuum of care for people living in regional, rural and remote areas must be addressed within the care and management provided by all nurses, regardless of location.

CONCEPT CHECK

1 When triaging a person, the primary survey includes:
1. rescue, retrieval and response
2. assessment of danger, response, send for help, airway, breathing, circulation, disability, exposure
3. calling for immediate transfer
4. assessment of available resources

2 The 2013 National Drug Strategy Household Survey showed alcohol consumption at which level for people living in regional, rural and remote areas?
1. low
2. moderate
3. moderate–high
4. risky–high risk

3 The considerations for discharge planning for people from a regional, rural or remote area:
1. are the same as those for all people regardless of location
2. include access to follow-up care and support services
3. include the assumption that the person will return home by the same means as they arrived
4. are the domain of the home health service

4 The challenges faced by regional, rural and remote communities in accessing healthcare:
1. are driven only by economic forces
2. are contingent upon the local weather at the time
3. are the same as those faced by all communities in Australia
4. represent a multi-level, multifaceted integration of diverse influences

5 Community engagement with rural and remote health services is vital because:
1. the community should like whoever is working for them
2. it makes the people feel better even though the health service knows best
3. the community will vote for the government that gives the most money
4. the sustainability of a service depends on community involvement

6 Three of the five principles of working with Indigenous people are:
1. reciprocity, respect, equality
2. spirituality, respect, equality
3. economics, culture, demographics
4. spirituality, culture, demographics

7 Nurses working in regional, rural and remote areas are predisposed to burnout as a result of:
1. community support
2. the opportunity to develop a broad range of clinical skills
3. the building of professional relationships with a smaller group of co-workers
4. longer work hours because the available resources are limited

8 Establishing and maintaining a therapeutic relationship with a person is:
1. easier in a small community because the nurse knows everyone already
2. more difficult in a small community where everyone knows everyone else
3. easier in a small community because the patients are the same ones all the time
4. more difficult in a small community because nurses cannot ethically provide care for people they already know

9 Clinical competency in rural and remote areas is:
1. directly linked to all domains of the NMBA *National Registered Nurse Standards for Practice (2016)*
2. directly linked to all domains of the National Health and Medical Research Council guidelines
3. not very important because all of the high-level cases are transferred to larger centres
4. defined by a specific set of regional, rural and remote competencies

UNIT 14 BUILDING CLINICAL COMPETENCE

Special topics in medical–surgical nursing

CASE STUDY

A Registered Nurse with 2 years' postgraduate experience commenced working at a small rural hospital 2 weeks ago. This is her second afternoon shift in charge of the hospital's 10 beds, of which five are occupied by long-term residents. A very experienced Enrolled Nurse is working alongside her and has been a great source of advice and information on where to find things and who to contact.

The dreary day outside has suddenly turned violent with gale-force winds, intermittent hail and torrential rain. The lights flickered into a brief moment of total darkness before the hospital generators kicked in. The ageing phone system is not working, so it appears that the Registered Nurse and the Enrolled Nurse are isolated at this time.

At first the knock on the door sounds like trees or doors banging in the wind, but when the Registered Nurse goes to investigate, there are three young men at the door in various states of distress and with obvious physical injuries. One of the young men appears to have a head injury, is being held up by his mates and is losing consciousness as the nurse watches. The Registered Nurse calls out to the Enrolled Nurse who brings the trolley to transport the man into the assessment area. The man with the head injury is now not responding to verbal commands and requires assistance to maintain his airway. As the communication lines are down, and the man's mates are injured, the Enrolled Nurse runs to the nearby doctor's residence to request medical assistance.

Critical thinking questions

1. If you were the Registered Nurse in this situation, how do you think you would react?
2. How would you ensure that you are still working within your scope of practice?
3. What are some of the ethical considerations of this case study? Does this constitute a professional dilemma? How did you come to this conclusion?
4. What do you think are some of the contributing factors to the above decisions being made?
5. If you think that this is not the right way to address this situation, what could the nurses have done differently?

CASE STUDY 2

Maryanne Freeman, aged 69 years, and her husband James, 72 years, prepared to travel from their home in Remoteville to the nearest metropolitan hospital in Regionalton, where Maryanne is to undergo removal of a cataract and implantation of an intraocular lens to her right eye. Maryanne has a history of type 2 diabetes and osteoarthritis. James has a history of pacemaker insertion and congestive cardiac failure, and he and Maryanne manage independently. The couple are fortunate that the RFDS clinic run is able to transfer them to Regionalton. While Maryanne is hospitalised, James is able to stay in hospital accommodation.

The operation goes smoothly and Maryanne remains as an inpatient for 3 days postoperatively. Maryanne is seen by the ophthalmic surgeon on the third morning and is cleared for discharge. The attending nurse provides education to both Maryanne and James, instructing them on how to instil eye drops, the need for Maryanne to cover her eyes at night and the need to continue wearing dark glasses. James becomes concerned and asks the nurse how they will get back home. The nurse contacts the hospital social worker who books two bus tickets for the journey and a taxi voucher for transfer from the hospital to the bus depot. James then asks if they could go back with the RFDS as the road journey is a 10-hour trip and he is concerned that Maryanne cannot sit that long on the bus. The social worker does not think that returning with the RFDS is possible. As the bus was to depart at 7 am, James became quite anxious that they would miss it and that they would need to leave the hospital at 6 am before Maryanne had had breakfast. The pharmacy organised discharge medications the night before.

The bus departed at 7 am and the couple endured the 10-hour journey home.

Critical thinking questions

1. What are some of the practical concerns with this case study?
2. Were James's concerns valid and/or acknowledged?
3. Was the discharge planning individualised for Maryanne?
4. Can you identify any other considerations the nurse and the social worker should have included in their provision of care?

APPENDIX STANDARD PRECAUTIONS

Standard precautions are safe work practices that are able to be applied to all patients regardless of their known or presumed infectious status. Standard precautions are minimum requirements for the control of infection in all settings and all situations, including those where a high risk of infection transmission exists, and are designed to protect both patients and healthcare workers.

Standard precautions comprise the following measures:

- handwashing
- use of appropriate personal protective equipment (PPE)
- immunisation of healthcare workers
- use of aseptic technique to reduce patient exposure to microorganisms
- management of sharps, blood spills, linen and waste to maintain a safe environment
- routine environmental cleaning.

Standard precautions apply to (1) blood; (2) all body fluids, secretions, and excretions except sweat, regardless of whether or not they contain visible blood; (3) non-intact skin; and (4) mucous membranes. These precautions are specifically designed for hospitals; however, they may also be implemented in extended and long-term care facilities, and to a more limited extent in providing home care or in other community-based care settings.

Handwashing

Handwashing is the single most important strategy to reduce the risk of infection. Handwashing comprises mechanical activity, use of soap and water, rinsing and drying to reduce the number of microorganisms on hands.

Wash hands with soap and water when visibly dirty or contaminated with proteinaceous material, or visibly soiled with blood or body fluids. An alcohol-based hand rub can be used for routine hand antisepsis in clinical situations if hands are not visibly soiled.

Handwashing should occur:

- before and after having direct contact with patients
- after removing gloves
- before handling an invasive device for patient care, regardless of whether or not gloves are used
- after contact with body fluids or excretions, mucous membranes, non-intact skin, or wound dressings
- if moving from a contaminated body site to a clean body site during patient care
- after contact with inanimate objects (including medical equipment) in the immediate vicinity of the patient.

Gloves

Gloves protect skin from direct contamination with blood and body fluids. The use of gloves within a healthcare setting is recommended to (a) prevent microorganisms that may be infecting, carried or present on healthcare workers' hands from being transmitted to patients and from one patient to another; and (b) to reduce the risk of transmission of an infection from the patient to the healthcare worker. The following guidelines apply:

- Gloves are not a substitute for handwashing.
- Hands should always be washed following glove removal.
- Gloves should be changed between patients, when punctured or torn, and between different procedures on the same patient.
- Gloves are not to be washed or disinfected between patients.

Wear clean, non-sterile gloves when touching blood, body fluids, secretions, excretions and contaminated items. Sterile gloves should be worn for all sterile procedures. Gloves should also be worn for all invasive procedures such as performing venipuncture or other vascular or surgical procedures. Gloves should always be removed promptly after use, and hands should always be washed immediately after the removal of gloves.

Mask, eye protection, face shield

When a splash or spray to the face is anticipated, both protective eyewear and a fluid-repellent surgical mask should be worn, or a full-face shield. Eye protection should always be used during procedures that have the potential to splash or spray the face. These should be able to be cleaned routinely and when visibly soiled.

A fluid-repellent surgical mask should be worn in conjunction with eye protection when the potential exists for splashes or sprays to the face. Masks should always be removed and discarded when the procedure is complete or if the mask becomes wet or visibly soiled.

Gown

Wear an unsterile gown or plastic apron (clean, disposable) to protect your skin and prevent soiling of clothing when there is potential for contamination with blood or body fluids, secretions or excretions. Remove soiled gowns promptly, washing your hands immediately after gown removal. Gowns should always be changed between patients.

Equipment

Handle used patient-care equipment that is soiled with blood, body fluids, secretions and excretions in a way that prevents exposing your skin and mucous membranes, contaminating your clothing and transferring microorganisms to other patients or environments. Ensure that reusable equipment is cleaned and appropriately reprocessed according to the facility's guidelines before using for the care of another patient.

Environmental control

Follow hospital procedures for routine care, cleaning and disinfecting environmental surfaces, beds, bed rails, bedside equipment and other frequently touched surfaces. Routine environmental cleaning of healthcare facilities is required to minimise the number of microorganisms in the environment. Microorganisms are unable to multiply on clean, dry surfaces.

Linen

All used linen should be handled with care to avoid dispersion of microorganisms into the environment and to avoid contact with clothing. Appropriate PPE should be used during the handling of soiled linen. Linen soiled with body fluids or substances should be placed into leak-proof laundry bags for safe transport. Hands should always be washed following the handling of used linen.

Occupational health and blood-borne pathogens

Contaminated sharps pose the greatest risk to healthcare workers of exposure to blood-borne viruses. They should be handled with due care.

Sharps handling and disposal

- All staff should be educated with regard to the safe use, handling and disposal of sharps.
- People using a sharp object are responsible for safely disposing of the item, preferably directly at the point of use. The task should not be delegated.
- Contaminated sharps should not be broken or bent, removed from disposable syringes prior to disposal, or passed by hand between healthcare workers.
- Avoid re-sheathing and passing needles; utilise safety devices—for example, retractable-needle/syringes, blood-taking devices.
- In the case of inappropriately disposed sharps, a sharps container should be taken to the location, the sharp handled and disposed of in a manner to avoid injury, and hands washed following disposal. Sharps should be disposed of in a labelled, puncture-resistant container that conforms to Australian Standards specifications.

Patient placement

Place patients who contaminate the environment or who do not (or are not expected to) assist in maintaining appropriate hygiene or environmental control (e.g. an ambulatory, confused patient with faecal incontinence) in a private room.

GLOSSARY

abrasion Partial-thickness denudation of an area of integument, generally resulting from falls or scrapes.

absence seizure (petit mal seizure) A type of generalised seizure characterised by a sudden brief cessation of all motor activity accompanied by a blank stare and unresponsiveness.

accommodation The ability of the eye to adjust to variations in distance.

achalasia Absence of peristalsis of the oesophagus and high gastro-oesophageal sphincter pressure resulting in dilation and loss of tone in the oesophagus.

acidosis The condition in which the hydrogen ion concentration increases above normal (reflected in a pH below 7.35).

acid A substance that releases hydrogen ions in solution.

acne Disorder of the pilosebaceous (hair and sebaceous gland) structure, resulting in eruption of papules or pustules.

acoustic neuroma (schwannoma) Benign tumour of cranial nerve VIII.

acquired immune deficiency syndrome (AIDS) A specific group of diseases or conditions that are indicative of severe immunosuppression related to infection with the human immunodeficiency virus.

acquired immunity Immunity developed after exposure to a pathogen. See *active immunity*.

acromegaly Meaning literally 'enlarged extremities', this is a condition resulting from excessive growth hormone secretion during adulthood.

actinic keratosis Also called senile or solar keratosis, this is an epidermal skin lesion directly related to chronic sun exposure and photo damage.

active immunity Production of antibodies or development of immune lymphocytes against specific antigens.

active sense of self The development of meaning, purpose and direction in one's life.

active transport Movement of molecules across cell membranes and epithelial membranes against a concentration gradient; requires energy.

acute care The provision of care for conditions of rapid onset that last a relatively short time and are self-limiting.

acute coronary syndrome (ACS) A general term used to describe the effects of coronary heart disease, including angina and myocardial infarction.

acute gastritis A benign, self-limiting disorder associated with ingestion of gastric irritants such as aspirin, alcohol, caffeine or foods contaminated with certain bacteria.

acute illness An illness that occurs rapidly, lasts for a relatively short time and is self-limiting.

acute inpatient unit A ward in a mental health facility that admits people who are generally very mentally unwell.

acute kidney failure Abrupt onset of kidney failure, often reversible.

acute kidney injury (AKI) Kidney injury characterised by a rapid onset of symptoms that are potentially reversible with prompt intervention that addresses the initial cause of the injury.

acute lymphoblastic leukaemia (ALL) Abnormal proliferation of lymphoblasts in the bone marrow, lymph nodes and spleen; the most common type of leukaemia in children and young adults.

acute myeloblastic leukaemia (AML) Uncontrolled proliferation of myeloblasts (*granulocyte precursors*) and hyperplasia of bone marrow and the spleen; the most common acute leukaemia in adults.

acute myocardial infarction (AMI) Necrosis (death) of myocardial cells.

acute pain Usually temporary, localised and of sudden onset; it lasts for less than 6 months and has an identifiable cause, such as trauma, surgery or inflammation.

acute renal failure See *acute kidney failure*.

acute respiratory distress syndrome (ARDS) Non-cardiac pulmonary oedema and progressive refractory hypoxaemia.

acute tubular necrosis (ATN) A syndrome of abrupt and progressive decline in tubular and glomerular function.

adaptive immune response A specific and systemic immune response initiated by and directed against particular antigens.

addiction Dependency on a drug, which can be either physical or psychological.

Addisonian crisis A life-threatening response to acute adrenal insufficiency; occurs in about 25% of patients.

Addison's disease A rare endocrine disorder wherein the adrenal glands produce insufficient steroid hormones.

adrenal crisis A constellation of symptoms that indicate severe adrenal insufficiency caused by insufficient levels of the hormone cortisol.

advance directive Also called a *living will*, this is a document in which a client formally states preferences for healthcare in the event that he or she later becomes mentally incapacitated and names a person who has durable power of attorney to serve as a substitute decision maker to implement the patient's stated preferences.

aesthetic surgery See *cosmetic surgery*.

affect Refers to the experience of feeling or emotion.

afterload The force the ventricles must overcome to eject their blood volume; the pressure in the arterial system ahead of the ventricles.

agnosia The inability to recognise one or more subjects that were previously familiar; agnosia may be visual, tactile or auditory.

agranulocytosis Severe neutropenia, with less than 200 cells/μm.

albuminuria Albumin (protein) in the urine.

alcohol An organic compound obtained by substituting a hydroxyl group for a hydrogen on a hydrocarbon.

alcoholic cirrhosis (Laënnec's cirrhosis) The end result of alcoholic liver disease.

alkalis Substances that accept hydrogen ions in solution.

alkalosis The condition where the hydrogen ion concentration decreases below normal (reflected in a pH above 7.45).

alleles Different forms of a gene or DNA occupying the same place on a pair of chromosomes; an allele for each gene is inherited from each parent.

allergy A hypersensitivity response to environmental or exogenous antigens.

allodynia Pain due to stimulus that normally does not evoke pain.

allografts Grafts between members of the same species but who have different genotypes and HLA antigens. See also *homograft*.

alopecia Loss of hair; baldness.

