Genetic factors also play a part in the development of other health problems. For example, an identical twin of a child with an autism spectrum disorder has 36% to 95% chance of also exhibiting an ASD. Similarly, parents who have one child with an ASD have a 2% to 18% chance of having a second child who is affected (NCBDDD, 2014b). Population health nurses would determine the prevalence of conditions with a genetic component in the overall population and work to initiate programs to prevent or address those conditions that have a high prevalence in the population.

Physiologic function. Considerations related to physiologic function include the incidence and prevalence of specific physical health problems in the child and adolescent populations. Information on the leading causes of child and adolescent deaths in the population provides an overview of the health status of these two groups. The top causes of infant and child mortality in the United States were presented in Table 16-1. The population health nurse would explore relevant mortality figures for the child and adolescent populations in his or her community.

Not all illnesses result in death, and assessment of the child and adolescent population may reveal high prevalence rates of other acute and chronic illnesses. If acute and chronic diseases are prevalent among the child and adolescent population in the community, population health nurses may need to advocate for effective illness prevention programs or services to deal with existing illness. For example, if a large proportion of the school population has asthma, the population health nurse may advocate for creation of school-based asthma management programs. Similarly, if the prevalence of childhood cancers is high, population health nurses may initiate investigation

FOCUSED ASSESSMENT**Assessing Biological Determinants
Influencing Child and Adolescent Health**

- What is the age composition of the child and adolescent population?
- What is the gender composition of the child and adolescent population?
- What is the racial/ethnic composition of the child and adolescent population?
- What are the gender-specific attitudes and expectations regarding boys and girls in the population?
- What is the extent of growth retardation in the child and adolescent population?
- What is the extent of developmental delay in the child and adolescent population? What are the typical causes of delays?
- What are cause-specific child and adolescent mortality rates in the population?
- What are the rates of morbidity for specific acute and chronic health problems in the child and adolescent population?
- What is the level of immunization coverage in the child and adolescent population?

of environmental factors that may be contributing to high prevalence.

Another aspect of physiologic function that should be explored with respect to the child and adolescent populations is immunization. Maintenance of high rates of immunization among children not only protects individual children from disease, but also serves to protect other members of the population via herd immunity. **Herd immunity** is the level of protection provided to unimmunized people when immunization rates are high among the rest of the population. If most children, for example, are immunized against varicella (chickenpox), the chances of an adult without immunity being exposed to the disease are considerably reduced. For further information about recommended immunizations for children and adolescents, see the *External Resources* section of the student resources site.

When immunization levels within the population are low, population health nurses may need to advocate with parents for needed childhood immunizations for individual children or with health care delivery systems to make sure that immunizations are available. For example, the population health nurse might advocate for development of outreach immunization clinics for low-income families in underserved neighborhoods. Elements of a focused assessment of biological determinants affecting the health of children and adolescents are presented above.

PSYCHOLOGICAL DETERMINANTS. A number of psychological determinants influence the health status of child and adolescent populations. These include family dynamics, parental coping and mental health, mental health problems in the child and adolescent population, and the potential for and extent of abuse.

Family dynamics, parental expectations, and discipline. Family dynamics affect the child's or adolescent's interactions with parents and other family members and influence self-image and development of self-esteem. Children who

are subjected to denigration, neglect, or harsh discipline may grow up considering themselves unworthy of love or esteem. Children may also internalize feelings and roles based on the dynamics of their families of origin. For example, children of divorced parents may experience feelings of guilt or emotional distress related to the dissolution of their family. Research has also shown consistently that children exposed to hostility and aggressive behaviors by other family members are more likely to display these behaviors themselves.

Parental expectations of children shape children's expectations of themselves and others. Failure to meet parental expectations may contribute to guilt and depression, whereas unrealistic parental expectations may result in inappropriate discipline for behaviors that are normal for a child's or adolescent's developmental stage. For example, parents may expect a 3-year-old child to be toilet trained even at night and punish the child for bedwetting when this is normal behavior at this age. Parental expectations may also stifle adolescent development. For example, in many Asian cultures, adolescents may be expected to choose an occupation that brings benefit or recognition to the family rather than one in which the adolescent may be personally interested. Such expectations may cause conflict within the family or psychological problems for the adolescent. At the population level, there may be societal expectations of children and adolescents that create stress for both the children and their families.

Parental coping and mental health. Parental stress levels affect their ability to parent effectively. The number of women with small children in the population may provide indirect information on coping abilities, since child rearing has been found to contribute to cumulative stress, and the mental health of women with young children tends to be worse than for those without children. Similarly, the level of mental health problems in the adult population can affect parents' abilities to be effective in caring for their children.

Discipline is frequently a thorny issue in raising children.

(JackF/Fotolia)

Mental health problems in the child and adolescent population. The frequency and types of mental health problems encountered in children and adolescents also provide information about the health status of these populations. For example, from 2004 to 2009 slightly more than 5% of U.S. children 4 to 17 years of age were reported by their parents as having serious mental health problems in the National Health Interview Survey (National Center for Health Statistics, 2011a). In addition, according to the 2011 YRBS, more than 28% of high school students reported feeling so sad or hopeless that they stopped one or more usual activities and nearly 16% had seriously considered suicide in the prior year. Thirteen percent of the respondents had actually made a suicide plan and 2.4% of students nationwide had attempted suicide (Eaton et al., 2012). High rates of mental illness in the child and adolescent population may necessitate population health nursing advocacy for effective treatment services. For example, a population health nurse may assist schoolteachers and counselors to set up a program that facilitates identification and referral of depressed students for treatment services.

Abuse and maltreatment. Physical, sexual, and psychological abuse and neglect are other problems that affect the psychological health of children and adolescents. The effects of childhood abuse are many and varied and may include future prostitution, drug and alcohol abuse, and more unprotected sexual activity.

Abused children are at risk for adverse health effects as well as behavior problems as adults.

Risk factors and protective factors for abuse are summarized in Table 16-2. The problem of child abuse and potential nursing interventions are addressed in more detail in Chapter 30. The *Focused Assessment* provided on the next page includes tips on assessing psychological determinants influencing child and adolescent health.

ENVIRONMENTAL DETERMINANTS. Children are more susceptible than adults to a variety of environmental pollutants. For example, because their nervous systems are not yet fully developed, young children are more susceptible than adults or older children to the effects of lead poisoning. According to the National Center for Environmental Health (NCEH), children in 4 million U.S. households are exposed to lead and approximately 500,000 children have elevated blood lead levels (NCEH, 2012). Lead poisoning may be more prevalent in some population groups than others. For instance, refugee children may arrive in the United States with higher blood lead levels than native children or may develop elevated blood lead levels

TABLE 16-2 Risk Factors and Protective Factors for Child Maltreatment

Risk Factors	Protective Factors
<p>Victimization Risk Factors</p> <ul style="list-style-type: none"> Age under 4 years Special needs that increase caregiver burden <p>Perpetration Risk Factors</p> <ul style="list-style-type: none"> Lack of understanding of children's needs, child development Lack of parenting skills Parental history of maltreatment as a child Parental substance abuse or mental illness Parental characteristics (young age, low education, single parenthood, multiple children, low income) Transient caregivers in the home Parental thoughts that justify maltreatment Social isolation Family disorganization, dissolution, or violence Parenting stress, poor parent-child relationships Community violence Low neighborhood social capital 	<ul style="list-style-type: none"> Supportive family environment Supportive social networks Nurturing parenting skills Stable family relationships Household rules and child monitoring Parental employment Adequate housing Access to needed health care and social services Caring adults outside the family who serve as role models or mentors Communities that support parents and take responsibility for preventing abuse

FOCUSED ASSESSMENT

Assessing Psychological Determinants of Child and Adolescent Health

- What is the extent of mental illness in the child and adolescent population? Among parents?
- What are the cultural expectations of children and adolescents in the population? To what extent do these expectations create stress for children and adolescents?
- What is the suicide rate among children and adolescents in the population?
- What are the typical approaches to discipline in the population?
- What is the extent of abuse in the child and adolescent population? What forms of abuse are prevalent? What factors contribute to abuse of children and adolescents? What is the attitude of the population to abuse of children and adolescents?

after resettlement due to living in older housing contaminated with lead-based paint. Overall, although more children have been routinely tested for elevated blood lead levels, prevalence has declined significantly in recent years. In 2012, 2.5 million children were tested with elevated levels found in less than 1%, a significant decrease from 7.6% in 1997. The percentage of children testing positive varied from state to state with the highest prevalence (19.65%) in Louisiana and the lowest (0.15%) in Arizona and Florida (NCEH, 2014).

Lead exposure is only one of several household environmental hazards that the population health nurse may want to assess in the population. Such an assessment can be guided by the U.S. Department of Housing and Urban Development's (HUD) (2008) "Healthy Housing Inspection Manual." In addition to poisoning hazards, such as lead, carbon monoxide, and so on, the manual addresses assessment for a variety of internal and external safety hazards, pests, and other household health risks. For further information about the manual, see the *External Resources* section of the student resources site.

Insecticide exposure and air pollution are other continuing problems for children and adolescents. In 2011, for example, 66% of U.S. children lived in counties with concentrations above recommended levels for one or more air pollutants. This figure represents an increase from 59% of children in 2009, but an overall decrease from 77% in 2003 (Federal Interagency Forum on Child and Family Statistics, 2012, 2013). Population health nurses should be alert to the presence of environmental pollutants and other hazards and their effects on children. See Chapter 4 for a more detailed discussion of environmental health hazards.

Safety hazards are another major factor in the physical environment that influences the health of children of all ages. Safety concerns are related to children's physical surroundings and their ability to gain access to dangerous substances. As we saw earlier, injuries account for significant morbidity and mortality among children and adolescents. Safety issues in the home can be assessed using the HUD inspection manual described above.

Playground safety is another area that should be assessed by the population health nurse. The National Program for

Playground Safety (2014b) has identified four components of playground safety, creating the acronym SAFE, that should be assessed. These components include supervision, age-appropriate playgrounds, fall surface, and equipment maintenance. Each of these components can be evaluated using assessment kits for child care and school settings developed by the National Program for Playground Safety (2014a). For further information about the tool kits, see the *External Resources* section of the student resources site.

Advocacy for child and adolescent safety is an important aspect of population health nursing for this population. In carrying out this advocacy role, population health nurses might campaign for effective enforcement of seat belt legislation or for gun safety education for local families and youth. Other

Childproofing a home entails different strategies for children of different ages. (JackF/Fotolia)

FOCUSED ASSESSMENT

Assessing Environmental Determinants of Child and Adolescent Health

- What pollutants affect the health of the child and adolescent population? What factors contribute to the presence of pollutants? What are the health effects of pollutants for children and adolescents?
- What safety hazards are present in the community? How do they affect the health of the child and adolescent population?
- How adequate is family housing in the community?

environmental initiatives may include housing inspection and advocacy for removal of environmental hazards or elimination of environmental pollutants. Questions for a focused assessment of environmental factors influencing child and adolescent health are provided above.

SOCIOCULTURAL DETERMINANTS. A variety of sociocultural factors affect the health of children and adolescents. As we saw earlier, a number of these factors have implications for children's psychological health. In addition, factors such as employment, family income, and education levels affect access to health care services and knowledge of health care needs. For example, in 2011, 16.1 million U.S. children (22%) under 18 years of age lived in poverty, an increase from 16% in 2001. In addition, 22% lived in households that were food insecure at least part of the time during the year (Federal Interagency Forum on Child and Family Statistics, 2013). Poverty has a variety of long-term effects on child health beyond access to care. For example, early childhood poverty has been associated with obesity in childhood and into adulthood that is influenced by cumulative exposures to associated factors such as crowding, noise, substandard housing, family turmoil, separation from parents, and exposure to violence (Wells, Evans, Beavis, & Ong, 2010). In addition, children in households with incomes below poverty level have been shown to be at greater risk for diminished learning ability, possibly as a result of increased stress (National Institute of Mental Health, 2012) and are more likely to have behavioral problems, complete fewer years of education, and have more years of unemployment as adults than more affluent children (Macartney, 2011).

Family structure and living arrangements may also affect the health of children and adolescents. Single-parent households, for example, are more likely than two-parent families to have incomes below poverty level. In 2012, 64% of children under 18 years of age lived with two parents, 28% with one parent (primarily a mother), and 4% with neither parent. Slightly more than half (55%) of those without a parent in the household lived with a grandparent (Federal Interagency Forum on Child and Family Statistics, 2013). A small percentage of children live in foster homes. Although foster home placement may be better than circumstances experienced in their birth families, children in foster homes are at greater risk than other children for both mental and physical health problems as adults (Ziotnick, Tam, & Soman, 2012).

Family function also affects the health of children and adolescents. Parental stress is associated with a variety of adverse effects on children, and in the National Survey on Drug Use and Health, nearly 9% of parenting adults reported serious levels of psychological stress (Russell, Sinclair, Poteat, & Koenig, 2012). The presence of substance abuse, smoking, and violence within the family adversely affect child health and the prevalence of these circumstances in the population should be explored by the population health nurse as an indication of factors that may affect child and adolescent health.

Parental employment and work schedules have also been shown to affect child and adolescent health and welfare. Although employment may improve income levels and access to needed goods and services, it may have other effects on child health. Many parents work nonstandard schedules precisely to allow them to arrange favorable child care; however, child care may be less available at nonscheduled times (e.g., during evening and night shifts). Nonstandard work hours also limit parent availability to children when children are home from school and diminish family time. Parents may be prevented from attending many family and community events involving their children, and nonstandard schedules may affect parental sleep and parenting capabilities.

Parental education level affects income and knowledge of effective parenting. These effects are compounded when one or more parents do not speak the dominant language of the community. In 2010, 22% of U.S. children under 18 years of age lived in homes where a language other than English was spoken. Children who do not speak English at home may face difficulties in school and in later employment (Federal Interagency Forum on Child and Family Statistics, 2013). Immigration and acculturation may have both positive and negative effects on children's health. In one study, for example, Spanish-speaking Hispanic boys in Texas were more likely to consume more milk and fruits than those who spoke English, but were less likely to be aware of the relationship between overweight and health problems (Lino et al., 2012).

Legislation and media are two other important sociocultural factors that influence the health of child and adolescent populations. Legislation may have positive or negative effects. For example, state legislation controlling food options available in California school settings has led to a decrease in childhood obesity prevalence. Similarly, legislation regarding

immunization of middle school students has been associated with increased immunity to several childhood diseases.

The United Nations Convention on the Rights of the Child addressed rights of children that should be supported by effective legislation. Among the rights specifically addressed in the convention were the right to education, health care, and protection from execution for crimes committed under the age of 18 years. Although the convention was signed by U.S. delegates, it was not approved by the U.S. Senate due to provisions in many states for trying youth as adults for certain serious crimes. As of 2013, only the United States and Somalia had not ratified the convention (Amnesty International, 2013). In addition, the rights of fetuses are not protected by U.S. law, although in some jurisdictions, fetal rights are protected once a fetus is considered viable. A growing number of states have fetal homicide laws, primarily laws that address the loss of a fetus after intentional injury to the mother (National Conference of State Legislatures, 2013). After birth, a child's rights are recognized, but decision-making rights are generally assigned to parents or to the state in loco parentis until a child reaches the age of majority.

Media coverage and role models are often associated with the assumption of risky behaviors such as smoking, drinking, and sexual activity by adolescents, but media may have beneficial effects as well. For instance, a mass media campaign effectively promoted smoking cessation among smokers exposed to it (Vallone, Duke, Cullen, McCausland, & Allen, 2011).

Prejudice in the social environment may also affect children. For instance, they may be subjected to ridicule by other children at school because of their dress, physical appearance, family culture, or religion. Prejudice may lead to bias-based harassment based on ethnicity, sexual orientation, disability, religion, or gender. Research has indicated that bias-based harassment may be even more detrimental to children's health than generalized harassment related to appearance or speech patterns. Harassment may lead to increased risk for mental illness, substance abuse, and truancy and may result in threats

of violence, victimization, or destruction of one's personal property. In studies, 35% to 40% of children have reported harassment based on prejudicial attitudes, and 15.5% related to their sexual orientation (Russell et al., 2012).

Family religious affiliation may provide social support, but can also lead to potential health problems. For example, children who receive exemption from immunization on the basis of religious beliefs may be at greater risk for disease than their immunized counterparts despite the effects of herd immunity. The *Focused Assessment* below provides tips for assessing sociocultural determinants of child and adolescent health.

BEHAVIORAL DETERMINANTS. Several behavioral determinants also affect the health of children and adolescents. Behavioral considerations in assessing these populations may relate to behaviors of children and adolescents themselves and those of their parents. Major areas for consideration in terms of behavioral determinants include nutrition, rest and exercise, exposure to hazardous substances, safety practices, and sexual activity.

Earlier we noted the need for the population health nurse to assess the extent of poverty and hunger in the population. This is particularly important in developing countries, but should not be neglected in the United States and other areas of the developed world where poverty affects certain subgroups within the population. In the United States, however, nutritional deficits are more likely to reflect the lack of specific nutrients or caloric excess.

Population health nurses should be alert to child feeding practices in the population such as the extent to which newborns are breast-fed or bottle-fed, the availability of fast food in the community, and the extent to which families frequent fast-food establishments. Exclusive breast-feeding for the first 6 months is the recommended dietary standard for infants. Based on CDC data, however, only approximately three fourths of mothers initiate breast-feeding at their child's birth and just 49% continue to breastfeed their infants for 6 months

FOCUSED ASSESSMENT

Assessing Sociocultural Determinants of Child and Adolescent Health

- What are the culturally defined roles for children and adolescents in the community? What effect do these roles have on health?
- How do social factors such as education level, employment, and income affect the health of the child and adolescent population?
- What is the extent of parental employment outside the home? How does this affect child and adolescent health?
- What is the extent of employment among the child and adolescent population? What effect does employment have on health?
- What is the availability of child care services in the community? How adequate are child care services to meet the needs of working parents?
- How adequate are educational opportunities available to the child and adolescent population?
- How do legislative initiatives affect the health of the child and adolescent population?
- To what extent are members of the child and adolescent population subjected to bias-based harassment? What are the effects of harassment on health?

(CDC, 2013). Less exclusive breast-feeding has been associated with increased asthma and allergies (e.g., atopic dermatitis) in children as well as other adverse effects. Breast-feeding is strongly influenced by cultural beliefs and practices and by a family's degree of acculturation. Cultural influences on breast-feeding were addressed in more detail in Chapter 5.

Dietary practices are also important among toddlers and older children and adolescents, and the population health nurse would assess dietary patterns among preschool, school age, and adolescent children in the population. As we saw earlier, obesity is a common problem related to diet and nutrition in the United States and worldwide. According to the National Health and Nutrition Examination Survey (NHANES), the 2009–2010 prevalence of obesity in infants and toddlers was 9.7%, and 16.9% of 2- to 17-year-olds were obese (Ogden, Carroll, Kit, & Flegal, 2012). A tool to assess the nutritional status of individual children and adolescents is available in the *Assessment Guidelines* section of the student resources site.

Problems of obesity can be combated by adequate exercise as well as healthier diets, yet few children and adolescents engage in recommended levels of physical activity. For example, in the 2011 YBRS, just under half of the students surveyed had engaged in any physical activity in the week prior to the survey, and nearly 14% had engaged in no physical activity at all (Eaton et al., 2012). In part, the decline in physical activity among school-age children over the last several years can be attributed to increased television viewing and computer use. In addition to their effects on physical activity levels, these activities have been associated with increased psychological difficulties in some children (de Leeuw, de Bruijin, de Weert-Van Oene, & Schrijvers, 2010).

Many public health professionals have called for an increase in physical education in schools to promote physical activity among school-age children and adolescents. Special attention should be given to the activity needs of children with chronic illness and handicapping disabilities. For example, children with asthma may have reduced activity levels as a result of their reactive airway disease and other children may have impediments to physical activity that limit their participation. Again, population health nurses can advocate for age-appropriate physical activities for children and adolescents, particularly those with special needs.

Exposure of children and adolescents to hazardous substances (e.g., lead) in the physical environment was addressed earlier; however, children and adolescents are exposed to other hazardous substances through their own behavior or that of parents and other family members. For example, from 2006 to 2010, 76% of pregnant women drank alcohol, and 1.4% engaged in binge drinking (Marchetta et al., 2012). Maternal smoking during pregnancy also has significant health effects on their children. Not only are children and adolescents exposed to the effects of smoking in utero, a large percentage of children are also exposed to second-hand smoke in the home setting. In addition, children and adolescents themselves may smoke or use other forms of tobacco. In 2011, for example,

23% of high school students responding to the YBRS reported current cigarette, cigar, or smokeless tobacco use, and nearly 8% of those who smoke, smoked more than 10 cigarettes per day. Nearly half of the smokers had unsuccessfully attempted to quit smoking (Eaton et al., 2012).

As with tobacco, children and adolescents may expose themselves to alcohol and other drugs. In 2011, for example, 40% of high school students in the YBRS reported using marijuana, and 6.8% had used any form of cocaine, while just over 11% had used inhalants. Nearly 71% reported having at least one alcoholic drink in their lifetimes, and roughly 22% of the students reported binge drinking (Eaton et al., 2012).

Use of safety measures is another area that the population health nurse would assess with respect to the child and adolescent population. Use of safety precautions by young children is usually controlled by their parents, but as children get older they should accept greater personal responsibility for their safety. Developmentally, however, adolescents and preadolescents tend to perceive themselves as invulnerable and may fail to use appropriate safety precautions, particularly with respect to safety equipment in recreational pursuits.

Adolescent sexual activity can have a profound influence on health in this population group, particularly in terms of unwanted pregnancy and sexually transmitted diseases (STDs). According to YBRS data, 47% of U.S. high school students in 2011 reported ever engaging in sexual intercourse (Kann, Lowry, Eaton, & Wechsler, 2012), 6% of them prior to age 13 (Eaton et al., 2012). More than a third of the students (37.5%) were currently sexually active, and nearly 19% had had sexual intercourse with more than four partners (Kann et al., 2012). Boys are slightly more likely than girls to report multiple sexual partners (National Center for Health Statistics, 2011b). Only 46% of the sexually active adolescents responding to the YBRS reported using a condom at last intercourse (Kann et al., 2012), and only 13% had been tested for HIV (Eaton et al., 2012).

Sexual activity puts preadolescents and adolescents at risk for STDs and unintended pregnancies. Approximately 400,000 U.S. teenagers 15 to 19 years of age give birth each year—the highest teen birth rate in the world. According to the Pregnancy Risk Assessment Monitoring System (PRAMS), approximately half of adolescents who got pregnant from 2004 to 2008 did not use any form of contraception, and one third of the nonusers thought they could not get pregnant at the time of intercourse, suggesting a significant lack of knowledge on the part of U.S. teens (Harrison, Gavin, & Hastings, 2012). In 2011, the rate of births to adolescent mothers 15 to 17 years of age was 15 births per 1,000 girls (Federal Interagency Forum on Child and Family Statistics, 2013). Although this is a decline from the prior year, adolescent pregnancy remains a significant problem leading to school dropout for the pregnant teen, low birth weight infants, lower academic achievement among the children, and an increased likelihood that girl children will themselves experience adolescent pregnancy (Harrison et al., 2012). Population health nurses should assess the extent of sexual activity in the population as well as the prevalence of STDs and pregnancies

in this population and the extent of educational and preventive services available to adolescents.

Consideration should also be given to sexual orientation and sexual identity in the adolescent population. A gay, lesbian, or bisexual orientation or a transgendered identity may lead to a variety of psychological difficulties for those involved, including feelings of guilt and depression. Sexual orientation or transgenderism may also lead to family difficulties as well as victimization by peers or others. From 2001 to 2009, nine sites administering the YRBS incorporated questions on adolescent sexual orientation. A median of 93% of respondents reported a heterosexual orientation, 1.3% reported a same-sex orientation, 3.7% reported a bisexual orientation, and 2.5% were unsure of their sexual orientation. In addition, 12 sites asked about the gender of sexual partners, 40.5% of the students responding reported no sexual encounters, 53.5% reported only heterosexual contacts, 2.5% reported same-sex encounters, and 3.3% reported encounters with both males and females (Kann et al., 2011). There may be a particular need for population health nurses to advocate for services for sexually active students. A focused assessment of behavioral determinants of child and adolescent health is included below.

HEALTH SYSTEM DETERMINANTS. A number of factors in the health care delivery system influence the health of children and adolescents. Some of these factors include attitudes toward health and health care, usual sources of health care, and use of health care services. According to the National Center for Health Statistics (2013), 4.7% of U.S. children under 18 years of age did not have a regular source of care or a “medical home” in 2010–2011. A *medical home* is a regular source of health care that is characterized by access to preventive care, 24-hour availability of ambulatory and inpatient care, continuity, access to subspecialty referrals and interaction between providers and school and community agencies as needed, and maintenance of a central health record for the child.

Poor children, in particular, may lack a regular source of care, relying on emergency departments for care. This practice increases the costs of care and decreases opportunities for basic preventive and health-promotive services. Having a regular source of care is impeded by reimbursement patterns of federal insurance programs for children, and parental job loss has contributed to periods of uninsurance for many low-income families including children.

In 2011, 7 million U.S. children (9%) had no health insurance coverage (Federal Interagency Forum on Child and Family Statistics, 2013). Children without health insurance are 18 times less likely to have a regular source of health care than those with private health insurance and are 14 times less likely than publicly insured children to have a regular provider (Federal Interagency Forum on Child and Family Statistics, 2013). Tips for assessing health system determinants influencing the health of child and adolescent populations are provided on page 404.

Population health nurses provide services to individual children and adolescents and their families as well as to these populations as aggregates. Whether services are provided to individuals or population groups, population health nurses must first assess their health status and health needs. The focus of this chapter is on meeting the needs of children and adolescents as population groups. A tool for assessing the overall health of an individual child or adolescent is provided in the *Assessment Guidelines* section of the student resources site.

Diagnostic Reasoning and the Health of Child and Adolescent Populations

Based on the data gathered in the assessment of the child or adolescent population, the population health nurse derives diagnoses or statements based on health status and health care needs. Both positive and problem-focused nursing diagnoses may be derived from the data obtained. Diagnoses may reflect

FOCUSED ASSESSMENT

Assessing Behavioral Determinants of Child and Adolescent Health

- What are the dietary patterns typical of children and adolescents in the population?
- What are the physical activity patterns typical of children and adolescents in the population?
- What recreational activities are available to the child and adolescent population? What health benefits and hazards are posed by recreational activities?
- What are the effects of dietary and physical activity patterns on the health of the child and adolescent population?
- What is the extent of child and adolescent exposure to tobacco in the home? To use of other substances?
- What is the extent of tobacco, alcohol, and drug use among the child and adolescent population?
- What is the extent of sexual activity among children and adolescents?
- To what extent is safety instruction (including sexual safety) provided to children and adolescents?
- To what extent do children and adolescents engage in effective safety practices (e.g., seat belt use, protective recreational equipment, condom use).

FOCUSED ASSESSMENT

Assessing Health System Determinants of Child and Adolescent Health

- What percentage of the child and adolescent population has a regular source of health care?
- What is the extent of insurance coverage in the child and adolescent population?
- How adequate are available health services in meeting the needs of the child and adolescent population?
- To what extent do health care needs of the child and adolescent population go unmet?
- To what extent does the child and adolescent population make use of available health promotion and illness prevention services?

the need for measures to promote health, prevent injury or illness, resolve existing health problems, or restore health. For example, a positive population nursing diagnosis related to disease prevention is “high immunization levels due to high parental motivation and access to immunization services.” On the other hand, a problem-focused nursing diagnosis related to immunizations is “lack of appropriate immunizations for age due to lack of access to low-cost immunizations.” Another problem-focused nursing diagnosis for the population related to injury prevention is “increased potential for child abuse due to widespread unemployment and increased community incidence of mental health problems.”

Nursing diagnoses related to resolution of existing health problems in the population are necessarily problem focused. An example of a nursing diagnosis for the child population might be “lack of services available in the community to meet the needs of children with developmental problems.” For adolescents, a relevant nursing diagnosis might be “increased incidence of adolescent pregnancy due to widespread sexual activity, lack of effective sexuality education, and lack of access to contraceptive services.” Nursing diagnoses at the population level might also reflect environmental, psychological, socio-cultural, or behavioral considerations affecting children’s and adolescents’ overall health status.

At the restoration level of health care, nursing diagnoses focus on the need to prevent complications of existing problems or to prevent the recurrence of problems. For example, the nurse might derive nursing diagnoses of “lack of respite for families of children with chronic health problems” or “barriers to effective participation in physical activity by children with handicapping conditions.”