Alzheimer's disease (AD) A form of dementia characterised by progressive, irreversible deterioration of the general intellectual functioning.

amenorrhoea Absence of menstruation.

amphetamine A psychostimulant drug that is known to produce increased wakefulness and focus in association with decreased fatigue and appetite.

amputation Partial or total removal of a body part.

amyotrophic lateral sclerosis (ALS) Progressive, degenerative neurological disease characterised by weakness and wasting of the involved muscles, without any accompanying sensory or cognitive changes; also called *Lou Gehrig's disease*.

anaemia An abnormally low number of circulating red blood cells, haemoglobin concentration or both.

anaesthesia State produced by medications given intravenously, intraspinally, subcutaneously or by inhalation to create temporary partial or total loss of sensation and consciousness in a person for invasive procedures such as surgery or painful diagnostic tests.

analgesic A medication that reduces or eliminates the perception of pain.

anaphylactic shock Shock resulting from a widespread hypersensitivity reaction (called *anaphylaxis*). The pathophysiology in this type of shock includes vasodilation, pooling of blood in the periphery and hypovolaemia with altered cellular metabolism.

anaphylaxis An acute systemic type I response that occurs in highly sensitive persons following injection of a specific antigen.

anaplasia The regression of a cell to an immature or undifferentiated cell type.

anasarca Severe, generalised oedema.

androgens Hormones synthesised in the testes, ovaries and adrenal cortex that promote expression of male sex characteristics.

anergy Inability to react to specific antigens.

aneurysm Abnormal dilation of a blood vessel, commonly at a site of a weakness or tear in the vessel wall.

angina pectoris (angina) Chest pain resulting from reduced coronary blood flow that causes a temporary imbalance between myocardial blood supply and demand.

angioma (haemangioma) Benign vascular tumour.

anion gap The difference between the sum of two measured anions, chloride and bicarbonate, and the principal measured cation, sodium.

ankylosing spondylitis A chronic inflammatory arthritis that primarily affects the axial skeleton, leading to pain and progressive stiffening and fusion of the spine.

anorexia Loss of appetite.

anorexia nervosa An eating disorder characterised by a body weight less than 85% of expected for age and height and an intense fear of gaining weight.

anorgasmia Absence of orgasm.

anosmia Inability to smell.

anthropometric measurements Measurement of height, weight, triceps skin folds and midarm circumference.

antibodies Immunoglobulin molecules that bind with an antigen to inactivate it.

antibody-mediated (humoral) immune response Activation of B cells to produce antibodies to respond to antigens such as bacteria, bacterial toxins and free viruses.

anticipatory grieving A combination of intellectual and emotional responses and behaviours by which people adjust their self-concept in the face of a potential loss.

antigen A substance capable of evoking a specific immune response; usually a protein, which the body recognises as foreign, causing an immune response to be stimulated.

anxiety An unpleasant feeling that is typically associated with uneasiness, apprehension, fear or worry.

aortic valve The semilunar valve between the left ventricle of the heart and the aorta in the heart. It prevents blood from flowing backwards into the ventricle.

aortitis Inflammation of the aorta, usually the aortic arch.

aphasia Defective or absent language function.

apical impulse A normal, visible pulsation (thrust) in the area of the midclavicular line in the left fifth intercostal space. It can be seen on inspection in about half of the adult population.

aplastic anaemia A condition manifested by failure of the bone marrow to produce all three types of blood cells.

apnoea Cessation of breathing lasting from a few seconds to a few minutes.

appendectomy Surgical removal of the appendix.

appendicitis Inflammation of the vermiform appendix.

apraxia The inability to carry out a motor pattern (such as drawing a figure) even when strength and coordination are adequate.

areflexia Lack of normal reflexes.

arrhythmia Abnormal heart rate or rhythm.

arterial blood gas (ABG) A laboratory test used to evaluate acid–base balance and gas exchange.

arteriovenous (AV) malformation A congenital intracranial lesion, formed by a tangled collection of dilated arteries and veins, that allows blood to flow directly from the arterial into the venous system, bypassing the normal capillary network.

arthralgia Joint pain.

arthritis Joint inflammation.

ascites Excess fluid in the peritoneal cavity.

asphyxiation Oxygen deprivation.

asthma Chronic inflammatory disorder of the airways that is characterised by recurrent episodes of wheezing, breathlessness, chest tightness and coughing.

astigmatism A condition that develops with abnormal curvature of the cornea or eyeball, causing the image to focus at multiple points on the retina.

ataxia Uncoordinated, irregular gait and muscle movement; weakness.

atelectasis Collapse of lung tissue following obstruction of the bronchus or bronchioles.

atherosclerosis A form of arteriosclerosis in which deposits of fat and fibrin obstruct and harden the arteries.

ATODS Alcohol tobacco and other drugs services.

atopic dermatitis (eczema) Common inflammatory skin disorder of unknown cause.

atrial kick Delivery of an additional bolus of blood to the ventricles resulting from atrial systole; occurs just prior to ventricular systole.

atrial natriuretic peptide (ANP) A hormone released by atrial muscle cells in response to distension from fluid overload.

aura Sensation preceding generalised seizure activity; may be a vague sense of uneasiness or an abnormal sensation.

auscultatory gap A temporary disappearance of sound between the systolic and diastolic blood pressure.

Australian College of Mental Health Nurses Peak professional college for mental health nurses in Australia.

Australian Organ and Tissue Donation and Transplantation Authority Act 2008 Legislation that requires people to be informed about their options related to organ donation.

autografting Transplanting of the person's own tissue; the most successful type of tissue transplant.

autoimmune disorder Failure of the immune system to recognise itself, resulting in normal host tissue being targeted by immune defences.

autonomic dysreflexia Exaggerated sympathetic response that occurs in people with spinal cord injuries at or above the T6 level.

autosome A single chromosome from any one of the 22 pairs of chromosomes not involved in sex determination (X or Y); humans have 22 pairs of autosomes.

azotaemia Increased blood levels of nitrogenous waste products.

B lymphocytes (B cells) Bursa-equivalent lymphocytes responsible for synthesising humoral antibody.

bacterial vaginosis Non-specific vaginitis.

bactericidal agent Capable of killing an organism without immune system intervention. These include the penicillins, cephalosporins and aminoglycoside antibiotics.

bacteriostatic agent Inhibits the growth of a microorganism, leaving its destruction to the host's immune system.

bacteriuria Bacteria in the urine.

balanced suspension traction Traction in which several forces of pull work in unison to raise and support the person's injured extremity off the bed and pull it in a straight fashion away from the body.

balloon tamponade The application of pressure to stop oesophageal bleeding using an inflatable balloon.

bariatrics The branch of healthcare that deals with the causes, prevention and treatment of obesity. The term *bariatrics* was created around 1965, from the Greek root *bar-* ('weight' as in barometer), suffix *-iatr* ('treatment', as in pediatrics), and suffix *-ic* ('pertaining to'). The field encompasses dieting, exercise and behavioural therapy approaches to weight loss, as well as psychotherapy, pharmacotherapy and surgery.

basal cell carcinoma (BCC) Epithelial tumour that is believed to originate either from the basal layer of the epidermis or from cells in the surrounding dermal structures. These tumours are characterised by an impaired ability of the basal cells of the epidermis to mature into keratinocytes, with mitotic division beyond the basal layer.

basal metabolic rate (BMR) Test to measure the energy used when the body is at rest; rarely used due to the availability of more accurate thyroid tests.

base excess (BE) A calculated value also known as buffer base capacity. Base excess reflects the degree of acid–base imbalance by indicating the status of the body's total buffering capacity.

bases (or alkalis) Substances that accept hydrogen ions in solution.

Bell's palsy (facial paralysis) Disorder of the facial nerve (seventh cranial nerve), characterised by unilateral paralysis of the facial muscles.

benign prostatic hyperplasia (BPH) Enlargement of the prostate gland.

benzodiazepines Minor tranquillisers belonging to the sedative-hypnotic group of drugs that have a CNS depressant effect through action at the gamma aminobutyric acid (GABA) receptor sites.

bereavement The time of mourning experienced after a loss.

bile A greenish, watery solution containing bile salts, cholesterol, bilirubin, electrolytes, water and phospholipids.

biliary colic A severe, steady pain in the epigastric region or upper right quadrant of the abdomen.

binge-eating disorder An eating disorder characterised by recurrent episodes of eating an excessive amount of food during a defined period of time, and a sense of lack of control over eating during binge episodes.

biofeedback An electronic method of measuring autonomic physiological responses, such as brain waves, muscle contraction and skin temperature, and then 'feeding' this information back to the person.

biofilms Polymicrobial microbial communities which proliferate and are encased in a protective glycocalax matrix.

biological terrorism Use of an aetiological agent (disease) to cause harm or kill a population, food and/or livestock.

biomedical model of health A model of health which mainly focuses on biological health determinants and broadly views health as the absence of disease. This model is also known as the medical model.

biopsychosocial model of health The biopsychosocial model of health broadly views health as individual holistic wellbeing.

bioterrorism Use of an aetiological agent (disease) to cause harm or kill a population, food and/or livestock.

biotherapy Treatment that modifies the biological processes that result in malignant cells, primarily through enhancing the person's own immune responses.

bivalving Process of splitting a cast down both sides to alleviate pressure on the injured extremity.

blood clot See *thrombus*.

blood flow The volume of blood transported in a vessel, in an organ or throughout the entire circulation over a given period of time.

blood pressure The tension or pressure exerted by blood against arterial walls.

blunt trauma The type of trauma that occurs when there is no communication from the damaged tissues to the outside environment.

body mass index (BMI) Used to identify excess adipose tissue, BMI is calculated by dividing the weight (in kilograms) by the height (in metres squared, m^2).

bone marrow transplant (BMT) Infusion of bone marrow cells to restore bone marrow function after chemotherapy or radiation; allogeneic BMT uses donor bone marrow cells from a donor; autologous BMT uses the person's own bone marrow.

borborygmi Excessive loud and hyperactive bowel sounds.

botulism A severe, life-threatening form of food poisoning caused by *Clostridium botulinum*.

brachytherapy A type of radiation therapy in which the source of radiation is placed directly into or adjacent to the tumour, a technique that delivers a high dose to the tumour and a lower dose to normal tissue.

bradycardia A heart rate of less than 60 beats per minute.

bradykinesia Slowed movements due to muscle rigidity.

bradypnoea Abnormally low respiratory rate.

brain abscess Infection with a collection of purulent material within the brain tissue.

brain death The cessation of cerebral blood flow with global brain infarction and permanent loss of all brain function.

brain death criteria Clinical signs used to determine whether a comatose person is brain dead.

breakthrough pain A sudden flare or increase in pain despite comfort with or without baseline analgesia.

bronchiectasis Permanent abnormal dilation of one or more large bronchi and destruction of bronchial walls, usually accompanied by infection.

bronchitis Inflammation of the bronchi.

bruit An adventitious sound heard during auscultation; of venous or arterial origin.

buffer A substance that prevents major changes in pH by removing or releasing hydrogen ions.

bulimia nervosa An eating disorder characterised by recurring episodes of binge eating followed by purge behaviours such as self-induced vomiting, use of laxatives or diuretics, fasting or excessive exercise.

burn An injury resulting from exposure to heat, chemicals, radiation or electric current.

burn shock Hypovolaemic shock resulting from the shift of a massive amount of fluid from the intracellular and intravascular compartments into the interstitium following burn injury.

bursitis Inflammation of the bursa.

cachectic The state of very poor health and malnourishment in a person.

cachexia The wasted physical appearance characteristic of cancer and other chronic illnesses. It is characterised by rapid depletion of the body's protein, particularly in skeletal muscle, with less rapid loss of fat.

caffeine A bitter, white crystalline xanthine alkaloid that is a psychoactive stimulant drug.

calculi An abnormal concentration in the body, commonly called a stone; occur in the kidneys, ureters, bladder or urethra.

cancer A family of complex diseases with manifestations that vary according to body system and type of tumour cells involved; marked by uncontrolled growth and the spread of abnormal cells.

cancer (palliative) pain A common condition of people suffering with advanced cancer, it is often persistent and arises from a number of factors.

candidiasis Infection of mucous membranes caused by *Candida albicans*, a yeast-like fungus.

cannabis The general name given to the psychoactive substances found in the marijuana plant, *Cannabis sativa*, the main active constituent being delta 9-tetra-hydrocannabinol (THC).

carbuncle A group of infected hair follicles.

carcinogen Cancer-causing agent.

carcinogenesis The production or origin of cancer.

carcinoma A tumour arising from epithelial tissue.

cardiac arrest Sudden failure of the heart to pump.

cardiac cycle The contraction and relaxation of the heart during one heartbeat.

cardiac index Cardiac output adjusted for body size.

cardiac output (CO) The amount of blood pumped by the ventricles into the pulmonary and systemic circulations in 1 minute.

cardiac rehabilitation A long-term program of medical evaluation, exercise, risk factor modification, education and counselling designed to limit the physical and psychological effects of cardiac illness and improve the person's quality of life.

cardiac reserve The ability of the heart to respond to the body's changing need for cardiac output.

cardiac tamponade Compression of the heart due to pericardial effusion, trauma, cardiac rupture or haemorrhage.

cardiogenic shock Shock that occurs when the heart's pumping ability is compromised to the point that it cannot maintain cardiac output and adequate tissue perfusion.

cardiomegaly Enlargement of the heart.

cardiomyopathy Primary abnormality of the heart muscle that affects its structural or functional characteristics.

cardiovascular disease (CVD) Generic term for disorders of the heart and blood vessels.

carpal spasm When the person's hand and fingers contract due to decreased calcium levels.

carpal tunnel syndrome Compression of the median nerve as a result of inflammation and swelling of the synovial lining of the tendon sheaths.

carrier Any individual who carries a single copy of an altered gene or mutation for a recessive condition on one chromosome of a chromosome pair and an unaltered form of that gene on the other chromosome; a carrier generally is not affected by the gene alteration; on average, each person in the general population is a carrier of five or six gene mutations for recessive disorders.

catabolism Biochemical process involving the breakdown of complex structures into simpler forms.

cataract Opacification (clouding) of the lens of the eye.

cell cycle The four phases that occur during growth and development of a cell.

cell-mediated (cellular) immune response Direct or indirect inactivation of antigen by lymphocytes.

cellulitis A localised infection of the dermis and subcutaneous tissue.

central nervous system depressants Drugs that can be used to slow down brain activity.

central obesity Obesity characterised by a waist-to-hip ratio of greater than 1 in men or 0.8 in women.

central pain Related to a lesion in the brain that may spontaneously produce high-frequency bursts of impulses that are perceived as pain.

cerebral concussion Transient, temporary, neurogenic dysfunction caused by mechanical force to the brain.

cerebral contusion Bruise on the surface of the brain.

cerebral oedema An increase in the volume of brain tissue due to abnormal accumulation of fluid.

cerumen Earwax.

chalazion Granulomatous cyst or nodule of the eyelid.

chancre Hard, syphilitic primary ulcer.

cheilosis Chemical peeling; the application of a chemical to produce a controlled and predictable injury that alters the anatomy of the epidermis and superficial dermis.

chemotherapy Cancer treatment involving the use of cytotoxic medications to decrease tumour size, adjunctive to surgery or radiation therapy; or to prevent or treat suspected metastases.

chlamydia A group of syndromes caused by *Chlamydia trachomatis*, a bacterium that behaves like a virus spreading within a host cell; spread by sexual contact and to the neonate by passage through the birth canal of an infected mother.

cholecystectomy Removal of the gallbladder.

cholecystitis Inflammation of the gallbladder, usually associated with stones in the cystic or common bile duct.

cholelithiasis Formation of stones (calculi) within the gallbladder or biliary duct system.

cholera Acute diarrhoeal illness caused by certain strains of *Vibrio cholerae*.

chorea Jerky, rapid, involuntary movements.

chromosome Genetic material carried by each cell; found in the cell nucleus.

chronic bronchitis Excessive secretion of bronchial mucus characterised by a productive cough lasting 3 or more months in 2 consecutive years.

chronic disease A disease involving a long course in its development or its symptoms.

chronic gastritis Disorders characterised by progressive and irreversible changes in the gastric mucosa.

chronic illness Illness that lasts for an extended period of time, usually greater than 6 months.

chronic kidney disease Kidney injury in a person with a glomerular filtration rate (GFR) < 60 mL/min/1.73 m^2 for > 3 months with or without evidence of kidney damage OR evidence of kidney damage (with or without decreased GFR) for > 3 months including microalbuminuria, proteinuria, glomerular haematuria or any anatomical or pathological abnormality.

chronic kidney failure Progressive kidney tissue destruction with loss of entire nephron unit and function; kidney mass decreases, and glomerular filtration, tubular secretion and reabsorption deteriorate.

chronic lymphocytic leukaemia (CLL) Proliferation and accumulation of small, abnormal, mature lymphocytes in the bone marrow, peripheral blood and body tissues; least common type of the major leukaemias.

chronic myelogenous leukaemia (CML) Abnormal proliferation of all bone marrow elements, usually associated with a chromosome abnormality (the Philadelphia chromosome).

chronic obstructive pulmonary disease (COPD) Chronic airflow obstruction due to chronic bronchitis and/or emphysema.

chronic otitis media Condition involving permanent perforation of the tympanic membrane, with or without recurrent pus formation and often accompanied by changes in the mucosa and bony structures (ossicles) of the middle ear.

chronic pain Prolonged pain, usually lasting longer than 6 months. It is not always associated with an identifiable cause and is often unresponsive to conventional medical treatment.

chronic renal failure See *chronic kidney failure*.

chronic sorrow A cyclical, recurring and potentially progressive pattern of pervasive sadness experienced in response to continual loss, throughout the trajectory of an illness or disability.

chronic stump pain The result of neuroma formation, causing severe burning pain.

chronic venous insufficiency A chronic disorder of inadequate venous return.

Chvostek's sign Contraction of the lateral facial muscles in response to tapping the face in front of the ear; caused by decreased blood calcium levels.

chyme Thick, fluid mixture of food and gastric juices formed in the stomach during the digestive process.

circulating nurse Assists scrub nurses and surgeons during surgery.

cirrhosis A progressive, irreversible disorder, eventually leading to liver failure; the end stage of chronic liver disease.

claudication Cramping, aching pain in the calves, thighs and buttocks that occurs with a predictable level of activity and is relieved by rest.

client A term used instead of 'patient' that is based on a philosophy that individuals are active participants in health and illness as well as consumers of healthcare services.

clinical governance A system of policies, processes and accountabilities that is directed at improving patient safety and the quality and effectiveness of patient care within a health service.

clinical pathway A healthcare plan designed to provide care with a multidisciplinary, managed action focus; developed for specific diagnoses, usually those that are high volume, high risk and high cost.

clinical reasoning The process by which nurses (and other clinicians) collect cues, process the information, come to an understanding of a person's problem or situation, plan and implement interventions, evaluate outcomes, and reflect on and learn from the process.

closed fracture (simple fracture) Break in continuity of bone with skin still intact.

clubbing Enlargement and blunting of the terminal portion of the fingers; associated with chronic hypoxaemia.

cluster headache A form of vascular headache predominantly experienced by men aged 20 to 40. The headache typically begins 2 to 3 hours after the person falls asleep.

coagulation The process of creating a fibrin meshwork that cements blood components together to form an insoluble clot.

cocaine An illegal drug extracted from a cocoa leaf that is white, odourless, and takes the form of a crystalline powder.

code of ethics An established and agreed-on group of principles of conduct that provide a professional framework.

coeliac disease (coeliac sprue, non-tropical sprue) Chronic hereditary disorder characterised by sensitivity to the gliadin fraction of gluten, a cereal protein.

cognition The ability to process information and apply knowledge.

cold sore See *herpes simplex*.

cold zone Considered the 'safe zone' during a disaster, it is adjacent to the warm zone and is the area where a more in-depth triage of victims would occur; survivors may find shelter in this area and command and control vehicles would be found here as well as the emergency transport vehicles.

colectomy Surgical removal of the colon.

collateral channels Connections between small arteries.

collateral vessels Accessory pathways connected to the smaller arteries in the coronary system.

colorectal cancer Malignant tumour arising from the epithelial tissues of the colon or rectum.

colostomy Ostomy made in the colon.

comedones Non-inflammatory acne lesions.

communication The exchange of information between two or more people, groups or entities. It involves verbal and written exchanges, as well as body language, attitude and tone (Nadzam, 2009).

community A collection of people who share some attribute of their lives.

community-based care Centres on individual and family healthcare needs. The nurse practising community-based care provides direct services to individuals to manage acute or chronic health problems and to promote self-care. The care is provided in the local community, is culturally competent and is family centred.

community mental health nursing nurse A branch of mental health nursing in which the nurse works with consumers who are living in the community. It often involves case management.

community nursing Care directed towards a specific population or group within the community; primary, secondary or tertiary care may be provided to individuals or groups.

compartment A space enclosed by a fibrous membrane or fascia.

compartment syndrome Condition in which excess pressure constricts the structures within a compartment and reduces circulation to muscles and nerves.

concussion Injury resulting from a violent jar, shake or impact with an object.

conjunctivitis Inflammation of the conjunctiva.

consanguinity Related by having a common ancestor; close blood relationship.

conscious sedation Anaesthesia that provides analgesia and amnesia, but in which the person remains conscious. People are able to breathe independently and are cardiovascularly stable.

consciousness A condition in which a person is aware of self and environment and is able to respond appropriately to stimuli; full consciousness requires both normal arousal and full cognition.

constipation The infrequent (two or fewer bowel movements weekly) or difficult passage of stools.

consultation liaison A specialist mental health nurse who is the interface between medicine and psychiatry.

consumer-directed care A model of service delivery designed to give more care choice and flexibility to consumers. This model provides consumers with more control over the types of care and services they access, and the delivery of those services, including who delivers the services and when they are delivered.

contact dermatitis Type of dermatitis caused by a hypersensitivity response or chemical irritation.

continuous renal replacement therapy (CRRT) A form of haemodialysis in which blood is continuously circulated through a highly porous haemofilter from artery to vein, or vein to vein.

continuum of care The provision of ongoing quality healthcare in acute and community settings to optimise quality of life for people, underpinned by an interprofessional consultative team approach.

contractility The inherent capability of the cardiac muscle fibres to shorten.

contracting The negotiation of a cooperative working agreement between the nurse and person that is continuously renegotiated.

contracture Permanent shortening of connective tissue.

contralateral deficit Manifestations of a stroke on the side of the body opposite the side of the brain that is damaged.

contusion Superficial tissue injury resulting from blunt trauma, such as a kick or blow from an object, that causes the breakage of small blood vessels and bleeding into the surrounding tissue.

conventional weapons Weapons such as bombs and guns that are used more frequently than non-conventional terrorist weapons.

convergence Moving inward of the eyes to see an object close to the face.

co-occurring disorders Concurrent diagnosis of a substance use disorder and a psychiatric disorder. One disorder can precede and cause the other, such as the relationship between alcoholism and depression.

cor pulmonale Condition of right ventricular hypertrophy and failure that results from longstanding pulmonary hypertension.

core competencies Standards that a profession agrees are essential for a person to be deemed competent in their field.

corneal reflex Closure of eyelids (blinking) due to corneal irritation.

corneal ulcer Local necrosis of the cornea, may be caused by infection, exposure trauma or the misuse/overuse of contact lenses.

coronary heart disease (CHD) Heart disease caused by impaired blood flow to the myocardium.

coryza (rhinorrhoea) Profuse nasal discharge.

cosmetic surgery (aesthetic surgery) One of two fields within plastic surgery. Cosmetic surgery enhances the attractiveness of normal features.

crackles Discontinuous lung sound heard by auscultation; can be fine or coarse. Produced by air passing over airway secretions or the opening of collapsed airways.

creatinine The end product from the breakdown of creatine phosphate in muscles.

crepitation A grating sound heard on movement of a joint.

Creutzfeldt–Jakob disease (CJD, spongiform encephalopathy) Rare, progressive neurological disease that causes brain degeneration without inflammation.

critical pathway See *clinical pathway*.

critical thinking Self-directed thinking that is focused on what to believe or do in a specific situation.

Crohn's disease (regional enteritis) Chronic, relapsing inflammatory disorder affecting the gastrointestinal tract.

crossing over A process that occurs during meiosis in which homologous maternal and paternal chromosomes break and exchange corresponding sections of DNA and then rejoin; this process can cause an exchange of alleles between chromosomes and provides human diversity.

cryosurgery The destruction of tissue by cold or freezing with agents such as fluorocarbon sprays, carbon dioxide snow, nitrous oxide and liquid nitrogen.

cultural competence Practising in a way that demonstrates the importance of social and cultural influences on patients' health beliefs and behaviours, and devising interventions that take these issues into account.

cultural safety The effective nursing practice of a person or family from another culture, as determined by that person or family.

culture A learned world viewpoint or paradigm shared by a population or group and transmitted socially. It influences values, beliefs, customs and behaviours, and is reflected in the language, dress, food, materials and social interactions of a group.

curettage The removal of lesions with a curette, a semi-sharp cutting instrument.

Curling's ulcers Acute ulcerations of the stomach or duodenum that form following a burn injury.

Cushing's syndrome A chronic disorder in which hyperfunction of the adrenal cortex produces excessive amounts of circulating cortisol or adrenocorticotropic hormone (ACTH).

Cushing's ulcers Stress ulcers occurring as sequelae of head injury or central nervous system surgery.

cutaneous melanoma See *malignant melanoma*.

cyanosis A bluish discolouration of the skin and mucous membranes due to oxygen deficiency.

cyst A sac containing fluid or semisolid fluid.

cystectomy Complete surgical removal of the urinary bladder and adjacent muscles and tissues.

cystic fibrosis (CF) Inherited disorder of the exocrine glands that results in the secretion of abnormal amounts of mucus.

cystitis Inflammation of the urinary bladder.

cysts of the skin Benign closed sacs in or under the skin surface that are lined with epithelium and contain fluid or a semisolid material. Epidermal inclusion cysts and pilar cysts are the most common types.

cytokines Hormone-like polypeptides produced primarily by monocytes, macrophages and T cells. Cytokines act as messengers of the immune system, facilitating communication between the cells to adjust or vary the inflammatory reaction or to initiate immune cell proliferation and differentiation.

dawn phenomenon A rise in blood glucose between 4 am and 8 am that is not a response to hypoglycaemia.

day surgery units/centres Facilities where surgery is performed and the person is discharged on the same day.

death Irreversible cessation of circulatory and respiratory functions or irreversible cessation of all functions of the entire brain, including the brainstem.

death anxiety Worry or fear related to death or dying.

debridement Process of removing dead tissue from a wound.

decerebrate posturing Abnormal posture with the neck extended; the jaw clenched; arms pronated, extended and close to the sides; legs extended and feet plantar flexed. Results from lesions of the midbrain, pons or diencephalons.

decorticate posturing Abnormal posture with the upper arms close to the sides; the elbows, wrists and fingers flexed; the legs extended and internally rotated; and the feet plantar flexed. Results from lesions of the corticospinal tracts.

deep venous thrombosis or deep vein thrombosis (DVT) Blood clot (thrombus) formation and inflammation within a deep vein, usually in the pelvis or lower extremities; a common complication of hospitalisation, surgery and immobilisation.

dehiscence An unintended separation of wound margins due to incomplete healing.

dehydration Loss of water.

delayed healing Healing that occurs at a slower rate than expected.

delegation To effectively assign appropriate work activities to other members of the healthcare team. When the nurse delegates nursing care activities to another person, that person is authorised to act in the place of the nurse, while the nurse retains the accountability for the activities performed.

delirium tremens (DT) A medical emergency usually occurring 3 to 5 days following alcohol withdrawal and lasting 2 to 3 days; characterised by paranoia, disorientation, delusions, visual hallucinations, elevated vital signs, vomiting, diarrhoea and diaphoresis.

delusion A fixed false belief that is firmly sustained despite what constitutes incontrovertible and obvious proof or evidence to the contrary. The belief is not one ordinarily accepted by other members of the person's culture or subculture.

dementia A global impairment of cognitive function that usually is progressive and may be permanent; interferes with normal social and occupational activities.

demyelination Destruction or removal of the myelin sheaths of nerves.

depolarisation The rapid inflow of sodium ions, causing an electrical change in which the inside of a cell becomes positive in relation to the outside.

dermatitis Acute or chronic inflammation of the skin characterised by erythema and pain or pruritus.

dermatome Area of skin innervated by cutaneous branches of a single spinal nerve.

dermatophytes Fungi that cause superficial skin infections.

dermatophytoses Superficial fungal infection of the skin; also called *ringworm*.

determinants of health Factors that influence health in either a positive or a negative way. Some of these function on an individual level (e.g. health behaviours such as smoking or exercise, or our genetic make-up). Others function at a broader societal level, such as the availability of health services, vaccination programs or clean drinking water and healthy food.

diabetes insipidus The result of antidiuretic hormone insufficiency.

diabetes mellitus (DM) Group of chronic disorders of the endocrine pancreas, all categorised under a broad diagnostic label. The condition is characterised by inappropriate hyperglycaemia caused by a relative or absolute deficiency of insulin or by a cellular resistance to the action of insulin.

diabetic ketoacidosis (DKA) A form of metabolic acidosis induced by stress in a person with type 1 diabetes mellitus.

diabetic nephropathy A disease of the kidneys characterised by the presence of albumin in the urine, hypertension, oedema and progressive renal insufficiency.

diabetic neuropathies Disorders of the peripheral nerves and the autonomic nervous system manifesting one or more of the following: sensory and motor impairment, muscle weakness and pain, cranial nerve disorders, impaired vasomotor function, impaired gastrointestinal function and impaired genitourinary function.

diabetic retinopathy The collective name for the changes in the retina that occur in the person with diabetes. The retinal capillary structure undergoes alterations in blood flow, leading to retinal ischaemia and a breakdown in the blood retinal barrier.

***Diagnostic and Statistical Manual of Mental Disorders* (DSM)** A manual that is published by the American Psychiatric Association and provides common language and standard criteria for the classification of mental disorders.

dialysate Dialysis solution.

dialysis The diffusion of solute molecules across a semipermeable membrane from an area of higher concentration to one of lower concentration.

diaphoresis Copious production of sweat.

diarrhoea An increase in the frequency, volume and fluid content of the stool.

diastolic blood pressure The minimum pressure maintained by elastic arterial walls during diastole (cardiac relaxation) to maintain blood flow through capillary beds; averages 80 mmHg in a healthy adult.

differentiation A process occurring over many cell cycles that allows cells to specialise in certain tasks.

'differentness' Being different from another person or group of people.

diffuse brain injury (DBI) A brain injury from a high-speed acceleration–deceleration accident with widespread disruption of axons in the white matter.

diffuse oesophageal spasm Non-peristaltic contraction of oesophageal smooth muscle.

diffusion The process by which solute molecules move from an area of high solute concentration to an area of low solute concentration to become evenly distributed.

dilemma A choice between two unpleasant, ethically troubling alternatives.

diplopia Unilateral or bilateral double vision.

dirty bomb Consists of a conventional explosive such as trinitrotoluene (TNT) packed with radioactive waste by-products from nuclear reactors that discharge deadly radioactive particles into the environment. See also *radiological dispersion bomb*.

disability The degree of observable and measurable impairment.

disaster Event that requires extraordinary efforts beyond those needed to respond to everyday emergencies.

discharge planning A planned process beginning with the person's initial presentation, considering the needs of the unique individual, based upon the availability of, and access to, support and resources. This process ensures that these needs are met through ongoing assessment and consultation involving the relevant healthcare professionals, client, family, carers and community services.

discovery Encompasses equality and respect. Equality is the belief that all people ought to be treated equally. Respect is esteem for, or a sense of the worth or excellence of, a person, a personal quality, ability or a manifestation of a personal quality or ability.

disease Literally meaning 'without ease', this term describes alterations in structure and function of the body or mind. Diseases may have mechanical, biological or normative causes.

dislocation Separation of contact between two bones of a joint.

dissection (aortic) A life-threatening emergency caused by a tear in the intima of the aorta with haemorrhage into the media.

disseminated intravascular coagulation (DIC) A disruption of haemostasis characterised by widespread intravascular clotting and bleeding; a syndrome that develops as a complication of many other disorders.

distal determinants Determinants of health which tend to be stable and concern historical, national, institutional, political, legal and cultural factors.

distributive shock Also called *vasogenic shock*, this includes several types of shock that result from widespread vasodilation and decreased peripheral resistance.

diverticula Sac-like projections of mucosa through the muscular layer of the colon.

diverticulitis Inflammation in and around the diverticular sac; typically affects only one diverticulum, usually in the sigmoid colon.

diverticulosis Indicates the presence of diverticula.

DNA-based tests Tests that incorporate new, sophisticated technology that permits the examination of the DNA itself, obtained from blood, bone marrow, amniotic fluid, fibroblast cells of the skin or buccal cells from the mouth.

dominant A characteristic or gene that is apparent even when the relevant gene is present in only one copy; a person with a dominant gene usually expresses that gene trait.

Do-Not-Resuscitate (DNR) order Usually written by the physician for the person who has a terminal illness or is near death, this order is usually based on the wishes of the person and family that no cardiopulmonary resuscitation be performed for respiratory or cardiac arrest.