Planning and Implementing Health Care for Child and Adolescent Populations

Population health nursing interventions may be planned to address needs for health promotion, illness and injury prevention, resolution of existing problems, or health restoration. Generally speaking, population health nurses will engage in collaborative planning with members of other disciplines as well as parents and other members of the population. Planning

groups may also include older children and adolescents expected to benefit from the programs developed.

PROMOTING HEALTH. A number of general interventions may be used to promote the health of children and adolescents. These categories of intervention include assuring access to health care; promoting growth and development; providing adequate nutrition; promoting physical activity; promoting dental care; and supporting effective parenting.

Assuring access to health care. One of the best means of promoting the health of children and adolescents is to ensure that they have access to needed health care services. Population health nurses can be instrumental in linking individual children and adolescents to needed services and in assuring that health services are available to these population groups. This can be accomplished by implementing several strategies that have been recommended for improving child health in general and reducing disparities in health status among subpopulations of children and adolescents. These strategies include the following:

- Assuring that all children and adolescents have a regular source of primary health care that includes health promotion services
- Eliminating co-payments and cost sharing for health promotion services
- Assessing the adequacy of health promotion services available to children and adolescents
- Educating parents and health care providers regarding health promotion, and
- Developing information systems to monitor health promotion activities and detect disparities among subpopulations of children and adolescents

Implementing these strategies at the level of the individual child or adolescent will usually require referral to an effective source of care. Implementation may also involve referral for public insurance programs such as the State Childrens Health Insurance Program (SCHIP) or Medicaid for those children and adolescents who are eligible for these programs. At the population level, implementing these strategies will most likely

require population health nurses to be politically active in advocating and planning for services to promote child and adolescent health. For example, nurses may need to advocate for programs that support good nutrition or that promote physical activity among school children.

Promoting growth and development. To develop properly, children need an environment conducive to growth and development. Population health nurses can assist parents and communities in creating such environments. They can educate both the general public and specific families regarding developmental milestones children and adolescents need to accomplish. They can alert parents to the challenges posed by these milestones through **anticipatory guidance**, the provision of information to parents and others regarding behavioral expectations of children and adolescents at a particular age, before they reach that age. Population health nurses can also advocate for community programs and environmental conditions that promote growth and development within safe parameters. For example, they can promote sports appropriate to children's abilities and developmental levels and foster the use of effective safety equipment in such programs. In addition, nurses can advocate for humanistic educational programs that promote emotional and physical, as well as cognitive development. A tool for assessing developmental levels in individual children and adolescents is provided in the *Assessment Guidelines* section of the student resources site.

Providing adequate nutrition. For infants, providing adequate nutrition can best be met by promoting breast-feeding. Population health nurses can encourage pregnant women to consider breast-feeding their infants and provide support with breast-feeding. They may also need to educate mothers on appropriate nutrition while breast-feeding and the need to increase fluid intake. Nurses may also make referrals to a variety of organizations that provide breast-feeding information, support, and assistance. For further information about sources for breast-feeding assistance, see the *External Resources* section of the student resources site. Population health nurses may also need to advocate for conditions that promote breast-feeding, including private areas for breast pumping in work places and places where women can breast-feed their infants in public facilities.

Good nutrition is also an issue for older children and adolescents. As we saw earlier, many U.S. children are overweight or obese and are not eating nutritious diets. Diets tend to be high in calories and carbohydrates and low in fruits and vegetables. Population health nurses can educate the public regarding the efficacy of breast-feeding and the need for and contents of an adequate diet for children and adolescents. In addition, they can advocate for nutritional supplementation programs and for adequate nutrition programs in schools and other institutional settings. Population health nurses can also promote policies that diminish access to “junk foods” for children and adolescents. For example, they can spearhead initiatives to remove candy and soft drink vending machines from schools and

recreation areas and promote healthy fast-food alternatives at popular chain restaurants.

Population health nurses should also be alert to the extent of unhealthy dieting practices, particularly among adolescents. In the 2011 YRBS, for example, 12% of students had not eaten for more than 24 hours, 5% had taken diet pills and similar preparations without a doctor's advice, and 4% had vomited or taken laxatives to lose weight or keep from gaining weight (Eaton et al., 2012). Population health nurses may need to assist children and adolescents to develop healthy body images and, for those who are overweight or obese, direct them to healthy approaches to weight loss. Nurses may also need to advocate for realistic media portrayals of appropriate body images.

Promoting physical activity. Promoting physical activity among children and adolescents is another intervention aimed at promoting health and, in particular, preventing obesity. Based on 2011 YRBS data, only 28.7% of high school students surveyed had participated in strenuous physical activity for at least 60 minutes on each of the preceding 7 days. Conversely, approximately a third of the students reported playing video or computer games or watching television more than 3 hours a day on an average school day (Eaton et al., 2012). Population health nurses can help to educate children and adolescents on the need for increased physical activity and advocate for the inclusion of physical activity in school curricula. They can also advocate for neighborhood environments that promote physical activity (e.g., schools within walking or biking distance of homes, bicycle paths, and safe activity areas).

Promoting dental health. Dental hygiene should begin as soon as the child's first tooth erupts. At this time, parents can be encouraged to rub teeth briskly with a dry washcloth. Later, parents can begin to brush the child's teeth with a soft toothbrush. Older children can be taught to brush and floss their own teeth with adult supervision. Use of fluoridated toothpaste should be encouraged in areas with unfluoridated water; parents can give fluoride-containing vitamins to infants in such areas. In addition to instructing parents about the need for preventive dental care, population health nurses can be actively involved in promoting fluoridation of community drinking water.

Population health nurses can educate the public about the need to wean infants from the bottle before a year of age to prevent bottle-mouth syndrome. The use of sugarless snacks and rinsing the mouth after eating—when brushing is not possible—can also be encouraged. Finally, population health nurses should encourage parents to obtain regular dental checkups for children and to get prompt attention for dental problems. Financial assistance may be needed for such services for low-income families. In such cases, the population health nurse may make a referral for Medicaid in those areas where dental care is covered or work to promote the availability of such services in the population.

Supporting effective parenting. Parenting has been described as one of the hardest jobs in the world and the one for which

we receive the least preparation. Many parents find their first years as parents overwhelming. Areas of difficulty often include lack of confidence in the parental role, meeting the demands of being parents, finding time for oneself, and feeling exhausted. The availability of support for parenting can assist parents in more effective performance of parental roles. Social support may include information resources, material support (e.g., financial help with health care or nutrition needs, educational needs, and so on), emotional support, or assistance in the actual performance of parenting tasks. Support may come from family members or health care and other professionals.

Social support for parents can be provided by population health nurses. For example, they may provide informational support by educating families regarding the needs of children and adolescents, or emotional support in dealing with the frustrations of parenthood. They may also provide emotional support by giving parents both positive and negative feedback on their performance as parents. Less often, population health nurses may assist parents in finding sources of material support through referrals for financial assistance. They may also assist parents to obtain help with actual parenting by arranging for respite services for a parent, or advocating the presence of such services in the community. Population health nurses may also assist parents to develop effective coping strategies to minimize the effects of parenting and other stresses on their health and that of their children.

Support for parenting for parents of young children may frequently address issues of discipline. Table 16-3• provides several general principles of child and adolescent discipline that population health nurses can use to educate community members.

The converse of promoting effective discipline of children and adolescents is preventing abuse of children and adolescents by their parents and other adults or older siblings. In the United States, the role of the population health nurse in identifying and reporting child abuse is quite clear cut. Population health nurses are part of a group of professionals, including health care providers, teachers, and others, who are required by law to report any suspicion of abuse of a child or adolescent. The role of the nurse may not be as clearly defined in other countries. Identification and reporting of child abuse can foster effective parenting because it gives parents an opportunity to learn more appropriate ways to interact with their children. Population health nurses may also refer parents to sources of information or programs that promote effective parenting. These include programs such as the Nurse Family Partnership (NFP) program discussed in Chapter 14 and the Triple P: Positive Parenting Program (n.d.), a program designed to prevent and treat behavioral and emotional problems in children and adolescents. For further information about the Triple P program, see the *External Resources* section of the student resources site.

Additional health promotion measures may be employed in caring for children and adolescents. For example, population health nurses may help to design and implement programs that foster healthy self-concepts and development of effective coping

TABLE 16-3 Principles of Effective Discipline and Related Considerations

Principle	Disciplinary Consideration
Importance	Employ discipline for important matters Do not automatically say “no” to everything Determine what is unacceptable behavior
Consistency	Maintain consistency in what is considered unacceptable behavior Maintain consistency between and among authority figures If a behavior is acceptable in some situations and not in others, make sure children understand the difference and why it is so
Calm	Never act in anger Employ a “cooling off” period, if needed, and make sure children understand the need to deal with anger appropriately
Time	Allow time for compliance with directions before taking disciplinary action
Limits	Set rules and limits for behavior ahead of time and make sure children are aware of them Make sure limits are within the child’s age and developmental capacity to comply Give a warning for unanticipated unacceptable behaviors the first time
Understanding	Make sure children understand the rules and the reasons for them
Prevention	Prevent unacceptable behavior rather than punish it whenever possible Remove sources of temptation from younger children Provide adequate adult supervision of children
Investigation	Ascertain the facts of the situation before taking disciplinary action Ask for the child’s explanation of the situation and his or her behavior When the behavior is unacceptable but the child’s reasons are appropriate, make sure he or she understands why the behavior should not be repeated
Meaningfulness	Make sure children understand the reason for disciplinary action Explain how the child can improve his or her behavior Use a form of discipline appropriate to the child and the situation

strategies in child and adolescent populations. Special intervention may also be warranted to create a healthy self-image in children with chronic conditions or disabilities. For example, the physically handicapped child can be helped to develop skills such as artistic ability that contribute to a positive self-image. Health promotion interventions employed by population health nurses in caring for children are summarized in Table 16-4•.

PREVENTING ILLNESS AND INJURY. The second level of health care involves interventions to prevent illness and

TABLE 16-4 Health Promotion Interventions for Child and Adolescent Populations

Focus	Interventions
Assuring access to health care	Making referrals to sources of health care Promoting a regular source of health care for all children and adolescents Advocating health insurance coverage for children and adolescents
Promoting growth and development	Educating parents and the public regarding normal growth and development Advocating environments that promote adequate growth and development of children and adolescents Promoting continued development of adolescent parents as well as their children
Providing adequate nutrition	Promoting breast-feeding Educating parents, children, and the public regarding nutritional needs of children and adolescents Advocating healthy nutrition in schools and day care centers Advocating for healthier food choices in restaurants and other venues
Promoting physical activity	Educating children and adolescents regarding the need for physical activity Advocating for physical activity in school curricula Advocating for environments conducive to physical activity
Promoting dental care	Promoting dental hygiene Advocating for access to dental care services
Supporting effective parenting	Providing support for parents Educating parents for care of children and adolescents Advocating for respite care as needed Assisting parents with discipline issues Educating parents for realistic expectations of their children Taking action to minimize parental sources of stress Promoting effective parental coping strategies
Other health promotion activities	Promoting effective coping strategies among children and adolescents Assisting in the development of healthy self-concepts among children and adolescents Meeting the health promotion needs of children with special needs

injury in the child and adolescent population. General areas for prevention to be addressed here include preventing prematurity, low birth weight, and infant mortality; preventing communicable diseases and chronic conditions; and preventing injury.

Preventing prematurity, low birth weight, and infant mortality. Premature birth and low birth weight (LBW) are two of the major contributors to infant mortality worldwide. Adolescent mothers are more likely than older mothers to have a low birth weight baby, so preventing adolescent pregnancies can reduce the incidence of prematurity and low birth weight. Population health nurses can advocate for and develop programs designed to delay initiation of sexual activity by providing adolescents and preadolescents with effective sexuality education. In addition, nurses can educate sexually active teenagers regarding contraception and make referrals to contraceptive services for individual teens. They can also advocate for the availability of contraceptive services for this population and encourage the use of long-term modes of contraception that do not rely on on-the-spot compliance or motivation for use (e.g., contraceptive implants). In addition, nurses can assist adolescents

to develop negotiation skills regarding contraceptive use with their partners (Harrison et al., 2012). Particular attention may be needed to see that adolescent mothers continue to meet their own personal developmental tasks as well as meeting those of their children. This may necessitate advocacy on the part of population health nurses for educational assistance and other support services for adolescent parents.

Mothers who smoke or drink alcohol during pregnancy also have a higher risk of premature delivery and LBW babies than nonsmokers. In addition to contributing to death, prematurity and low birth weight start young children off at a disadvantage that may or may not be overcome in later years. Both prematurity and low birth weight and subsequent infant mortality can be prevented by a group of population health nursing interventions including delayed pregnancy, early and effective prenatal care, adequate prenatal nutrition, and prevention of smoking and use of alcohol during pregnancy. Population health nurses can refer individual clients to prenatal services and engage in political advocacy to make sure that such services are available to all women of childbearing age. They can also educate the public regarding the need for adequate prenatal care.

In addition, population health nurses can promote smoking cessation among pregnant women, discourage the use of alcohol in pregnancy, and promote the use of folic acid (NCBDDD, 2013b). Nurses can educate pregnant women and may refer clients to smoking cessation services or advocate for the availability of low-cost smoking cessation services.

In addition to promoting prenatal care, population health nurses can educate pregnant women regarding the need for good nutrition during pregnancy and make referrals for programs such as the Supplemental Nutrition Program for Women, Infants, and Children (WIC). They can also assist women of childbearing age with diabetes control and prepregnancy weight control to minimize the potential for premature births and low birth weight babies (CDC, 2012).

Preventing Communicable Diseases. The most effective means of preventing many communicable diseases among children and adolescents is, of course, immunization. The *Healthy People 2020* target is to achieve 95% immunization rates among all kindergarteners for polio, diphtheria, pertussis, tetanus, measles, mumps, rubella, hepatitis, and varicella vaccines. In 2011, coverage rates among federal immunization program grantees ranged from 54% for varicella to 95% coverage for DTP, with coverage for most other vaccines above 90% (Stokley, Stanwyck, Avey, & Greby, 2011). Vaccination for human papillomavirus (HPV) is also recommended, initially for girls, but also for boys since 2011 (ACIP, 2011a), but coverage remains relatively low. Low coverage rates are also noted for HIB, hepatitis A, and rotavirus vaccines among U.S. children from 19 to 35 months of age, and only approximately 64% of children in this age group had received all of the recommended vaccine doses in 2009 (Wooten, Kolasa, Singletown, & Shefer, 2010).

Similar targets for immunization have been set by the World Health Organization (WHO). In 1974, WHO and UNICEF developed a Global Immunization Vision and Strategy (GIVS). One of the goals of this strategy was to increase to 90% the extent of coverage with three doses of DTP vaccine by 2010. By that time, however, only 67% of countries had achieved the goal (WHO, UNICEF, & Global Immunization Division, Center for Global Health, 2011).

Effective immunization levels may be hampered by health care provider errors as well as parental failure to get their children immunized. For example, many providers mistakenly believe that the presence of mild fever is a contraindication for immunization and forego many valid opportunities to immunize children and adolescents. There have also been a growing number of errors in giving adult Tdap vaccine to children instead of pediatric DTaP. The lower case letters in the Tdap designation indicate the use of a weaker antigen sufficient to boost immunity in previously immunized individuals but not strong enough to support initial development of immunity. These errors result in underimmunization of young children. The Institute for Safe Medication Practices (2010) recommends educating parents on the vaccines their children

Global Perspectives

Global Vaccination Coverage

In 1974, only 5% of the world's children were fully immunized with the vaccines available at the time. In response to improved, but still low immunization rates, the World Health Organization (WHO) and the United Nations Children's Fund (UNICEF) initiated the Global Immunization Vision and Strategy (GIVS) in 2005. GIVS is designed to decrease vaccine-preventable disease-related mortality and morbidity throughout the world through increased immunization rates (WHO, UNICEF, & Global Immunization Division, 2011).

By 2010, worldwide coverage for three doses of DTP vaccine was 85%, as was the rate for receipt of at least one dose of measles-containing vaccine. Rates for immunization with at least three doses of polio vaccine were slightly higher at 86%, while rates for three doses of hepatitis B vaccine were 75% and three doses of Hib vaccine were lowest at only 42%. Approximately 19.3 million children had not received some or all of the routinely recommended vaccines, leaving them susceptible to disease and death from preventable conditions. Nearly half of these children lived in three nations (India, Nigeria, and the Democratic Republic of Congo), and two thirds of them live in 10 countries (WHO, UNICEF, & Global Immunization Division, Center for Global Health, 2011).

Coverage with newer vaccines is even lower. Rotavirus, for example, is the number one cause of diarrheal morbidity and mortality among young children in Latin America and the Caribbean, contributing to more than 8,000 deaths each year. In 2009, WHO recommended rotavirus immunization for all children less than 32 weeks of age. In 2010, only 66% of Latin American and Caribbean children less than 1 year of age had been immunized. As of June, 2011, rotavirus vaccine had been incorporated in the recommended immunization schedule in 14 of the 32 nations in Latin America and the Caribbean (de Oliveira et al, 2011) placing increased emphasis on prevention of this deadly disease but indicating the need for further efforts.

should be receiving and having them double check vaccine appropriateness with providers.

Population health nurses may be actively involved in referring individual children and adolescents for immunizations and in assuring that immunization services are available to these populations. They may also be involved in initiatives to promote immunization. For example, text messages have been found to be effective in reminding parents of the need for immunizations (Stockwell et al., 2012).

Use of immunization services is also facilitated by the development of **immunization information systems (IISs)**, confidential databases that collect and store vaccination data from multiple providers and generate reminders to providers or parents when subsequent immunizations are due. In 2010, the

Task Force on Community Preventive Services recommended that all immunizations be documented in IISs, and the *Healthy People 2020* objectives call for 95% of children under 6 years of age to be included in an IIS. In 2009, however, only 77% of U.S. children's immunizations were recorded in an IIS (Brand, Rasulnia, & Urquhart, 2011). As of 2010, among 54 federal immunization program grantees, more than 11,000 public and 36,500 private immunization providers participated in an IIS, but monitoring of the extent of participation is hampered by lack of knowledge of all vaccine providers in a given jurisdiction and the transient nature of some providers (e.g., settings that provide influenza immunizations only during certain months) (Fath, Ng, & Pabst, 2012).

Population health nurses may also educate the public, particularly adolescents, regarding practices to prevent specific communicable diseases such as HIV/AIDS. UNICEF (2013) has developed four goals to prevent worldwide transmission of HIV infection and development of AIDS in children and adolescents. These include preventing mother-to-child transmission, treating pediatric infection, preventing infection among children and adolescents, and protecting and supporting children affected by AIDS in the family. CDC (2014) has identified several strategies for preventing perinatal transmission of HIV infection including routine testing of pregnant women, repeat screening of women at high risk for infection in the third trimester of pregnancy, antiretroviral treatment for infected women during pregnancy and for their newborns, and elective cesarean sections for women with high viral loads at the time of delivery. Population health nurses can be actively involved in promoting HIV screening for pregnant women and referring individual women for screening. Prenatal care and screening can also help identify women with other STDs (e.g., syphilis, genital herpes, and hepatitis B) that can be transmitted perinatally to their infants. For those women who are infected, population health nurses can provide case management services for diagnosis and treatment as well as educating them and the general public about the dangers of breast-feeding in the presence of HIV infection. They can also arrange for screening of infants born to HIV-infected women and make referrals for treatment as needed.

Population health nurses can also educate sexually active adolescents regarding safe sexual practices to prevent HIV infection and other STDs. They can also advocate for condom availability for this population to prevent transmission and educate adolescents on their use. In addition, population health nurses can help to educate the public and adolescents on the potential for infection with injectable drug use as well as advocate for harm reduction policies and treatment availability for adolescents who use drugs.

Hygiene and protection of food and water supplies are additional measures to prevent communicable diseases in children and adolescents, particularly in developing areas of the world. Population health nurses can educate the public regarding hygiene and preventing contamination of food and water supplies. For example, good hand hygiene, appropriate disposal

Population health nurses can educate both parents and teens about STDs and pregnancy prevention. (Arti Om/Fotolia)

of soiled tissues, and appropriate coughing and sneezing “etiquette” can minimize disease transmission for a wide variety of airborne and enteric pathogens. Nurses can also advocate for safe water and food supplies at the societal level.

Preventing chronic conditions. Population health nurses may also be actively involved in initiatives to prevent the development of chronic conditions in children and adolescents. Preventing injury that leads to chronic disability is discussed later in this section, but population health nurses can help to prevent chronic and handicapping conditions with a genetic component by making referrals for genetic testing and counseling. They can also assist families in making informed decisions about future pregnancies based on screening results.

Population health nursing activities to prevent or resolve problems of overweight and obesity can help to prevent a variety of chronic conditions in childhood and later in life. Weight control may prevent the development of diabetes as well as cardiovascular disease. Similarly, nurses can advocate for elimination of exposures to environmental toxins such as lead and other heavy metals, air pollution, and pesticides. This may involve advocacy to eliminate toxins in the external environment or for parental smoking cessation to prevent exposure to second hand smoke in the home. Population health nurses may also be involved in the development and implementation of programs to prevent initiation of tobacco use and other harmful substances by children and adolescents.

Preventing injury. As we saw earlier, accidental injuries are a major cause of death and disability among children and adolescents, and population health nurses should be actively involved in promoting safety across the age spectrum. Again, parental and public education are the primary means for accomplishing this objective, but population health nurses can also campaign for safe conditions in play areas as well as the development and enforcement of safety regulations such as seat belt and helmet

Safety education is an important issue for parents and children. (Mat Hayward/Fotolia)

use, effective labeling and storage of household chemicals, and so on.

Population health nurses can promote the use of safety devices and equipment. For example, they can educate individual families and their children, as well as the general public, regarding the correct use of age-appropriate restraints in motor vehicles. In addition, they may campaign for strict enforcement of restraint legislation for all vehicle occupants.

Playground safety is another issue for children and adolescents. The National Program for Playground Safety (2014b) has developed recommendations that can be used by population health nurses to educate parents and the general public regarding playground safety. These recommendations include:

- **Adult supervision of children in play activities:** Children should be visible to adults in all areas of the playground. This may necessitate the use of see-through walls for crawl spaces and tunnels. Easily understood rules for play should be posted, reviewed with children, and enforced.
- **Choice of age and developmentally appropriate play equipment:** Playgrounds should be designed with separate areas for children of different ages, with play equipment scaled to child size. Guardrails should be installed to prevent falls off platforms, and standing areas should be provided on platforms more than 6 feet high to permit children to rethink their descent options.
- **Provision of safe surfacing below play equipment:** Approximately 12 inches of loose fill or unitary surfaces (e.g., resilient mats) should be provided under play structures and for six feet in all directions (with more space in front of slides and swings). Structures should be limited to a height of 6 feet for preschool children and 8 feet for school age children.
- **Regular maintenance of all equipment and play surfaces:** Gaps or snags in which clothing can catch or body parts be trapped should be eliminated. Broken equipment or equipment with missing parts should be repaired or removed, and rusted metal, broken plastic, or splintered wood should be eliminated or repaired.

Accidental and, among adolescents and preadolescents, intentional poisoning are other areas of concern for population health nurses caring for child and adolescent populations. Nurses can actively promote safety education regarding the use and storage of poisonous materials among the general public. They may also be involved in efforts to promote effective labeling of hazardous substances and in suicide prevention activities with youth. These activities are discussed in more detail in Chapter 30∞. Selected elements of an education program to promote child and adolescent safety are included in Table 16-5●. An assessment tool that population health nurses can use to assess home safety for children and adolescents is included in the *Assessment Guidelines* section of the student resources site.

Preventing violence. The final area to be addressed in the prevention of illness and injury among children and adolescents is prevention of violence. Prevention of abuse of children and adolescents should focus on reducing risk factors and enhancing protective factors as outlined in Table 16-2. NCIPC (2014c) has identified several effective programs to prevent child maltreatment. Strategies for prevention of violence against youth and youth suicide are addressed in detail in Chapter 30∞.

Prevention of violence by youth is also of concern. The National Center for Injury Prevention and Control (2012c) has identified four strategies to minimize youth violence. The first of these strategies is parent- and family-based programs that improve family function and provide parents with strategies for promoting nonviolent conflict resolution among their children. The second strategy is education of children on handling difficult social situations. Such efforts may occur in schools or other settings frequented by children and adolescents. Mentoring programs that pair young people with caring adults can provide effective role models in conflict resolution. Finally, changes in social and economic circumstances that promote violence can be undertaken. Population health nurses may be involved in advocating for, developing, and implementing programs that address each of these four strategies. For example, they may refer parents to existing support programs or assist in the development of such programs. Similarly, they may be actively involved in educating children and youth for nonviolent conflict resolution or in developing mentoring programs for youth. They may also advocate for societal changes that modify social and economic conditions that promote violence, such as school policies on bullying and harassment. Prevention of violence in the school setting will be addressed in more detail in Chapter 22∞. Table 16-6● summarizes population health nursing interventions related to injury and illness prevention for child and adolescent populations.

RESOLVING EXISTING HEALTH PROBLEMS. Population health nursing interventions to resolve existing health problems in child and adolescent populations centers on screening for health problems, caring for minor illness, and caring

TABLE 16-5 Education to Prevent Injury in Children and Adolescents

Age	Safety Education
Infant (birth–1 year)	Not leaving child unattended on elevated surfaces or in bath Use of car seat restraint Use of safety straps in high chairs, strollers, swings, infant seats, etc. Use of flame-retardant sleepwear Crib safety: Narrow spaces between slats, bumper pads, no plastic coverings, nontoxic paint, no soft pillows Toy safety: No sharp edges or small parts, no long strings, siblings' toys out of reach
Toddler (2–3 years)	Not leaving child unattended in bath or pool Use of car seat restraint Adequate adult supervision Home safety: Outlet covers, sharp and poisonous objects locked away, medications out of reach, child-resistant containers, gated stairs, bathroom doors closed, no dangling electrical cords Play equipment: Age-appropriate and in good repair, on appropriate surface Toy safety: Age-appropriate toys, no small parts Fenced yard/swimming pool
Preschool child (4–6 years)	Use of booster seat in vehicle Adequate adult supervision Home safety: Outlet covers, sharp and poisonous objects locked away, medications out of reach, child-resistant containers, gated stairs, bathroom doors closed, no dangling electrical cords Play equipment: Age-appropriate and in good repair, on appropriate surface Toy safety: Age-appropriate toys, no small parts, adult supervision with potentially hazardous toys Safety practices: Education regarding interaction with strangers, crossing the street, fire safety, water safety
School-age child (6–12 years)	Use of booster seat/adult seat belt based on height and weight Sports safety: Age-appropriate sports, use of safety equipment, adequate adult supervision Firearms: Locked separately from ammunition Safety practices: Education regarding stranger interactions, caring for self at home, sports, bicycling and helmet use, water safety, use of medications, swimming instruction
Adolescent (13–18 years)	Safe driving Use of seat belts Sports safety: Age-appropriate sports, use of safety equipment, adequate adult supervision Safety practices: Education regarding use of firearms, caring for self and others at home, use of medications, dangerous situations (e.g., alcohol and driving, fighting), stranger interactions Sexuality: Abstinence, safe sexual practices Use of drugs and alcohol

for children and adolescents with chronic and life threatening conditions. Each of these areas will be briefly addressed here.

Screening for health problems. Screening for conditions at birth is usually employed when treatment soon after birth leads to improved health outcomes. Each state determines the panel of required screenings for newborns born in that state. Screening occurs for core conditions and secondary conditions. Core conditions are those for which routine screening is conducted; secondary conditions are those that may be identified in the process of screening or confirmatory testing resulting from core screenings. Criteria for the selection of mandatory screening tests include the availability of specific and sensitive screening tests, well understood health outcomes of the condition, availability of an effective treatment that minimizes the effects of the condition, and the possible influence of screening outcomes for future family reproductive decisions. Newborn screening categories include a variety of inherited metabolic disorders including several disorders of amino acid metabolism (e.g., maple sugar urine disease, phenylketonuria), disorders of fatty acid metabolism (e.g., dehydrogenase deficiencies, carnitine

uptake deficit), and disorders of organic acid metabolism (e.g., cobalamin disorders, glutaric acidemia). Other categories of core conditions include endocrine disorders (e.g., congenital hypothyroidism, adrenal hyperplasia), hemoglobin disorders (e.g., sickle cell anemia, S beta-thalassemia), and other conditions such as cystic fibrosis, galactosemia, hearing loss, and severe combined immunodeficiencies (Chen et al., 2012).