Down syndrome A human genetic disease caused by the presence of an extra chromosome 21; characterised by mental retardation and heart and respiratory defects.

dual diagnosis The coexistence of substance use/dependence and a psychiatric disorder in one individual (used interchangeably with *dual disorder* and *co-occurring disorders*).

dual disorder See *dual diagnosis*.

dumping syndrome Complication of partial gastrectomy characterised by nausea, weakness, sweating, palpitation, syncope, sensation of warmth and occasionally diarrhoea.

duodenal ulcers Peptic ulcer disease affecting the duodenum.

dwarfism A medical disorder, the term being used to describe a person of short stature.

dysarthria Difficulty speaking.

dysfunctional uterine bleeding (DUB) Vaginal bleeding that is usually painless but abnormal in amount, duration or time of occurrence.

dysmenorrhoea Pain associated with menstruation.

dyspareunia Painful intercourse.

dysphagia Difficulty swallowing.

dysphonia Change in the tone of voice.

dysplasia The loss of DNA control over differentiation occurring in response to adverse conditions.

dyspnoea Difficult or laboured breathing.

dysrhythmia See *arrhythmia*.

dysuria Painful urination.

ecchymosis A flat, irregularly shaped lesion of varying size with no pulsation; caused by blood collecting under the skin.

ectopic beats Impulses originating outside normal conduction pathways of the heart.

ejection fraction (EF) The percentage of total blood remaining in the ventricle at the end of diastole (relaxation); normal is 50–70%.

electrical bone stimulation Application of electrical current at the fracture site to treat fractures that are not healing appropriately. The electrical stress increases the migration of osteoblasts and osteoclasts to the fracture site. Mineral deposition increases, promoting bone healing.

electrocardiography The graphic recording of the heart's electrical activity detected and recorded through electrodes placed on the surface of the body.

electrolytes Substances that dissociate in solution to form charged particles called ions.

electrosurgery The destruction or removal of tissue with high-frequency alternating current.

embolic CVA Cerebrovascular accident (CVA) occurring when a blood clot or clump of matter travelling through the cerebral blood vessels becomes lodged in a vessel too narrow to permit further movement.

embolism Sudden obstruction of a blood vessel by debris.

emergency Encompasses an unforeseen combination of circumstances calling for immediate action for a range of victims from one to many.

emphysema Destruction of the walls of the alveoli, with resulting enlargement of abnormal air spaces.

empowerment Developing confidence in one's own capacities.

empyema Accumulation of purulent exudate in the pleural cavity.

encephalitis An acute inflammation of the parenchyma of the brain or spinal cord.

end-of-life care Care provided in the final weeks of life when death is imminent.

endocarditis Inflammation of the endocardium.

endogenous insulin The insulin the pancreas makes.

endometriosis A condition in which multiple, small implants of endometrial tissue develop throughout the pelvic cavity.

endoscopy Inspection of organs or cavities of the body using an endoscope.

endotoxins Found in the cell wall of Gram-negative bacteria, endotoxins are released only when the cell is disrupted. They act as activators of many human regulatory systems, producing fever, inflammation and potentially clotting, bleeding or hypotension when released in large quantities.

end-stage kidney disease (ESKD) The final stage of chronic kidney failure in which the kidneys are unable to excrete metabolic wastes and regulate fluid and electrolyte balance adequately; characterised by a glomerular filtration rate of less than 5% of normal.

enduring power of attorney A document that can delegate the authority to make health, financial and/or legal decisions on a person's behalf. It must be in writing and must state that the designated person is authorised to make healthcare decisions.

enophthalmos Sunken appearance of the eyes.

enteral nutrition Administration of liquid nutritional formulas to meet kilojoule and protein needs in people unable to consume adequate food; also called *tube feeding*.

enucleation Surgical removal of an eye.

epicondylitis (tennis elbow, golfer's elbow) Inflammation of the tendon at its point of origin into the bone.

epididymitis Infection or inflammation of the epididymis.

epidural haematoma (extradural haematoma) A collection of blood between the dura and the skull.

epilepsy Chronic seizure activity.

epistaxis Nosebleed.

equianalgesia Equal analgesia; used when referring to the doses of various opioid analgesics that provide approximately the same pain relief.

erectile dysfunction Inability of the male to attain and maintain an erection sufficient to permit satisfactory sexual intercourse.

erosive gastritis See *stress-induced (erosive) gastritis*.

erysipelas Infection of the skin most often caused by group A streptococci.

erythema A reddening of the skin.

erythropoiesis Red blood cell production.

eschar Hard, leathery crust that covers a burn wound and harbours necrotic tissue.

escharotomy Surgical removal of eschar from the torso or extremity to prevent circumferential constriction.

ethics Principles of conduct. Ethical behaviour is concerned with moral duty, values, obligations and the distinction between right and wrong.

euthanasia From the Greek for 'painless, easy, gentle or good death', now commonly used to signify a killing prompted by a humanitarian motive.

euthyroid The state of having normal thyroid gland function.

eventually fatal condition Any illness in which it is expected that death will be a direct consequence.

evisceration Protrusion of body contents through a surgical wound.

exacerbation A period during chronic illness in which symptoms reappear.

exfoliative dermatitis Inflammatory skin disorder characterised by excessive peeling or shedding of skin.

exogenous insulin The insulin people inject or infuse via an insulin pump.

exophthalmos Protrusion of the eyeballs.

exotoxins Soluble proteins secreted into surrounding tissue by the microorganism. Exotoxins are highly poisonous, causing cell death or dysfunction.

external otitis Inflammation of the ear canal.

extracapsular fractures Fractures of the trochanteric region.

extracorporeal shock wave lithotripsy (ESWL, transcutaneous shock wave lithotripsy) Non-invasive technique for fragmenting kidney stones using shock waves generated outside the body.

faecal impaction A rock-hard or putty-like mass of faeces in the rectum.

faecal incontinence Loss of voluntary control of defecation.

faecalith A hard mass of faeces.

family Two or more persons joined by emotional closeness and shared bonds and who identify themselves as being part of a family.

fascial excision (fasciectomy) Process of excising the wound to the level of fascia.

fasciculations Involuntary twitching.

fat embolism syndrome (FES) Characterised by neurological dysfunction, pulmonary insufficiency, and a petechial rash on the chest, axilla and upper arms due to fat globules lodged in the pulmonary vascular bed or peripheral circulation.

fibrocystic changes (FCC) Physiological nodularity and breast tenderness that increases and decreases with the menstrual cycle.

fibroid tumours (uterine leiomyomas) Solid, pedunculated benign tumours.

fibromyalgia (fibrositis) A common rheumatic syndrome characterised by musculoskeletal pain, stiffness and tenderness.

filtration The process by which water and dissolved substances (solutes) move from an area of higher hydrostatic pressure to an area of lower hydrostatic pressure.

fistula Abnormal opening or passage between two organs or spaces that are normally separated, or an abnormal passage to the outside of the body.

flaccidity Decreased muscle tone in disease or trauma of the lower motor neurons.

flail chest Free-floating segment of the chest wall, resulting from two or more consecutive ribs fractured in multiple places.

flap A piece of tissue whose free end is moved from a donor site to a recipient site while maintaining a continuous blood supply through its connection at the base or pedicle.

flatus Gas in the digestive tract.

fluid resuscitation Replacement of the extensive fluid and electrolyte losses associated with major burn injuries.

fluid volume deficit (FVD) A decrease in intravascular, interstitial and/or intracellular fluid in the body.

fluid volume excess (FVE) Excess extracellular fluid resulting from retention of both water and sodium in the body.

focused assessment A physical assessment that concentrates on the part of the body that may be affected by disease or injury.

folic acid deficiency anaemia An anaemia resulting from folic acid deficiency, a necessary nutrient for DNA synthesis and red blood cell maturation.

folliculitis Bacterial infection of the hair follicle, most commonly caused by *Staphylococcus aureus*.

forensic mental health A subspecialty of mental health in which scientific and clinical expertise is applied in legal contexts, combining civil, criminal, correctional and legislative matters.

fracture A break in a bone, usually due to trauma.

freestanding outpatient surgical facilities Surgical units independent of a hospital with or without financial connections to a hospital or healthcare organisation.

friction rub The sound heard when two dry surfaces are rubbed together.

frostbite An injury of the skin from freezing.

full-thickness avulsion injuries Injuries that result in loss of all of the layers of the skin, causing fat and muscle to be exposed.

full-thickness burn A burn that involves all layers of the skin, including the epidermis, dermis and epidermal appendages.

fulminant hepatitis Hepatitis with a rapid and severe onset and course.

furuncle Often called a boil, but also an inflammation of the hair follicle.

fusiform excision The removal of a full thickness of the epidermis and dermis, usually with a thin layer of subcutaneous tissue.

galactorrhoea Lactation not associated with pregnancy or nursing.

gamma hydroxybutyrate A dissociative anaesthetic agent; another of the newer drugs diverted to illicit use.

gastric lavage Irrigation of the stomach with large quantities of normal saline.

gastric mucosal barrier A protective barrier consisting of lipids, bicarbonate ions and mucous gel that protects the stomach lining from the damaging effects of gastric juices.

gastric outlet obstruction Obstruction of the pyloric region of the stomach and duodenum that impairs gastric outflow; a potential complication of peptic ulcer disease.

gastric ulcers Ulcers of the stomach lining, usually in the lesser curvature and antrum; more common in older adults.

gastritis Inflammation of the stomach lining.

gastroduodenostomy (Billroth I) Excision of the pylorus of the stomach with the anastomosis of the upper stomach to the duodenum; commonly used partial gastrectomy procedure.

gastroenteritis Inflammation of the gastrointestinal tract; not a specific disease, but a group of syndromes or a collection of related manifestations.

gastrojejunostomy (Billroth II) Subtotal excision of the stomach with closure of the duodenum and side-to-side anastomosis of the jejunum to the stomach; commonly used partial gastrectomy procedure.

gastro-oesophageal reflux Backward flow of gastric contents into the oesophagus.

gastro-oesophageal reflux disease (GORD) Causes heartburn, usually after meals, when bending over or reclining.

gastroparesis Slowed gastrointestinal motility, which causes early satiety.

gene A sequence of DNA on a chromosome that represents a fundamental unit of heredity; occupies a specific spot on a chromosome (gene locus).

gene expression When the protein product of a gene is visible (e.g. through the presence of a body structure or identifiable through biochemical tests such as insulin or phenylalanine levels).

general anaesthesia Deep sedation, which includes analgesia and muscle paralysis. This type of anaesthesia requires respiratory maintenance without the aid of the person's respiratory musculature.

genetic locus The term used to describe a gene's location on a specific chromosome.

genetics The scientific study of heredity and hereditary variation.

genital herpes (herpes simplex genitalis) An infection of the external genitalia caused by herpes simplex genitalis; transmitted by vaginal, anal or oral–genital contact.

genital warts (condyloma acuminatum, venereal warts) A sexually transmitted condition caused by the human papillomavirus.

genomics The study of whole sets of genes and their interactions.

genotype The genes and the variations therein that a person inherits from his or her parents.

germ cells Cells that give rise to a sperm or egg.

gigantism Occurs when growth hormone hypersecretion begins before puberty and the closure of the epiphyseal plates, leading the person to become abnormally tall.

gingivitis Inflammation of the gums, characterised by inflammation, redness and bleeding.

gland Tissue that synthesises hormones.

glaucoma Condition characterised by increased intraocular pressure of the eye and a gradual loss of vision.

glomerular filtration rate (GFR) The rate at which plasma is filtered through the glomeruli of the kidney.

glomerulonephritis Inflammation of the capillary loops of the glomeruli.

glossitis Inflammation of the tongue.

glucocorticoid A group of hormones secreted by the adrenal cortex; they regulate carbohydrate levels in the body.

gluconeogenesis Formation of glucose from fats and proteins.

glucose-6-phosphate dehydrogenase (G6PD) anaemia Anaemia due to a hereditary defect in red blood cell metabolism.

glucosuria Excessive glucose in urine.

glycogenolysis Breakdown of liver glycogen to glucose.

goitre An enlarged thyroid gland. Enlargement results from both inadequate and excessive synthesis of thyroid hormones.

gonorrhoea (GC, clap) An infection caused by *Neisseria gonorrhoeae* that is transmitted by direct sexual contact or by delivery of a neonate by an infected mother.

gout A syndrome that occurs from an inflammatory response to the production or excretion of uric acid resulting in high levels of uric acid in the blood (hyperuricaemia) and in other body fluids, including synovial fluid.

Grave's disease Caused by a defect in immunoregulation in genetically predisposed individuals, leading to production of thyroid-stimulating antibodies.

grief The emotional response to loss and its accompanying changes.

grieving The internal process the person uses to work through the response to loss.

Guillain–Barré syndrome (GBS) Acute demyelinating disorder of the peripheral nervous system characterised by progressive, usually rapid muscle weakness and paralysis.

gynaecomastia Breast enlargement in men.

haemangioma See *angioma*.

haemarthrosis The collection of blood in the elbow joint.

haematemesis Blood in the vomit.

haematochezia Blood in the stool.

haematoma A contusion with a large amount of bleeding.

haematopoiesis Blood cell formation.

haematuria Blood in the urine.

haemianopia Loss of half of the visual field of one or both eyes.

haemiparesis Weakness of one side of the body.

haemiplegia Paralysis in one-half of the body vertically.

haemodialysis A procedure in which electrolytes, waste products and excess water are removed from the body by diffusion and ultrafiltration as blood passes by an artificial semipermeable membrane outside the body.

haemodynamics Study of the forces involved in blood circulation.

haemoglobin The oxygen-carrying protein within red blood cells; composed of the haem molecule and globin, a protein molecule.

haemolysis The process of red blood cell destruction.

haemolytic anaemia Premature destruction (lysis) of red blood cells.

haemophilia A group of hereditary clotting factor disorders that lead to persistent and potentially severe bleeding.

haemophilia A (classic haemophilia) The most common type of haemophilia, caused by clotting factor VIII deficiency.

haemophilia B (Christmas disease) Haemophilia caused by factor IX deficiency.

haemoptysis Bloody sputum.

haemorrhage Rapid or excessive bleeding.

haemorrhagic CVA (intracranial haemorrhage) Cerebrovascular accident (CVA) occurring when a cerebral blood vessel ruptures.

haemorrhoids (piles) Clusters of dilated veins in swollen anal tissue.

haemostasis Control of bleeding.

haemothorax Blood in the pleural space.

halitosis (bad breath) A common condition caused by an increase in sulfur-producing bacteria in the oral cavity.

hallucination An alteration of perception in the absence of a stimulus.

hallucinogens Drugs that produce hallucinations.

hallux valgus (bunion) The enlargement and lateral displacement of the first metatarsal.

hammer toe (claw toe) The dorsiflexion of the first phalanx with accompanying plantar flexion of the second and third phalanges.

handicap The total adjustment to disability that limits functioning at a normal level.

harm minimisation A way of reducing the impact of drug- and/or alcohol-related harm to individuals and the community through a range of cost-effective public health policies, strategies and practices.

Hashimoto's thyroiditis An autoimmune disorder caused by the development of antibodies that destroy thyroid tissue.

hazardous materials Substances that pose a potential risk to life, health or property if they are released because of their chemical, biological or physical nature.

health As defined by the World Health Organization 'A state of complete physical, mental and social well-being, and not merely the absence of disease or infirmity.'

health determinants Factors that affect the health of people.

health education Individualistic strategies to improve health, often by increasing knowledge or influencing attitudes to alter behaviours and lifestyle. Health education is often used interchangeably with health promotion although they are not the same.

health maintenance Care focused on supporting people to manage their health and medical conditions in a way that maintains their current health and prevents further deterioration.

health promotion Any activity undertaken for the purpose of achieving a higher level of health and wellbeing.

healthcare-associated infection (HAI) An infection contracted during residence in a hospital or extended care facility.

healthcare surrogate An individual selected to make medical decisions when a person is no longer able to make them for themself.

heart block A block in the normal conduction pathways.

heart failure Inability of the heart to pump adequate blood to meet the metabolic demands of the body.

heave An excessive thrust.

hemianopia The loss of half of the visual field of one or both eyes.

hemiparesis Weakness of the left or right half of the body.

hemiplegia Paralysis of the left or right half of the body.

hepatic encephalopathy Altered consciousness, mentation and motor function affecting people with cirrhosis.

hepatitis Inflammation of the liver, usually caused by a virus; may be acute or chronic.

hepatorenal syndrome Kidney failure accompanied by azotaemia, sodium retention, oliguria and hypotension in people with cirrhosis and ascites.

hernia A defect in the abdominal wall that allows abdominal contents to protrude out of the abdominal cavity.

herniated intervertebral disc Rupture of the cartilage surrounding the intervertebral disc with protrusion of the nucleus pulposus.

herpes simplex (fever blister, cold sore) Acute viral infections of the skin and mucous membranes caused by two types of herpes virus: HSV I and HSV II.

herpes zoster (shingles) Viral infection of a dermatome section of the skin caused by varicella zoster, the same herpes virus that causes chickenpox.

heterograft (xenograft) Skin obtained from an animal, usually a pig.

heterozygous Non-identical copies of a particular gene (different alleles) on the paired chromosomes.

hiatal hernia Protrusion of part of the stomach through the oesophageal hiatus of the diaphragm into the mediastinal cavity.

hirsutism Increased growth of coarse hair, usually on the face and trunk.

histocompatibility The ability of cells and tissues to survive transplantation without immunological interference by the recipient.

Hodgkin's disease A single lymph node or chain of nodes which spreads to adjoining nodes. Involved lymph nodes contain *Reed–Sternberg cells* (malignant cells) surrounded by host inflammatory cells. These malignant cells secrete inflammatory mediator substances, attracting inflammatory cells to the tumour site. They may invade almost any tissue in the body.

holistic healthcare Care in which all aspects of a person (physical, psychosocial, cultural, spiritual and intellectual) are considered as essential components of individualised care.

home care Services for people who are in need of treatment or support to function effectively in the home environment.

homeostasis The body's tendency to maintain a state of physiological balance in the presence of constantly changing conditions.

homograft (allograft) Human skin that has been harvested from cadavers.

homologous chromosomes Chromosomes that are members of the same pair and normally have the same number and arrangement of genes; usually one copy is from the mother and the other copy is from the father.

homonymous hemianopia Impaired vision or blindness in one side of both eyes.

homozygous Identical copies of a particular gene (same alleles) on both paired chromosomes.

hope A belief in a positive outcome related to events and circumstances in one's life; the foundation of recovery from mental illness.

hordeolum (sty) Staphylococcal abscess that may occur on either the external or internal margin of the lid.

hormone Chemical messengers secreted via body fluids that have specific targets where they increase or inhibit organ functions.

hospice The delivery of care for terminally ill people either in healthcare facilities or in the person's home.

hospice care A special component of home care, designed to provide medical, nursing, social, psychological and spiritual care for terminally ill people and their families. Hospice care relies on a philosophy of relieving pain and suffering and allowing the person to die with dignity in a comfortable environment.

hot zone The site of a disaster where a weapon was released or where contamination occurred.

human genome The total amount of the DNA (genes) in an individual's cells.

human immunodeficiency virus (HIV) Virus responsible for AIDS.