Routine screening for existing conditions takes place at other ages as well as at birth. The U.S. Preventive Services Task Force (USPSTF, 2010) has found sufficient evidence of effectiveness to warrant routine screening of newborns for many of the conditions presented earlier. Evidence has also been found for the efficacy of screening for amblyopia, strabismus, and visual acuity in children under 5 years of age, obesity in children from age 6 years on, and major depressive disorders when there is access to services to address positive screening in children from 12 to 18 years of age. The task force, however, has not found sufficient evidence for other routine screenings that are often employed with children. For example, the task force reported insufficient evidence of the utility of screening children for scoliosis or high blood lead levels in the absence of symptoms, even for children

TABLE 16-6 Illness and Injury Prevention Interventions for Children and Adolescents

Focus	Interventions
Reducing prematurity, low birth weight, and infant mortality	<ul style="list-style-type: none"> Providing sexuality education Promoting effective contraception to prevent unplanned pregnancies Promoting effective prenatal care and advocating for low-cost pregnancy services Promoting supplemental nutrition programs for pregnant women and children and making referrals to existing programs Encouraging smoking cessation and elimination of alcohol during pregnancy Assisting with prepregnancy weight control and control of diabetes
Preventing communicable diseases	<ul style="list-style-type: none"> Promoting immunization and referring for immunization services Advocating for development and participation in immunization information systems Promoting cocooning to protect young infants from vaccine preventable diseases Modifying immunization practices or schedules for children with special needs Promoting prenatal care and screening and treatment for HIV and other STDs in pregnant women Promoting condom use and safe sexual practices among adolescents Educating the public and families with respect to good hygiene and protection of food and water supplies Advocating for effective sanitation and safe food and water supplies
Preventing chronic conditions	<ul style="list-style-type: none"> Preventing or resolving obesity and overweight Preventing exposure to environmental toxins Advocating for elimination of environmental toxins Encouraging parental smoking cessation Preventing or resolving obesity and overweight
Preventing injury	<ul style="list-style-type: none"> Encouraging provision of adequate supervision of children and adolescents Advocating for strong legislation and strict enforcement to protect children and adolescents Promoting use of effective safety devices Teaching children and adolescents regarding safety issues Advocating for elimination of safety hazards in the environment

with multiple risk factors (USPSTF, 2010). Some health insurance organizations, however, continue to recommend a variety of screening measures for children of different ages (Wellmark Blue Cross Blue Shield of Iowa & Wellmark Blue Cross Blue Shield of South Dakota, 2013). Table 16-7 provides information about screening procedures recommended for selected age groups.

Other screening procedures may be warranted for children and adolescents in certain circumstances. For example, children with a family history of diabetes may be screened for this condition. Similarly, children or adolescents who have been exposed to traumatic events (e.g., school violence, natural disaster) should be screened for depression and other mental health problems. Population health nurses may be actively involved in providing routine and specialized screening services or may need to advocate for access to these services for the child and adolescent populations.

Caring for minor illness. Children and adolescents experience a variety of minor health problems. Many of these problems can

be addressed effectively at home if parents or other caregivers know how to deal with them. For other problems, or when home care does not resolve the problem, professional care is required. Population health nurses can educate the public regarding appropriate home treatment for minor illness and when professional care is required.

Population health nurses can educate parents and the public on the signs of illness in children, appropriate measures to be taken at home, and when to seek medical intervention. Some approaches to parent education may be more effective than others, for example, a systematic review of related literature found that formal education strategies using mixed educational methods were effective in educating parents about fever control, but semi-formal and informal strategies were not (Young, Watts, & Wilson, 2010).

Caretakers and the public should be acquainted with what is normal and what is abnormal, as well as what home remedies are appropriate and what might be harmful. In addition to providing such information at the population level, population

TABLE 16-7 Screening Procedures for Children and Adolescents

Age	Screening Procedure
Children of all ages	Health history, physical examination, height and weight, development, immunization status
Newborn	Inherited metabolic disorders, endocrine disorders, hemoglobin disorders, other conditions including cystic fibrosis, biotinidase deficiency, galactosemia, hearing loss, and immunodeficiency
Infant	Head circumference (to 24 months), subjective hearing and vision screening (parental report), immunization status, hematocrit/hemoglobin (12 months). Infants at risk should also be screened for low hematocrit or hemoglobin at 4 months, tuberculosis, lead
Early childhood	BMI, blood pressure, objective vision (3 years) and hearing (4 years), autism (24–30 months), amblyopia, strabismus, visual acuity, dental health, and fluoride availability. Young children at risk should be screened for hematocrit/hemoglobin, tuberculosis, cholesterol, lead
Middle childhood	BMI, blood pressure, objective vision and hearing screening, obesity, and fluoride availability. Children at risk should be screened for hemoglobin/hematocrit, tuberculosis, cholesterol, lead
Adolescence	BMI, blood pressure, objective vision and hearing screening, depression, obesity, and fluoride availability. Adolescents at risk should also be screened for hematocrit/hemoglobin; tuberculosis; cholesterol; STDs; drug, alcohol, and tobacco use; pelvic exam

health nurses frequently are called on to assess the health status of specific children and recommend appropriate interventions or make referrals for medical assistance.

Caring for children and adolescents with chronic illness. We most often think of chronic illness in the context of caring for elderly clients, but as we saw earlier many children are also affected in some way by chronic illness. Chronic conditions may also affect children's performance or their interactions with others in the school setting. Problems posed by chronic illness in school settings are addressed in more detail in Chapter 22. Children and adolescents with chronic conditions are sometimes referred to as children and youth with special needs, defined by the Maternal and Child Health Bureau (n.d., p. 1) as "all children who have, or are at increased risk for, chronic physical, developmental, behavioral, or emotional conditions and who also require health and related services of a type or amount beyond that required by children generally."

Much intervention with families with children experiencing chronic illness has focused on development of family resilience or hardiness discussed in Chapter 14. Families dealing with children and adolescents with chronic illnesses encounter a number of needs that population health nurses can assist them with. Some of these needs relate to medical care, education of the parent and/or child for self-management, emotional support, and respite care. Population health nurses also need to help families deal with the disruptions of normal family life caused by the presence of chronic illness in a child, while recognizing the expertise of parents in caring for their own children.

Health system factors that affect family response to chronic illness include fragmentation of care and lack of social support for parental caregivers. Parents may find themselves engaged in frequent battles to obtain needed health and education services

for their children. Support programs for families of children with chronic illnesses are usually severely underfunded, if they exist at all. Parents are often unprepared for the demands of their new caregiver role and may view the presence of a population health nurse as both helpful and disruptive of family routine and privacy.

The need for adaptation to a chronic condition in a child begins with the diagnosis of the condition. Warner and Hauser (2011) noted that diagnosis of chronic illness in a child is related to a series of "ambiguous losses." Ambiguity begins prior to diagnosis with uncertainty about what is wrong with the child. Once a diagnosis has been made, there is ambiguity regarding the meaning of the condition and its effects on the life of the child and the family. Finally, there is ambiguity on what the life course of the child will be like and how the chronic illness will affect abilities and the child's identity. The effects of these aspects of ambiguity are seen in at least five areas. The first is how the family should respond to the diagnosis. The second deals with the adaptation of family roles, rules, and rituals required by the child's illness. Ambiguity may also make it difficult for family members to validate their distress and seek assistance due to the lack of visible signs of a loss. Similarly, the ambiguity of the loss may lead to changes in individual views of the world. For example, either parents or child may view the existence of the condition as unfair or unjust. Finally, ambiguity and uncertainty may compound the physical and psychological exhaustion experienced by family members (Warner & Hauser, 2011).

Initial areas of concern for parents of children with a chronic condition include developing specific care skills (e.g., medication administration, suctioning, physical therapy), reorganizing family roles to incorporate care of the affected child, and continuing to meet other family and social responsibilities.

Meeting medical needs may involve coordinating services, juggling appointments, and obtaining needed supplies and equipment as well as learning how to use them. Parents may also experience lack of time for themselves or to maintain family and social relationships, dealing with their own emotional responses and those of the child and other family members, dealing with feelings of guilt or loss or changes in personal identities (e.g., becoming a caregiver versus other roles) (Hewitt-Taylor, 2008a).

Parents often exhibit exhaustion due to the need to be on 24-hour “call.” Even when children are involved in school or other activities, parents may be called upon to deal with emergencies or questions that arise. Exhaustion or hopelessness may also arise in the context of thoughts of the long-term nature of care for some conditions. For example, if the child is not expected to be able to fend for him or herself as an adult, parents and other family members may need to engage in long-term planning. Another area of concern is parental abilities to maintain their own health. For example, Chen and Clark (2010) found that the level of family support and parental perceptions of their child’s illness were significantly associated with parental health status in families with a child with Duchene muscular dystrophy.

Families with children experiencing a chronic illness may need assistance in developing coping skills that will help them adapt to the burden of care. Families may use three types of coping to help them adjust (Warner & Hauser, 2011). Appraisal-focused coping addresses family members’ appraisal of the meaning of the stressor. For example, family members who perceive the stress as a challenge or care as a demonstration of love and caring may adapt better than those who perceive care demands as a burden. Or, family members may cope by comparing themselves favorably to others who “have it much worse.” Problem-focused coping is action oriented and involves planning and action to deal with sources of stress. Reorganization of family roles so one parent can stay with the child during an extended hospital stay or to relieve some of the caretaking burden from one parent are examples of problem-focused coping. Finally, emotional coping strategies are designed to regulate emotional responses to stress. For example, parents may adopt meditation, exercise, or journaling to help them deal with negative emotions generated by the situation.

The presence of a child with a chronic condition within the family may also have profound effects on relationships within and outside of the family. There may be changes in a spousal relationship, if one exists, as parents take on roles related to the care of the child. Parents may also have less time to spend with other children, and siblings may need to curtail some activities due to the needs of the ill brother or sister. Family outings or vacations may necessitate intensive planning and logistical arrangements to accommodate the care and equipment needs of the child affected. Similarly, the home environment may need to be rearranged to accommodate equipment and supplies needed (Hewitt-Taylor, 2008a).

The effects of a brother or sister with a chronic condition on siblings may be both positive and negative. Research has suggested that they are often more tolerant of individuals who are “different,” but may experience frustration and discrimination when peers react to the ill sibling. Similarly, they may be expected to mature more rapidly than other children their ages and take some responsibility for care of their brothers or sisters (Hewitt-Taylor, 2008a).

The child with a chronic condition also has unique needs that population health nurses can assist the family with. This is particularly true of adolescents with chronic conditions, who need to achieve balance between parental oversight of their disease management (as well as other aspects of life) with autonomy and self-management (Warner & Hauser, 2011). Population health nurses can assist adolescents and their parents to achieve realistic compromises that promote development of adult responsibility. They can also assist parents to recognize that risk taking is a normal part of adolescent development, but make sure that the adolescent is fully aware of the potential consequences of typical risk-taking behavior. For example, the nurse may need to impress upon youth the potential for interactive effects between alcohol and medications taken for a chronic condition. Adolescents may also need help with sexual identity development and sexual expression which is often dependent on the reaction of others to one’s condition (Hewitt-Taylor, 2008b). Population health nurses can also help adolescents to accept more responsibility for management of their own illness (O’Donohue & Tolle, 2011).

In addition, population health nurses may need to be active advocates for transition care for adolescents approaching adulthood. For example, access to many supportive services for children with chronic conditions may cease when they reach their majority. Population health nurses can advocate for supportive care for these young adults as well as advocate for social conditions that help meet the needs of younger children with chronic illness and their families. For example, they may need to work for transportation access for children and adolescents with mobility difficulties or changing rooms in stores that accommodate wheelchairs (Hewitt-Taylor, 2008b).

Both the *Healthy People 2010* and *Healthy People 2020* national objectives call for access to comprehensive services for children and youth with special needs. In 2005–2006, however, less than 18% of children with special needs received care in a health care delivery system that met all the quality indicators for comprehensive services. These indicators include family involvement in decision making, availability of a medical home, adequate health insurance coverage that assures continuity and comprehensiveness of services, provision of screening and surveillance as well as preventive medical and dental services, ease of use, and effective planning for successful transitions into adulthood (Strickland et al., 2011).

Caring for children and adolescents with terminal illness. Families with children with terminal illnesses face many of the same challenges as those whose children have chronic illnesses.

A review of studies of parents with children with cancer indicated four common themes which may characterize families dealing with any life-threatening illness in a child (da Silva, Jacob, & Nasciemento, 2010). Parents reported changes in their relationships, some positive and some negative, that occurred over the course of the child's illness. A second theme was that of communication difficulties when parents found it difficult to discuss their feelings about their child's impending death. Such communication difficulties may also affect others in the family, such as the ill child and siblings. Parents also often found themselves unable to provide mutual support, and gender differences were noted in parental stress and the ability to identify the other's stress. Mothers usually experienced higher levels of stress than fathers, probably due to greater assumption of caretaking roles.

Another theme was that of role changes. Mothers often traded the wife role for the mother role, although many fathers assumed greater caretaking roles over time. In the caretaking role, mothers were often absent from the home to be with the child during extended hospitalizations. This absence resulted in their inability to fulfill roles in relation to other members of the family, with these roles often assumed by the father or other children. Sometimes the fatigue accompanying these role changes meant that neither parent was able to effectively fulfill household and family roles. A final concern voiced by parents was the frequent inability to get input from a co-parent in care decisions due to the time sensitive nature of many of those decisions (da Silva et al., 2010).

All of these issues may lead to deteriorating health in other family members, particularly adult caretakers of the ill child. A longitudinal study of parents of children with terminal illness in Canada found the health of parents worsened in conjunction with the increasing complexity of the child's condition (Brehaut et al., 2011).

The two primary functions of population health nurses in the care of children and adolescents with terminal illnesses are palliative care and assisting families with grieving. WHO (2014) has noted that palliative care for children is "active total care of the child's mind, body, and spirit, and also involves giving support to the family" (para. 1). The goal of palliative care is to enhance the quality of life of the child and his or her family through control of symptoms and alleviation of other conditions (e.g., loneliness, depression) that may diminish quality of life. Palliative care also seeks to ensure continued effective functioning of the family unit. Population health nurses may be involved in the provision of palliative care for individual children or adolescents or refer clients for palliative and hospice care services. At the aggregate level, they can work to assure the availability of pediatric palliative and hospice care services in the community and their accessibility to all those in need of them.

Assisting families to deal with grief is another important function of the population health nurse in caring for children and adolescents with terminal illnesses. These families engage in anticipatory grieving that may be characterized by feelings of despair, hopelessness, and worthlessness. Such feelings

have been found to be more intense in families whose child is newly diagnosed (Al-Gamal & Long, 2010), but may resurface throughout the trajectory of the child's illness. Population health nurses can assist family members, including the child affected, to discuss their feelings and to seek mutual support. The nurse can also refer families to hospice services, or to religious counselors, if desired by the family. Nurses can also link family members with support groups to help them deal with their grief before and/or after the child's death.

One innovative and effective approach to providing mutual support is the use of computer technology. Population health nurses can refer families to existing services or may be involved in their development and implementation. In addition, population health nurses may advocate for the availability of bereavement services for families of children with terminal illnesses. Table 16-8 • summarizes potential population health nursing interventions for resolving problems related to the care of children and adolescents with terminal illnesses as well as other physical and mental health problems experienced by children and youth.

RESTORING HEALTH AND MANAGING LONG-TERM CONDITIONS.

Health restoration addresses the particular health problems experienced by children or adolescents. Generally, there are three aspects to health restoration with children and adolescents: promoting self-management, preventing further consequences, and promoting adjustment.

Promoting self-management. Population health nurses may assist parents and older children and adolescents to develop self-management expertise related to care of chronic conditions or to engage in other self-management activities. For example, resolving an existing problem of teenage pregnancy may involve referral for prenatal care and education to promote a healthy pregnancy, but restoring a state of health and promoting self-management may involve educating the adolescent parent on child care and promoting further development for the teenager as well as for the newborn. Self-management in this instance may also involve assisting the family to adjust to the presence of a new member and modifying family roles to allow the teenager to assume the parenting role while providing adequate support for that role.

In the case of chronic illness, self-management may involve assisting an older child or adolescent to take increasing responsibility for medication compliance, adherence to dietary restrictions and so on. The population health nurse may also help the child to maintain as normal a lifestyle as possible in the face of the chronic condition.

At the population level, the population health nurse might be involved in the development of programs that promote self-management by families and children affected by a variety of health problems. For example, he or she might initiate educational programs and self-help groups for families of children with asthma. The nurse may also need to advocate for insurance coverage for such services and for their availability and accessibility in the community.

TABLE 16-8 Interventions to Resolve Existing Health Problems in Child and Adolescent Populations

Focus	Interventions
Screening for health problems	<ul style="list-style-type: none"> • Providing routine screening services for children and adolescents • Interpreting screening test results for families and making referrals for follow-up diagnosis and treatment • Advocating for available and accessible screening services • Planning and implementing population-based health screening programs for children and adolescents
Caring for minor illness	<ul style="list-style-type: none"> • Educating families and the public to recognize signs of minor illness in children and adolescents • Educating families and the public regarding home care of minor illness and how to know when professional care is needed • Providing or referring for treatment for minor illness for individual children/adolescents, when needed • Advocating available and accessible services for minor illness care
Caring for children and adolescents with chronic illnesses	<ul style="list-style-type: none"> • Educating families and the public regarding signs of chronic illness in children and adolescents • Referring individual children and adolescents for diagnosis and treatment of chronic illness • Providing case management services for children and adolescents with chronic illness • Assisting families to adapt to the care needs of a child or adolescent with chronic illness • Teaching children and adolescents and their families for self-management of chronic illness • Referring caretakers of children and adolescents with chronic illnesses for respite services • Promoting normal growth and development in children with chronic illness • Advocating environmental changes to minimize disabilities due to chronic illness • Advocating available and accessible diagnostic and treatment services for children and adolescents with chronic illness
Caring for children and adolescents with terminal illness	<ul style="list-style-type: none"> • Providing or referring families for palliative care and hospice services • Assisting families with the grief process • Referring children and adolescents and their families for support services as needed • Initiating bereavement care • Advocating available and accessible palliative and bereavement care for children and adolescents and their families • Developing technology-mediated mutual support groups for families of children with terminal illnesses

Preventing consequences. Health restoration also involves maintaining health by preventing further consequences of health problems. For example, the child with diabetes requires attention to diet, exercise, and medication to control the diabetes and prevent physical consequences of the disease itself. At the same time, attention must be given to promoting the child's adjustment to the condition and normalizing his or her life as much as possible. Nursing interventions would be geared toward convincing the child to stick to his or her diet and promoting social interactions with peers.

The nurse might also need to intervene to prevent or minimize the consequences of a child's condition for the rest of the family. For example, the nurse might need to point out to parents that in their concern for the child with a chronic heart

condition, they are neglecting the needs of siblings. Health restoration for an infant with AIDS may entail educating parents on the disposal of bodily fluids and excreta to prevent infection of other family members. Health restoration may entail a wide variety of activities on the part of the nurse, from education on how to deal with specific conditions to referral for assistance with major medical expenses. Nurses may also need to act as advocates for children with chronic conditions. The example that most readily comes to mind is the need for advocacy for children with AIDS who are still well enough to attend school.

Emotional support by the nurse is a very important part of health restoration for children with chronic conditions and their families. Parents' and children's feelings about the condition need to be acknowledged and addressed. The nurse can

also reinforce positive activities on the part of parent or child. Again, this support may need to be extended as families go through the grieving process. Grieving will probably occur with most chronic illnesses, even those that are not terminal, and the nurse should be prepared to reassure families that their feelings of grief are normal and to support them through this process.

Again, advocacy may be needed at the population level to assure access to needed services that prevent consequences of health problems. For example, the population health nurse may need to advocate for special education arrangements for adolescent parents that permit them to continue their education while fulfilling their parental responsibilities.

Promoting adjustment. The population health nurse may also engage in activities that are designed to return the child and family to a relatively normal state of existence. For children or adolescents with chronic illnesses or disabilities, this means restoring function as much as possible, preventing further loss of function, and assisting the child and his or her family to adapt lifestyles and behaviors to the presence of a chronic condition. The population health nurse might accomplish this by encouraging the family to discuss problems posed by the child's condition and to view the condition in the most positive light possible. The nurse should also encourage the family to normalize family life as much as possible. For example, if the Little League activities of a sibling have been curtailed because of an exacerbation of the child's illness, parents should make an attempt to reinstitute those activities as soon as the youngster's condition is stable, or the family can be encouraged to call on members of their support network to take the sibling to baseball practice and games. Interventions that might be used by population health nurses in health restoration with children and adolescents and their families are presented in Table 16-9.

Evaluating Health Care for Child and Adolescent Populations

The effectiveness of nursing interventions for the individual child or adolescent is assessed in the same manner that care of any specific client is evaluated. Has intervention fostered the child's growth and development? Is the child's nutrition adequate to meet his or her needs? Is the child up to date on his or her immunizations? Have physical or psychological hazards been eliminated from the child's environment? Is the child receiving health care as needed? Have acute health care problems been resolved?

The population health nurse would also examine the extent to which care has contributed to the adjustment of the child and family to an existing chronic disease or disability. Are parents comfortable and adequately prepared to parent a child with special needs? Do they perform this role adequately? Have complications of the child's condition been prevented?

The population health nurse may also be involved in evaluating the effects of interventions at the aggregate level. This might entail evaluating the extent to which national objectives for the health of children and adolescents have been achieved. The *Healthy People 2020* objectives on pages 418 to 420 address selected issues related to child and adolescent health. Current data for these and other related objectives for child and adolescent health are available from the U.S. Department of Health and Human Services *Healthy People 2020* website. Population health nurses might be involved in gathering data related to the status of these objectives in their own communities to evaluate the effectiveness of child and adolescent care. They may also be involved in activities to evaluate the effects of other initiatives related to child and adolescent health.

TABLE 16-9 Health Restoration Interventions for Child and Adolescent Populations

Focus	Interventions
Promoting self-management	<ul style="list-style-type: none"> • Educating children, adolescents, their families, and the public to promote self-management related to health problems • Advocating for societal and environmental changes needed to promote self-management of health issues among children and adolescents and their families • Advocating for, planning, and implementing accessible services that promote self-management
Preventing consequences	<ul style="list-style-type: none"> • Monitoring and promoting effective disease management for children and adolescents with chronic conditions • Advocating for support services for children and adolescents with chronic conditions • Promoting development of children and adolescents with chronic conditions • Providing or referring for counseling for children and adolescents and their families as needed • Providing emotional support for children, adolescents, and their families • Referring caretakers for respite care as needed
Promoting adjustment	<ul style="list-style-type: none"> • Promoting lifestyle changes consistent with effective disease management • Promoting normal family life as much as possible • Promoting communication within the family and between the family and health care providers • Initiating or referring families to existing support groups • Advocating for societal and environmental changes necessary for effective adjustment to a chronic illness

Healthy People 2020

Selected Objectives Related to Child and Adolescent Health

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCE
MICH-1 Reduce the rate of fetal and infant deaths MICH-1.3 All infant deaths	6.7 infant deaths per 1,000 live births (2006)	6.0 infant deaths per 1,000 live births	6.4 (2009)	National Vital Statistics System (NVSS), CDC, NCHS
MICH-3 Reduce the rate of child deaths MICH-3.1 Children aged 1–4 years MICH-3.2 Children aged 5–9 years	29.4/100,000 (2007) 13.8/100,000 (2007)	26.5/100,000 12.4/100,000	26.5 (2010) 11.4 (2010)	National Vital Statistics System (NVSS), CDC, NCHS
MICH-4 Reduce the rate of adolescent and young adult deaths MICH-4.1 Adolescents 10–14 years MICH-3.1 Adolescents 15–19 years	16.5/100,000 (2007) 60.3/100,000 (2007)	14.8/100,000 54.3/100,000	14.3 (2010) 49.4 (2010)	National Vital Statistics System (NVSS), CDC, NCHS
MICH-8.2 Reduce very low birth weight	1.5% of live births (2007)	1.4% of live births	1.4% (2010)	National Vital Statistics System (NVSS), CDC, NCHS
MICH-10-2 Increase the proportion of pregnant women who receive early and adequate prenatal care	70.5% (2007)	77.6%	NDA	National Vital Statistics System (NVSS), CDC, NCHS
MICH-11.3 Increase abstinence from cigarette smoking among pregnant women	89.6% (2007)	98.6%	NDA	National Vital Statistics System (NVSS), CDC, NCHS
MICH-21.5 Increase the proportion of infants who are breast-fed exclusively through 6 months	14.1% (2006)	25.5%	14.6% (2008)	National Immunization Survey (NIS), CDC, NCIRD, and NCHS
MICH-25 Reduce the occurrence of fetal alcohol syndrome (FAS)	3.6//10,000 live births (2006)	N/A*	NDA	Fetal Alcohol Syndrome Surveillance Network (FASSnet), CDC, NCBDDD
MICH-30.1 Increase the proportion of children who have access to a medical home	57.5% of children under age 18 years (2007)	63.3%	54.4% (2011–2012)	National Survey of Children's Health (NSCH), HRSA, MCHB and CDC, NCHS
MICH-30.2 Increase the proportion of children with special health care needs who have access to a medical home	47.1% of children under age 18 years	51.8%	43% (2009–2010)	National Survey of Children with Special Health Care Needs (NSCSHCN), HRSA, MCHB and CDC, NCHS
AH-5.6 Decrease school absenteeism among adolescents due to illness or injury	5% missed 11 or more whole school days (2008)	TBD	5.3% (2011)	National Health Interview Survey (NHIS), CDC, NCHS
AH-10 Decrease the proportion of public schools with a serious violent incident	17.2% of public schools (2007–2008)	15.5%	NDA	School Survey on Crime and Safety (SSOCS), ED, IES, NCES

Healthy People 2020 (Continued)

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCE
AH-11.1 Decrease the rate of minor and young adult perpetration of violent crimes	444/100,000 adolescents and young adults aged 10 to 24 years (2008)	399.6 arrests/100,000 population aged 10 to 24 years	NDA	Violent Crime Index, Uniform Crime Reporting Program, DOJ, FBI, CJIS
IID-8 Increase the proportion of children aged 19 to 35 months who receive the recommended doses of DTaP, polio, MMR, Hib, hepatitis B, varicella and PCV vaccines	44.3% of children (2009)	80%	68.5% (2011)	National Immunization Survey (NIS), CDC, NCIRD, and NCHS
IID-18 Increase the proportion of children under 6 years of age whose immunization records are in fully operational, population-based immunization information systems	75% (2008)	95%	83.6% (2011)	Immunization Program Annual Reports, CDC, NCIRD
NWS-2.1 Increase the proportion of schools that do not sell or offer calorically sweetened beverages to students	9.3%	21.3%	NDA	School Health Policies and Programs Study, CDC
NWS-10 Reduce the proportion of children and adolescents 2–19 years who are considered obese	16.1% (2005–2008)	14.5%	16.9% (2009–2010)	National Health and Nutrition Examination Survey (NHANES), CDC, NCHS
NWS-12 Eliminate very low food security among children	1.3% of households with children (2008)	0.2%	1% (2011)	Food Security Supplement to the Current Population Survey, U.S. Department of Commerce, Bureau of the Census
NWS-14 Increase the contribution of fruits to the diets of the population aged 2 years and older	0.5 cup equivalents of fruits per 1,000 calories (2001–2004)	0.9 cup equivalents per 1,000 calories	NDA	National Health and Nutrition Examination Survey (NHANES), CDC, NCHS and USDA, ARS
NWS-18 Reduce consumption of saturated fat in the population aged 2 years and older	11.3% of total calorie intake (2003–2006)	9.5%	11% (2007–2010)	National Health and Nutrition Examination Survey (NHANES), CDC, NCHS and USDA, ARS
PA-5 Increase the proportion of adolescents who participate in daily school physical education	33.3% (2009)	36.6%	31.5% (2011)	Youth Risk Behavior Surveillance System (YRBSS), CDC, NCCDPHP
PA-8.2.3 Increase the proportion of adolescents in 9th through 12th grade who view television, videos, or play video games for no more than 2 hours a day Comparable objectives for preschool and school-age children	67.2% (2009)	73.9%	67.6% (2011)	National Health and Nutrition Examination Survey (NHANES)

CHAPTER RECAP

Population health nursing services for children and adolescents are one of the most effective means of enhancing the health of the overall population. Population health nurses can educate the public, parents, and children on health-promoting and illness and injury preventing behaviors and engage in early

intervention and health restoration for existing health problems to minimize their effects on the health of individual children and on the population during childhood and adolescence and on into adulthood.