Huntington's disease Progressive, degenerative, inherited neurological disease characterised by increasing dementia and chorea; also called *chorea*.

hydrocoele Fluid-filled mass within the scrotum.

hydrocephalus An abnormal accumulation of cerebrospinal fluid within the cranial vault and dilation of the ventricles.

hydronephrosis Distension of the urinary tract with urine behind an obstruction.

hydroureter Distension of the ureter with urine.

hypercapnia Increased blood levels of carbon dioxide.

hyperglycaemia Elevated blood glucose levels (above 126 mg/dL), which causes osmotic diuresis and, if chronic, damages vessel epithelium and renal glomeruli.

hyperopia (farsightedness) The condition in which the eyeball is short, causing the image to focus behind the retina.

hyperosmolar hyperglycaemic state (HHS) A condition of very high blood glucose with adequate insulin to prevent ketosis, but which does cause diuresis.

hyperparathyroidism Results from an increase in the secretion of parathyroid hormone, which regulates normal serum levels of calcium and phosphate.

hyperplasia An increase in the number or density of normal cells.

hypersensitivity Exaggerated response of the immune system to an antigen.

hypertension Excess pressure in the arterial portion of systemic circulation.

hyperthyroidism A disorder caused by excessive delivery of thyroid hormone to the peripheral tissues. Also called thyrotoxicosis.

hypertrophic scar Overgrowth of dermal tissue that remains within the boundaries of the wound.

hypervolaemia Excess intravascular fluid.

hyphaema Bleeding into the anterior chamber of the eye, possibly as the result of blunt eye trauma.

hypoglycaemia Low blood glucose levels; deficiency of blood sugar.

hypoparathyroidism A condition that results from abnormally low parathyroid hormone levels, causing hypocalcaemia and an elevated blood phosphate level.

hypothyroidism A disorder that results when the thyroid gland produces an insufficient amount of thyroid hormone.

hypovolaemia Decreased circulating blood volume.

hypovolaemic shock Shock caused by a decrease in intravascular volume of 15% or more. This form of shock is caused by the loss of whole blood, blood plasma or extracellular fluid.

hypoxaemia Decreased oxygen concentration in the blood, measured by PaO_2.

hypoxia Insufficient supply of oxygen to the tissues.

ichthyosis An inherited dermatological condition in which the skin is dry, fissured and hyperkeratotic; the surface of the skin has the appearance of fish scales.

ileostomy An ostomy made in the ileum of the small intestine.

illness A highly personal state in which the person feels unhealthy or ill; may or may not be related to disease.

illness–wellness continuum A continuum representing health as a dynamic process, with high-level wellness at one extreme of the continuum and death at the opposite extreme.

illusion A distortion of the senses.

immunity The protection of the body from disease.

immunocompetent Possessing an immune system that can identify antigens and effectively destroy or remove them.

immunocompromised Possessing an immune response that has been weakened by a disease or an immunosuppressive agent.

immunoglobulin (Ig) A protein that functions as an antibody.

immunosuppression Inability of the immune system to respond to an antigen. Occurs in response to disease or medications; may be intentional to prevent rejection of transplants or a side effect of some medications.

impairment A disturbance in structure or function resulting from physiological or psychological abnormalities.

impetigo Infection of the skin caused by either *Staphylococcus aureus* or beta-haemolytic streptococci.

impotence Inability to achieve or maintain an erection.

impulse control The ability to control behavioural impetuosity.

incident pain A type of breakthrough pain that is predictable because it is associated with movement such as turning or coughing.

increased intracranial pressure (IICP, intracranial hypertension) Sustained elevated pressure (10 mmHg or higher) within the cranial cavity.

independent nursing care Care provided by nurses within the scope of their practice without the direction or supervision of a physician.

Indigenous health A broad term which generally refers to the health status and health outcomes of the Aboriginal and Torres Strait Islander population of Australia.

infection Colonisation by and multiplication of an organism within a host. The host can be any organism capable of supporting the nutritional and physical growth requirements of the microorganism—for example, humans.

inflammation A complex, non-specific, adaptive response to injury that brings fluid, dissolved substances and blood cells into the interstitial tissues where the invasion or damage has occurred.

inflammatory bowel disease (IBD) Chronic inflammation of the bowel common to a group of conditions that includes Crohn's disease and ulcerative colitis.

influenza Highly contagious viral respiratory disease characterised by coryza, fever, cough and constitutional manifestations such as headache and malaise.

informed consent Disclosure of risks associated with the intended procedure or operation to the client. The language of the document varies according to statutory and common law of each state.

inhalants Inhaled solvents categorised into three types: anaesthetics, volatile nitrites and organic solvents.

innate immunity Specific and non-specific responses that prevent or limit the entry of invaders into the body, thereby limiting the extent of tissue damage and reducing the workload of the adaptive immune system.

insight The degree to which a person has an understanding of their illness or disorder.

instrument nurse The nurse primarily responsible for technical skills, manual dexterity and in-depth knowledge of the anatomic and mechanical aspects of a particular surgery. The instrument nurse handles sutures, instruments and other equipment immediately adjacent to the sterile field.

insulin A hormone that facilitates entry of glucose into fat and muscle cells for energy.

insulin reaction Hypoglycaemia in people with type 1 diabetes mellitus.

intermediate determinants Determinants of health which concern community infrastructure, personal wealth or access to resources, natural, physical and built environments. This level also includes access to healthcare and health systems.

International Classification of Diseases (ICD) Classification of diseases, functioning and disability.

interprofessional care Care provided by an interprofessional team where two or more professions work together as a team with a common purpose, commitment and mutual respect (Freeth et al. 2005, cited in Dunston et al., 2009, p. 6).

intersectorial Working with more than one sector of society to take action on an area of shared interest, such as health.

intracerebral haematomas A collection of blood in the brain tissue, most often located in the frontal or temporal lobes.

intracranial aneurysm Saccular outpouching of a cerebral artery that occurs at the site of a weakness in the vessel wall.

intracranial hypertension See *increased intracranial pressure*.

intracranial pressure (ICP) The pressure within the cranial cavity, usually measured as the pressure within the lateral ventricles.

intraductal papilloma A tiny wart-like growth on the inside of the peripheral mammary duct that causes discharge from the nipple.

intraoperative phase The time during surgery, from beginning to end.

iron deficiency anaemia The most common type of anaemia; results from inadequate iron for optimal red blood cell formation.

irritable bowel syndrome (IBS) A motility disorder of the gastrointestinal tract characterised by alternating periods of constipation and diarrhoea.

ischaemia Deficient blood flow to tissue.

ischaemic Deprived of oxygen.

islets of Langerhans Hormone-producing cells (alpha cells, beta cells and delta cells) scattered through the pancreas.

isograft Tissue transplant where the donor and recipient are identical twins.

jaundice Yellow-to-orange colour visible in the skin and mucous membranes; most often the result of a hepatic disorder.

joint arthroplasty Reconstruction or replacement of a joint.

Kaposi's sarcoma (KS) A vascular malignancy (a tumour of the endothelial cells lining small blood vessels) that presents as vascular macules, papules or violet lesions affecting the skin and viscera. It is often the presenting symptom of AIDS.

keloid Elevated, irregularly shaped, progressively enlarging scar arising from excessive amounts of collagen in the stratum corneum during scar formation in connective tissue repair.

keratin A fibrous, water-repellent protein that gives the epidermis its tough, protective quality.

keratitis Inflammation of the cornea.

keratosis Any skin condition in which there is a benign overgrowth and thickening of the cornified epithelium.

ketamine A central nervous system depressant, best described as a dissociative anaesthetic agent; one of the newer drugs to migrate into the illicit drug-using world.

ketoacidosis A condition of very high blood glucose and insufficient insulin that results in accumulation of ketones and fatty acids in the blood and urine and diuresis.

ketonuria The presence of ketones in the urine.

ketosis An accumulation of ketone bodies produced during the oxidation of fatty acids.

kidney failure A condition in which the kidneys are unable to remove accumulated metabolites from the blood, resulting in altered fluid, electrolyte and acid–base balance.

kidney replacement therapy Therapy provided through haemodialysis, peritoneal dialysis or kidney transplantation.

kidney transplant The surgical insertion of a functioning kidney.

kindling Long-term changes in brain neurotransmission that occur after repeated detoxifications.

kinesthaesia The ability to perceive movement and sense of position.

Klinefelter's syndrome A syndrome in which males have an extra X chromosome in most of their cells (also known as the XXY condition).

knowledge resource base Ways in which knowledge is developed.

Korotkoff's sounds Sounds heard during auscultation of blood pressure.

Korsakoff's psychosis Secondary dementia caused by thiamine (B_1) deficiency that may be associated with chronic alcoholism; characterised by progressive cognitive deterioration, confabulation, peripheral neuropathy and myopathy.

Kussmaul's respirations Deep, rapid respirations associated with compensatory mechanisms.

kwashiorkor protein energy undernutrition (protein energy malnutrition, PEM) Chronic protein deficiency with adequate kilojoules to meet body needs.

kyphosis Exaggerated thoracic curvature of the spine common in older adults.

labyrinthectomy Surgical removal of the labyrinth.

labyrinthitis Inflammation of the inner ear.

laceration Open wound that results from sharp cutting or tearing. Injuries to the integument are at risk of contamination from dirt, debris or foreign objects.

lacunar strokes Thrombotic stroke of smaller cerebral blood vessels that causes tissue to slough off, leaving a small cavity in the brain tissue.

laminectomy Removal of the lamina of the vertebrae.

laparoscopic cholecystectomy Removal of the gallbladder using an endoscope.

laryngectomy Removal of the larynx.

laryngitis Inflammation of the larynx.

leiomyoma See *fibroid tumours*.

leucocytes Also called white blood cells, these are the primary cells involved in both non-specific and specific immune system responses. These cells isolate the infecting organism or injury, destroy pathogens and promote healing.

leucocytosis An increase in the number of leucocytes in the blood (above 10 000/mm^3), usually caused by infection.

leucopenia Abnormal decrease of circulating leucocytes, usually below 5000/mm^3; occurs when bone marrow activity is suppressed, or when leucocyte destruction increases.

leucoplakia Formation of white patches or spots on the mucous membranes or tongue; these lesions may become malignant.

leukaemia ('white blood') A group of chronic malignant disorders of white blood cells (WBCs) and WBC precursors; characterised by replacement of bone marrow by malignant immature WBCs, abnormal immature circulating WBCs and infiltration of malignant cells into other tissues.

libido Instinctual drive associated with sexual desire.

lichen planus Benign inflammatory disorder of the mucous membranes and skin.

life-limiting illness Any illness where it is expected that death will be a direct consequence of the specified illness.

lift A more sustained thrust than normal.

lipoatrophy Atrophy of subcutaneous tissue.

lipodystrophy Hypertrophy of subcutaneous tissue that may result if the same injection sites are used repeatedly, especially with pork and beef insulins.

liposuction A method of changing the contours of the body by aspirating fat from the subcutaneous layer of tissue.

lithiasis Stone formation.

lithotripsy Crushing of renal calculi.

liver transplantation Surgery to remove a diseased liver and transplant a healthy liver (whole or segment) from another person.

lobectomy Surgical removal of tumours in a single lobe of lung.

locked-in syndrome Person is alert and fully aware of the environment, but is unable to communicate through speech or movement as a result of blocked efferent pathways to the brain.

lordosis Increased lumbar curve.

loss An actual or potential situation in which a valued ability, object or person is inaccessible or changed so that it is perceived as no longer valuable.

lower body obesity (peripheral obesity) A waist-to-hip ratio of less than 0.8.

lung abscess Localised area of lung destruction or necrosis and pus formation.

lung compliance Distensibility of the lungs.

lyme disease An inflammatory disorder caused by a spirochete, *Borrelia burgdorferi*, which is transmitted primarily by ticks.

lymphadenopathy The enlargement of lymph nodes (over 1 cm) with or without tenderness. It may be caused by inflammation, infection or malignancy of the nodes or the regions drained by the nodes.

lymphangitis Inflammation of a lymphatic vessel.

lymphocytes Lymphocytes account for 20–40% of circulating leucocytes. Lymphocytes are the principal effector and regulator cells of specific immune responses.

lymphoedema Extremity oedema due to accumulated lymph; may be primary or secondary, resulting from inflammation, obstruction or removal of lymphatic vessels.

lymphoid tissues Connective tissues containing lymphocytes; include tissues of the bone marrow, thymus, lymph nodes and spleen.

lymphomas Malignancy of lymphoid tissue.

macrophages Monocytes mature into macrophages after settling into tissue. Macrophages are large phagocytes. They are important in the body's defence against chronic infections.

macular degeneration Destructive changes in the macula due to injury or gradual failure of the outer pigmented layer of the retina (the retinal layer adjacent to the choroid), which removes cellular waste products and keeps the retina attached to the choroid.

major trauma Serious single-system injury (such as the traumatic amputation of a leg) or multiple-system injuries. Also known as multiple trauma.

malabsorption A condition in which nutrients are ineffectively absorbed by the intestinal mucosa, resulting in their excretion in the stool.

malignant hypertension A hypertensive emergency, marked by a diastolic pressure greater than 120 mmHg.

malignant melanoma (cutaneous melanoma) Skin cancer that arises from melanocytes.

malignant pain Pain associated with a life-threatening illness such as cancer but not limited to cancer pain.

malnutrition Inadequate nutrient intake to meet body needs; may include deficiency of major nutrients (kilojoules, carbohydrates, proteins and fats) or micronutrients such as vitamins and minerals.

manifestations Signs and symptoms of a disease or condition caused by alterations in structure or function.

man-made disasters Either accidental or intentional, they are complex emergencies, technological disasters, material shortages and other disasters not caused by natural hazards.

marasmus (protein energy undernutrition) Insufficient protein and kilojoule intake to meet metabolic needs.

mass casualty incidents Situations in which 100 or more casualties are involved, significantly overwhelming available emergency medical services, facilities and resources.

mastoidectomy Surgical removal of infected mastoid air cells.

mastoiditis Bacterial infection of the mastoid process.

maturity-onset diabetes of the young (MODY) Diabetes in young obese adults.

mean arterial pressure (MAP) The average pressure in the arterial circulation throughout the cardiac cycle; the product of cardiac output and systemic vascular resistance (SVR).

medical–surgical nursing The health promotion, healthcare and illness care of adults, based on knowledge derived from the arts and sciences and shaped by knowledge (the science) of nursing.

meiosis A modified type of cell division in sexually reproducing organisms consisting of two rounds of cell division but only one round of DNA replication. It results in cells with half the number of chromosome sets as the original cell.

melanin Skin pigment that forms a protective shield to protect keratinocytes and nerve endings in the dermis from the damaging effects of ultraviolet light.

melaena Black, tarry stool that contains blood.

memory The ability to store, retain and recall information.

Ménière's disease Chronic disorder of unknown cause characterised by recurrent attacks of vertigo with tinnitus and a progressive unilateral hearing loss.

meningitis Inflammation of the meninges of the brain and spinal cord.

menopause Permanent cessation of menses.

menorrhagia Excessive or prolonged menstruation.

menstrual cycle Cyclic build-up of the uterine lining, ovulation and sloughing of the lining occurring approximately every 28 days in non-pregnant females.

menstruation Periodic shedding of the uterine lining in a woman of childbearing age who is not pregnant.

Mental Health Act Mental health legislation.

mental state assessment (MSA) A clinical assessment that describes the sum total of the examiner's observations at the time of the interview or interaction.

metabolic syndrome A cluster of manifestations often associated with type 2 diabetes. Includes hypertension, visceral obesity, low high-density lipoproteins, high triglycerides, elevated C-reactive protein and fasting glucose > 110mg/dL.

metabolism Consisting of the breakdown of complex structures into simpler forms to produce energy (catabolism) and the combination of simpler molecules to produce and maintain more complex structures necessary to living organisms (anabolism).

metaplasia A change in the normal pattern of differentiation such that dividing cells differentiate into cell types not normally found in that location in the body.

metastasis Secondary tumour; the process by which spreading of malignant neoplasms occurs; the transfer of disease from one organ or part to another not directly connected with it.

metrorrhagia Bleeding between menstrual periods; may be caused by hormonal imbalances, pelvic inflammatory disease, cervical or uterine polyps, uterine fibroids, or cervical or uterine cancer.

microalbuminuria Protein in the urine.

micturition Releasing urine from the urinary bladder (voiding).

mild concussion Brain trauma resulting in a brief loss of consciousness that lasts from seconds to hours.

minor trauma Injury to a single part or system of the body, usually treated in the hospital or emergency department.

mitigation The action taken to prevent or reduce the harmful effects of a disaster on human health or property; it involves future-oriented activities to prevent subsequent disasters or to minimise their effects.

mitochondria Mitochondria provide the energy a cell needs to move, divide, produce secretory products and contract.

mitosis A process of nuclear division in eukaryotic cells conventionally divided into five stages: prophase, prometaphase, metaphase, anaphase and telophase. Mitosis conserves chromosome numbers by allocating replicated chromosomes equally to each of the daughter nuclei.

mitral valve (bicuspid valve) Valve between the left atrium and ventricle in the heart; prevents blood from flowing backwards into the atrium.

monosomy (monosomic) When one member of the chromosome pair is missing—for example, in Turner syndrome (45, X0).

mood The way in which a person describes their feelings at a particular time.

morbid obesity Weight greater than 100% over ideal body weight.

Morton's neuroma A tumour-like mass formed within the neurovascular bundle of the intermetatarsal spaces.

mosaicism A chromosome variation or abnormality that occurs after fertilisation during mitosis at an early cell stage, so that not all cells are affected with the variation; for example, a child who is mosaic for Down syndrome will have some cells with two copies of chromosome 21 and some that have an extra chromosome 21.

mourning The actions or expressions of the bereaved, including the symbols, clothing and ceremonies that make up the outward manifestations of grief.

multifactorial Health conditions determined by multiple factors, including genetic and environmental factors, each having an additive effect.

multiple casualty incidents Incidents in which more than 2 but fewer than 100 persons are injured.

multiple myeloma A malignancy in which plasma cells multiply uncontrollably and infiltrate the bone marrow, lymph nodes, spleen and other tissues.

multiple sclerosis (MS) A chronic degenerative disease of the central nervous system primarily affecting the white matter.

multiple trauma Most often the result of a motor vehicle crash, this type of trauma requires immediate intervention specifically focused on ensuring survival.

murmurs Sounds made by turbulent blood flow through the heart.

muscular dystrophy (MD) A group of inherited muscle diseases that cause progressive muscle degeneration and wasting.

myasthenia gravis Chronic, progressive neuromuscular disorder characterised by fatigue and severe weakness of skeletal muscles.

myocarditis Inflammatory disorder of the heart muscle.

myopia (nearsightedness) A condition in which the eyeball is elongated, causing the image to focus in front of the retina instead of on it.

myringotomy Incision of the tympanic membrane.

myxoedema Systemic condition that develops from inadequate levels of thyroid hormone.

myxoedema coma A life-threatening complication of longstanding, untreated hypothyroidism usually triggered by an acute illness or trauma.

naevi (moles) Flat or raised macules or papules with rounded, well-defined borders.

natural disasters Disasters caused by acts of nature or emerging diseases. Some are unexpected, and some are predictable through advanced meteorological technologies.

natural killer cells (NK cells, null cells) Large, granular lymphocytes (found in the spleen, lymph nodes, bone marrow and blood) that provide immune surveillance and resistance to infection and play an important role in the destruction of early malignant cells.

nausea An unpleasant sensation usually followed by vomiting.

necrosis Tissue cell death.

neglect syndrome (unilateral neglect) A disorder of attention. In this syndrome, the person cannot integrate and use perceptions from the affected side of the body or from the environment on the affected side and, hence, ignores that part.

neoplasm A mass of new tissue (a collection of cells) that grows independently of its surrounding structures and has no physiological purpose.

nephrectomy Removal of the kidney.

nephrotic syndrome A condition marked by massive proteinuria, hypoalbuminaemia, hyperlipidaemia and oedema.

neurogenic bladder Dysfunctional urinary bladder due to lesion of central or peripheral nervous system.

neurogenic shock Shock resulting from an imbalance between parasympathetic and sympathetic stimulation of vascular smooth muscle. If parasympathetic overstimulation or sympathetic understimulation persists, sustained vasodilation occurs and blood pools in the venous and capillary beds.

neuropathic pain Pain caused by a lesion or dysfunction in the nervous system from the primary afferent conducting mechanism to the central nervous system.

neuropathy Damage to peripheral nerves causing hyper- or hyposensation and leading to pain and injury.

neutropenia A decrease in circulating neutrophils.

nicotine An alkaloid found in the nightshade family of plants (*Solanaceae*) which constitutes approximately 0.6–3.0% of the dry weight of tobacco, with biosynthesis taking place in the roots and accumulating in the leaves.

nociception The physiological processes related to pain perception.

nociceptors Sensory nerve fibres that conduct pain impulses from the periphery to the central nervous system.

nocturia Voiding two or more times at night.

node Elements of the immune system connected by lymphatics; upregulates immune function; does not synthesise hormones.

non-conventional terrorist weapons Chemical, biological and nuclear weapons of terrorism; used less frequently than conventional terrorist weapons.

nondisjunction An error in meiosis or mitosis in which members of a pair of homologous chromosomes or a pair of sister chromatids fail to separate properly from each other.

non-Hodgkin's lymphoma (NHL) Lymphoid tissue malignancies that do not contain Reed–Sternberg cells.

non-union A state that exists when the ends of a fracture fail to heal together.

normal sinus rhythm (NSR) Normal heart rhythm, in which impulses originate in the sinus node and travel through normal conduction pathways without delay.

nosocomial Pertaining to or occurring in a hospital.

nosocomial infection Infection contracted during residence in a hospital or extended care facility.

nuclear terrorism Use of a nuclear device to cause mass murder and devastation.

nursing process The series of critical thinking activities nurses use as they provide care to clients; this logical approach to care ensures that clients receive comprehensive and effective care.

nutrients Substances found in food that are used by the body to promote growth, maintenance and repair.

nutrition The process by which the body ingests, absorbs, transports, uses and eliminates food.

nystagmus Rapid involuntary eye movements.

obesity An excess of body fat (adipose tissue).

obstructive shock Shock caused by an obstruction in the heart or great vessels that either impedes venous return or prevents effective cardiac pumping action.

occult bleeding Hidden bleeding.

occult blood Blood that is not obvious on examination from a non-specific source, with obscure signs and symptoms. It may be detected by means of a chemical text or immunological reaction. Occult blood is often present in the stools of people with gastrointestinal lesions.

oedema Accumulation of fluid in the body's tissues; an excess accumulation of fluid in the interstitial space.

oesophageal varices Enlarged, thin-walled veins that form in the submucosa of the oesophagus.

oesophagojejunostomy Removal of the entire stomach with anastomosis of the distal oesophagus to the jejunum.

oestrogen Hormone produced by the ovary.

oligomenorrhoea Scant menses.

oliguria Urine output of less than 400 mL in 24 hours.

oncogene Gene capable of triggering cancerous characteristics.

oncology The study of cancer.

onycholysis The separation of the distal nail plate from the nail bed.

onychomycosis A fungal or dermatophyte infection of the nail plate.

opioids A chemical that works by binding to opioid receptors, which are found principally in the central nervous system and the gastrointestinal tract.

orchitis Infection or inflammation of the testicle.

orthopnoea Difficulty breathing when supine.

orthostatic hypotension A decrease in systolic blood pressure of more than 10 to 15 mmHg and a drop in diastolic blood pressure on standing.

osmosis The process by which water moves across a selectively permeable membrane from an area of lower solute concentration to an area of higher solute concentration.

ossification The process of bone formation.

osteitis deformans See *Paget's disease of bone*.

osteoarthritis (degenerative joint disease) The most commonly occurring of all forms of arthritis. This disease is characterised by loss of articular cartilage in articulating joints and hypertrophy of the bones at the articular margins.

osteomalacia (adult rickets) Metabolic bone disorder characterised by inadequate mineralisation of bone matrix.

osteomyelitis Infection within the bone that can lead to tissue death and necrosis.

osteophytes Bony outgrowths often called 'joint mice'.

osteoporosis Literally defined as 'porous bones', a metabolic bone disorder characterised by loss of bone mass, increased bone fragility and an increased risk of fractures.

osteotomy An incision into or transection of the bone.

ostomy General term for an operation in which an artificial opening is created.

otitis externa Inflammation of the ear canal, commonly known as *swimmer's ear*.

otitis media Inflammation or infection of the middle ear.

otorrhoea Leakage of cerebrospinal fluid through the ear.

otosclerosis Abnormal bone formation in the osseous labyrinth of the temporal bone causing the footplate of the stapes to become fixed or immobile in the oval window. The result is a conductive hearing loss.

ovarian cycle The female cycle that occurs from puberty until menopause in which the production of ova occur.

oxyhaemoglobin The combined form of haemoglobin and oxygen; found in arterial blood, it carries oxygen to body tissues.

pacemaker A pulse generator used to provide an electrical stimulus to the heart when the heart fails to generate or conduct on its own a rate that maintains the cardiac output.

$paCO_2$ Partial pressure of carbon dioxide in arterial blood.

Paget's disease of bone (osteitis deformans) A skeletal disorder that results from excessive osteoclastic activity. Paget's disease is characterised by bone deformity, especially of the long bones of the lower limbs, the pelvis, the lumbar vertebrae and the skull.

pain A subjective response to both physical and psychological stressors.

pain tolerance The amount of pain a person can endure before responding to it.

palliative care An area of care that has evolved out of the hospice experience, but exists outside of hospice programs and is not restricted to the end of life. Palliative care is focused on the relief of physical, mental and spiritual distress for individuals who have an incurable illness and is used earlier in the disease experience than hospice care. The goal of palliative care is to prevent and relieve suffering by early assessment and treatment of pain and other physical, psychosocial and spiritual needs to improve the person's quality of life.

pallor Lack of colour; paleness of skin.

pancreatitis Inflammation of the pancreas.

pannus Granulation tissue that forms in joints affected by rheumatoid arthritis and leads to the formation of scar tissue that immobilises the joint.

PaO_2 Partial pressure of oxygen in arterial blood.

papilloedema Swelling of the optic nerve.

paracentesis Aspiration of fluid from the peritoneal cavity.

paralytic ileus Impaired propulsion or forward movement of bowel contents.

paraplegia Paralysis of the lower portion of the body, sometimes involving the lower trunk.

parasites Organisms that live within, on or at the expense of the person.

parenchyma The key elements of an organ essential to its functioning, as distinct from the capsule that encompasses it and other supporting structures.

Parkinson's disease (PD) Progressive, degenerative neurological disease characterised by non-intention tremor, bradykinesia and muscle rigidity.

paronychia An infection of the cuticle of the fingernails or toenails.

paroxysmal Abrupt onset and termination.

paroxysmal nocturnal dyspnoea (PND) Attacks of acute shortness of breath that occur at night, waking up the person.

partial gastrectomy Removal of a portion of the stomach, usually the distal half to two-thirds.

partial seizures Seizures that involve a restricted part of one cerebral hemisphere; may be simple partial (without loss of consciousness) or complex partial (with loss of consciousness).

partial-thickness burn Burn that involves the entire dermis and the papillae of the dermis (superficial partial-thickness burn) or extends into the hair follicles (deep partial-thickness burn).

passive immunity Temporary protection—provided by antibodies produced by other people or animals—against disease-producing antigens. Protection is gradually lost when these acquired antibodies are used up either by natural degradation or by combining with the antigen.

pathogens Virulent organisms rarely found in the absence of disease.

patient A person who is waiting for or undergoing medical treatment or care. The term used interchangeably with *client* in the Australian nursing context.

patient-controlled analgesia (PCA) A pump with a control mechanism that allows the person to self-manage pain.

pediculosis An infestation with lice, parasites that live on the blood of an animal or human host.

pediculosis capitis An infestation with head lice.

pediculosis corporis An infestation with body lice.

pediculosis pubis An infestation with pubic lice (often called 'crabs').

pelvic inflammatory disease (PID) A term used to describe infection of the pelvic organs.

pemphigus vulgaris Chronic disorder of the skin and oral mucous membranes characterised by vesicle (blister) formation.

penetrance The percentage or likelihood that an individual who has inherited a gene mutation will actually express the disease signs and symptoms in his or her lifetime.

penetrating trauma Occurs when a foreign object enters the body causing damage to body structures.

penicillin-resistant *Streptococcus pneumoniae* (PRSP) Infection transmitted by droplets from the respiratory tract; requires transmission-based droplet precautions.

peptic ulcer An ulcer that occurs in any area of the gastrointestinal tract exposed to acid-pepsin secretions, including the oesophagus, stomach or duodenum.

peptic ulcer disease (PUD) A break in the mucous lining of the gastrointestinal tract where it comes in contact with gastric juice.

perforation Penetration of ulcer through mucosal wall.

pericarditis Inflammation of the pericardium.

perioperative nursing A specialised area of nursing practice that incorporates the three phases of the surgical experience: preoperative, intraoperative and postoperative.

peripheral obesity Obesity characterised by a waist-to-hip ratio of less than 0.8, more commonly seen in women.

peripheral vascular disease (PVD) Impaired blood supply to peripheral tissues, particularly the lower extremities.

peripheral vascular resistance (PVR) The opposing forces or impedance to blood flow as the arterial channels become more and more distant from the heart.

peristalsis Alternating waves of contraction and relaxation of involuntary muscle.

peritoneal dialysis Procedure in which electrolytes, waste products and excess water are removed from the body by diffusion using the peritoneum surrounding the abdominal cavity as the dialysing membrane.

peritonitis Inflammation of the peritoneum.

pernicious anaemia Anaemia resulting from failure to absorb dietary vitamin B_{12} due to lack of intrinsic factor.

persistent (chronic) pain Ongoing and prolonged pain, not always associated with an identifiable cause but often arising from an acute cause.

persistent vegetative state (PVS) Condition of complete unawareness of self and the environment.

personal protective equipment (PPE) Equipment used for the protection of personnel including gloves, masks, goggles, gowns and biological disposal bags (red bags); may also include hoods, helmets, headgear and impermeable suits.

personal responsibility (empowerment) Admitting responsibility for choices made.

person-centred care A holistic approach to the planning, delivery and evaluation of healthcare that is grounded in mutually beneficial partnerships between healthcare professionals, patients and families. Person-centred care is underpinned by the principles of trust, empathy, dignity, autonomy, respect, choice, transparency and desire to help individuals lead the life they want.

pertussis (whooping cough) A highly contagious acute upper respiratory infection cause by the bacterium *Bordetella pertussis*.

phagocytosis A process by which a foreign agent or target cell is engulfed, destroyed and digested. Neutrophils and macrophages, known as phagocytes, are the primary cells involved in phagocytosis.

phantom limb syndrome (phantom pain) A confusing pain syndrome that occurs following surgical or traumatic amputation of a limb. The person experiences pain in the missing body part even though there is complete mental awareness that the limb is gone.

pharmacogenetics The study of how genetic factors influence drug action.

pharyngitis Acute inflammation of the pharynx.

phenotype The expression of a person's entire physical, biochemical and physiological make-up, as determined by the individual's genotype and environmental factors.

pheochromocytoma Tumours of chromaffi in tissues in the adrenal medulla. These tumours, which are usually benign, produce catecholamines (adrenaline or noradrenaline, also known as epinephrine and norepinephrine) that stimulate the sympathetic nervous system.

phimosis Constriction of the foreskin so that it cannot be retracted over the glans penis.

plasmapheresis (plasma exchange) Removal of the plasma component from whole blood.

plastic surgery The alteration, replacement or restoration of visible portions of the body, performed to correct a structural or cosmetic defect.

platelets (thrombocytes) Cell fragments that have no nucleus and cannot replicate.

pleural effusion Collection of excess fluid in the pleural space.

pleuritis Inflammation of the pleura.

pneumonectomy Removal of an entire lung.

pneumonia Inflammation of the lung parenchyma (the respiratory bronchioles and alveoli).

pneumothorax Results when air enters the pleural space due to blunt and penetrating injuries to the chest.

polycystic kidney disease (PKD) A hereditary disease characterised by cyst formation and massive kidney enlargement.

polycythaemia (erythrocytosis) Excess red blood cells characterised by a haematocrit higher than 55%.

polydipsia Excessive thirst.

polymorphisms DNA sequences that have many forms but give the genetic 'directions' for the same thing.

polymyositis A systemic connective-tissue disorder characterised by inflammation of connective tissue and muscle fibres leading to muscle weakness and atrophy.

polyp Mass of tissue that arises from the bowel wall and protrudes into the lumen.

polyphagia Excessive eating.

polysubstance abuse The simultaneous use of many substances.

polyuria A condition where increased blood volume increases renal blood flow and the hyperglycaemia acts as an osmotic diuretic, thereby increasing urine output.

portal hypertension Elevated pressure in the portal venous system that causes rerouting of blood to adjoining lower pressure vessels.

portal systemic encephalopathy Impaired consciousness and mental status due to the accumulation of toxic waste products in the blood (ammonia in particular) as blood bypasses the congested liver.

positioning Positioning exposes the operative site in conjunction with access for anaesthesia administration. Proper positioning is imperative to prevent injury to the person.

post-acute care See *acute care*.

post-concussion syndrome Persistent headache, dizziness, irritability, insomnia, impaired memory and concentration and learning problems following a concussion; may last for several weeks or up to 1 year.