CASE STUDY

Protecting Children's Health

You are a population health nurse in a small town on the Arizona-Mexico border. The pediatric nurse practitioner in the local well-child clinic comes to you with concerns about the high blood lead levels he has encountered in a number of school-age

children in the community. When you look at past figures for lead poisoning in the area, you find that the incidence has steadily increased until it is about twice that of other nearby communities. The community is bisected by a major interstate highway

and new cases of lead poisoning seem to be clustered along the interstate and in a part of town that houses a large population of Hispanic migrants and their families. Epidemiologic investigation indicates that there are high levels of lead in the soil adjacent to the highway and deteriorating lead-based paint in a large portion of the older homes in low-income areas of town. In addition, the investigation finds that several small stores in the Hispanic part of town sell a brand of candy imported from Mexico that has high levels of lead contamination. The candy is inexpensive and very popular with local children.

1. What biological, psychological, environmental, sociocultural, behavioral, and health system factors are contributing

to the high incidence of elevated blood lead levels in children in the community?

2. In addition to yourself, who should be involved in planning programs to decrease the incidence of lead poisoning?
3. What evidence-based interventions might the planning group employ to address the problem?
4. What level(s) of health care would be involved in addressing the problems of lead poisoning incidence and prevalence?
5. How might the effectiveness of the interventions be evaluated?

Care of Men

Learning Outcomes

After reading this chapter, you should be able to:

1. Describe major considerations in assessing biophysical, psychological, environmental, sociocultural, behavioral, and health care system determinants affecting men's health.
2. Identify major considerations in health promotion and illness/injury prevention for men and analyze the role of the population health nurse with respect to each.
3. Describe areas of focus in resolving existing health problems among men and related population health nursing roles.
4. Describe considerations in restorative health care for men and analyze the role of the population health nurse in each.

Key Terms

erectile dysfunction (ED)

infertility

joblessness

masculinity

reframing

unemployment

Advocating for Men’s Health and Men in Nursing

Nurses themselves often need advocacy to be assured fair treatment. This has been no less true for male nurses than for females. Although early nursing outside of the family was primarily a masculine endeavor carried out by male religious orders, nursing in the 19th and 20th centuries became a largely feminine profession. Men were frequently denied admission to schools of nursing and were not eligible to become members of the Army Nurse Corps until 1955 and the Navy Nurse Corps until 1965 (Tranbarger, 2007).

Recognizing the need for advocacy for the rights of male nurses, Steve Miller, a nurse, established a “Men in Nursing in Michigan” organization in 1971. After some initial setbacks, the organization was reorganized in 1974 as the Male Nurses Association and became the American Assembly for Men in Nursing (AAMN) in 1981. The initial aim of the assembly was to recruit men to the nursing profession, but this focus was later expanded to provide networking and mentorship opportunities and address issues that concerned men in nursing. The organization also promotes research and education regarding men’s health issues (Tranbarger, 2007).

Today, AAMN is a national organization with myriad local chapters (AAMN, 2011). Recent activities include promotion of gender-neutral language in nursing education (AAMN Board of Directors, 2010) and a position statement on the development of a men’s health curriculum in schools of nursing to address the health needs of the male population (AAMN, 2010).

What does it mean to be a man? Relevant literature distinguishes between being male and masculinity. Maleness is perceived as a biological phenomenon, while **masculinity** is a personal and social construct that varies within individuals and across cultural groups (Synnott, 2009). Some authors propose five different conceptualizations or models of gender as depicted in Table 17-1.

According to 2010 census data (U.S. Census Bureau, 2012a), men over 20 years of age constituted 48% of the U.S. adult population. This amounted to nearly 109.2 million men. By 2015, men over age 18 are expected to comprise 48.7% of the adult

population (U.S. Census Bureau, 2012b). The worldwide male population amounts to 3.3 billion (Synnott, 2009). Although health care services have traditionally been designed around men’s health care needs, U.S. men encounter a number of health disparities when compared to women. Failure to attend to men’s health as a population group is attested to by the fact that only in the two most recent sets of national health objectives, have issues unique to men’s health, such as prostate cancer mortality, been addressed (U.S. Department of Health and Human Services [USDHHS], 2013), whereas uniquely female health problems (e.g., maternal and cervical cancer mortality) have been addressed in multiple sets of objectives.

TABLE 17-1 Models of Gender Conceptualization

Model	Characteristic Features
Romantic	Men and women are different but complementary and equal opposites, united by mutual interdependence
Patriarchal	Men are superior to women and dominate women. Males sacrifice themselves to protect women and women are privileged in some ways (e.g., not being subject to military service).
Misandric	Women are superior to men. Men are viewed as villains, and women, as a group, are engaged in a war against men.
Postmodern	Gender is a continuum rather than a dichotomy. Humans are biologically and psychologically bisexual, and there are multiple fluid sexualities. Gender roles are cultural rather than biological and are based on behavioral performance (e.g., how one dresses or one’s mannerisms). There are greater differences within traditional male/female genders than between them.
Multiple conflict/identity	Gender relations are predicated on power. Men and women are not the same, nor are they opposite. They are not usually equal in all respects; nor is one gender always powerful and the other powerless. Gender differences are interwoven with power differences in other societal aspects including class, race, religion, ethnicity, language, and political affiliation.

Data from: Synnott, A. (2009). *Rethinking men: Heroes, villains, and victims*. Burlington, VT: Ashgate.

Men differ from women in their patterns of physical health disorders and health-related needs. These differences are attributable to (a) physiologic differences between men and women, (b) differences in health-related habits and health-seeking behavior, and (c) differences in social roles, stress, and coping. A great deal of health-related literature has been written about specific problems that influence men's health status (e.g., cardiovascular disease, lung cancer, etc.). Very little, however, is written about the overall health needs of men. The health care of men has been fragmented, approached from an episodic perspective, and little effort has been made to provide comprehensive, holistic health services.

Evidence of health disparities between men and women is seen in differences in life expectancy, mortality, and rates of illness and injury. Men die younger than women and overall have higher incidences of most chronic diseases than women. Average life expectancy for U.S. men at birth in 2010 was 76 years compared to 81 years for women, and the all-cause mortality rate for males of all ages was 887.1 per 100,000 population versus 634.9 per 100,000 women. Years of productive life lost due to death before age 75 came to 8,735 for men and only 5,195 for women (National Center for Health Statistics [NCHS], 2013). Life expectancy for men is less than for women in all regions of the world, and men are more likely than women to die between ages 15 and 60 years (World Health Organization, 2013).

These differences do not seem to be solely a product of differences in gender socialization or roles. Some authors have suggested that the universal disparity in longevity between men and women may be the result of innate biological differences. For example, it is known that female hormones have a protective effect with respect to cardiovascular disease. This and other biological differences may play a significant role in differences in longevity between men and women.

Chronic disease incidence also tends to be higher among men than women. For example, 2008 cancer incidence was higher for men than women for all sites except reproductive cancers. Likewise, diabetes incidence is higher for men than women (Beckles, Zhu, & Moonsinghe, 2011). In addition, diabetes is less likely to be controlled among men than women (NCHS, 2013). Similar differences in the incidence and degree of control of hypertension are noted between men and women (Keenan & Rosendorf, 2011). HIV infection rates for men are three times those for women and climbing, whereas infection rates for women have declined slightly since 2005 (Hall, Hughes, Dean, Mermin, & Fenton, 2011).

Men are also more likely than women to be victims of war, crime, homicide, suicide, and accidental injury and death, particularly in occupational settings (Synnott, 2009). For example, in 2007 motor vehicle accident mortality was higher among men than women for all racial and ethnic groups (West & Naumann, 2011). In addition, suicide rates are nearly four times higher for men than for women (NCHS, 2013).

Three explanatory paradigms have been advanced to explain these disparities. These include personal behaviors, cultural factors, and health system factors (Synnott, 2009).

Personal behaviors include elements of risk taking as well as lack of personal health care activities. Cultural factors include gender socialization, occupational exposures to hazardous conditions, and so on, and health system factors include the lack of attention to men's health issues presented above as well as lack of access to health care services. Factors related to each of these three paradigms are addressed below in terms of behavioral, sociocultural, and health systems determinants of health, respectively.

Population Health Nursing and Care of Men

Population health nursing activities in care of the male population involve use of the nursing process at both the individual and population levels. Assessment of men's health status addresses each of the categories of determinants of health to identify factors contributing to health and illness among men. Planning and implementation of interventions geared toward health promotion and illness/injury prevention, resolution of existing health problems, and restoration of health are also part of the population health nurse's role with respect to men. Finally, population health nurses evaluate the effects of care on men's health status at individual and population levels.

Assessing the Health Status of Men

Factors related to each of the six categories of determinants of health affect men's health status. We will briefly consider major factors related to biological, psychological, environmental, sociocultural, behavioral, and health system determinants and their influence on the health of the male population. Assessment of the male population can be conducted using the *Population Health Assessment and Intervention Guide* included in the *Assessment Guidelines* for Chapter 15. A tool to assess the health of an individual male client is included in the *Assessment Guidelines* section of the student resources site.

BIOLOGICAL DETERMINANTS. Considerations in assessing biological determinants of men's health are presented in the focused assessment on the next page. Areas to be addressed include the demographics of the population, as well as morbidity and mortality related to physical health conditions, and levels of immunity. Much of this information is available from data collected by official health agencies and health care facilities and providers in the area. Local emergency departments may be able to provide statistics on accidental injuries among men. Similarly, local police departments may have data on accident-related calls and the injuries suffered. For other conditions, such as erectile dysfunction, extent of disability, and immunization levels among men, there are often no statistical data available, and information may be best obtained by means of community surveys.

Men experience a variety of physical health conditions, many of which can be prevented or their effects ameliorated

FOCUSED ASSESSMENT

Assessing Biological Determinants of Men's Health

- What is the age composition of the male population?
- What is the racial/ethnic composition of the male population?
- What are the main causes of mortality in the male population?
- What acute and chronic illnesses are prevalent in the male population? What factors contribute to the prevalence of these conditions?
- What is the prevalence of sexual dysfunction in the male population?
- What is the level of immunity to specific communicable diseases among the male population?

by effective population health nursing intervention. Table 17-2 provides a comparison of male and female mortality for selected causes of death in the United States in 2008. As indicated in the table, only for Alzheimer's disease, are female mortality rates higher than those for males, with the greatest differences in suicide and homicide mortality.

Men also experience higher levels of morbidity for many health problems than do women (Table 17-3). For example, men tend to develop coronary heart disease (CHD) 10 to 15 years earlier than women and account for 70% of premature mortality (before age 65) from CHD. In addition to being more likely than women to be overweight or obese, men tend to have more abdominal obesity that is associated with coronary heart disease (Salzman & Wender, 2006). Generally, men are likely to report less difficulty seeing with corrective lenses but have greater difficulty hearing with advancing age and are slightly less likely than women to report themselves as in poor health (NCHS, 2012a).

Men also have higher rates of sexually transmitted diseases (STDs) than women. For example, the incidence of HIV

infection in men is more than three times that in women. Men also experience other reproductive conditions, such as breast cancer (although at a much lower rate than women) and prostate cancer. Prostate cancer is the most common cancer diagnosis in men. In 2009, 206,640 men in the United States were diagnosed with prostate cancer, and 28,088 U.S. men died from prostate cancer. The overall incidence rate was 137.7 per 100,000 men (U.S. Cancer Statistics Working Group, 2013). One in every six men will develop prostate cancer in his lifetime. Prostate cancer may result in feelings of inadequacy that lead to changes in relationships, feelings of lost manhood, and changes in sexual feelings, as well as to erectile dysfunction. Although prostate cancer is frequently not life threatening, its implications for men's quality of life cannot be underestimated. Prostate cancer and benign prostatic hyperplasia or hypertrophy (BPH) may both obstruct urinary flow, resulting in reduced urinary flow, increasing frequency, and nocturia. Approximately half of men over 60 years of age experience BPH (Deters & Kim, 2011).

TABLE 17-2 Male and Female Mortality from Selected Causes, United States, 2008 (per 100,000 population)

Cause of Mortality	Men	Women	Ratio Men to Women
Overall	900.6	643.4	1.4 to 1
Heart disease	232	150.4	1.5 to 1
Malignant neoplasms	213	148.5	1.4 to 1
Unintentional injury	53.6	25.1	2.1 to 1
Chronic lower respiratory disease	51.4	39.1	1.3 to 1
Cerebrovascular disease	40.9	39.9	1.02 to 1
Diabetes mellitus	25.6	18.8	1.4 to 1
Alzheimer's disease	20.1	26.7	0.75 to 1
Suicide	18.9	4.8	3.9 to 1
Chronic liver disease and cirrhosis	12.7	6.0	2.1 to 1
Homicide	9.3	2.4	3.9 to 1
HIV disease	4.8	1.9	2.5 to 1

TABLE 17-3 Male and Female Morbidity from Selected Causes, United States

Cause of Morbidity	Men	Women	Ratio Men to Women
HIV infection (per 100,000)	35.9	11.5	3.1 to 1
Hypertension	30.6%	28.7%	—
Diabetes mellitus (per 100,000)	8.1	7.7	1.05 to 1
Colorectal cancer (per 100,000)	49.2	37.1	1.3 to 1
Prostate cancer (per 100,000)	137.7	—	—
Lung cancer (per 100,000)	78.2	54.1	1.4 to 1
Malignant melanoma	24.7	15.8	1.6 to 1
Pancreatic cancer (per 100,000)	13.5	10.3	1.3 to 1
Asthma (current)	6.2%	10%	—
Arthritis (per 100,000)	4.1	9.8	0.42 to 1
Basic activity limitation	53.8%	63.6%	—
Elevated blood cholesterol	32.5%	31%	—
Overweight	43%	27%	—
Obesity	27%	23%	—
Injury (per 100,000)	10,285	8,622	1.19 to 1

Male sex: A major health disparity. In C. A. Haines & R. C. Wender (Eds.), *Primary care: Clinics in office practice: Men's health*, 33, 1–16. doi: 10.1016/j.pop.2005.11.014

Erectile dysfunction is another reproductive problem common among men. **Erectile dysfunction (ED)**, formerly called impotence, occurs when a man cannot achieve or maintain an erection sufficient for satisfactory sexual activity. ED may result in total or periodic inability to achieve an erection or the inability to sustain an erection. As many as 30 million U.S. men may be affected, and the incidence of ED increases with age. ED may occur as a result of diabetes, atherosclerosis, hypertension, obesity, or nerve damage or as a side effect of many medications or surgery (e.g., following prostatectomy). ED may also be associated with lifestyle factors, such as smoking and alcohol consumption, or with stress and fear of sexual failure. Occasionally, ED is the result of low testosterone levels. In addition to its psychological effects on men's health, ED may also signal undiagnosed chronic conditions and should not be ignored. Unfortunately, many men are reluctant to admit to erectile dysfunction and may not seek help (National Kidney and Urologic Diseases Information Clearinghouse, 2012).

Infertility also poses significant threats to men's self-image. **Infertility** is the inability to become pregnant or to impregnate one's female partner after at least a year of intercourse without using contraceptives. In approximately one third of couples unable to get pregnant, the difficulty lies with the male partner (American Academy of Family Physicians, 2014). Possible causes of infertility include prior surgeries, pelvic trauma,

sexually transmitted disease, genetic causes such as Klinefelter's syndrome, medication use, and toxic exposures.

Another area to be addressed in assessing men's physiologic function is the presence of long-term consequences of accidental injury. Males at all ages have higher rates of unintentional injuries than females. In 2012, for example, U.S. men over 20 years of age sustained more than 10.6 million unintentional injuries for an incidence rate of 10,285 injuries per 100,000 men, compared to only 13.7 million injuries in women (8,622 per 100,000). Male–female differences are particularly evident with respect to unintentional firearms injuries (9.5 per 100,000 men versus 1.41 per 100,000 for women) and injuries resulting from assault (672.71 and 449.75 per 100,000 population for men and women, respectively) (National Center for Injury Prevention and Control, 2013). As we will see later in this chapter, many of these differences arise from risk behaviors engaged in by men. Other factors that may contribute to accidental injuries and should be assessed by the population health nurse are sensory impairments. These impairments, if undetected and uncorrected, may contribute to a variety of physical and psychological health problems.

The last aspect of physiologic function to be considered in assessing the health status of men is immunization levels. Men, as well as women, should be immunized against tetanus, diphtheria, and pertussis (Tdap), influenza, and pneumococcal disease,

and susceptible men should also receive varicella vaccine. Although men may be more likely than women to have received tetanus vaccines in the last 10 years, they are less likely to have received influenza vaccine in the past year or to ever have received pneumococcal vaccine. *Healthy People 2020* objectives have not been achieved for either men or women, however. For example, in 2011–2012, only 35% of men and 43% of women aged 18 years of age and older had received influenza vaccine, far below the 2020 target of 70%. Similarly, only 15% of men and 18% of women had received pneumococcal vaccination targeted at 60% of the population (USDHHS, 2014a).

PSYCHOLOGICAL DETERMINANTS. Several psychological determinants are of concern to population health nurses caring for men. These elements include socialization, stress, and coping abilities, as well as suicide as an outcome of ineffective coping. Other considerations related to psychological determinants of health include the incidence and prevalence of mental illness in the population. The *Focused Assessment* below provides questions that can be used to assess this aspect of men's health. Information to address some of the questions may be available from official health agencies and mental health providers in the area, but much of it may need to be solicited from members of the population through surveys and other data collection methods.

Men, like women, have several basic psychological needs. These include the needs to know and be known to others, to be mutually interdependent, to love and be loved, and to live meaningful lives. Society, however, has socialized both men and women to accept a stereotypical male role that makes it difficult to meet these needs. General dimensions of this stereotyped role include a need to actively differentiate oneself from women and refrain from behaviors ascribed to women (such as demonstrating affection or seeking help) and a need to see oneself as superior to others. Other dimensions include the need to be strong and self-reliant and to be more powerful than others, even if this means resorting to violence to demonstrate one's power.

Because of this stereotyped view of the masculine role, men experience social pressures to conform that sometimes

conflict with health. Socialized to view the male role as strong or invulnerable, a man may have difficulty admitting health-related frailties to a population health nurse or seeking health care. Similarly, men who believe that taking physical risks is fundamental to their masculinity may experience more frequent health impairment from trauma. Pressure to assert one's manliness also contributes to early initiation of sexual activity by young men, putting them at risk for STDs and unintended fatherhood. As can be seen in these examples, when societal messages about male roles are internalized by men, they become psychological factors influencing health-related behaviors.

Men may also have a stronger psychological need than women to see themselves as healthy and even invulnerable. Because men tend to value strength and endurance more than women, they are more likely to conceal or suppress pain and other perceived indicators of frailty. An example of this state of mind can be seen in the male post-myocardial infarction client who resumes shoveling snow against the recommendations of health care professionals and his family, and who continues the activity despite the return of the now-familiar angina. As a result of this need for strength in his self-image, the male client minimizes the importance of the problem. Consequently, when shoveling snow causes further angina, he may seek health care less readily and use it less effectively than would a female client in a similar situation.

Similar responses may occur with mental health problems. Traditional American culture prohibits men from expressing emotions other than anger and aggression, and men may be unable to express grief, sadness, or powerlessness, allowing these emotions to fester and contributing to depression. Based on data from the National Center for Health Statistics (NCHS, 2013) for 2010–2011, men less frequently reported serious psychological distress in the prior 30 days than women (2.8% and 3.7%, respectively).

Postpartum depression is a mental health concern that is not often acknowledged with respect to men. Postpartum depression is normally associated with women. Research suggests, however, that 24% to 50% of men whose wives experience postpartum depression may experience it themselves.

FOCUSED ASSESSMENT

Assessing Psychological Determinants of Men's Health

- What are the primary sources of stress to which men in the population are exposed?
- What are the incidence and prevalence of mental illness in the male population? What specific mental health problems are prevalent in the population?
- How are mental health problems viewed by men in the population? Are there cultural differences in how mental illness is viewed?
- What is the extent of postpartum depression among men in families with young infants?
- What is the rate of suicide in the male population?
- How are men socialized in the population? Does socialization contribute to health problems among men? How does male socialization affect coping abilities?

Overall, 10% of new fathers may experience this condition. Postpartum depression in men may arise from worsening symptoms in their wives or changes in the marital relationship and may be compounded by economic concerns or substance abuse. Depression in new fathers affects father–infant interaction, and infants with two depressed parents are at high-risk for poor development. Again, male socialization may influence men’s willingness to seek help, and many men may have difficulty identifying sources of professional and social support that are often available only to women (Letourneau, Duffett-Leger, Dennis, Stewart, & Tryphonopoulos, 2010). Population health nurses dealing with families with a new infant should be alert to the potential for postpartum depression in fathers as well as mothers.

Male values of strength and endurance do not always adversely affect a male client’s health. Some men who value strength actually may be more motivated to exercise and maintain a higher level of general fitness and to seek preventive health care to preserve their sense of themselves as strong and invulnerable. For example, men are slightly less likely than women to be physically inactive (NCHS, 2012b).

Another psychological barrier to men’s health is the male client’s conflicting response to feelings regarding a health problem. For example, a man who values strength may exercise regularly, but he may avoid having a swelling in his groin examined because he cannot cope effectively with the fear that the swelling may represent a threat to his sexuality.

Men and women are exposed to different types of stress and cope with stress in different ways. For example, men may be more likely than women to engage in avoidant coping strategies. Similarly, post-traumatic stress disorder (PTSD) arises from different types of events and manifests differently in men and women. Although previously thought a condition primarily affecting men, more women actually experience PTSD than men (National Institute of Mental Health [NIMH], 2009). PTSD will be addressed in more detail in Chapter 28, but the population health nurse should be alert to its potential appearance among individual men clients and its incidence in the male population. PTSD and other mental health problems may contribute to suicide. As we saw in Table 17-2, suicide incidence is nearly four times higher in men than in women. Suicide claims more lives among men annually than

many of the diseases that health care professionals combat so effectively. Because suicide is such a frequent cause of mortality for men, it is important that population health nurses assess individual men and the male population for the presence of suicide risk factors, including bereavement, social isolation, unemployment, depression or other psychiatric disorders, substance abuse, risk-taking or avoidance behaviors, and reluctance to seek help. Protective factors against suicide include social and peer support and a stable domestic situation (Centre for Suicide Prevention, 2011).

ENVIRONMENTAL DETERMINANTS. With the exception of the occupational environment, which is addressed in the discussion of sociocultural factors, the effects of the physical environment on men’s health are much the same as they are on women’s health; pollution, overcrowding, and safety hazards adversely affect both. Men, however, may have increased exposure to environmental hazards due to occupational and leisure activity choices. In addition, there is some evidence that climate may have differential effects on mortality among men and women. For example, some research has indicated that differences in gender mortality rates are greater at extreme latitudes, suggesting that men may be more adversely affected by climate extremes than women (Salzman & Wender, 2006).

One’s living environment also influences health status. In 2009, nearly 5% of male householders lived in inadequate housing units (those with plumbing, heating, electrical, and upkeep deficiencies), only slightly less than women at 5.5%. In addition, 22.5% of male householders lived in unhealthy housing with rodents, leaks, peeling paint, and lack of smoke detectors in addition to the criteria of inadequate housing noted above (Raymond, Wheeler, & Brown, 2011). Questions to assess environmental determinants of men’s health are provided in the *Focused Assessment* below. Much of the related assessment data will be obtained through observation of environmental conditions to which men are exposed. Information on occupations and occupational hazards may be available from a local Chamber of Commerce or area businesses or from injury and disability claims filed with insurance companies.

SOCIOCULTURAL DETERMINANTS. Many influences on men’s health arise from sociocultural determinants. We have

FOCUSED ASSESSMENT

Assessing Environmental Determinants of Men’s Health

- To what environmental health hazards are men in the population exposed?
- What environmental hazards are posed by occupational settings? By recreational pursuits among men?
- What environmental hazards are posed by housing conditions for men in the population?
- To what extent does the physical environment promote or impede healthy behaviors by men (e.g., physical activity)?

already discussed the influences of gender socialization, a sociocultural factor, on men's psychological health. Other considerations in the sociocultural dimension affecting men's health include family interactions, economic and occupational issues, and issues related to violence. Much of the assessment data related to sociocultural determinants of men's health will be obtained from area statistics, observation, and surveys and interviews with men in the population. Questions to guide the assessment are presented in the *Focused Assessment* included below.

Family interactions. By far, the largest proportion of men lives within a family situation, which may create both positive and negative health effects. Worldwide, most men are married by the time they are in their 30s, but delayed marriage is associated with higher educational levels. By their 40s to mid-50s, most men have been married, some of them several times. In 2011, 58% of U.S. men over 15 years of age were married, 35% had never married, approximately 2% were widowed, and more than 9% were divorced (U.S. Census Bureau, 2011).

Marriage has been shown to have a protective health effect for both men and women; however, because of socialization to a stereotyped male role and gender communication styles discussed earlier, men may have difficulty interacting within the family in ways that effectively meet their psychological needs. Differing role expectations between spouses may lead to marital conflicts and, in some cases, spouse or child abuse. Family violence and its effects on health are discussed in more detail in Chapter 30. It is, however, important for the population health nurse dealing with male clients to assess the marital status of the male population.

Parenting is another aspect of family interaction that may affect men's health. Young men in the United States are delaying initiation of sexual activity to a slightly older age than in previous years; however, by age 19 approximately 71% of young men and 36% of women are sexually active. The rate of adolescent fatherhood declined from 1991 to 2010 (25 per 1,000 males 15 to 19 years of age to 16 per 1,000), but adolescent males continue to father children (Guttmacher Institute, 2014). Population health nurses should be alert to the needs of individual adolescent fathers as well as the population of teen fathers.

Approximately one fourth of U.S. men have had a child by 20 years of age and 50% by age 30. Approximately 13% of sexually active males 15 to 19 years of age reported being involved in a pregnancy. Younger age at initiation of sexual activity contributes to risk of pregnancy, with 22% of adolescent males who have sex prior to age 15 involved in a pregnancy. Conversely, use of contraceptives during the first sexual experience decreases the risk of pregnancy from 18% to 12% (Planned Parenthood Federation of America, 2012). Early parenthood is more likely among minority men and those with lower educational levels (Guttmacher Institute, 2014).

More than half (56%) of teenage fathers are not living in the same household at the time of the child's birth (Scott, Steward-Streng, Manlove, & Moore, 2012), but often continue to be involved with their children, providing significant levels of informal support (e.g., transportation to and from school, help with school work, child care) (Resilience Advocacy Project, 2012). In addition, teen fathers frequently have additional children by the time they are 22 to 24 years of age. In one study, for example, 49% of those who fathered children as

FOCUSED ASSESSMENT

Assessing Sociocultural Determinants of Men's Health

- What are the social roles expected of men? What effects do these role expectations have on men's health? What differences in men's roles are present within different cultural groups in the population?
- What opportunities for social interaction are available to men in the population? How do men in the population typically interact with others?
- To what extent are men perpetrators or victims of violence? What are the health effects of exposure to violence?
- What is the extent of social support available to men in the population?
- What is the percentage of single-parent families headed by men in the population?
- What is the typical educational level of men in the population?
- What is the economic status of men in the population? What is the average income of men in the population?
- What effects do economic, educational, and employment levels have on men's health?
- What transportation opportunities are available to men in the population?
- To what extent do men in the population function as caretakers for other family members? To what extent do these men experience caretaker burden?
- What percentage of men in the population is employed? What are the typical occupations for men in the population? What effects do occupation and employment setting have on men's health? What support do employers provide for men's other roles and responsibilities?
- What child care services are available to working single male parents? What is the cost of these services?

adolescents had more than one child by this age, and 17% had three or more children (Scott et al., 2012), often by different women, compounding difficulties in interactions with children and financial support.

Like adolescent mothers, teenaged fathers are at increased risk for low educational attainment and low-income levels. In some studies, 38% of young fathers do not complete high school, and less than 30% continue beyond a high school education. The lack of education and income further impair their abilities to provide child support. Teen fathers are also disadvantaged by the complexity of family court systems and lack of access to legal assistance (Resilience Advocacy Project, 2012).