postoperative phase Period when a procedure or surgery has been completed and the person is recovering from the stress associated with the surgery.

postpoliomyelitis syndrome A complication of a previous infection by the poliomyelitis virus.

preload The amount of cardiac muscle fibre tension or stretch that exists at diastole, just before ventricular contraction.

premenstrual syndrome (PMS) Complex of symptoms characterised by irritability, depression, oedema and breast tenderness preceding the monthly menses.

preparedness Having a comprehensive disaster plan in place that coordinates efforts among many people, agencies and levels of government.

preoperative phase Time when preparation of the person for surgery is conducted and completed.

presbycusis Age-related loss of the ability to hear high-frequency sounds; may occur because of cochlear hair cell degeneration or loss of auditory neurons in the organ of Corti.

presbyopia Impaired near vision resulting from a loss of elasticity of the lens related to ageing.

pressure injury Ischaemic lesion of the skin and underlying tissue caused by external pressure that impairs the flow of blood and lymph.

pretibial myxoedema Also known as thyroid dermopathy, pretibial myxoedema refers to lesions of the skin resulting from the accumulation of hyaluronic acid, as a result of thyroid disease.

priapism Sustained, painful erection that lasts at least 4 hours and is not associated with sexual arousal.

primary care Community-based day-to-day healthcare provided by a healthcare provider who acts as the first contact, and principal point of continuing care, for people within the healthcare system, as well as coordinating other specialist care (e.g. general practitioner). Primary care services focus on a person's specific disease or illness using a disease or biomedical management orientation.

primary healthcare (PHC) Essential healthcare based on practical, scientifically sound and socially acceptable methods and technology made universally accessible to individuals and families in the community through their full participation and at a cost that the community and country can afford to maintain in order to prevent illness in the population for which it is provided. A sustainable, community-driven and evidence-based healthcare approach underpinned by the social, cultural, economic and practical determinants of the community.

primary hypertension (idiopathic, essential) A persistently elevated systemic blood pressure.

primary polycythaemia (polycythaemia vera) A neoplastic stem cell disorder characterised by overproduction of red blood cells and, to a lesser extent, white blood cells and platelets.

primary prevention Activities directed toward the protection from or avoidance of potential health risks.

primary survey An initial assessment of a person to determine if there is serious compromise to airway, breathing or circulation.

professional boundaries A health professional's individual determination of the limits of the therapeutic relationship.

progesterone Hormone produced by the ovary; works with oestrogen to control the menstrual cycle.

proptosis Forward bulging of one or both eyes.

prostatitis Inflammation of the prostate gland.

protein energy malnutrition (PEM) The state of decreased body pools of protein with or without fat depletion or a state of diminished functional capacity, caused at least partly by inadequate nutrient intake relative to nutrient demand and/or which is improved by nutritional repletion.

protein-kilojoule malnutrition Deficient protein and kilojoules to meet metabolic needs.

proteinuria Abnormal proteins in the urine.

proximal determinants Determinants which have a more direct impact on health, and include lifestyle and behavioural factors as well as underlying health conditions.

pruritus Subjective itching sensation producing an urge to scratch.

psoriasis Chronic, non-infectious skin disorder that is characterised by raised, reddened, round circumscribed plaques covered by silvery white scales.

psychogenic pain Pain that is experienced in the absence of any diagnosed physiological cause or event.

psychosis A mental health condition in which there is a loss of contact with reality.

psychostimulants A diverse group of natural and synthetic drugs with a wide range of psychological and physical effects, including euphoria, increased energy and irregular heartbeat.

ptosis Drooping of the eyelid.

pulmonary oedema An abnormal accumulation of fluid in the interstitial tissue and alveoli of the lung.

pulmonary embolism Sudden occlusion of a pulmonary artery resulting in disruption of blood supply to the lung parenchyma.

pulmonary hypertension Condition in which the pulmonary arterial pressure is elevated to an abnormal level.

pulmonic valves One of the semilunar valves, separating the ventricles from the great vessels.

pulse Rhythmic pressure wave that can be felt over an artery.

pulse deficit Condition in which the radial pulse is less than the apical pulse, indicating weak, inefficient left ventricular contractions.

pulse pressure The difference between the systolic and diastolic blood pressure.

puncture wound Wound that occurs when a sharp or blunt object penetrates the integument.

pupillary light reflex Reflex in which the pupil contracts in response to a bright light.

pyelonephritis Upper urinary tract inflammation affecting the kidney and renal pelvis.

pyoderma Purulent bacterial infection of skin.

pyuria (bacteriuria) Pus in the urine.

quadriplegia See *tetraplegia*.

quality assurance The process of ensuring quality control activities that evaluate, monitor or regulate the standard of services provided to the consumer.

rabies Viral (rhabdovirus) infection of the central nervous system transmitted by infected saliva that enters the human body through a bite or an open wound.

radiation sickness One of the results of DNA mutation inside cells exposed to ionising radiation.

radiation therapy Therapy that uses radiation to kill a tumour, to reduce its size, to decrease pain or to relieve obstruction.

radiological dispersion bomb Also called a 'dirty bomb', consists of a conventional explosive such as trinitrotoluene (TNT) packed with radioactive waste by-products from nuclear reactors that discharge deadly radioactive particles into the environment.

Raynaud's disease (Raynaud's phenomenon) Disorders characterised by episodes of intense vasospasm in the small arteries and arterioles of the fingers and possibly the toes.

reactive arthritis (Reiter's syndrome) An acute, non-purulent inflammatory arthritis that complicates a bacterial infection of the genitourinary or gastrointestinal tracts.

rebound tenderness Pain that occurs with withdrawal or release of pressure applied during abdominal palpation.

recessive A characteristic that is apparent only when two copies of the gene encoding it are present, one from the mother and one from the father.

reconstruction The recovery aspect of disaster response; during this period restoration, reconstitution and mitigation take place.

recovery A recognised and accepted paradigm, related to a personal journey, that has significant implications for people who have mental health problems, their carers, mental health professionals and mental health services.

recovery (stage of disaster) The stage where restoration, reconstitution and mitigation take place. See also *reconstruction*.

red blood cell (RBCs, erythrocytes) Blood cells shaped like a biconcave disc that contain haemoglobin required for oxygen transport to body tissues; the most common type of blood cell.

referral Timely consultation and handing over of clinical care of people to the appropriate personnel and facility for ongoing management.

referred pain Pain that is perceived in an area distant from the site of the stimuli.

reflex sympathetic dystrophy A group of poorly understood post-traumatic conditions involving persistent pain, hyperaesthesias, swelling, changes in skin colour and texture, changes in temperature and decreased motion.

reflux, urinary Backflow of urine towards the kidneys.

refraction The bending of light rays as they pass from one medium to another medium of different optical density.

refractory period A period in which myocardial cells are resistant to stimulation.

regional anaesthesia Anaesthesia that desensitises the area to be operated but does not involve the full central nervous system or cause sedation.

regional, rural and remote health workforce A statistical representation of nurses working in identified rural and remote areas which includes the number of currently employed nurses, acknowledging their age, experience and qualifications.

regurgitation (valvular) Backflow of blood through an incompletely closed valve into the area it just left.

rehabilitation The process of learning to live to one's maximum potential with a chronic impairment and its resultant functional disability.

Reiter's syndrome See *reactive arthritis*.

remission A period in which symptoms are not experienced even though the disease is still clinically present.

renal artery stenosis Narrowing of the renal artery.

renal colic Acute, severe, intermittent pain in the flank and upper outer abdominal quadrant generally associated with acute obstruction of a ureter and resulting ureteral spasm.

renal failure See *kidney failure*.

renal impairment (decreased renal reserve) A glomerular filtration rate of approximately 50% of normal with normal blood urea nitrogen (BUN) and serum creatinine levels.

renal insufficiency A glomerular filtration rate of 20–50% of normal with azotaemia and some manifestations of renal failure.

renal replacement therapy (RRT) See *kidney replacement therapy*.

renal transplant See *kidney transplant*.

renin–angiotensin mechanism Method of controlling the glomerular filtration rate by releasing chemicals that cause intense vasodilation of the afferent arterioles. Conversely, an increase in the flow of filtrate results in the promotion of vasoconstriction, decreasing the glomerular filtration rate.

repolarisation Restoration of the resting cell membrane potential following generation of an action potential.

respiratory failure Inability of lungs to oxygenate the blood and remove carbon dioxide adequately to meet the body's needs, even at rest.

respite care Short-term or intermittent home care, often using volunteers. These services exist to give the primary caregiver some relief from the burden of full-time care.

response Occurs in the emergency stage of disaster response, after the impact of the disaster event has occurred, the community has been rapidly assessed for damage, and the types and extent of injuries suffered as well as the immediate needs of the community have been determined.

reticular activating system (RAS) A system of reticular neurons within the reticular formation that passes steady streams of impulses through thalamic relays in order to stimulate the cerebral cortex into wakefulness.

retinal detachment Separation of the retina or sensory portion of the eye from the choroid.

retinitis pigmentosa Hereditary degenerative disease characterised by retinal atrophy and loss of retinal function progressing from the periphery to the central region of the retina.

retractions A pulling in of the tissue of the precordium; a slight retraction just medial to the midclavicular line at the area of the apical impulse is normal and is more likely to be visible in thin people.

retrieval Specialised transfer of people with needs exceeding the capacity of their current location to a clinical facility providing a higher level of specialised healthcare.

retrograde ejaculation Seminal fluid discharged into the bladder.

reverse triage Working from the principle of the greatest good for the greatest number, reverse triage is an 'upside-down triage' used in mass casualty events in which the victims who are most severely injured, requiring extensive resources with little chance of surviving, are treated last.

rheumatic disorders Refers to diseases of the muscles and bones as well as the joints.

rheumatic fever A systemic inflammatory disease caused by an abnormal immune response to pharyngeal infection by group A beta-haemolytic streptococci. The condition is characterised by acute inflammation, joint pain, fever and cardiac valve scarring.

rheumatic heart disease (RHD) Slowly progressive valvular deformity following acute or repeated attacks of rheumatic fever; characterised by rigid and deformed valve leaflets; fused valve commissures and fibrosis of chordae tendineae.

rheumatoid arthritis A chronic systemic autoimmune disease that causes inflammation of connective tissue, primarily in the joints.

rhinitis Inflammation of the nasal cavities.

rhinoplasty Surgical reconstruction of the nose.

rhinorrhoea Leakage of cerebrospinal fluid through the nose.

risk factors Defined as individual or environmental variables that are related to the increased likelihood that a negative outcome will occur.

ruptured disc See *herniated intervertebral disc*.

salmonellosis A form of food poisoning caused by ingestion of foods contaminated with one or more varieties of *Salmonella* bacteria.

sarcoidosis Systemic disease characterised by granulomas in the lungs, lymph nodes, liver, eyes, skin and other organs.

sarcoma A tumour arising from supportive tissues.

scabies Parasitic infestation caused by the mite *Sarcoptes scabei*.

schizophrenia A mental disorder characterised by abnormalities in the perception or expression of reality.

sciatica Pain over the sciatic nerve.

scleroderma Hardening of the skin; a chronic condition characterised by the formation of excess fibrous connective tissue and diffuse fibrosis of the skin and internal organs.

sclerotherapy The removal of benign skin lesions with a sclerosing agent that causes inflammation with fibrosis of tissue.

scoliosis A lateral curvature of the spine.

scope of practice Referred to when nurses and employers are deciding what constitutes nursing duty.

scrub person Prepares the sterile field, surgical supplies and equipment for surgical procedures; also assists surgeon and physician assistant by passing instruments, suctioning blood and maintaining the sterile field.

seborrhoeic dermatitis Common and chronic inflammatory disorder of the skin that involves the scalp, eyebrows, eyelids, ear canals, nasolabial folds, axillae and trunk. The cause is unknown.

sebum An oily substance secreted from sebaceous glands; softens and lubricates the skin and hair and also decreases water loss from the skin in low humidity. Sebum also protects the body from infection by killing bacteria.

secondary hypertension Elevated blood pressure resulting from an identifiable underlying process.

secondary prevention Activities designed for early diagnosis and treatment of disease or illness.

secondary survey A head-to-toe assessment of a person that includes all body systems.

seizure An episode of excessive and abnormal discharge of electrical activity within the central nervous system.

semen Contains sperm and fluids secreted by the male reproductive system glands.

seminoma A tumour from seminal or germ tissue.

septic arthritis The type of arthritis that develops when a joint space is invaded by a pathogen.

septic shock One part of a progressive syndrome called systemic inflammatory response syndrome. Beginning with an infection, septic shock progresses to bacteraemia, then sepsis, then septic shock and finally multiple organ failure syndrome.

septicaemia Systemic disease associated with the presence of bacteria or their toxins in the blood.

seroconversion Antibody response to a disease or vaccine.

serum biocarbonate (HCO_3^-) Reflects the renal regulation of acid–base balance. It is often called the metabolic component of arterial blood gases.

severe acute respiratory syndrome (SARS) Lower respiratory illness of unknown aetiology; spread by close person-to-person contact.

sex chromosome A chromosome responsible for determining the sex of an individual.

sexually transmitted infection (STI, sexually transmitted disease, venereal disease) Any infection transmitted by sexual contact, including vaginal, oral and anal intercourse.

shigellosis (bacillary dysentery) An acute bowel infection caused by microorganisms of the *Shigella* genus.

shingles See *herpes zoster*.

shock A clinical syndrome characterised by a systemic imbalance between oxygen supply and demand. This imbalance results in a state of inadequate blood flow to the peripheral tissues, causing life-threatening cellular dysfunction, hypotension and oliguria.

sickle cell anaemia A hereditary, chronic haemolytic anaemia characterised by episodes of sickling, during which red blood cells become abnormally crescent shaped.

sickle cell crisis Severe episodes of fever and intense pain that are the hallmark of sickle cell anaemia.

sinusitis Inflammation of the mucous membranes of one or more of the sinuses.

Sjögren's syndrome An autoimmune disorder that causes inflammation and dysfunction of exocrine glands throughout the body.

skeletal traction Application of a pulling force through placement of pins into the bone.

skin graft Surgical method of detaching skin from a donor site and placing it in a recipient site, where it develops a new blood supply from the base of the wound.

skin tags Soft papules on a pedicle.

skin tear A traumatic wound occurring principally on the extremities of older adults, as a result of friction alone or shearing and friction forces that separate the epidermis from the dermis (partial-thickness wound), or which separate both the epidermis and the dermis from underlying structures (full-thickness wound).

skin traction Traction in which the cradle-like sleeve placed around the extremity exerts its pulling force through the person's skin.

sleep apnoea Absence of airflow through the upper airways for 10 or more seconds.

social determinants of health The social factors that influence the health status and health outcomes of individuals and communities.

social model of health A model of health which views health as multifaceted, focusing on social rather than biological determinants of health. This model emphasises health equity and prevention of illness or injury, as well as collaboration and empowerment. The social model of health is also referred to as new public health or the social ecological model.

solvents Solvents produce a depressant effect on the central nervous system and comprise a range of products producing vapours which, when inhaled through the nose or mouth, may cause an intoxicated feeling and lead to an altered state of consciousness.

somatic cell Any cell in the body that is not a sex cell (ova and sperm).

somatic pain Pain arising from nerve receptors originating in the skin or close to the surface of the body.