Child health and development is fostered by interactions with both parents, even when one is functioning in a noncustodial role. Fatherless children, particularly boys, have higher rates of incarceration, suicide, behavioral disorders, dropping out of high school, delinquency, and juvenile detention rates than those whose fathers are actively involved in their lives. They may also receive less family support for educational attainment and display worse scholastic performance than children from two-parent households (Parker, n.d.). Divorce may also separate many men from their children. According to census data, in 2010, slightly more than 23% of U.S. children under 18 years of age were living in homes without their father present. Conversely, 3.4% were living with their fathers alone (U.S. Census Bureau, 2012c).

Roles related to fatherhood differ among cultural groups and are changing in many societies. In more traditional cultures emphasis tends to be placed on indirect parental care among fathers, for example, provision of family resources. The amount of time fathers spend with children also differs from group to group. In polygynous societies, for example, men are more focused on their mates than on their children. In most societies, however, fatherhood often entails elements of socialization or discipline of children. The amount of time that men in many social groups are spending in child care activities is increasing, however (Gray & Anderson, 2010).

More men are raising children as single parents.

(Wavebreakmedia/Micro/Fotolia)

Because of typical male socialization, many men have little or no child care experience, yet the increase in the number of working women has led to greater assumption of child care duties by men. Many men may find themselves single parents as a result of divorce or the death of their wives. Others may have partial custody of children as a result of divorce. Population health nurses should be alert to the needs of adolescent and adult fathers and engage in advocacy to assure that these needs are met at both individual and population levels.

Changes in family interactions within cultural groups also influence marital relationships and role expectations. Many men who have been socialized to more traditional gender roles, may find it difficult to adapt to changing expectations of their family roles. In addition to assuming greater responsibility for child care, men may encounter expectations of their engagement in other household activities such as cooking and house-keeping. Similarly, men, whose models for women's roles were their more traditional mothers may have difficulty adapting to women's growing expectations for equality in decision making within the family as well as their participation in careers and employment outside the home. Changes in gender roles and power differentials between men and women have been likened to other transfers of power that have occurred throughout history, such as the transfer of power from master to slave, from employer to employee, and from monarchs and government to the general public (Synnott, 2009).

Divorce constitutes another aspect of family relations that may influence men's health status. Divorce is one of the most significant stressors a person can experience, and it may have a profound effect on the physical and psychological health of all family members. Divorced men, in particular, have been shown to experience increased morbidity and mortality as compared with married men. Men may respond to divorce or its aftermath with intense anger, a profound sense of loss, or significant depression. Suicidal behavior occasionally occurs as the man reacts to the divorce as an assault against his self-image and self-worth, or homicidal behavior if he directs his anger toward his ex-spouse. Widowed men also tend to fare less well than widowed women.

Economic and occupational issues. In most cultures, men are the primary breadwinners for the family, although more and more women throughout the world can be found in the workforce. Worldwide poverty and poor employment prospects undermine men's ability to fulfill their provider roles. Unemployment may be high in many developing countries and urbanization may lead young men to leave their families for extended periods of time to seek employment where it can be found. In the United States, men fare better than women in terms of their economic status, yet economic influences can have profound effects on their health status.

Economic status is closely linked to employment and unemployment. Some authors make a distinction between the societal experience of unemployment and the individual experience of "joblessness." From this perspective, **unemployment**

Global Perspectives

WHO: A Gender and Health Development Program

In every region of the world, men have a lower life expectancy at birth than women, with the greatest difference in life expectancy (8 years) seen in the European region. Men also have a higher probability than women of dying between the ages of 15 and 60 years. In addition, men have higher rates of elevated blood pressure and smoking and other tobacco use (World Health Organization [WHO], 2013). There is obviously a need for gender equity in health care services. The WHO Eastern Mediterranean Regional Office (EMRO) (n.d.) has initiated a Gender and Health Development Program. Although the program is designed to address many gender inequities related to women's health, it emphasizes the need for overall gender-based data analysis and health care planning. EMRO has designed the following test of one's knowledge of gender as it relates to health status.

Circle T for "true" or F for "false" for each question to test your knowledge on gender and health.

1. A gender-responsive workplan recognizes the differences between women's and men's health needs and vulnerabilities and includes actions to ensure these differential needs are addressed. **T/F**
2. Gender norms are standards set by society that determine what roles and responsibilities men and women should assume in society. **T/F**
3. Time, money, information, transportation, and social support networks are all resources that impact health outcomes. **T/F**
4. A women who is unable to see a doctor without head of household permission is an example of a gender issue in health. **T/F**
5. Women and men always have the same access to time, money, information, transportation, and social support networks. **T/F**
6. Gender mainstreaming is concerned only with integrating perspectives and realities of female populations groups. **T/F**
7. Sex disaggregated health data enables identification of differences between men, women, boys and girls. **T/F**
8. Gender in health refers only to reproductive health and conditions related to hormonal changes, and genetic or hereditary conditions. **T/F**
9. Fairness and justice in the distribution of benefits, power, resources, and responsibilities between women and men according to their needs is called gender discrimination. **T/F**
10. Health policies that do not distinguish between the needs of male and female population groups are called "gender blind." **T/F**

Correct answers: T, T, T, T, F, F, T, F, F, T

is the proportion of the workforce that is not employed at a specific point in time and is a statistical measure reflecting the general state of the economy. **Joblessness**, on the other hand, is the personalized experience of being out of work when one desires employment. Joblessness can have significant implications for both physical and mental health among men since men often base their self-worth on occupational performance and success. Although joblessness affects the mental health of both men and women, its mental health effects may be worse for men than women. In 2010, 71% of the U.S. adult male population was employed, and 10.5% of those in the workforce were unemployed (U.S. Census Bureau, 2012d). Among men who lost their jobs between 2007 and 2009, 39% remained unemployed in January 2010 (U.S. Census Bureau, 2012e) suggesting implications for their mental health.

The median weekly income for all men in 2010 was \$824 (U.S. Census Bureau, 2012f). More than 19 million men (13% of all U.S. men) had incomes below poverty level in 2009 (U.S. Census Bureau, 2012g). Poverty is one of several reasons that men are more likely than women to be homeless. Despite the differences in the incidence of homelessness among men and women, homeless shelter systems are often better designed to meet the needs of women and children than those of men. Issues related to homelessness will be addressed in more detail in Chapter 21∞.

Men are more likely than women to be employed in jobs that entail physical health risks. In 2011, for example, men experienced 11 times more occupational fatalities than women. The highest rates of death occurred as a result of transportation incidents in the course of employment (Bureau of Labor Statistics, 2012).

Violence and trauma. Earlier, we discussed the implications of PTSD for men's psychological health. PTSD and other health problems arise from exposure to a variety of forms of violence and trauma. Men are more likely than women to be exposed to societal violence in many forms. With few exceptions, men constitute the bulk of homicide victims throughout the world (United Nations Office on Drugs and Crime, 2013). For example, in 2010, the global homicide rate for men was 8.4 per 100,000 men, down from 16.6 in 1980, but still nearly three-and-a-half times that of women (4.3 per 100,000) (NCHS, 2013). Men are also exposed to slightly higher rates of physical assault than women. In 2012, the serious violent crime victimization rate for men was 9.4 per 1,000 males over 12 years of age compared to 6.6 per 1,000 females (Langton, Planty, & Truman, 2013).

Violence also occurs in families, and men, as well as women, are subjected to intimate partner violence (IPV). More than 35% of women and 28% of men report being subjected to IPV at some point in their lives, but the number of men who are victims may be inaccurate due to many men's unwillingness to admit to victimization by their partner. Men are less likely than women to be injured as a result of IPV (Black et al., 2011). IPV is addressed in more detail in Chapter 30∞.

Overall, men in 2007 were nearly four times more likely than women to sustain a violence-related injury. Trauma also results from unintentional injury, and a consistent pattern in male–female differences in unintentional injuries has been seen, with men more than twice as likely as women to be injured (Sorenson, 2011). Legal and educational systems are other sociocultural determinants that may result in health status disparities between men and women. For example, laws are more often enacted to protect women than men, and men are more likely than women to be incarcerated. In the educational system, boys may be “treated as defective girls” (Synnott, 2009, p. 228) because of their frequently rowdy behavior. In addition, boys are more likely than girls to have learning disabilities and most elementary school teachers are women. There has also been a tendency to “criminalize” school discipline problems, calling the police for minor infractions (Synnott, 2009).

Men may also have less extensive social networks than women and may be less likely to call on members of social networks for assistance, again related to the idea of masculine strength and the weakness perceived in needing help. Aside from the psychological effects of an adequate social network, the extent of one’s social network has also been shown to be associated with other health-related behaviors, such as engaging in physical activity (Shelton et al., 2011).

BEHAVIORAL DETERMINANTS. Behavioral factors seem to make a greater contribution to men’s health status than to that of women. Because of their gender socialization, men are more inclined to engage in high-risk behaviors and less apt to perform healthful behaviors (Sorenson, 2011). Some behavioral considerations to be addressed in assessing men’s health include consumption patterns, exercise and leisure, sexual activity, and other behavioral risk factors. Questions to guide assessment of behavioral determinants influencing men’s health are provided in the *Focused Assessment* below. Some population level behavioral data may be available from government health agencies

(e.g., smoking, alcohol use, seat belt use); other information may be gleaned through police records (e.g., arrests for illegal drug use or driving while intoxicated) or through community surveys.

Consumption patterns. Consumption patterns include diet as well as substance use and abuse. As we saw earlier, U.S. men are more likely than women to be both overweight and obese. A healthy weight is defined as one that is appropriate to one’s height and body type. Healthy weight is most often determined on the basis of body mass index (BMI) and waist circumference. BMI is an indicator of the extent of body fat and is based on the relationship between height and weight (Centers for Disease Control and Prevention [CDC], 2011).

Waist circumference is related to BMI, but is also an independent predictor of risk for many chronic diseases, including type 2 diabetes, hypertension, and cardiovascular disease (National Heart, Lung and Blood Institute, n.d.). For more information on assessing waist circumference and calculating BMI, see the *External Resources* section of the student resources site.

Men may be somewhat less likely than women to eat a healthy diet. Looking at targets for specific nutrients included in the *Healthy People 2020* objectives, men are farther from achieving objectives related to fruit, vegetable, and sodium consumption. Men and women are essentially equal in terms of solid fat and added sugar consumption. Neither men nor women, however, have achieved the targets for any of these nutrients (Health Indicators Warehouse, n.d.a, n.d.b, n.d.c, n.d.d).

With respect to substance use and abuse, men 18 to 64 years of age were more likely than women to be current cigarette smokers in 2011 (23.6% and 18.8%, respectively). Among those over 12 years of age, men were more likely than women to use any illicit drug (nearly 3% and 2.5%, respectively). Male–female differences in use of alcohol are similar, with 57.4% of men and 46.5% of women using any alcohol. Men, however, are nearly twice as likely as women to engage in binge drinking and nearly

FOCUSED ASSESSMENT

Assessing Behavioral Determinants of Men’s Health

- What are the dietary consumption patterns typical of men in the population? How do these patterns differ within subgroups within the population?
- What is the prevalence of smoking among men in the population?
- What is the extent of alcohol and other drug use in the population?
- To what extent do men in the population engage in safety practices (e.g., seat belt use)?
- To what extent do men who are sexually active engage in safe sexual practices?
- To what extent do men engage in health screening or health promotion/illness prevention practices such as colorectal screening, routine dental care, or annual influenza immunizations?

Tobacco and alcohol use are more common among men than among women. (Bst2012/Fotolia)

three times more likely to report heavy drinking (NCHS, 2013). In addition, drug-induced mortality rates are higher for men (15.8 per 100,000 population in 2007) than for women (9.3 per 100,000) (Paulozzi, 2011).

Exercise and leisure. Men are more likely than women to engage in leisure-time physical activity. In 2010, for example, just over 25% of men, but only 16.5% of women over 18 years of age met both aerobic and muscle strengthening targets for *Healthy People 2020*. On the negative side, however, nearly 44% of men met neither target (NCHS, 2012a).

Men and women increasingly share similar leisure patterns in American culture. Nevertheless, men still tend to be more active in competitive contact sports and, more often than women, to choose leisure activities involving some degree of physical risk (skydiving, white-water rafting, rock climbing). Participation in athletic sports is closely linked with images of masculinity and reinforces tendencies to

aggressiveness and violence, increasing the potential for injury. Expectations of masculinity may also lead men to downplay the severity of injuries, delay treatment, and take insufficient time for healing. Men also tend to choose leisure activities associated with alcohol consumption. For these reasons, men experience relatively greater incidence of recreation-related trauma.

Other behavioral risk factors. Sexual activity among men was addressed earlier in this chapter, but population health nurses should assess the extent of sexual activity and number of partners for individual men as well as for the male population in general. Other assessment considerations include the extent of sexuality education among young men, knowledge and use of contraceptives, and use of condoms to prevent sexually transmitted infections.

Use of seat belts and other safety devices is another behavior that can significantly affect men's health. Because of masculine socialization to risk as an element of manliness, men are less likely than women to engage in a variety of safety practices, including seat belt or helmet use. They are also more likely to engage in high-risk recreational activities, particularly in the context of alcohol or drug use. In addition, media portrayals of men engaged in unhealthy behaviors contribute to risk taking and negative health effects in men.

Men may also be less likely than women to engage in health-related behaviors, such as screening for disease. For example, 2008 figures indicated that only 65% of men had received colorectal cancer screening (Rim, Joseph, Steele, Thompson, & Seeff, 2011). Similarly, in 2010, only 49% of men over 50 years of age received influenza immunizations (NCHS, 2013). Population health nurses should assess the extent to which men in the population engage in relevant screening and preventive activities, such as colorectal cancer screening, preventive dental visits, and so on.

Men are somewhat more likely than women to engage in vigorous leisure-time physical activity. (ArenaCreative/Fotolia)

HEALTH SYSTEM DETERMINANTS. Population health nurses also assess determinants within the health system that influence men's health status. The *Focused Assessment* below provides guidelines for assessing these determinants. Generally speaking, men define health as the ability to be employed and to be economically independent, and, in some cases, to have adequate sexual function. Despite unhealthy lifestyles and shorter lives than women, most men consider themselves to be in good health. As noted earlier, gender socialization may lead men to "tough out" pain and delay seeking help until conditions interfere with their ability to work.

Factors other than gender socialization may also prohibit men from seeking health care. Some of these factors include lack of trust in providers, language barriers, lack of health insurance, financial difficulties, and difficulty relating to providers. Lack of health insurance and cost of care are particularly salient factors in men's failure to access health care services. In 2011, for example, 13% of men aged 18 to 64 years did not get, or delayed, health care due to costs, and men who did seek care had average out-of-pocket expenses of \$219 per person in 2009. In addition, nearly 9% of men did not get prescription drugs and 14.5% did not receive needed dental care due to costs in 2011 (NCHS, 2013).

Men are more likely than women to be uninsured and less likely than women to have Medicaid coverage. For example, in 2011, nearly 19% of men under 65 years of age had no health insurance coverage, compared to less than 16% of women. Medicaid coverage for men was just over 16% versus 19.3% for women. Women also have a larger proportion of health care expenditures covered by private insurance than men (NCHS, 2013).

Another factor in men's failure to use health care services on a level commensurate with women is their perceived lack of a need for health care. Women routinely enter the health care system through services related to pregnancy, contraception, and routine screenings (e.g., Papanicolaou smears). These services serve as avenues for other health promotion activities as well as for detection of illness. Men do not routinely access any

health-promotive services that would provide a similar door to other needed health care. Health care services are not crafted to target men, nor are many providers educated specifically to address the health care needs and motivations (or lack thereof) of men.

Diagnostic Reasoning and Men's Health

Based on factors in each of the categories of determinants of health that affect the health of individual male clients or men as a population group, the population health nurse would develop relevant nursing diagnoses, and plan and implement interventions to improve men's health. Nursing diagnoses may reflect positive or negative health states or increased risk for disease. A positive diagnosis might be "high prevalence of adequate physical activity due to presence of multiple low-cost opportunities for exercise." An example of a negative diagnosis might be "increased risk of sexually transmitted diseases among young adult men due to unprotected sexual activity." Based on the diagnoses derived from the assessment of men's health status and health needs, the population health nurse would collaborate with other segments of the population to plan, implement, and evaluate health care delivery programs to meet the identified health needs of men.

Planning to Meet the Health Needs of Men

Interventions to improve the health status of men in the population may focus on health promotion, illness and injury prevention, health restoration, or rehabilitation. The level of health care at which intervention occurs depends on the status of health problems to be addressed.

HEALTH PROMOTION. Although it is difficult to generalize about male clients' attitudes toward health promotion activities, there are some commonly encountered patterns of health behavior among men. One such behavior is a tendency to view exercise as sufficient to compensate for unhealthy behaviors such as a high intake of fats in the diet. Men also tend to attribute greater significance to health changes they can sense

FOCUSED ASSESSMENT

Assessing Health System Determinants of Men's Health

- What percentage of the male population has a regular source of health care?
- What are the attitudes of men to health and health care services? How do they define health and illness?
- What percentage of the male population has health insurance coverage?
- What health services are available to men in the population? Are health care services needed by men available to all segments of the population?
- What barriers to obtaining health care do men encounter?
- What are the attitudes of health care providers to care of men? To care of nonheterosexual men? How do these attitudes affect health care utilization by men?

than to those they cannot (e.g., they can sense pain but not elevated blood pressure). Because men tend to rate their health as very good or excellent more often than women, they may feel they do not need to be actively involved in health promotion activities. They may also err in their health appraisal efforts, stemming from a tendency to believe that their past athletic or current work activities may provide for their present health needs (“When I was a teenager I would run all day.” “I work hard all day in the fresh air. What could be healthier than that?”). Population health nurses may need to advocate among men for changing attitudes to health and health-related behaviors through health education initiatives and reframing approaches.

Reframing, which focuses on helping clients to see the same situation in a different light, is one technique that can be used to promote positive behavioral change. A second technique for promoting change involves emphasizing alternate ways of coping with anxiety or fearfulness. Education, of course, is a crucial aspect of any health promotion strategy. Education is perhaps most effective when teaching is initiated with school-age male youngsters, as this is the stage when lifelong health values and habits are forming. Health promotion by family members is known to be a significant motivator and predictor of client compliance and outcomes, and involvement of family members in educational efforts and treatment planning is usually of significant benefit.

General approaches to promoting health among men are included in the HEALTH program, a six-point program intended to facilitate creation of health care services that better meet the health promotion needs of men. HEALTH is an acronym that stands for **H**umanize, **E**ducate, **A**ssume, **L**ocate, **T**ailor, and **H**ighlight (Courtenay, 2004). Health services for men should humanize the experience of illness by emphasizing the normality of experiencing and acknowledging pain, weakness, fear, and similar emotions to defuse the “macho” gender socialization to which men are subjected. Population health nurses can advocate for realistic health-related messages that emphasize the normality of these experiences and assist men to see them in the light of catalysts for health-related behaviors. Population health nurses working with men should educate them regarding the need for screening, health promotion, and risk reduction. It may also be helpful in working with men to assume the worst and to over exaggerate risks to make the point of the need for change in health-related behaviors. Population health nurses and other health care providers should also support men’s health through follow-up telephone calls and advocate return visits for health promotion purposes after acute care needs have been met. Health care services for men should also be tailored to their specific needs with input from those involved. Population health nurses, in particular, are in a position to advocate for the inclusion of men in planning health services relevant to their needs. For example, a population health nurse might identify men who are single parents and encourage them to be involved in the development of support services for men who are parenting alone. Finally,

effective health care services for men highlight strengths and lay out the costs and benefits of health-promoting behaviors such as exercise, diet, and so on, in terms that are relevant to men. Population health nurses can help to draft health-related messages in language that is meaningful to men, addressing consequences and benefits in meaningful terms. For example, a population health nurse might approach the need for health promotion and illness prevention among men in terms of their continued ability to work or support their families, both elements of male gender socialization.

Health promotion interventions for men should focus on the development of healthy lifestyles related to diet and physical activity as well as the promotion of effective coping skills. For example, population health nurses may advocate for environments that promote physical activity among men as well as engagement in physical activity by individual men. Promoting coping strategies among men would focus primarily on moving men from a reliance on avoidant coping mechanisms to more confrontive types of coping. This may necessitate specific education for coping as early as grade school and continuing on throughout the educational process. Coping education can also be employed in settings where men experience considerable stress such as the workplace. Population health nurses can advocate for and develop coping skills training programs tailored to men in both school and work settings. Table 17-4 • summarizes major foci in health promotion for men and provides examples of related population health nursing interventions.

INJURY AND ILLNESS PREVENTION. Injury and illness prevention concerns specific to men focus on chronic disease prevention behaviors, immunization, safety practices, and elimination of high-risk behaviors. Chronic diseases in men can be prevented through adequate nutrition, physical activity and weight control, and elimination of behaviors such as smoking. Education for the prevention and control of other underlying

TABLE 17-4 Health Promotion Interventions in the Care of Men

Focus	Sample Interventions
Reframing	<ul style="list-style-type: none"> • Creating health care systems tailored to address men’s needs and health-related perceptions
Promoting healthy lifestyles	<ul style="list-style-type: none"> • Promoting healthy diet • Promoting physical activity
Promoting coping	<ul style="list-style-type: none"> • Enhancing coping through teaching of confrontive coping strategies
Advocacy	<ul style="list-style-type: none"> • Advocating for environmental modifications to promote health • Advocating for access to health promotion education and services for men

diseases can also help to prevent chronic disease. For example, compliance with hypertension treatment can minimize the risk of developing cardiovascular disease. More information on prevention of chronic illnesses is provided in Chapter 27.

Environmental modification can also help to prevent chronic diseases and injuries. For example, population health nurses can be advocates for elimination of hazardous exposures in work and other settings that put men at risk for environmentally caused diseases.

Immunizations for men should focus on prevention of diseases such as tetanus, hepatitis A and B, influenza, and pneumonia for those at highest risk of disease due to occupational exposure (e.g., working outdoors or around animals) or high-risk behaviors such as oral-anal intercourse or injection drug use. Men with chronic conditions, particularly chronic respiratory conditions, or who work with susceptible populations should routinely receive immunizations for influenza and pneumonia. Because most adult men are part of the workforce, population health nurses may need to advocate for immunization services at times and locations that fit busy schedules. In addition, they can advocate for workplace policies that promote immunization, particularly in settings where risk of infectious disease is high. For example, a population health nurse might promote development and enforcement of a policy mandating regular tetanus boosters among construction workers. The nurse working in this setting might also monitor immunization status among employees and provide tetanus immunizations as needed.

Prevention interventions for men would also focus on injury prevention and safe sexual practices. Because of men's socialization to accept personal risk and their tendency to engage in high-risk behaviors, injury prevention often depends on legislation and regulation. Population health nurses can advocate for the passage and enforcement of legislation related to use of seat belts and other protective devices. Population health nurses can also monitor and report occupational safety hazards that put men at risk for injury or toxic exposures. Legislative advocacy may also be required in this area. Groups of men can also be educated regarding the need for effective injury prevention and the possible long-term consequences of injury.

Education may also need to focus on safe sexual practices. The U.S. President's Emergency Plan for AIDS Relief (PEPFAR, n.d.) has recommended an ABC approach for sexual health promotion for men: **A**bstinence, **B**eing faithful to one partner, and **C**ondom use. Specific services are needed for men's reproductive health needs as well as women's. In addition, the U.S. Preventive Services Task Force (USPSTF, 2012) has recommended high-intensity counseling on STI prevention for sexually active adolescents and adults. Again, population health nursing advocacy may be required before such programs for men are developed.

Another approach to illness and injury prevention in men is the elimination of high-risk behaviors. Elimination of high-risk

sexual behaviors has already been addressed, but attention should also be given to smoking cessation and prevention or cessation of illicit drug use. Population health nurses can educate men about the need for smoking cessation and make referrals to smoking cessation services. They can also advocate for smoke-free workplace legislation to limit places where smoking is permitted or for coverage of smoking cessation assistance under health insurance plans. They can engage in similar interventions related to drug use, which is discussed in more detail in Chapter 29. Population health nurses may also need to advocate for the availability of such services and for their coverage under health insurance.

Table 17-5 summarizes illness/injury prevention foci for men as well as examples of population health nursing interventions related to each focus.

RESOLUTION OF EXISTING HEALTH PROBLEMS.

Resolving health problems among men involves the earliest possible detection of health needs through effective screening. Resolution of existing problems also encompasses the actual treatment of the health needs or disorders themselves.

Population health nurses may participate in health screening activities by providing or encouraging the client's use of such health measures as blood pressure screening and cardiovascular risk-assessment programs in public, educational, or occupational settings. Men are more likely than women to have multiple risk factors for heart disease and stroke, and population health nurses can design, implement, and promote participation in risk assessments for the male population.

TABLE 17-5 Illness and Injury Prevention Interventions in the Care of Men

Focus	Sample Interventions
Control of disease risk factors	<ul style="list-style-type: none"> • Referring for treatment of underlying conditions that contribute to chronic illness (e.g., hypertension) • Promoting smoking cessation • Promoting safe sexual practices • Promoting and providing immunization services
Injury prevention	<ul style="list-style-type: none"> • Promoting safety behaviors (e.g., seat belt and helmet use) • Monitoring and eliminating environmental safety hazards and exposures
Advocacy	<ul style="list-style-type: none"> • Advocating for available and accessible prevention services • Advocating for safety legislation and enforcement • Advocating insurance coverage of adult immunizations

Nurses can also facilitate the offering and use of screening examinations by other health care professionals within the community, such as rectal examinations and screening for type 2 diabetes in men with blood pressures over 135/80 (USPSTF, 2012).

Routine screening procedures for men include tobacco use and alcohol misuse, colorectal cancer, hypertension, lipid disorders, and obesity. Other screening tests are recommended for men at particular risk for certain conditions. Recommendations of the U.S. Preventive Services Task Force (2012) for screening in men are presented in Table 17-6. Population health nurses may need to advocate for access to routine screening services, particularly among low-income men and those without health insurance. Of note are the changes in prostate and testicular cancer screening recommendations based on scientific evidence described below.

Population health nurses may refer men with existing health problems for medical evaluation and treatment. They may also participate in the treatment of illnesses experienced by male clients. In the case of ischemic and certain other cardiac disorders, for example, stress has been shown to impact negatively on treatment outcomes, in some cases leading to a threefold increase in mortality (e.g., in post-myocardial infarction clients). Treatment programs that identify high-stress clients during hospitalization, track and reduce their stress levels after discharge, and provide prompt assistance from nurses in the community when episodes of increased stress occur can result in significant reduction of the stress-related mortality experienced by post-myocardial infarction clients.

Again, advocacy may be required to assure access to diagnostic and treatment services for men. For example, a population health nurse might assist in the development of stress-reduction programs in the workplace or coping skills training programs in school and work settings.

HEALTH RESTORATION. Health restoration services for men are directed at those disorders that influence men's health in some ongoing manner or that have a likelihood of recurrence. The goals of rehabilitation are to assist men in coping with the continuing manifestations of illness and to reduce the likelihood of future episodes of an illness. To this end, it is useful to group rehabilitation measures into care directed toward those disorders that affect men's sexual functioning or sexual identity or as they present a threat to notions about masculinity and male strength. Restoration measures also would be directed at supporting compliance with long-term therapy.

One area for restoration intervention by the population health nurse involves those disorders that affect the male client's sexual functioning or sexual identity, such as testicular cancer and ED. Male clients with testicular cancer may face significant emotional distress owing to the effects of treatment on their sexuality. Treatment for testicular cancer is surgical removal of the affected testes followed by hormonal therapy. These treatments, along with their side effects (loss of fertility, emasculation), can have a profound impact on the client's self-image and psychosocial functioning. Similarly, long-standing ED may have implications for men's psychological health and population health nurses may need to refer men for assistance in creating healthier self-images that are not based on sexual prowess. Population health nurses may need to advocate for development of and access to services dealing with sexual dysfunction. They may also be instrumental in changing men's attitudes to sexual dysfunction and their willingness to seek help.

An important intervention in this regard involves encouraging men to join support groups. Interaction with other men who have experienced the same problems can be very effective in facilitating adjustment to treatments that so tangibly affect men's sense of masculinity. On a one-to-one basis, the nurse can be accepting, supportive, and facilitative of the male client's expression of his feeling of loss. Population health nurses may also be instrumental in initiating support groups for these men or in advocating their availability in the community.