Somogyi phenomenon A morning rise in blood glucose to hyperglycaemic levels following an episode of nocturnal hypoglycaemia and a counter-regulatory hormone response.

spasticity Increased muscle tone in disease of the corticospinal motor tract.

speech The manner in which words are articulated.

spermatocoele A mobile, usually painless mass containing dead spermatozoa that forms in the epididymis.

spinal cord injury Injury to spinal cord, usually due to trauma and classified according to systems.

spinal cord tumours Benign or malignant, primary or metastatic tumour of the spinal cord.

spinal shock Temporary loss of reflex function below the level of injury.

splenomegaly Enlargement of the spleen.

sprain Tearing or stretching of a ligament that results from a twisting motion.

sprue A chronic primary disorder of the small intestine in which the absorption of nutrients, particularly fats, is impaired.

squamous cell cancer (SCC) A malignant tumour of the squamous epithelium of the skin or mucous membranes.

squamous cell carcinoma Malignant tumour of the squamous epithelium of the skin or mucous membranes.

standard A statement or criterion that can be used by a profession and by the general public to measure quality of practice.

starvation Inadequate dietary intake; the condition of being without food for long periods of time.

status asthmaticus Severe, prolonged asthma that does not respond to routine treatment. Without aggressive therapy, status asthmaticus can lead to respiratory failure with hypoxaemia, hypercapnia and acidosis.

status epilepticus Continuous seizure activity with only very short periods of calm occurring between intense and persistent seizures.

steatorrhoea Greasy, frothy, yellow stools resulting from excess fat in the faeces.

stem cells (haemocytoblasts) Bone marrow precursor cells for all blood cells.

stem cell transplant (SCT) Infusion of donor stem cells to replace the recipient's blood cell lines (white blood cells, red blood cells and platelets).

stenosis Condition where valve leaflets fuse together and are unable to open or close fully.

stigma Severe social disapproval.

stoma Surface opening.

stomatitis Inflammation of the oral mucosa.

straight traction A pulling force applied in a straight line to the injured body part resting on the bed.

strain Stretching or tearing of muscle fibres that results in bleeding into the tissues.

stress incontinence Loss of usually less than 50 mL of urine occurring with increased abdominal pressure.

stress-induced (erosive) gastritis Inflammation and superficial erosions of the gastric mucosa that may occur as a complication of other life-threatening conditions such as shock, severe trauma, major surgery, sepsis, burns or head injury.

striae A line above or below tissue that differs in colour and texture from surrounding tissue.

stridor High-pitched, harsh inspiratory sound indicative of upper airway obstruction.

stroke (brain attack, cerebrovascular accident, CVA) A condition in which neurological deficits occur as a result of decreased blood flow to a focal (localised) area of brain tissue.

stroke volume (SV) The amount of blood pumped into the aorta with each contraction of the left ventricle.

subacute thyroiditis Inflammation of the thyroid gland.

subdural haematoma A localised mass of blood that collects between the dura mater and the arachnoid mater.

subluxation Partial separation (or dislocation) of the bones of a joint.

substance dependence A severe condition occurring when the use of a chemical substance is no longer under an individual's control for at least 3 months. Continued use of the substance usually persists despite adverse effects on the person's physical condition, psychological health and interpersonal relationships (used interchangeably with 'addiction').

substance-related disorder Described as being maladaptive patterns of substance use leading to clinically significant impairment or distress.

substance use The use of any chemical in a fashion inconsistent with medical or culturally defined social norms despite physical, psychological or socially adverse effects.

sudden cardiac death (SCD) Unexpected death occurring within 1 hour of the onset of cardiovascular symptoms.

sundowning A behavioural change in Alzheimer's disease characterised by increased agitation, time disorientation and wandering during afternoon and evening hours.

superficial burn Burn involving only the epidermal layer of the skin; most often results from damage from sunburn, ultraviolet light, minor flash injury (from a sudden ignition or explosion) or mild radiation burn associated with cancer treatment.

surfactant A lipoprotein produced by the alveolar cells; interferes with adhesion of water molecules, reducing surface tension and helping to expand lungs.

surge capacity The healthcare system's ability to rapidly expand beyond normal services to meet the increased demand for qualified personnel, medical care and public health in the event of a large-scale disaster.

surgery An invasive medical procedure performed to diagnose or treat illness, injury or deformity. Although surgery is a medical treatment, the nurse assumes an active role in caring for the person before, during and after surgery.

surgical debridement The process of excising a wound to the level of fascia (fascial excision) or sequentially removing thin slices of a burn wound to the level of viable tissue (sequential excision).

surveillance Collecting and analysing data to establish a baseline and determine a point at which there is a change or trend in the health of the population.

syndrome of inappropriate ADH secretion (SIADH) Characterised by high levels of antidiuretic hormone (ADH) in the absence of serum hypo-osmolality, and most often caused by the ectopic production of ADH by malignant tumours.

synovitis Inflammation of the synovial membrane lining the articular capsule of a joint.

syphilis A sexually transmitted infection caused by a spirochete that may invade almost any body tissue or organ. It enters the body through a break in the skin or mucous membranes and can be transferred to the foetus through the placental circulation.

systemic lupus erythematosus (SLE) A chronic, inflammatory immune complex connective tissue disease.

systemic sclerosis (scleroderma) Hardening of the skin; a chronic disease characterised by the formation of excess fibrous connective tissue and diffuse fibrosis of the skin and internal organs.

systole A phase during which the ventricles contract and eject blood into the pulmonary and systemic circuits.

systolic blood pressure This arterial pressure wave produced by ventricular contraction (systole) averages 120 mmHg in healthy adults.

T lymphocytes (T cells) Type of lymphocyte that matures in the thymus gland.

tachycardia A heart rate exceeding 100 beats per minute.

tachypnoea Abnormally rapid respiratory rate.

telehealth A broad term that refers to the use of technology to contribute to the provision of healthcare, usually at a distance.

tendonitis Inflammation of a tendon.

tension headache Poorly localised headache characterised by ill-defined bilateral head aching, tightness, pressure or a vice-like feeling.

tension pneumothorax A condition in which an injury to the chest allows air to enter but not escape the pleural cavity.

terrorism An action, or threat of action, that causes harm or interference and is made with the intention of advancing a political, religious or ideological cause.

tertiary prevention Activities designed to restore individuals with disabilities to their optimal level of functioning.

test sensitivity How specifically a test identifies (positive test result) individuals who are affected and/or who have a disease phenotype.

test specificity How specifically a test does not identify (negative test result) individuals who are unaffected or do not have a disease phenotype.

testicular torsion Twisting of the testes and spermatic cord.

testosterone Male hormone produced in the testes.

tetanus Disorder of the nervous system caused by a neurotoxin elaborated by *Clostridium tetani*.

tetany Tonic muscular spasms.

tetraplegia (formerly called quadriplegia) Injury to cervical segments of the cord thus impairing function of the arms, trunk, legs and pelvic organs.

thalassaemia An inherited disorder of haemoglobin synthesis in which either the alpha or beta chains of the haemoglobin molecule are missing or defective.

therapeutic relationship A relationship that aims to empower the person with the knowledge and ability to recover from their illness.

third spacing The accumulation and sequestration of trapped extracellular fluid in an actual or potential body space as a result of disease or injury.

thoracentesis Invasive procedure in which fluid (or occasionally air) is removed from the pleural space with a needle.

thoracotomy Incision of the chest wall to gain access to the lung for surgery.

thought content The actual content of what a person is thinking.

thrill Palpable vibration over the precordium or an artery.

thromboangiitis obliterans (Buerger's disease) An occlusive vascular disease involving inflammation, spasm and clot formation in small- and medium-sized peripheral arteries.

thrombocytopenia A platelet count of less than 100 000 per millilitre of blood.

thromboembolus A thrombus that breaks loose from the arterial wall.

thrombophlebitis See *venous thrombosis*.

thrombotic cerebrovascular accident Cerebrovascular accident caused by occlusion of a vessel by a thrombus (a blood clot) on the interior wall of an artery.

thrombus A blood clot that adheres to a vessel wall.

thyroid gland A gland situated at the front of the throat which secretes thyroid hormones (thyroxine (T_4) and triiodothyronine (T_3)) to regulate the body's metabolic process.

thyroid storm or crisis An extreme state of hyperthyroidism that is rare today because of improved diagnosis and treatment methods. Also called thyroid crisis.

thyroidectomy A procedure performed to treat cancer of the thyroid.

thyroiditis Inflammation of the thyroid gland.

thyrotoxicosis See *hyperthyroidism*.

tidal volume (TV) The amount of air (approximately 500 mL) moved in and out of the lungs with each normal, quiet breath.

tinea capitis A fungal infection of the scalp.

tinea corporis A fungal infection of the body.

tinea pedis A fungal infection of the toenails and feet.

tinnitus Perception of sound such as ringing, buzzing or roaring in the ears.

titrate To determine the concentration of (a solution) by titration or perform the operation of titration.

titration Administration of analgesics in small increasing or decreasing increments.

tolerance A cumulative state in which a particular dose of a chemical elicits a smaller response than before. With increased tolerance, the individual needs higher and higher doses to obtain the desired effect.

tonic–clonic seizures Alternating contraction (tonic phase) and relaxation (clonic phase) of muscles during seizure activity.

tonsillitis Acute inflammation of the palatine tonsils.

tophi Small white nodules in subcutaneous tissue composed of urate deposits resulting from gout.

total colectomy Surgical removal of the entire colon.

total gastrectomy Removal of the entire stomach.

total hip arthroplasty (THA) Replacement of both the femoral head and the acetabulum.

total parenteral nutrition (TPN) Intravenous administration of carbohydrates (high concentrations of dextrose), protein (amino acids), electrolytes, vitamins, minerals and fat emulsions.

toxic epidermal necrolysis (TENS) Rare, life-threatening disease in which the epidermis peels off the dermis in sheets, leaving large areas of denuded skin.

toxic megacolon A condition characterised by acute motor paralysis and dilation of the colon.

toxic multinodular goitre A tumour characterised by small, discrete, independently functioning nodules in the thyroid gland tissue that secrete excessive amounts of thyroid hormone.

trachoma A chronic conjunctivitis caused by *Chlamydia trachomatis,* and a significant preventable cause of blindness worldwide.

traction The application of a straightening or pulling force to return or maintain the fractured bones in normal anatomic position.

transcutaneous electrical nerve stimulation (TENS) A unit that consists of a low-voltage transmitter connected by wires to electrodes that are placed by the person as directed by the physical therapist. The person experiences a gentle tapping or vibrating sensation over the electrodes. The person can adjust the voltage to achieve maximum pain relief.

transdermal Medication absorbed through the skin without injection.

transdisciplinary Transdisciplinary approaches in health involve partnerships and strategies that cross many health and other

professional discipline boundaries to create a holistic approach, addressing multiple influences.

transfusion An infusion of blood or blood components.

transient ischaemic attack (TIA) Brief period of localised cerebral ischaemia that causes neurological deficits lasting for less than 24 hours.

transjugular intrahepatic portosystemic shunt (TIPS) Used to relieve portal hypertension and its complications of oesophageal varices and ascites. A channel is created through the liver tissue using a needle inserted transcutaneously; an expandable metal stent is inserted into this channel, to allow blood to flow directly from the portal vein into the hepatic vein, bypassing the cirrhotic liver. The shunt relieves pressure in oesophageal varices and allows better control of fluid retention with diuretic therapy. Generally it is used as a short-term measure until a liver transplant is performed.

translocation The joining of a part of or a whole chromosome to another separate chromosome.

trauma An injury to human tissues and organs resulting from the transfer of energy from the environment.

traumatic brain injury (TBI) A traumatic insult to the brain capable of causing physical, intellectual, emotional, social and vocational changes.

tremors Rhythmic movement.

triage Means 'sorting'. Triage is a continuous process in which client priorities are reassigned as needed treatments, time and the condition of the clients change.

triage in rural, regional and remote areas Clinical determination of the acuity of the presenting health problems for people seeking healthcare in rural, regional and remote areas.

trichomoniasis A sexually transmitted disease (STD) caused by a parasite passed from person to person.

tricuspid valve A valve between the right atrium and ventricle of the heart; prevents blood from flowing backwards into the atrium.

trigeminal neuralgia (tic douloureux) A chronic disease of the trigeminal cranial nerve (cranial nerve V) that causes severe facial pain.

triglycerides Molecules of glycerol with fatty acids used to transport and store fats in body tissues.

trisomy Possessing three chromosomes instead of the usual two as in trisomy 21 or Down syndrome.

Trousseau's sign Contraction of the hand and fingers in response to occlusion of the blood supply by a blood pressure cuff; caused by decreased blood calcium levels.

tuberculosis (TB) Chronic, recurrent infectious disease caused by *Mycobacterium tuberculosis*; usually affects the lungs, although any organ can be affected.

tumour marker A protein molecule detectable in serum or other body fluids. This marker is used as a biochemical indicator of the presence of a malignancy.

Turner's syndrome A chromosomal abnormality in which all or part of one of the sex chromosomes is absent.

tympanoplasty Surgical reconstruction of the middle ear.

type 1 diabetes One of two types of diabetes characterised by the destruction of beta cells, usually leading to absolute insulin deficiency.

type 1 diabetes mellitus The result of pancreatic islet cell destruction and a total deficit of circulating insulin.

type 2 diabetes One of two types of diabetes the characteristics of which may range from predominantly insulin resistance with relative insulin deficiency to a predominantly secretory defect with insulin resistance. There is no immune destruction of beta cells.

type 2 diabetes mellitus Results from insulin resistance with a defect in compensatory insulin secretion.

ulcer A lesion of the skin or mucous membranes.

ulcerative colitis Chronic inflammatory bowel disorder of the mucosa and submucosa of the colon and rectum.

ultrafiltration Removal of excess body water using a hydrostatic pressure gradient.

unilateral neglect State in which a person is unaware of and inattentive to one side of their body.

upper body obesity (central obesity) Excess intra-abdominal fat characterised by a waist-to-hip ratio greater than 1 in men and 0.8 in women.

uraemia Literally, 'urine in the blood'; the syndrome or group of symptoms associated with end-stage renal failure.

urea An end product of protein metabolism and, along with water, the main constituent of urine.

ureteral stent Thin catheter inserted into the ureter to provide for urine flow and ureteral support.

ureteroplasty Surgical repair of a ureter.

urgency A sudden, compelling need to urinate.

urinary calculi Calculi or 'stones' in the urinary tract.

urinary diversion Procedure to provide for urine collection and drainage following cystectomy. The most common urinary diversion is the ileal conduit.

urinary drainage system The ureters, urinary bladder and urethra.

urinary incontinence Involuntary urination.

urinary retention Incomplete emptying of the bladder.

urolithiasis Development of stones within the urinary tract.

urticaria Hives.

vaccine Suspensions of whole or fractionated bacteria or viruses that have been treated to make them non-pathogenic.

Valsalva manoeuvre Closing the glottis and contracting the diaphragm and abdominal muscles to increase intra-abdominal pressure to facilitate expulsion of faeces.

valvular heart disease Interference of blood flow to, within and from the heart.

vancomycin intermediate-resistant *Staphylococcus aureus* (VISA) A form of *S. aureus* with intermediate resistance to vancomycin.

varicocoele Dilation of the pampiniform venous complex of the spermatic cord.

varicose veins Irregular, tortuous veins with incompetent valves.

vasectomy Sterilisation procedure in which a portion of the spermatic cord is removed.

vasoconstriction Smooth muscle contraction that narrows the vessel lumen.

vasodilation Smooth muscle relaxation that expands the vessel lumen.

vasogenic shock See *neurogenic shock*.

venous stasis Occurs when venous blood collects and stagnates in the lower leg.

venous thrombosis (thrombophlebitis) Blood clot (thrombus) formation on the wall of a vein, accompanied by inflammation of the vein wall and obstructed venous blood flow.

vertigo Sensation of whirling or rotation.

very-low-kilojoule diet (VLKD) A protein-sparing modified fast (1700 to 3500 kilojoules/day or less) under close medical supervision that may be used to treat significant obesity.

vesicoureteral reflux Condition in which urine moves from the bladder back towards the kidney.

visceral pain Pain arising from body organs. It is dull and poorly localised because of the low number of nociceptors.

vital capacity The sum of TV (tidal volume) + IRV (inspiratory reserve volume) + ERV (expiratory reserve volume); approximately 4500 mL in healthy people.

vitamin B_{12} deficiency anaemia Anaemia due to inadequate vitamin B_{12} consumption or impaired absorption.

vitiligo Abnormal loss of melanin in patches.

volatile acids Acids eliminated from the body as a gas.

Volkmann's contracture A common complication of elbow fractures; can result from unresolved compartment syndrome. Arterial blood flow decreases, leading to ischaemia, degeneration and contracture of the muscle.

vomiting The forceful expulsion of the contents of the upper gastrointestinal tract resulting from contraction of muscles in the gut and abdominal wall.

von Willebrand's disease The most common hereditary bleeding disorder, caused by a deficit of or defective von Willebrand factor.

warts (verrucae) Lesions of the skin caused by the human papillomavirus.

weaning Process of removing the person from ventilator support and re-establishing spontaneous, independent respirations.

Weber test A test of hearing; a vibrating tuning fork is placed on the midline of the top of the head and the person is asked to describe where the sound is heard. Normally, sound is heard equally in both ears.

wellness A state of wellbeing; engaging in attitudes and behaviours that enhance quality of life and maximise personal potential.

Wernicke's encephalopathy Caused by thiamine (B_1) deficiency and characterised by nystagmus, ptosis, ataxia, confusion, coma and possible death. Thiamine deficiency is common in chronic alcoholism.

wheeze Continuous, musical sound caused by narrowing of the lumen in a respiratory passage.

white blood cell (WBCs, leucocytes) The blood cells that contribute to the body's defence against microorganisms.

wild-type gene The most common type of gene; designated as normal.

withdrawal Cessation of use of a substance to which an individual has become addicted.

withdrawal symptoms Constellation of signs and symptoms that occurs in physically dependent individuals when they discontinue drug use.

xenograft A transplant from an animal species to a human.

xeroderma A chronic skin condition characterised by dry, rough skin.

xerosis Dry skin.

xerostomia Excessive dryness of the mucous membranes (due to chemotherapy or radiation).

X-linked dominant Any gene found on the X chromosome or traits determined by such genes; also refers to the specific mode of inheritance of such genes. One altered gene on an X chromosome in a male can produce disease, such as haemophilia.

X-linked recessive The result of an altered gene on the X chromosome.

Zollinger–Ellison syndrome Peptic ulcer disease caused by a gastrinoma or gastrin-secreting tumour of the pancreas, stomach or intestines.

INDEX

Page numbers in **bold** indicate definitions of key terms.
Page numbers followed by *t*, *f*, and *b* indicate tables, figures, and boxes.