Some disorders may affect men's sense of strength; this is particularly true of cardiovascular disorders. The heart is a symbol of masculine strength for some men. Consequently, cardiovascular disorders not only can leave residual symptoms and physiological impairment, but can also threaten a man's self-image. Men with cardiovascular disease often benefit from interventions that support their self-image as masculine and from discussing their feelings about their illness. As

TABLE 17-6 Routine Screening Recommendations for Men

Type of Screening	Recommendation
Abdominal aortic aneurysm	One time for men aged 65 to 75 years who have ever smoked tobacco
Alcohol misuse	All adult men
Colorectal cancer	Men 50 to 75 years of age by fecal occult blood, sigmoidoscopy, and/or colonoscopy
Depression	Adult men in practice settings where follow-up is available
Diabetes	Adult men with blood pressures >135/80 mm Hg
Hypertension	All men over 18 years of age
HIV infection	All adult and adolescent men at risk of infection
Lipid disorders	All men over 35 years of age and men 20 to 35 years of age at risk of CHD
Obesity	All adult men
Syphilis	All men at risk
Tobacco use	All adult men

Data from: U.S. Preventive Services Task Force. (2013). *Recommendations for adults*. Retrieved from <http://www.uspreventiveservicestaskforce.org/adultrec.htm>

Evidence-Based Practice

Prostate and Testicular Cancer Screening

In spite of the relatively common practice of routine screening for prostate cancer using prostate-specific antigen (PSA testing), the U.S. Preventive Services Task Force (2010, 2013) has found insufficient evidence for screening men under 75 years of age. In addition, the task force has recommended against screening men over age 75. This recommendation is based on lack of evidence of the need for and effectiveness of treatment when prostate cancer is detected. The conclusion of the task force was that routine screening benefits only a few men and may cause harm to many men due to unnecessary

treatment, treatment side effects, and mental suffering for them and their families.

In addition, the USPSTF has recommended against screening for testicular cancer in adolescent or adult males noting that there is inadequate evidence that early detection through either testicular self-examination or clinical examination influences cure rates. In fact, the evidence reviewed indicates that 90% of testicular cancer will be cured regardless of stage at diagnosis. The task force also noted the potential for harm related to false positive results, anxiety, or the results of diagnostic tests or treatments (USPSTF, 2011a, 2011b).

noted elsewhere, stress management training also can have a significant positive effect on outcomes for men who have cardiovascular disease. These interventions are essential to promote adjustment and compliance with treatment.

Of course, population health nurses should also support and reinforce men's positive responses to cardiac rehabilitation efforts initiated in other treatment settings. Foremost among these would be weight control, limited intake of saturated fats, regular exercise, compliance with follow-up examinations and medications, and control of other disorders that exacerbate cardiovascular disease (hypertension, diabetes).

In the case of some chronic disorders, especially those producing no overt symptoms, men tend to be lax about complying with long-term treatment recommendations. This is especially true for male clients with hypertension. Interventions that help men understand the importance of controlling this disorder and that build on their perceptions of masculinity are very helpful. Maintaining a regimen of antihypertensive medications may be especially difficult for men when side effects interfere with necessary masculine roles. Examples of such side effects could include impotence, dizziness, and decreased tolerance for physical activity. Nurses can assist men by teaching ways to compensate for these side effects, thereby helping them to maintain a sense of control over circumstances. In cases in which the side effects are not manageable and are affecting clients' masculinity (impotence), collaborating with the client's physician or assisting the client to discuss the problem with the physician can lead to acceptance of the treatment for hypertension.

Preventing recidivism, or rehospitalization, in instances of substance abuse is a major rehabilitation intervention in working with men. Interventions that decrease the likelihood of recidivism include encouraging the use of therapeutic support groups (Alcoholics Anonymous) and education regarding

factors that predispose one to continued substance abuse (poor coping skills, co-dependent relationships, maintaining social contacts with abusers). It is also important for the population health nurse to consider the client's family and significant others when caring for substance-abusing men. Families and significant others can be either enablers of substance abuse or corrective forces leading to its elimination. Education of family and support persons regarding behaviors that produce improvement and those that permit further substance abuse is essential, and referrals to family treatment and support services are also of value.

The Internet may be a particularly valuable tool for educating men regarding rehabilitation and self-management of chronic illnesses as well as for motivating primary prevention activities by men. More and more, the U.S. population is turning to the Internet as a source of information. Population health nurses can help to create websites to provide such information as well as monitor existing sites for their accuracy and credibility.

Evaluating Health Care for Men

As in working with other population groups, population health nursing plans and interventions are evaluated by determining the degree to which population health goals have been met. It is also important to determine whether interventions were efficient. Could the same results have been accomplished with less expense of time or other resources?

The effects of interventions for men at the aggregate level can be assessed in terms of the accomplishment of national health objectives (USDHHS, 2014b). Selected objectives related to men's health are presented in the *Healthy People 2020* feature on pages 441 and 442. Information about objectives related to men's health and their current status is available on the *Healthy People 2020* website.

Healthy People 2020

Selected Objectives Related to Men's Health

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
AHS-1.1 Increase the proportion of men with medical insurance	83.2% (2008)	100%	81.2 (2011)	National Health Interview Survey (NHIS), CDC, National Center for Health Statistics (NCHS)
AHS-3 Increase the proportion of men 18–64 years of age with a usual primary care provider	75.5% (2008)	83.9%	72.9% (2010)	NHIS, CDC, NCHS
AHS-5 Increase the proportion of men with a source of ongoing care	74.3 (2010)	89.4	76.6% (2010)	NHIS, CDC, NCHS
AHS-6 Reduce the proportion of men unable to obtain or delay obtaining medical care, dental care, or prescription medications	9.1% (2007)	9%	8.8% (2010)	Medical Expenditure Panel Survey (MEPS), AHRQ
AOCBC-2 Reduce the proportion of men with Dr. diagnosed arthritis who experience a limitation in activity due to arthritis or joint symptoms	37.6% (2008)	35.5%	37.9% (2011)	NHIS, CDC, NCHS
AOCBC-12 Reduce activity limitation due to chronic back conditions per 1,000 men	28.8% (2008)	26.6	34.4% (2011)	NHIS, CDC, NCHS
C-1 Reduce cancer deaths per 100,000 men	218.8 (2007)	161.4	209.9 (2010)	National Vitals Statistics System–Mortality (NVSS-M), CDC, NCHS
C-2 Reduce lung cancer deaths per 100,000 men	64.9 (2007)	45.5	60.3 (2010)	NVSS-M, CDC, NCHS
C-5 Reduce colorectal cancer deaths per 100,000 men	20.4	14.5	19.1 (2010)	NVSS-M, CDC, NCHS
C-7 Reduce prostate cancer deaths per 100,000 men	24.2 (2007)	21.8	21.9 (2010)	NVSS-M, CDC, NCHS
C-8 Reduce melanoma cancer deaths per 100,000 men	4.0 (2007)	2.4	4.1 (2010)	NVSS-M, CDC, NCHS
C-16 Increase the proportion of men who receive colorectal cancer screening	52.2% (2008)	70.5%	59.3% (2010)	NHIS, CDC, NCHS
D-3 Reduce diabetes deaths per 100,000 men	88.8 (2007)	65.8	86.1 (2010)	NVSS-M, CDC, NCHS
HDS-2 Reduce coronary heart disease deaths per 100,000 men	169.2 (2007)	103.4	151.3 (2010)	NVSS-M, CDC, NCHS
HDS-3 Reduce stroke deaths per 100,000 men	43.7 (2007)	34.8	39.3 (2010)	NVSS-M, CDC, NCHS

Healthy People 2020 (Continued)

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
HDS-5.1 Reduce the proportion of men with hypertension	30.6% (2005–2008)	26.9%	NDA	National Health and Nutrition Examination Survey (NHANES), CDC, NCHS
HDS-6 Increase the proportion of men who have had their blood cholesterol level checked in the past 5 years	72.2% (2008)	82.1%	NDA	NHIS, CDC, NCHS
HDS-7 Reduce the proportion of men with high blood cholesterol levels	13.5% (2005–2008)	13.5%	NDA	NHANES, CDC, NCHS
HIV-4 Reduce new cases of AIDs per 100,000 adult and adolescent men	20.6 (2007)	12.4	20 (2010)	HIV Surveillance System, CDC, NCHHSTP
IVP-1.3 Reduce emergency department visits for nonfatal injuries per 100,000 men	9156.7 (2007)	7453.4	10,441.1 (2010)	National Hospital Ambulatory Medical Care Survey (NHAMCS), CDC, NCHS
IVP-11 Reduce unintentional injury deaths per 100,000 men	55.9 (2007)	36	51.5 (2010)	NVSS-M, CDC, NCHS
IVP-29 Reduce homicides per 100,000 men	9.7 (2007)	5.5	8.4 (2010)	NVSS-M, CDC, NCHS
NWS-9 Reduce the proportion of adult men who are obese	32.5% (2005–2008)	30.5%	35.5% (2009-2010)	NHANES, CDC, NCHS
PA-1 Reduce the proportion of adult men who engage in no leisure time physical activity	33.9% (2008)	32.6%	29.8% (2011)	NHIS, CDC, NCHS
SA-12 Reduce drug-induced deaths per 100,000 men	16 (2007)	11.3	15.9 (2010)	NVSS-M, CDC, NCHS
TU-1.1 Reduce cigarette smoking by adult men	20.6% (2008)	12%	19% (2011)	NHIS, CDC, NCHS
TU-4.1 Increase smoking cessation attempts by adult men smokers	48.3% (2008)	80%	48.9% (2011)	NHIS, CDC, NCHS

CHAPTER RECAP

Men have a variety of health care needs that they may or may not acknowledge. Population health nurses identify factors related to biological, psychological, environmental, sociocultural, behavioral, and health system determinants of health and use this information to develop population level or individual nursing diagnoses. They then engage in health promotion, illness and injury prevention, health restoration, and rehabilitation interventions to address the needs identified. Population health

nurses can be actively involved in fostering health promotion and illness/injury prevention activities by men and encouraging men to seek health care as needed. They may also provide direct services to male clients, particularly with respect to education for promotion, prevention, and disease management. In addition, population health nurses may be involved in advocacy activities to assure the availability and accessibility of needed services to improve men's health status.

CASE STUDY

Promoting Sexual Health in Men

There is a high rate of sexually transmitted diseases among men in the community where you are employed as a population health nurse. Particularly high incidence rates are noted for *Chlamydia trachomatis* and gonorrhea. Significant disparities are noted in incidence rates among Caucasian, African American, and Latino men, with incidence higher among young African American and Latino men than among Caucasians, although incidence among all three groups is high. STD incidence does not seem to be associated with sexual orientation

since high rates are noted for both exclusively heterosexual men and those who have sex with other men.

1. How might you address the problem of STD incidence at the population level?
2. What additional information might you need to determine appropriate interventions for the problem?
3. What other segments of the community would you involve in developing your interventions?

Care of Women

Learning Outcomes

After reading this chapter, you should be able to:

1. Identify at least two factors in each category of determinants of health that influence the health of women.
2. Identify health problems common to women.
3. Identify concerns in health promotion for women and analyze the role of the population health nurse with respect to each.
4. Discuss strategies for illness and injury prevention for women and related population health nursing interventions.
5. Describe areas of health problem resolution for women and design population health nursing interventions related to each.
6. Describe considerations in health restoration for women.

Key Terms

bioidentical hormone replacement therapy (BHRT)

dysmenorrhea

gender

gestational diabetes mellitus (GDM)

menopause

osteoporosis

perimenopause

postmenopause

premenopause

premenstrual dysphoric disorder (PMDD)

premenstrual syndrome (PMS)

sex

Margaret Sanger and Contraceptive Services for Women

As a result of exposure to the health effects of multiple pregnancies on her mother's health, Margaret Sanger, one of the early nurses of the Henry Street Settlement was particularly sympathetic to the plight of poor women in New York City who were affected by multiple unwanted pregnancies. Distribution of contraceptive devices and information was prohibited by the Comstock Act passed in 1873, putting women at risk for multiple pregnancies or illegal abortions in unsafe conditions (Lewis, 2010).

Sanger founded the American Birth Control League, which eventually became the Planned Parenthood Foundation, to provide birth control information and services to women. She also started the first birth control clinic in the United States. Sanger dedicated herself to providing contraceptive information to women and was subjected to prosecution and imprisonment for "mailing obscenities" and "creating a public nuisance." In large part, her arrests and the resulting public outcry led to legal changes permitting contraceptive availability for women (Margaret Sanger, 2013).

Sanger was also instrumental in the development of birth control pills, or a "magic pill" that women could take as easily as aspirin. She recruited a reproductive specialist, Gregory Pincus, to begin development of a hormonal contraceptive and found funding for the project through Katherine McCormick, widow of the International Harvester magnate. This project eventually resulted in FDA approval of the first birth control pill in 1960 (Margaret Sanger, 2013). Sanger died in 1966, just after the U.S. Supreme Court ruled that private use of contraceptives by married couples was legal (Margaret Sanger Papers Project, 2010).

Sanger's contributions to women's health are not uncontroversial, and she is reviled by some as being racist because of her eugenicist beliefs. Those beliefs are used by some as evidence of a conspiracy to limit the African American population (Goldberg, 2012). Her grandson, however, noted that Sanger saw women as "natural eugenicists" striving to improve the health of their children (and subsequently the overall gene pool) by limiting their number through birth control (Margaret Sanger, 2013). In addition, in a 1957 interview with TV commentator, Mike Wallace, archived by the University of Texas at Austin's Harry Ransom Center, Sanger herself cited her motivation as the need to prevent the pain and suffering of women forced by legal sanctions to bear child after child (*Mike Wallace Interview*, 1957). She also voiced her concern about population control. Finally, the point is made that recognition of racism on Sanger's part would have precluded Martin Luther King, Jr.'s acceptance of Planned Parenthood's Margaret Sanger award in 1966, and his praise of her for launching "a movement which is obeying a higher law to preserve human life under humane conditions" (Goldberg, 2012, p.6).

Some of Sanger's beliefs, for example the desirability of involuntary sterilization of the mentally incompetent, are admittedly appalling and foreign to today's nursing advocacy for the rights of the disenfranchised, and should not be upheld; however, her contribution to access to contraceptive information and services for all women in the face of extreme opposition should be recognized.

Dorothy Irene Height and Women's Rights

For much of her 98 years of life, Dorothy Irene Height fought for the rights of African Americans, women, and the underprivileged. Encouraged by her mother to obtain an education, Height was denied admission to Barnard College, although accepted, because the institution had already filled its quota of African American students. Instead she earned her undergraduate degree in psychology and social work at New York University, then went on to earn a master's in Educational Psychology and finally a doctoral degree (Williams, 2011).

A victim of both racial and gender-based discrimination herself, Height was actively involved in the National Council of Negro Women, which she headed for more than 20 years. Initiatives of the organization focused on women's rights, including equal employment and education for women.

Height was the only woman included in the United Council of Civil Rights Leaders and supported a campaign to register African American voters through a “Wednesdays in Mississippi” initiative bringing northern women to Jackson, Mississippi to promote voting rights (Shulman, 2012). She later extended her human rights activities on an international basis through the Women’s Federation of the World Council of Churches (NASW Foundation, 2004).

At her 2010 memorial service in Washington, DC, speakers noted her ability to build coalitions to direct attention to the needs of all disadvantaged individuals and for “fighting against all our nation’s evil isms: racism, sexism, classism, and ageism” (Cosby as quoted in Williams, 2011, p. 8). Similarly, President Barack Obama praised Height’s ability “to make us see the drive for civil rights and women’s rights not as a separate struggle, but as part of a larger movement to secure the rights of all humanity, regardless of gender, regardless of race, regardless of ethnicity” (as quoted in Williams, 2011, p. 8).

Women’s health encompasses the health status of women as well as the factors that promote or impede health. Population health nursing has long been involved in strategies and interventions to improve the health of individual women and of women as a population group.

In 2010, women constituted 51.5% of the U.S. population over 18 years of age (U.S. Census Bureau, 2012a). By 2015, women are projected to comprise a similar proportion of the population (51.3%) (U.S. Census Bureau, 2012b). About 64% of U.S. women in 2010 were between the ages of 20 and 64 years, and 10% were over 65 years of age (Howden & Meyer, 2011). The health care needs of this latter group are addressed in Chapter 19. In this chapter, we will focus on the care of young and middle adult women.

Distinctions are made between the terms sex and gender as they relate to men and women. **Sex** is an individual characteristic determined by biological parameters, the differential possession of X and Y chromosomes. **Gender**, on the other hand, is a social construction encompassing behavioral expectations that are loosely associated with one’s biological sex but are culturally defined and vary from one cultural group to another. Two perspectives on gender have been suggested: an equality perspective and a difference perspective (Annandale, 2009). In the equality perspective, women should have parity with men and have equal access to valued spheres of life such as education, employment, and so on. The focus in an equality perspective is on overall health status. The difference perspective views men and women as equal but different as a result of biological differences. Emphasis is on control of one’s own body and the focus is more on reproductive health than health in general.

Some authors point to the paradox in the health status of men and women. Women live longer than men, but experience greater levels of illness and disability. In part, the difference lies in the types of health problems experienced by men and women. Men tend to experience more acute life-threatening conditions, while women have more chronic debilitating

conditions that do not result in death. Worldwide, the average life expectancy for women in 2011 was 72 years compared to only 68 years for men, with a slightly larger longevity advantage for women in the Americas (79 years for women and 73 years for men) (World Health Organization [WHO], 2013). In 2010, a 65-year-old man in the United States could expect to live another 17.7 years, compared to 20.3 years for a woman of 65 (National Center for Health Statistics [NCHS], 2013).

The importance of improving the health of women in the United States is reflected in the national health objectives for the year 2020. Multiple objectives specifically target the health needs of women (U.S. Department of Health and Human Services [USDHHS], 2014). These objectives can be viewed by accessing the *Healthy People 2020* website; selected objectives are included at the end of this chapter.

Population Health Nursing and Women’s Health

Population health nursing care of women involves use of the nursing process at both individual and population levels. Assessment of women’s health status addresses each of the categories of determinants of health to identify factors contributing to health and illness in this population. Planning and implementation of interventions geared toward health promotion and illness/injury prevention, resolution of existing health problems, and restoration of health are also part of population health nurses’ care of women. Finally, population health nurses evaluate the effects of care on women’s health status at individual and population levels.

Assessing the Health Status of Women

Factors influencing women’s health status occur in each of the six categories of health determinants. In this chapter, we will briefly examine factors in the biophysical, psychological, environmental, sociocultural, behavioral, and health system dimensions that contribute to health and illness among women. Assessment of the female population can

Global Perspectives

Addressing Women's Health Issues

A 2009 report by the World Health Organization (WHO, 2009a) contended that women are significantly disadvantaged with respect to health status and health care throughout the world. In part, disparities between men and women are due to lack of attention to some problems that affect only women, differential impact of some health conditions on men and women and the subsequent need to tailor services specifically to women's needs, differential access to health care services, and women's more limited ability to wield resources needed to protect and promote their health. The WHO report delineates concerns for disparities throughout women's life spans from childhood through adolescence, childbearing years, and old age (WHO, 2009a).

Differences in women's health status also occur from one nation to another. The table below indicates the top causes of mortality for females of all ages in low-, middle-, and high-income countries. These findings suggest that different strategies are needed in different parts of the world to effectively address women's health issues.

WHO recommendations for improving women's health status worldwide include the following:

- Developing strong leadership that incorporates participation of women in setting health priorities and agendas that go beyond maternal mortality and reproductive health.
- Promoting "gender mainstreaming" to minimize male-female inequities that affect health. *Gender mainstreaming* is a process of considering the implications of all actions, including

legislation, policies, and health care delivery programming, for the health of both men and women. It involves "making women's as well as men's concerns and experiences an integral dimension of the design, implementation, monitoring, and evaluation of policies and programmes in all political, economic, and societal spheres, so that women and men benefit equally and inequality is not perpetuated" (United Nations Economic and Social Council, as quoted in WHO 2009a, p. 74).

- Building accountability in government systems by tracking and monitoring indicators of health.
- Developing health services and programs that
 - Respond specifically to women's health needs.
 - Promote women's autonomy and participation in decision making related to their health.
- Promoting universal access to care.
- Removing gender-based differentials in public policy, particularly with respect to property rights; employment accessibility, promotion, and compensation; education; health promotion services; economic opportunity; access to resources, including technology; gender-based discrimination, norms, and policies; violence; and opportunities for older women to contribute productively.
- Tracking progress toward achievement of health-related goals and targets. (WHO, 2009a)

Differences in Female Causes of Death in Low-, Middle-, and High-income Countries

Low-income Countries	Middle-income Countries	High-income Countries
Lower respiratory infections	Stroke	Ischemic heart disease
Ischemic heart disease	Ischemic heart disease	Stroke
Diarrheal diseases	Chronic obstructive pulmonary disease	Alzheimer's and other dementias
Stroke	Lower respiratory infections	Lower respiratory infections
HIV/AIDS	Hypertensive heart disease	Breast cancer
Maternal conditions	Diabetes mellitus	Trachea, bronchus, and lung cancer
Neonatal infections	HIV/AIDS	Colon and rectal cancers
Prematurity and low birth weight	Breast cancer	Chronic obstructive pulmonary disease
Malaria	Stomach cancer	Diabetes mellitus
Chronic obstructive pulmonary disease	Trachea, bronchus, and lung cancer	Hypertensive heart disease

be conducted using the *Population Health Assessment and Intervention Guide* included in the *Assessment Guidelines* for Chapter 15. A tool to assess the health of an individual woman is also included in the *Assessment Guidelines* on the student resources site.

BIOLOGICAL DETERMINANTS. Biological factors are of concern to the population health nurse working to improve the health of women in the community. Specific areas for consideration include genetic inheritance, maturation and aging, and physiologic function.

Genetic inheritance. Women are prone to a number of genetically related or genetically linked conditions. For example, cancers of the breast have been shown to occur more frequently among women whose mothers, sisters, aunts, or grandmothers have had similar cancers. Similarly, diseases of the thyroid gland seem to occur more frequently among women than men, as do diabetes, asthma, various forms of dermatitis, and hay fever-type allergies, all of which may involve genetic predisposition to disease.

Maturation and aging. In general, physical maturation of females follows the developmental schedule typical of children. Sexual maturation, however, follows a unique trajectory in women. Stages of sexual maturation and the relevant time periods are presented in Table 18-1. As we saw in Chapter 16, menarche occurs at slightly different ages in different racial and ethnic groups.

Perimenopause is the period of a woman's life in which she is most likely to become pregnant, the years of fertility. These childbearing years generally last from menarche to age 44, when women enter the perimenopausal period. In 2008, approximately 61.7 million U.S. women were of childbearing age (Dye, 2010).

Menstruation during premenopause is usually free of medical complications. Some women, however, experience dysmenorrhea or premenstrual syndrome. **Dysmenorrhea** is painful menstruation, usually manifested in abdominal cramping. **Premenstrual syndrome (PMS)** includes a variety of physical or emotional symptoms that occur 7 to 10 days prior to menstruation and disappear shortly after menstruation

starts (Gallenberg, 2012). In addition, 3% to 8% of women may be affected by **premenstrual dysphoric disorder (PMDD)**, a condition of depressed mood and irritability severe enough to interfere with interpersonal relationships and everyday activities. Both PMS and PMDD may be related to hormonal changes that occur during the menstrual cycle. Other possible contributing factors include alcohol abuse, being overweight, excessive caffeine intake, a family history of PMDD, or lack of exercise (*Premenstrual dysphoric disorder*, 2013).

Perimenopause is a transition period between premenopause and menopause, when the physical and hormonal changes that herald cessation of menstruation occur. Perimenopause may begin as early as the 30s in some women, but more typically begins in the 40s (Mayo Clinic Staff, 2012). Perimenopause is characterized by less predictability regarding menstrual cycles in terms of frequency, duration, and amount of bleeding. Perimenopause may also be associated with a variety of vasomotor symptoms, sleep disturbance, anxiety, and depression. Hormone replacement therapy may be effective in addressing the discomforts of the perimenopausal period. Some herbal preparations, such as black cohosh and plant phytochemicals, may also be used to deal with the symptoms associated with perimenopause. Population health nurses should be aware of the extent to which these preparations are used by women in the community, as well as their knowledge about potential adverse effects. There is some evidence to suggest that the discomforts experienced by some women during perimenopause are, at least in part, a function of cultural expectations. For this reason, population health nurses should also explore cultural beliefs, attitudes, and behaviors related to perimenopause and

TABLE 18-1 Stages of Female Sexual Maturation

Sexual Characteristic	Stage Description	Related Ages
Pubic hair development	1. Prepubertal: similar to hair on the abdomen	Childhood
	2. Sparse growth of long, pigmented, straight or slightly curly hair	9.4 years–10.6 years
	3. Sparsely distributed, longer, darker, more curly hair	10.5 years–11.8 years
	4. Coarser adult type hair not yet spread to medial thighs	11.9 years–13.1 years
	5. Adult quality hair in classic triangular distribution, may extend to medial aspects of thighs	14.7 years–16.3 years
Breast development	1. Prepubertal: No breast tissue, slightly elevated nipple	Childhood
	2. Wider, darker, elevated areola, palpable bud of glandular tissue below areola	9.4 years–10.3 years
	3. Further enlargement of breast and areola, rounded contour, no contour change between areola and breast	10.7 years–11.7 years
	4. Projection of papilla and areola as secondary mound above breast	12.2 years–13.2 years
	5. Mature adult breast, loss of secondary mound	13.9 years–15.4 years (may never occur in some women)

menopause among women in the community. The effects of perimenopause may also arise from socioeconomic factors in women's lives, but it is at present unknown how much psychological distress is the result of hormonal changes and how much derives from socioeconomic and cultural influences.

Menopause is defined by WHO as “the permanent cessation of menstruation resulting from the loss of ovarian follicular activity or follicle depletion” (Weismiller, 2009, p. 199). Menopause has occurred when the woman has been without menses for 12 months (Mayo Clinic Staff, 2012). The average age for menopause is 51 years, but normal menopause can occur as early as age 40. Some women experience menopause as a result of surgical interventions such as hysterectomy. Early menopause may be associated with increased health problems such as osteoporosis and increased mortality risk. Hormonal treatments commonly used to treat the discomforts of menopause have also been linked to increased risk of heart attack, breast cancer, stroke, and blood clots (NCCAM, 2012).

Postmenopause is the period of time that extends from menopause until death and may cover as much as one third of women's lives. Because of the hormonal changes that occur with menopause, the postmenopausal period is a time of increased risk for a number of health problems. Several of these, such as osteoporosis and heart disease, are discussed in the section addressing physiologic function. Population health nurses may engage in advocacy to change negative social attitudes toward perimenopausal and menopausal women. Conversely, they may assist women to deal effectively with the effects of these negative attitudes as well as the physical discomforts of menopause. Finally, population health nurses can be actively involved in educating women to minimize the negative effects of menopausal changes (e.g., bone loss) on their health.

Other areas for consideration with respect to maturation and aging include the effects of aging in general on health status (which will be addressed in Chapter 19) and women's emotional maturation.

Physiologic function. Physiologic function is another biological determinant influencing the health of women as a population group. Specific considerations related to physiologic function include the incidence and prevalence of specific illnesses and functional limitations, reproductive issues of pregnancy and infertility, and immunization levels.

Physical illness and disability. Women are affected by a variety of acute and chronic illnesses that may not occur in men (e.g., uterine cancer), have different risk factors and manifestations than for the same diseases in men, or may require different approaches to treatment than the same diseases in men. Women are more likely than men to experience multiple chronic diseases and to be disabled as a result of them. In addition, physiologic differences in drug metabolism between men and women lead to differences in treatment effects. Several conditions and their effects on women will be discussed here. In addition, women are more likely to experience disability with chronic conditions than

men, so the prevalence and effects of disability in women are also examined. The leading causes of mortality in U.S. women in 2010 were compared to those for men in Chapter 17 and included heart disease; malignant neoplasms; cerebrovascular disease; chronic lower respiratory diseases; Alzheimer's disease, unintentional injury; diabetes mellitus; influenza and pneumonia; nephritis, nephrotic syndrome, and nephrosis; and septicemia (NCHS, 2013).

Heart disease accounts for 25% of deaths among U.S. women. In addition, women more often experience uncommon symptoms of heart attack and are less likely than men to seek care (Division for Heart Disease and Stroke Prevention, 2013). Women are less likely than men to have heart disease, but are almost as likely to have hypertension and more likely than men to experience stroke (NCHS, 2012). Overall breast cancer mortality among women in 2010 was 22.1 per 100,000 women and increased with age. Homicide mortality among women of all ages in the same year was 2.3 per 100,000 population and suicide mortality was 5 per 100,000 women (NCHS, 2013).

Other conditions affecting women may not cause death but contribute to significant morbidity. For example, women are more likely than men to have emphysema, asthma, hay fever, sinusitis, and chronic bronchitis, as well as ulcers, kidney disease, diagnosed arthritis, and other chronic joint symptoms (NCHS, 2012).

Women are slightly less likely than men to have diabetes, but are more likely to have their diabetes under control (NCHS, 2013). Similarly, approximately 28% of women have hypertension compared to more than 30% of men, but nearly half of the women affected have their blood pressure under control

Women are more likely than men to experience disability.

(Antonioguilllem/Fotolia)

(Keenan & Rosendorf, 2011). The prevalence of overweight and obesity among women, however, is less encouraging. After 20 years of age, approximately 29% of women become obese compared to only 26% of men. Overweight prevalence among women increases with age to 37% of those aged 40 to 59 years (Freedman, 2011).

Human immunodeficiency virus (HIV) infection and acquired immune deficiency syndrome (AIDS) are other diseases that affect large numbers of women. Although initially considered a disease of gay men, the proportion of women affected has steadily risen. Between 1990 and 2010, for example, the proportion of new AIDS cases involving women increased from 11% to 21% (Division of HIV/AIDS Prevention, 2014). Advocacy by population health nurses is needed to increase efforts to protect women from HIV infection, particularly in cultural groups where women are not empowered to insist on condom use by their partners. Population health nurses may also advocate for available screening and treatment services for women.

Osteoporosis is another physiologic condition of concern for women during the perimenopausal and postmenopausal years. **Osteoporosis** is a “systematic skeletal disorder characterized by low bone mass and microarchitectural deterioration of bone tissue predisposing to an increased risk for fracture” (Lash, Nicholson, Velez, Harrison, & McCort, 2009, p. 182). Approximately 8 million U.S. women and 2 million men have osteoporosis, which results in 1.5 million fractures annually, including 300,000 hospitalizations and 180,000 nursing home placements for hip fractures alone. More than half of postmenopausal women in the United States have decreased bone mineral density, and 16% of them have osteoporosis. Like many conditions, the prevalence of osteoporosis increases with age, with women over age 80 having a rate of disease 10 times higher than those in their 50s. Approximately 20% of people with osteoporotic fractures require long-term care, and the estimated annual cost for hip fractures alone amounts to \$15 billion (Lash et al., 2009).

Osteoporosis has a variety of causes, including long-term use of certain medications (e.g., glucocorticoids and other immunosuppressants, hormonal and anti-hormonal agents,

and some anti-convulsants), renal failure, hypogonadism, and alcoholism. Osteoporosis may also occur as a result of cancer therapies or organ transplant (Lash et al., 2009).

In addition to causing mortality and morbidity in the population, many of the conditions discussed above, as well as others, contribute to disability among women. Disability results from an interaction between a person’s functional abilities and the environment and tends to increase with increasing age. Women are more likely than men to have difficulty with all types of physical activity. In addition, women are more likely to have vision problems and to be edentulous (NCHS, 2012). In 2011, for example, nearly 15% of women needed assistance with personal care activities compared to roughly 10% of men, and women were in need of more physical assistance in all physical activity categories (NCHS, 2011). In addition, nearly two thirds of women, versus just over half of men, have difficulty with at least one basic activity. Similarly, more women than men have difficulty with at least one complex activity related to self-care, have difficulty seeing even with corrective lenses, and are more likely to rate their health as fair or poor (NCHS, 2013).

Pregnancy. Pregnancy and related issues are unique to women and should be considered in assessing biological determinants of women’s health. Half of all U.S. pregnancies (51%) are unintended often leading to abortion. In 2008, for example, 40% of unintended pregnancies were aborted. For unintended pregnancies ending in birth, 65% were funded by public insurance. The overall public cost for unintended pregnancy was \$12.5 billion (Guttmacher Institute, 2013b).

U.S. rates of unintended pregnancy are higher than many other developed nations, and approximately 30% of U.S. women become pregnant before the age of 30 (Planned Parenthood Federation of America, 2012). Unintended pregnancy is related to poverty, cohabitation, membership in minority groups, lower educational level, and younger age. Unintended pregnancy is also associated with delayed prenatal care, premature birth, and physical and mental effects for both mother and child (Guttmacher Institute, 2013b). *Healthy*

Evidence-Based Practice

Contraceptive Options

Women with chronic health conditions are often limited in the use of various forms of contraception in the mistaken belief that particular methods are contraindicated. To eliminate these mythical contraindications, the Centers for Disease Control and Prevention (CDC) has developed evidence-based guidelines for providers to use in joint contraceptive decision making with women clients. Use of these guidelines is intended to reduce the high rate of unintended pregnancy among American women. The guidelines were published in 2010 and were based on medical

eligibility criteria established by WHO in 2009. The guidelines are based on recent evidence-based data and should supercede what is included in product information inserts that are often outdated (Turok, Wsocki, Grimes, & Deal, 2011).

The guidelines are updated periodically. In fact, in 2012, revised guidelines were published related to the use of hormonal contraceptives for HIV-infected women and those at high risk for infection (CDC, 2012). For more information about the most recent guideline, see the *External Resources* section of the student resources site.

People 2020 objectives include the goal of reducing unintended pregnancies to 10% of all pregnancies.

More than half of unintended pregnancies are the result of failure to use contraceptives. Approximately two thirds of women at risk for an unintended pregnancy use contraception consistently and correctly (Guttmacher Institute, 2013b); those who use contraceptives consistently and correctly account for only 5% of unintended pregnancies. As of 2012, approximately 11% of women at risk for unintended pregnancies did not engage in regular use of contraceptives. Rates of nonuse are highest among adolescents (18%) and lowest among women 40 to 44 years of age. Lack of access to and promotion of long-acting contraceptive options (e.g., hormonal implants, intrauterine devices) also contribute to the problem, particularly among women without a steady sexual partner. Use of such options addresses the unplanned nature of many sexual encounters. Based on 2009 data, 8.5% of women using contraceptives used long-acting reversible methods, up from 2.4% in 2002. Use of emergency contraception after unprotected intercourse is also low (Guttmacher Institute, 2013a).

Even when pregnancy is intended and desired, it gives rise to needs for care and poses risks to the health of the woman and fetus. Early prenatal care promotes mother and child health, but is often lacking. In 2011, for example, not quite 74% of U.S. women received care in the first trimester of pregnancy, and 6% began care in the third trimester or received no care at all. Teenagers and members of ethnic minority groups were

Health promotion for women and their children should begin before conception. (Monkey Business/Fotolia)

least likely to receive early care (Maternal and Child Health Bureau [MCHB], 2013).

Lack of prenatal care is a significant contributor to complications of pregnancy such as gestational diabetes mellitus, preeclampsia, and toxemia. **Gestational diabetes mellitus (GDM)** is a condition characterized by increased blood glucose levels resulting from the body's inability to meet the increased insulin needs posed by pregnancy (National Diabetes Information Clearinghouse [NDIC], 2013). Anywhere from 2% to 10% of pregnant women develop GDM, but new diagnostic criteria have suggested incidence as high as 18% of pregnant women. One to two thirds of these women will go on to develop type 2 diabetes in 10 to 20 years (NDIC, 2013). GDM can be prevented through attention to diet and exercise, and population health nurses can assist prepregnant women to lose extra weight and promote adequate diet and physical activity among those who are pregnant.

Preeclampsia and eclampsia are other pregnancy-related conditions that may affect maternal and child health. Preeclampsia and eclampsia are sometimes referred to as pregnancy-induced hypertension (PIH) and are characterized by a rapid elevation in blood pressure that may result in seizures, stroke, organ failure, and death. Risk factors include early teenage years or age over 40 years, first pregnancy, obesity, multiple pregnancies, connective tissue diseases, and chronic hypertension, diabetes, and kidney disorders. Preeclampsia occurs in approximately 5% to 8% of pregnancies worldwide. Eclampsia accounts for 13% of maternal deaths (18% of maternal deaths in the United States) and 15% of premature deliveries. In addition, it is the most common reason for the decision to perform a cesarean section. Signs and symptoms of preeclampsia and eclampsia include sudden weight gain, elevated blood pressure, edema, headache, changes in vision, and proteinuria, all of which are monitored closely by population health nurses caring for pregnant women (Preeclampsia Foundation, n.d.).

Pregnancy may also complicate control of other health conditions, for example, diabetes and thyroid disorders. Hormonal changes that occur in pregnancy may have differential effects on several autoimmune diseases, improving some and worsening others. For example, lupus erythematosus may become worse during pregnancy, or after delivery, and common symptoms of pregnancy must be distinguished from a flareup (Khurana & Isaacs, 2014). Conversely, rheumatoid arthritis may improve (Temprano & Chelmos, 2013).

Some women must cope with fetal or infant death. As noted earlier, culture plays a significant role in the response to the death of an infant. Fetal loss also leads to depression and anxiety in subsequent pregnancies for both partners, but more so for women than men. Population health nurses can assist women who have lost infants to cope with their grief. For example, nurses may link these women to support groups or counseling services. They may also need to advocate for time to grieve with family members or friends who expect the woman to "grieve, and then get on with her life."

Even a pregnancy with a normal course and favorable outcome may result in problems for the mother. For example, some

women may experience postpartum depression that has significant health effects for them and their children. Postpartum or postnatal depression (PND) is characterized by dysphoric mood, feelings of guilt, inadequacy in the maternal role, anxiety, poor sleep and appetite, excessive fatigue and emotional lability (Wylie, Martin, Marlands, Martin, & Rankin, 2011). Overall incidence of PND has been estimated at 13% of women within 1 month of delivery (Letourneau, Duffet-Leger, Dennis, Sewart, & Tryphonopoulos, 2010). Postpartum depression in mothers has been associated with delayed language development and behavior problems in their children. In addition, a depressed mother is less likely to be able to effectively care for and nurture her infant.

Development of postpartum depression appears to be mediated by social support and cultural factors. The postpartum period is characterized by major changes and adjustments in women's lives. During this time women need to recover from the physical stresses of pregnancy and delivery, while meeting the needs of their newborn infants and often maintaining other responsibilities as well. Refugee women may be particularly susceptible to PND due to the stress of immigration, social isolation and lack of social support, and lack of financial resources (O'Mahony & Donnelly, 2010).

Immunizations are the last aspect of physiologic function to be considered in relation to women's physiologic health status. Women's immunization rates, like those for all adults, are lower than recommended. Immunizations of particular concern for women include rubella and tetanus vaccine, as well as other vaccines that create antibodies that can cross the placental barrier and provide protection for newborn infants. Women should also receive HPV, influenza, and other immunizations as appropriate. Some questions that can assist the population health nurse to assess biological determinants of women's health are provided in the *Focused Assessment* below.

PSYCHOLOGICAL DETERMINANTS. Psychological factors can have a profound effect on women's health. Areas of particular concern are stress and coping abilities and mental health and illness in the female population.

Stress and coping. The first area for consideration related to psychological determinants of women's health is the extent of women's exposure to stress and their abilities to cope with that stress. It is well known that stress contributes to a variety of illnesses in both men and women. For example, stress plays a part in the development of tuberculosis and hypertension. Severe life events and the stress that accompanies them have also been shown to be related to breast cancer in women. Women, in general, have been found to be less happy and to experience more stress than men. Although women tend to experience more stress than men, they often have better coping skills and are more likely than men to seek social support to deal with stress.

Sources of stress for women include stresses related to interpersonal relationships, financial status, children, and family health. Women generally tend to use confrontive, rather than avoidance, coping strategies.

Mental health and illness. Women often internalize emotional stress, leading to internalized disorders such as depression and anxiety. In one national study, nearly 4% of women over the age of 18 reported experiencing serious psychological distress in the past 30 days, compared to less than 3% of men (NCHS, 2013). Incidence rates for depression are 50% to 100% higher in women than in men. In addition, women experience longer episodes of depression, more frequent recurrences, and more chronic depression than men. Depressed women are also more likely than men to have co-morbid anxiety and other psychiatric disorders (Anxiety and Depression Association of America, n.d.). General risk factors for depression include genetic predisposition, hormonal factors, previous episodes of depression, poor coping, poverty, negative life events and psychosocial stressors, and substance abuse. The presence of chronic illness, particularly cardiovascular disease, has also been linked to the incidence of depression.

Women at all ages are less likely than men to commit suicide, but a significant number of women each year succumb to despair and end their lives. In 2007, the highest rate of suicide among women was for those 40 to 60 years of age, and ranged from 8 to 8.8 suicides per 100,000 women. Population

FOCUSED ASSESSMENT

Assessing Biological Determinants of Women's Health

- What is the age composition of the female population?
- What is the racial/ethnic composition of the female population?
- What are the main causes of mortality in the female population?
- What acute and chronic illnesses are prevalent in the female population? What factors contribute to the prevalence of these conditions?
- What percentage of the female population is of childbearing age? What is the annual birth rate in the population? What is the fertility rate?
- What is the level of immunity to specific communicable diseases among the female population?

estimates of depression in women as well as rates for attempted and completed suicide are important data for an aggregate assessment of women's health.

Other mental health problems that are prevalent among women include eating disorders, post-traumatic stress disorder (PTSD), and chronic fatigue syndrome. As many as 24 million people in the United States experience eating disorders, including anorexia nervosa, bulimia, and binge eating. The vast majority of these people (85% to 90%) are women. Eating disorders tend to manifest most often in adolescence, but can last for a lifetime (National Association of Anorexia Nervosa and Associated Disorders [ANAD], 2014).

Research on women and trauma exposure and its effects suggests that, although women are slightly less likely to be exposed to trauma than men, they are more likely to develop chronic PTSD. Estimates from the National Comorbidity Survey indicate that 50% of women and 60% of men experienced at least one traumatic life event. Rape and sexual assault, parental neglect, childhood physical abuse, domestic violence, and sudden death of a loved one are the most common traumatic events experienced by women. Lifetime estimates of the prevalence of PTSD are twice as high for women as for men (10% vs. 5%) (U.S. Department of Veterans Affairs, 2014). Gender differences in the incidence and prevalence of PTSD in response to traumatic events may stem from women's tendency to blame themselves for the event and the relative importance of interpersonal relationships in women's lives.

Chronic fatigue syndrome (CFS) occurs four times more often in women than in men and most often manifests between 40 and 50 years of age (CDC, 2013). CFS can have severe debilitating effects that profoundly affect one's mental health.

Women also experience schizophrenia, which tends to occur at a later age in women than in men, but symptoms rarely begin after age 45 (National Institute of Mental Health, 2009). Tips for assessing psychological determinants of health for the female population are presented in the *Focused Assessment* below.

ENVIRONMENTAL DETERMINANTS. Physical environmental factors also influence the health of women. They are exposed to physical environmental hazards both at home and in

the work setting. In the home, environmental hazards include household chemicals used to clean, inhalants such as powders and sprays, and the potential for falls related to stools, stairs, and throw rugs. The effects of the workplace on women's health are covered later in this chapter during the discussion of the occupational component of the sociocultural dimension. Environmental determinants are particularly evident in rates for accidental injuries. Although women have far lower injury rates than men, significant morbidity and mortality are related to unintentional injuries in women. Another area for consideration is the reproductive effects of environmental pollutants, and the population health nurse should be alert to connections between environmental conditions and adverse pregnancy outcomes in the population. In addition, lack of exposure to sunlight in the physical environment may lead to vitamin D deficiency. Since vitamin D is required for calcium absorption, this physical environmental factor may increase the potential for osteoporosis and fracture injuries. The *Focused Assessment* on the next page provides questions that can guide the population health nurse's assessment of environmental determinants affecting women's health.

SOCIOCULTURAL DETERMINANTS. Many sociocultural factors affect the health status of women. Sociocultural determinants of health appear to be more relevant for women than men and appear to contribute significantly to disparities in health status, self-rated health, functional ability, and chronic conditions between men and women. Some of the more influential factors among these are societal pressures regarding roles and relationships, occupational and economic issues, and violence and abuse.

Roles and relationships. Women often define themselves in terms of relationships with others. Women's roles in these relationships are culturally defined by the society in which they live. Society even specifies how women should look. U.S. entertainment media, in particular, promote a strong cultural value for thinness, often leading women to engage in poor health behaviors and resulting in eating disorders and depression.

Many of women's relationships entail caregiving roles in which they have primary responsibility for the care of children,

FOCUSED ASSESSMENT

Assessing Psychological Determinants of Women's Health

- What are the sources of stress to which women in the population are exposed?
- What are the incidence and prevalence of mental illness in the female population? What specific mental health problems are prevalent in the population?
- What is the societal attitude toward women? Does this attitude contribute to stress for women in the population?
- What is the extent of nonheterosexual orientation in the female population? What are the societal attitudes toward nonheterosexual orientation? How does this affect the level of stress experienced by women in the population?

FOCUSED ASSESSMENT

Assessing Environmental Determinants of Women's Health

- To what environmental health hazards are women in the population exposed?
- What environmental hazards are posed by occupational settings?
- Are women engaged in recreational pursuits that pose physical environmental hazards?
- To what extent does the physical environment promote or impede healthy behaviors by women (e.g., physical activity)?
- What are the reproductive effects of environmental conditions?

spouses, aging parents, and ill family members that compound the stresses of daily life. In 2010, for example, 55% of U.S. women were married, and more than 20% were divorced or widowed (U.S. Census Bureau, 2012c). In 2009, nearly 30% of all U.S. households with children were headed by single parents (U.S. Census Bureau, 2012g), and in 2012, 84% of more than 12 million single-parent families were headed by women. Approximately half of these female-headed families had incomes below poverty level (Single Mother Guide, 2013).

Women are often responsible for caring for the home and children as well as older family members. In addition, women are often employed outside the home. For example, in 2010, women constituted more than 47% of the U.S. workforce (U.S. Census Bureau, 2012d), but women continue to provide the bulk of family caregiving, caring for both children and aging parents. About 70% of all families with children have adults in the workforce and 25% of U.S. workers also have elder care responsibilities.

Women often need to take time from work to care for family members during major life events, such as the birth of a child or serious illness. The Federal Family and Medical Leave Act provides some coverage for working men and women with family responsibilities, but covers only about half of the workforce. As of 2009, only California and New Jersey had comprehensive paid family leave policies for care of a family member and eight other states had proposed family leave policies. Several other states had more restrictive policies (Weber, 2009).

Child care responsibilities have been shown to pose a cumulative burden for women due to chronic strain that is exacerbated by low levels of resources and low socioeconomic status. Idealized concepts of motherhood, for example, include ideals of sacrifice and may lead to guilt and stigmatization when women choose to work outside the home (Zoellner & Hedlund, 2010). Parenting stress may contribute to lower levels of mental health in mothers of young children that is often compounded by problems with child care and stressful working situations, which results in adverse effects for both parents and children. For example, in one study, maternal depression was associated with parenting stress and limited ability to engage in positive child bedtime routines (Zajicek-Farber, Mayer, & Daugherty, 2012). Suicide rates are highest among middle-aged women 40 to 60 years of age, those most likely to experience multiple stressors related to family responsibilities. In 2007, for example, the

suicide rate for women in this age group ranged from 8.0 to 8.8 per 100,000 women (Crosby, Ortega, & Stevens, 2011).

These effects may be mitigated by social support from family and friends. In general, women tend to have larger social networks than men, providing them with more sources of support. For some women, this support comes in the form of electronic social media interactions (Dare & Green, 2011). The assistance of spouses also mitigates the stress of caretaking burdens for married women.

In spite of access to more sources of interpersonal support than men, women often experience inequalities in access to other resources as a result of constraints on the choices within society. These choices may be constrained at any of three levels. At the social policy level, societies may choose to treat men and women equally or differently. For example, decisions could be made to increase social security payments to older women because of wage inequalities experienced during their working lives. Conversely, women may receive lower levels of resources due to continuing perceptions of men as the “family breadwinners.” Population health nurses should advocate for examination of the effects of social policy decisions on the health of both women and men.

Women's choices may also be constrained by the extent of their exposure to the hassles of daily life. For example, in a two-parent household, mothers, more often than fathers, are expected to stay home from work with an ill child or to care for aging parents. Similarly, they may be expected to integrate multiple aspects of their lives, for example, combining shopping trips with their daily work commute. Finally, women's choices are constrained by the need to balance work and family responsibilities and the “family unfriendly” nature of many work cultures. These constraints arise because men's and women's work and family roles have not changed as rapidly as changes in social opportunities.

Cultural expectations also define communication patterns in terms of gender. Gender determines appropriate topics of conversation as well as the words and phrases that may appropriately be used. Gender differences lead to the lack of a common language between men and women and contribute to miscommunication, particularly in the area of sexuality, but also in other aspects of life. Cultural factors and related expectations may also lead women to “self-silence” and sacrifice

Women may find it difficult to balance work and family roles.

(Scott Griessel/Fotolia)

their own desires to meet social expectations. Self-silencing is often done to avoid conflict, maintain a relationship, or to promote one's physical or psychological safety, but may lead to inner anger and confusion and result in depression (Jack & Ali, 2010). In fact, some authors have noted that risk factors for depression in women "might, more accurately, be conceptualized as proxy variables for a range of rights violations" (Astbury, 2010, p. 23). Some of these often violated rights were delineated by the 1948 United Nations General Assembly Universal Declaration of Rights and include rights to liberty and personal security; freedom from slavery, servitude, torture, or degrading treatment; equality and equal protection before the law; freedom of movement; just and favorable working conditions (including equitable pay); and a standard of living that supports health and well-being (Astbury, 2010).

Other authors have noted that women are disadvantaged by a variety of social justice issues including constraints on reproductive decisions and disproportionate effects of poverty and violence. Causes of social injustice derive from an assumption of a male social norm that leads to gender discrimination in multiple areas (e.g., research, underrepresentation in academic, medical, business, policy formation, government arenas).

Occupational and economic issues. Both occupational and economic issues can have direct and indirect effects on women's health. More than 15% of adult women in the United States lived in poverty in 2009, and employed women earned just 80% of men's income for the same jobs. Salary discrepancies are worse

for women with baccalaureate degrees or higher levels of education (U.S. Census Bureau, 2012e, 2012f).

Economic status also influences one's housing adequacy. Women are generally less likely than men to experience homelessness. In 2009–2010, for example, roughly one third of sheltered homeless individuals were women (Substance Abuse and Mental Health Services Administration [SAMSHA], 2011). Women, however head up nearly two thirds of homeless families with children (National Coalition for the Homeless, 2011). In large part, the increasing numbers of homeless women with children arises from low-wage employment and welfare reform that has minimized support to low-income families (National Coalition for the Homeless, 2012). Even when women are housed, they are more likely than men to live in inadequate housing. For example, in 2009, 4.9% of men lived in inadequate housing units (those with plumbing, heating, electrical, or upkeep deficiencies) compared to 5.5% of women. Similarly, 24.6% of female householders lived in unhealthy housing units with rodents, leaks, peeling paint, and no smoke alarms, in addition to the characteristics of inadequacy noted above, compared to 22.5% of men (Raymond, Wheeler, & Brown, 2011).

Lower income is frequently associated with higher incidence of disability, chronic disease, and generally poor health; and women's health status has been shown to decline as their income declines.

Many women in the paid labor force continue to work in traditional "women's jobs" such as nursing, teaching, the garment industry, and secretarial/clerical and service jobs. Although considered "women's work," these jobs are not without health risks. Physical risks arise from chemicals, radiation, infectious disease, noise, vibration, and repetitive movements. Employed women may also experience a higher incidence of musculoskeletal problems than men, possibly due to repetitive work, poor ergonomic work design, and reduced opportunity to rest and exercise at home as a result of family obligations outside of work.

As more women enter the world of "men's work," such as heavy industry, construction, mining, and factory work, they face a different set of physical hazards. Health risks arise from heavy lifting, use of dangerous machinery, and tools that were designed for larger men rather than smaller women. Minority women are at higher risk than White women for job-related injury because they often take jobs that others will not. Their economic need prevents them from saying no or quitting. Women are also more likely than men to work in small companies that do not provide health insurance benefits.

High-tech employment, once touted as safe, also entails health risks. The scrupulously clean area needed to produce a computer chip or to work with computers contains potential threats to human reproduction posed by radiofrequency or microwave radiation, video display terminal radiation, and arsine and chlorine gases. Working women today face essentially the same physical hazards as working men. They have the same risks for reproductive failure, respiratory ailments, skin disorders, and cancer. The health risks of the work setting are discussed in more detail in Chapter 24∞.

The psychological environment of the workplace can be as detrimental to women's health as its physical hazards. For example, studies have shown that it is not the female administrator who suffers the most from stress and depression, but women in the more traditional positions of secretary and clerk. It is postulated that stress is intensified by the lack of freedom to control one's work that secretaries and clerks experience. The "dead-end" quality of these jobs with little possibility of advancement may decrease incentive. In addition, the low salaries available for secretaries and clerks add stresses related to financial insecurity.

Labor force participation by women increases their access to both material and social support, but adds to the burden of their work when combined with family responsibilities. In addition, work increases the potential for toxic exposures and other occupational risks. Women, more often than men, are employed in low-income, high-risk jobs. Even women who work at home are exposed to more risks from the use of hazardous cooking fuels and pesticides.

Social factors in the work environment also affect women's health. The world of work for women differs from that for men in several ways. First, more jobs are open to men than to women. In addition, those jobs that are open to women often provide unequal pay and levels of benefits compared with similar jobs among men. Finally, until a 1991 Supreme Court ruling, women were more often barred from work based on reproductive capacities than were men. Childbearing has also been blamed for women's late entry into the workforce and women's lack of training and education.

Child care is another social environmental factor that creates problems for the working woman. Employer or community assistance with child care is practically nonexistent. Invariably, women must find quality child care on their own. If children are sick, it is usually the mother who stays home, often without pay, to care for them. Work may also interfere with child care responsibilities in other ways. For example, although breastfeeding is encouraged, few places of employment offer private spaces or time for mothers to pump their breasts.

Disproportionate pay between traditional women's jobs and such "men's work" as road construction is a strong incentive for women to seek such jobs. Women who enter male-dominated jobs often feel pressure to prove they are equal to men in ability. They may not speak out against safety hazards because they do not want to appear weak or "unable to take it." Sexual harassment is another problem that may be encountered by women in the work setting. Although there are laws prohibiting such abuse, women may not complain because they need work so badly.

Social factors related to approaching retirement may affect the health status of the middle-aged woman. The woman who is nearing retirement needs to be aware of and plan for the financial shortfalls that are likely to occur with retirement. Leaving the workforce means living in poverty for many older people. Retirement assets are usually tied to lifetime income. Women who worked for low pay and poor benefits will have

neither pensions nor full Social Security benefits. A divorced woman may draw Social Security from her ex-husband's account if they were married at least 10 years, but widows face declining incomes following the death of a spouse.

Violence and abuse. Abuse of women is the product of many psychological and sociocultural determinants, and it fosters a psychological environment detrimental to women's health. Because it is primarily social and cultural conditions that allow abuse to occur, the issue is addressed as a sociocultural determinant of women's health.

Women are subjected to a variety of abusive situations throughout the world. These may include abuse during war and social upheaval, sex-selective abortion of female fetuses, honor killings, trafficking, genital mutilation, sexual harassment, objectification in advertising, and restricted educational opportunities (Synnott, 2009). Women may also experience sexual and reproductive coercion, which is defined as "behavior intended to maintain power and control in a relationship related to reproductive health by someone who is, was, or wishes to be involved in an intimate or dating relationship with an adult or adolescent" (American College of Obstetricians and Gynecologists [ACOG], 2013, p. 1). Coercion may involve attempts to impregnate a woman who does not wish to become pregnant, to control pregnancy outcomes (e.g., by urging or forbidding abortion), to force unprotected sexual activity, or to interfere with contraceptive use (ACOG, 2013).

In addition, more than 35% of U.S. women will be subjected to physical abuse, rape or stalking by an intimate partner in their lifetimes (Black et al., 2011). Each year more than 324,000 pregnant women are abused by their partners (ACOG, 2012). According to U.S. Department of Justice statistics, women are four times more likely than men to be victims of rape or assault (Truman, Langton, & Planty, 2013). In addition, the 2012 non-fatal sexual assault injury rate was 49.44 per 100,000 women compared to 5.2 per 100,000 men (National Center for Injury Prevention and Control, 2013). Physical abuse of women often results in death, with the highest rate occurring among women 20 to 24 years of age (4.2 per 100,000 women) and declining with advancing age (Logan, Smith, & Stevens, 2011). Exposure to abuse and to other stressors may also contribute to suicide among women.

Psychological dependence on males and poor self-esteem on the part of both the victim and the abuser are some of the psychological factors resulting in abuse. Feelings of shame and worthlessness may hamper the woman's ability to seek help while in an abusive situation. Societal attitudes toward abused women often compound the problems of abuse for victims. Assessment of violence and other sociocultural determinants affecting women's health can be guided by the questions included in the *Focused Assessment* on the next page.

BEHAVIORAL DETERMINANTS. Behavioral factors also affect the health of women clients. Areas of particular concern include dietary consumption patterns; tobacco, alcohol, and

FOCUSED ASSESSMENT

Assessing Sociocultural Determinants of Women's Health

- What are the social roles expected of women? What effects do these role expectations have on women's health?
- What opportunities for social interaction are available to women in the population?
- What is the extent of social support available to women in the population?
- What is the percentage of single-parent families headed by women in the population?
- What is the typical educational status of women in the population?
- What is the economic status of women in the population? Are women allowed to own property in their own names? Are they allowed to control money and other family resources?
- What transportation opportunities are available to women in the population?
- To what extent do women in the population function as caretakers for other family members? To what extent do these women experience caretaker burden?
- What percentage of women in the population is employed? What are the typical occupations for women in the population? What effects do occupation and employment setting have on women's health? What support do employers provide for women's other roles and responsibilities?
- What child care services are available to working women? What is the cost of these services?
- What are the incidence and prevalence of abuse of women in the population? What are the societal attitudes toward abuse of women? What resources are available to abused women in the population?

drug use; physical activity and exercise, and health screening behaviors. Unprotected sexual activity, another behavioral consideration, was addressed in the context of issues related to contraception and pregnancy earlier in the chapter.

Consumption patterns. Dietary concerns may be particularly problematic among women, many of whom are obese or overweight or who engage in fad diets to attain or maintain a fashionably slim figure. Fad dieting is especially prevalent among adolescent females who also have high incidence rates for eating disorders such as bulimia and anorexia nervosa.

Women are more likely than men to be underweight (NCHS, 2012), but slightly less likely to be obese and more likely to eat healthier diets. Unfortunately, women still fail to achieve dietary indicators delineated by *Healthy People 2020*. For example, women eat fewer than the recommended number of servings of fruits and vegetables, and their average sodium and fat intake is higher than recommended (Health Indicators Warehouse, n.d.i, n.d.p, n.d.q, n.d.t).

Smoking is another consumption pattern that is problematic for some women. Although the number of male smokers has declined rather dramatically in the last few years, the number of women who smoke has not declined as rapidly, leading to corresponding increases in lung cancer and heart disease among women. In 2011, approximately two thirds of women were non-smokers, compared to less than half of men (NCHS, 2012). In 2011, 21.2% of men were current smokers, but only 16.8% of women smoked (NCHS, 2013). Several factors contribute to the continued prevalence of smoking among women. These include attempts to control weight, perceptions that smoking controls negative mood, extensive targeting of women by tobacco company advertising, and the dependence

of the media on tobacco revenue and sponsorship of women's fashions, athletics, and other events by tobacco companies that stifle media coverage of the negative effects of smoking.

Substance use and abuse among women is another area of concern related to consumption patterns. Although women still tend to abuse alcohol and drugs less often than men, the incidence of such problems among females is increasing. In 2011, roughly one quarter of women abstained from alcohol use, but 43% were engaged in regular use (NCHS, 2012), and a median 17.2% reported binge drinking in 2012 (National Center on Birth Defects and Developmental Disabilities, 2014). In addition, from 2006 to 2010 76% of pregnant women reported alcohol use during pregnancy, and 1.4% reported binge drinking (Marchetta et al., 2012). In general, men tend to have higher rates of alcohol and drug abuse, while women, particularly younger women, are more likely than men to engage in all forms of nonmedical use of prescription drugs (Volkow, 2010).

Women also engage in the use of other drugs. In 2009, for example, 6.8% of women over 12 years of age used any illicit drug, 4.7% used marijuana, and 2.5 made nonmedical use of psychotherapeutic drugs (NCHS, 2013). Drug-induced mortality rates for women were approximately two thirds those of men in 2007 (9.3/100,000 women vs. 15.8/100,000 men) (Paulozzi, 2011). Problems of substance abuse are addressed in Chapter 29∞.

Physical activity and exercise. Another major behavioral determinant that influences women's health is physical activity and exercise. An active lifestyle promotes overall health and is associated with a variety of positive health effects. In spite of the benefits of physical activity, however, less than half of U.S. women engage in sufficient physical activity to meet *Healthy People 2020* goals. In 2011, for example, more than

Physical activity is an important aspect of health promotion for women of all ages. (Konstantin Yuganov/Fotolia)

half of women (51.5%) met neither aerobic exercise nor muscle strengthening recommendations, and only 17.2% of women met the recommendations for both areas (NCHS, 2013). Women report a number of constraints for physical activity, including

job and family demands, fatigue, illness, and lack of facilities and opportunities for physical activity. Other barriers included economics, safety concerns, weather, and the hassles associated with personal care (e.g., showering) after physical activity.

Other health-related behaviors. The final behavioral determinant to be addressed includes behaviors related to health promotion, illness prevention, and screening. Some of these behaviors include health promoting behaviors such as getting sufficient sleep. Others are related to prevention of specific health problems, like immunization and skin cancer prevention, while others reflect women's participation in screening behaviors such as mammography. Table 18-2• presents information on the extent of selected health promotion, illness prevention, and screening behaviors among U.S. women. Questions to guide assessment of behavioral determinants affecting women's health are provided in the *Focused Assessment* on the next page.

HEALTH SYSTEM DETERMINANTS. Lack of attention to women's health needs, lack of illness prevention and health

TABLE 18-2 Women's Use of Selected Health Promotion, Illness and Injury Prevention, and Screening Services

Service	Percentage Use	Data Year
Blood pressure screening	93.5%	2008
Cervical cancer screening	82.8%	2010
Cholesterol screening—in last 5 years	76.8%	2008
Colorectal cancer screening—50–75 years of age	59.1%	2010
Condom use by unmarried females—15–44 years of age	35.1%	2006–2010
Contraceptive use at most recent sexual encounter	83%	2006–2008
Depression screening by primary care provider	2.8%	2010
Flu vaccination—18–64 years of age	28.7%	2008
Flu vaccination—pregnant women	27.6%	2008
HIV testing—pregnant women	72%	2006–2010
HIV status awareness	84.7%	2009
HPV vaccination—girls 13–15 years of age	30%	2011
Mammography—50–74 years of age	72.4%	2010
Oral and pharyngeal cancer early detection	41.5%	2009
Skin cancer protective measures	73.4%	2010
Sufficient sleep	68.8%	2012
Tobacco screening in physician office visits	68.3%	2010

FOCUSED ASSESSMENT

Assessing Behavioral Determinants of Women's Health

- What are the dietary consumption patterns typical of women in the population?
- What is the prevalence of smoking among women in the population?
- What is the extent of alcohol, tobacco, and other drug use in the population?
- To what extent do women in the population engage in safety practices (e.g., seat belt use)?
- To what extent do women who are sexually active engage in safe sexual practices?
- What is the extent of contraceptive use in the population?
- To what extent do women engage in health promotion, illness and injury prevention, and screening practices?

promotion resources, and health insurance discrimination are health care system factors that adversely affect women. The medical system tends to focus on female reproductive problems, frequently to the exclusion of other health problems faced by women. Failure to recognize and deal with physical abuse is just one example of failure of the health care system to meet the needs of women. By and large, the health care system has only recently come to recognize the special health needs of the female client.

Services provided by the health care system tend to focus on problem resolution and health restoration following injury or illness. Few efforts are made to provide preventive health care, particularly for women, and those preventive health services that are available are not always offered at a time when busy working women can take advantage of them. Compounding this problem is the lack of provision for child care while women seek preventive health care services.

In a periodic review of state policies affecting women's health, the National Women's Law Center (2010) grades the nation and each state with respect to the achievement of policy goals related to health. For the most part, these goals reflect the *Healthy People 2020* objectives. States are graded F – failing, U – unsatisfactory, S – not quite satisfactory, or S – satisfactory. Table 18-3 • summarizes the extent to which some of these major policy goals for women's health have been met by the states.

The cost of health care is a barrier to health service utilization for women. Women are less likely than men to have employment-based health insurance, and they are more likely to work in part-time jobs or jobs that do not offer this benefit. Single women are also less likely to be able to pay the monthly insurance premiums. This situation is particularly hard on divorced and separated women with children who are already faced with financial difficulties. According to NCHS (2013) figures, in 2011, 15.6% of women under 65 years of age had no health insurance and another 19.3% were covered by Medicaid.

Having a regular source of health care is the greatest predictor of the use of preventive services, yet from 2010 to 2011, nearly 15% of women had no regular source of care (NCHS, 2013). By 2011, this figure had decreased slightly to 11% of

U.S. women (NCHS, 2012). For many women who do have insurance coverage, it is often as spousal dependents, increasing their loss of insurance in the case of spousal job loss, divorce, or widowhood. Only about a third of women (35%) are covered by their own employment-based insurance plan (Kaiser Family Foundation, 2013). Discontinuous insurance coverage increases lack of access to care due to the inability to develop a relationship with a consistent health care provider. Many uninsured women rely on emergency departments or hospital clinics for care, thereby increasing societal expenses for care.

Even when women do have health insurance coverage, many essential services are not covered or out-of-pocket costs prohibit them from receiving needed services. For example, in 2010, nearly 16% of women aged 18 to 64 years did not get or delayed needed care due to costs. Similarly, 13.5% of women did not get prescriptions filled, and nearly 20% did not receive needed dental services. In 2008, annual mean out-of-pocket costs for services that were received were higher for women than men (\$285 and \$258, respectively). Lack of access to services is particularly noticeable for preventive care. For instance, only two thirds of women over 40 years of age had received a mammogram in the prior 2 years in 2010, and roughly 74% received a pap smear within the last 3 years (NCHS, 2013).

Prior to recent legislation such as the Affordable Care Act (ACA) and the Health Care and Education Affordability Reconciliation Act of 2010, insurance companies could engage in gender discrimination in premiums, eligibility, and services covered. For example, under some insurance plans, pregnancy could be considered a preexisting condition, which was not covered. Similarly, women could be charged higher premiums than men or be excluded from coverage altogether based on a prior cesarean section. The two pieces of legislation prohibit gender differences in premiums in the individual and small group insurance markets, but continue to allow “gender rating” of premiums in the large group insurance market. For example, at age 25 women in large group employer-sponsored insurance programs could expect to pay 6% to 45% higher premiums than men. Two other provisions of ACA benefit women

TABLE 18-3 Selected Indicators for Women's Health and Their Achievement in the United States

Indicator	Number of States Rated*				National Rating
	S	S-	U	F	
Health insurance		1	14	36	F
Pap smear in the last 3 years		1	39	11	F
Mammogram in the last 2 years	44		2	5	S
Colorectal cancer screening	51				S
Cholesterol screening	23	11	12	5	S-
Leisure time physical activity	4	17	11	19	U
Percentage of obesity		3	13	35	F
Five fruits and vegetables a day			1	50	F

by mandating preventive screenings for women without higher premiums or co-payments and prohibiting lack of coverage for victims of domestic violence (Pearsall, 2011). The *Focused Assessment* questions below can be used to identify health system determinants affecting the health of the female population.

Diagnostic Reasoning and Women's Health

Based on information obtained during assessment, population health nurses develop nursing diagnoses that direct further interventions. These diagnoses reflect both positive health states and potential or existing health problems and the factors

FOCUSED ASSESSMENT

Assessing Health System Determinants of Women's Health

- What percentage of the female population has a regular source of health care?
- What are the attitudes of women toward health and health care services?
- What percentage of the female population has health insurance coverage?
- What health services are available to women in the population? Are health care services needed by women available to all segments of the population?
- What barriers to obtaining health care do women encounter?
- What are the attitudes of health care providers to care of women? To the care of nonheterosexual women?

contributing to them. Nursing diagnoses might relate to health problems experienced by an individual woman such as “role overload due to employment, single parenthood, and lack of a social support network.” Or diagnoses may be made at the aggregate level regarding the health needs of groups of women. An example of a nursing diagnosis at this level might be a “need for adequate and inexpensive child care due to the number of single-parent working women and a lack of affordable child care.”

Planning to Meet the Health Needs of Women

In planning to meet the identified health needs of the female population, population health nurses incorporate the general principles of planning discussed in Chapter 15. It is important to keep in mind the unique needs of female clients. Participation by women in planning health care services is particularly important in view of the passive and dependent role expected of female clients by health care providers of the past. Women need to be encouraged to be active participants in health care decision making.

Planning and implementing care for groups of women also need to be based on women’s unique circumstances. Services should be offered at times when women, especially working women, can take advantage of them. Provision for transportation and child care services during appointments might also need to be considered. Financing of such programs can be problematic, given the lower earning capacity of many women, and political activity to ensure program funding may need to be part of the planning process. Meeting the health needs of female clients may involve planning and implementing health promotion, illness and injury prevention, problem resolution, and health restoration interventions.

HEALTH PROMOTION. Planning and implementing health promotion services for women focus on four main goals:

- Promoting healthy behaviors
- Developing and maintaining healthy relationships and living conditions
- Developing adequate coping strategies
- Promoting healthy pregnancy outcomes

Health promotion measures related to each of the goals will be briefly discussed.

Promoting healthy behaviors. Although women are more likely than men to engage in health promoting behaviors, they still may need assistance in developing and sustaining these behaviors. For example, population health nurses may need to educate women on the elements of a healthy diet or the need for adequate rest and physical activity. Given women’s multiple roles, they may also need help in integrating these activities into their busy schedules.

Women may also need encouragement to focus on meeting their own needs and to balance those needs with those of

others for whose care they may be responsible. Intervention in this area may be particularly important for single women with children who may be fulfilling both parental roles as well as the breadwinner role. Women caretakers may also need respite from continual demands on their time and energy. Population health nurses can refer to or advocate for the availability of needed supports and services for women. For example, they might assist in the development of respite services for women who care for young children or disabled family members. Or they might advocate with the women themselves, encouraging them to take needed time for themselves and to delegate some of their responsibilities to others if possible.

Developing and maintaining healthy relationships and living conditions.

Population health nurses may also assist women to develop and maintain healthy interpersonal relationships. For example, they may help women to develop healthy self-images that contribute to satisfying relationships. This may be particularly true for young women in their development of sexual intimacy. Population health nurses can educate women about sexuality as well as how to resist sexual advances or negotiate contraceptive use. In one study, for example, interviews with 10 young women indicated that none of them attempted to initiate condom use by their partners. In many cases, this failure was based on reliance on the male partner to protect them, being in an abusive situation, or believing they were involved in a monogamous relationship, sometimes even after being informed of a diagnosis of a sexually transmitted infection. In large part, these young women indicated they did not feel empowered to negotiate condom use (East, Jackson, O’Brien, & Peters, 2011).

Sexuality education is needed by women throughout the world. To promote effective education, there is a need for political and social leadership that recognizes women’s needs. Resources needed and available for such education as well as social and economic constraints should be identified. In addition, there is a need for preparation of qualified teachers and incorporation of women in the planning of such educational services (Boonstra, 2011).

Young girls approaching menarche, women experiencing perimenopause and menopause, and infertile women may also be in particular need of interventions to assist them to develop or maintain strong self-images. Working women who are entering retirement or mothers who are experiencing the departure of children from the home may need help coming to grips with changes in their roles without feeling devalued or useless. Similarly, women who have decided to leave an abusive situation or obtain a divorce may need assistance in dealing with feelings of guilt, loss, and depression. Population health nurses can provide anticipatory guidance regarding all of these changes and assist women to work through them effectively without diminished self-esteem. In addition, nurses can provide assistance with the practical aspects of change (e.g., menstrual education, referral for hormone replacement therapy [HRT], financial assistance, etc.).

Women can be assisted to develop assertiveness skills as well as to believe in their own self-worth. These skills may help women to refrain from developing unhealthy relationships with men or with others in their environments. There may also be a need to assist women to achieve healthy relationships in the work setting. The population health nurse may work to change the psychosocial environment of the work setting by means of several strategies. These strategies include educating and socializing women to expect wage equity and to believe that their work is as important as a man's, promoting legislation to prevent job discrimination, educating women about their rights, and encouraging women to challenge sexual harassment. The population health nurse working in the occupational setting can provide effective care for women by identifying and understanding stressors affecting women in the work setting, counseling them regarding work options, and assisting them with child care resources. Additional strategies include supporting women running for political office, influencing the legislative process, and promoting collective bargaining, mentoring, and networking among women.

Another major contribution can be made by population health nurses who have clients experiencing role proliferation. These nurses can assist clients to plan efficient use of time, to use outside help when possible, and to let go of minor household duties that can wait. Single women with children may particularly need help in this area.

Population health nurses can also assist women to create healthful living conditions. In 2009, for example, more than 5% of U.S. women lived in inadequate housing, and nearly 25% lived in unhealthy housing units (Raymond et al., 2011). Population health nurses can advocate for healthy housing and other environmental conditions that promote health (e.g., the

presence of walking or biking trails in the community). They can also refer women experiencing substandard housing to housing authorities for assistance or to social resources for assistance with rent and so on.

Developing adequate coping strategies. Health promotion for female clients may also involve assistance in the development of coping skills and assertiveness. Interventions can be designed to improve women's self-esteem and to teach them how to cope with life stress in effective ways. Development of coping skills and self-esteem not only assists women in maintaining balance in their lives, but also assists in the development of healthy relationships.

Promoting healthy pregnancies. One health promotion strategy specific to women is provision of prenatal care. Population health nurses can educate women prior to and during pregnancy regarding adequate diet and physical activity and can refer pregnant women for prenatal care services. In addition, they can provide antenatal care monitoring women for risk factors and engage in strategies to modify those risk factors. They can also help women with anticipatory guidance regarding child birth and infant care as well as help them adapt to the changes in interpersonal relationships that occur with the advent of a child. Population health nurses may also need to educate the public regarding the need for early prenatal care and advocate for access to prenatal care services for all segments of the population. Population health nursing strategies for health promotion among women are summarized in Table 18-4. A prenatal care inventory is included among the *Assessment Guidelines* included on the student resources site. For more information

TABLE 18-4 Health Promotion Strategies for Women

Focus	Strategies
Promoting healthy behaviors	<ul style="list-style-type: none"> • Educate women regarding the need for nutrition and physical activity • Assist women to integrate healthy diet and exercise behaviors into their schedules • Encourage women to balance their own needs with those of others • Refer women to support and respite services as needed • Advocate for support/respite services
Developing and maintaining healthy relationships and living conditions	<ul style="list-style-type: none"> • Assist women to develop assertiveness skills • Assist women to develop healthy self-images • Advocate for and provide sexuality education • Assist women to negotiate for safe sexual practice • Provide anticipatory guidance for life transitions • Advocate for changes in psychosocial environments in the work setting • Promote equitable working conditions • Help women with time management skills • Refer women for housing assistance as needed
Developing effective coping strategies	<ul style="list-style-type: none"> • Teach and model effective coping skills
Promoting healthy pregnancies	<ul style="list-style-type: none"> • Educate women regarding diet and physical activity before and during pregnancy • Refer pregnant women for prenatal care • Advocate for prenatal services • Provide anticipatory guidance for pregnancy, childbirth, and infant care as well as changes in relationships

on assessing waist circumference and calculating BMI, see the *External Resources* section of the student resources site. A postpartum newborn care inventory is also provided.

ILLNESS AND INJURY PREVENTION. Population health nurses are also actively involved in preventing illness and injury among women.

Illness prevention. Illness prevention interventions focus primarily on screening for and elimination of risk factors and immunization. Population health nurses can provide services to prevent such risk behaviors as smoking, binge drinking, and unprotected sexual activity. Nurses can also refer women who are current smokers to smoking cessation programs to prevent the development of a host of tobacco-related health problems.

Osteoporosis prevention is another important aspect of illness and injury prevention for women, and population health nurses can educate women regarding calcium and vitamin D intake and the need for physical activity as well as the contributions of tobacco and heavy alcohol use to osteoporosis (Lash et al., 2009). They may also refer women with existing osteoporosis for treatment to prevent fractures and subsequent disability.

There is considerable controversy regarding the use of HRT to prevent osteoporosis or treat symptoms of menopause. Growing evidence of possible breast cancer and cardiovascular disease risks related to HRT have led many women to choose natural remedies or bioidentical hormone replacement therapy to deal with menopausal discomforts. A number of botanical preparations, including black cohosh, red clover, *don quai*, ginseng, kava, and soy have been used to treat various menopausal symptoms, but most have been shown to be ineffective or to cause potential harm. For example, black cohosh and kava use may result in liver problems, and *don quai* interacts with warfarin (National Center for Complementary and Alternative Medicine [NCCAM], 2012).

Bioidentical hormone replacement therapy (BHRT) involves the use of laboratory manufactured compounds similar to natural hormones to combat symptoms of menopause.

These preparations are not approved by the Food and Drug Administration and can vary widely in their composition. Because their safety and effectiveness have not yet been demonstrated, clients should be cautioned against their use. There is some evidence, however, that mind and body therapies such as yoga, tai chi, qi gong, and acupuncture may provide relief for menopausal symptoms (NCCAM, 2012).

Prevention of sexually transmitted infections (STIs) may involve education regarding condom use or referral for access to condoms and other services. Similarly, preventing unwanted pregnancies may include educating women on contraceptive options and referring them for available services as well as advocating for access to publicly funded family planning services. In 2008, for example, a \$1.9 million expenditure on contraceptive services saved more than \$7 billion in costs related to unwanted pregnancies. Without public funding for contraceptive services, the costs for unwanted pregnancies could increase to as much as \$18 billion per year (Guttmacher Institute, 2013b).

Immunization is another strategy for disease prevention among women. CDC (2014) recommendations for immunization of women are summarized in Table 18-5. As indicated in the table, women should be routinely immunized for certain conditions and women at high risk for disease should receive additional immunizations.

Injury prevention. Attention should also be given to injury prevention through personal behaviors such as the use of seat belts and other safety devices. In the work setting, population health nurses can encourage women to report safety hazards (or the nurse can report them personally) and foster personal preventive measures such as the use of safety gear and protective devices. With respect to physical activity, women should also be educated regarding prevention of exercise-related musculoskeletal injury and encouraged to be realistic in goal setting and injury prevention.

Prevention of violence against women is another strategy for injury prevention. Women can be educated to identify and avoid dangerous situations. When women are in situations in

TABLE 18-5 Recommended Immunizations for Women 19 to 59 Years

Immunization	Age Group	Comments
Influenza	All ages	1 dose annually
Td/Tdap	All ages	1 dose Tdap, followed by Td booster every 10 years
Varicella	All ages	2 doses (contraindicated in pregnancy)
Human papillomavirus (HPV)	19–26 years	3 doses
Measles, Mumps, Rubella	19–55 years	1 or 2 doses (contraindicated in pregnancy)
Pneumococcal polysaccharide (PPSV23)	19–59 years	1 or 2 doses for women at risk
Pneumococcal 13-valent conjugate (PCV13)	19–59 years	1 dose for women at risk
Meningococcal	19–59 years	1 or more doses for women at risk
Hepatitis A	19–59 years	2 doses for women at risk
Hepatitis B	19–59 years	2 doses for women at risk

Data from: Centers for Disease Control and Prevention. (2014). *Recommended adult immunization schedule – United States – 2014*. Retrieved from <http://www.cdc.gov/vaccines/schedules/downloads/adult/adult-schedule.pdf>

which the potential for abuse is high, population health nurses can refer them to safe houses and assist them with obtaining physical and legal protection. Nurses can also work for public policies that promote the safety of women and preservation of their rights. Strategies for illness and injury prevention among women are summarized in Table 18-6.

RESOLUTION OF EXISTING HEALTH PROBLEMS.

Resolution of existing health problems in the female population focuses on screening, diagnosis, and treatment.

Screening. Several organizations make recommendations for routine screening procedures among women. For example, the American Cancer Society has made recommendations for breast and cervical cancer screening in women. Similarly, the U.S. Preventive Services Task Force has examined evidence regarding the effectiveness of specific screening procedures in different population groups (e.g., men, women, children, adults, and people with specific risk factors) and developed an extensive set of recommendations for routine screening practices. Routine screening procedures specifically recommended for women are summarized in Table 18-7. Individual women

TABLE 18-6 Illness and Injury Prevention Strategies for Women

Focus	Strategy
Illness Prevention	<ul style="list-style-type: none"> • Screening for and elimination of risk factors for disease • Osteoporosis prevention through diet and physical activity • STD prevention through monogamous relationships and condom use • Prevention of unwanted pregnancies through access to and use of contraceptive services • Immunization
Injury Prevention	<ul style="list-style-type: none"> • Promoting safe environments at home and work • Promoting use of safety devices and practices • Advocacy for policies and services that prevent abuse of women

should, of course, also be screened for other health problems for which they may be at risk.

USPSTF (2013b) has recommended screening of women of childbearing age for IPV. As noted earlier, the American

TABLE 18-7 Recommendations for Routine Screening for Women

Type of Screening	Recommendation
Alcohol misuse	All adult women (including pregnant women)
Bacteruria	Pregnant women on the first visit or at 12 to 16 weeks gestation
Breast cancer	Biannual mammography for women aged 50 to 74 years, individualized decision after age 75
Cervical cancer	Papanicolaou smear every 3 years age 21 to 65 years or with cytological testing and HPV testing every 5 years in women aged 30 to 35 to extend the screening interval
Chlamydia	Sexually active or pregnant women under 24 years of age and those over 24 who are at risk
Colorectal cancer	Women 50 to 75 years of age by fecal occult blood, sigmoidoscopy, and/or colonoscopy
Depression	Adult women in practice settings where follow-up is available
Diabetes	Adult women with blood pressures >135/80 mm Hg
Gonorrhea	All sexually active women at risk of infection
Hepatitis B	Pregnant women at the first prenatal visit
Hypertension	All women over 18 years of age
HIV infection	All adult and adolescent women at risk of infection, all pregnant women
Intimate partner violence	Women of childbearing age
Iron deficiency anemia	Pregnant women
Lipid disorders	All women over 45 years of age and those 20 to 45 years of age at risk of CHD
Neural tube defects and preeclampsia	Screening recommendations are currently being updated
Obesity	All adult women
Osteoporosis	Women over 65 years of age and those with fracture risk equal to a 65-year-old woman with no additional risk factors
Rh incompatibility	All pregnant women on the first prenatal visit, repeated at 24 to 28 weeks gestation for women who are unsensitized Rh-negative unless the father is known to be Rh-negative
Rubella	Screening recommendations are currently being updated
Syphilis	All women at risk, all pregnant women
Tobacco use	All adult women

Data from: U.S. Preventive Services Task Force. (2013a). *Recommendations for adults*. Retrieved from <http://www.uspreventiveservicestaskforce.org/adultrec.htm>

College of Obstetricians and Gynecologists (2013) has also recommended screening women for sexual or reproductive coercion.

Population health nurses can educate the public regarding the need for routine screening procedures and can advocate for the availability of screening services for all segments of the female population. Population health nurses may also be involved in case management for women whose screening tests are positive. These women may need assistance in accessing further diagnostic and treatment services.

Treatment. Population health nurses refer women for medical or social assistance with any identified health problems. Problems unique to female clients for which treatment may be required include infertility, fertility control, menopause, and physical abuse. Intervention may also be required for existing acute and chronic health conditions.

Treatment for infertility generally requires referral to a fertility specialist. The role of the population health nurse, with respect to infertility, focuses on case finding, referral, and support during a fertility workup. The nurse can also assist the client and her significant other in considering alternative options such as adoption, artificial insemination, and in vitro fertilization. The nurse may also refer couples to self-help groups for assistance in dealing with psychological problems of infertility. In addition, the population health nurse may assist infertile women to deal with the psychological ramifications of their condition. This may be particularly needed for women from cultural groups in which a woman's identity or worth is based on her ability to have children. At the population level, population health nurses can work with other elements of the health and social systems to assure that infertility services are available to those who need them.

During perimenopause, population health nurses may refer clients to a physician or nurse practitioner for discomfort related to hot flashes or other symptoms. Population health nurses can also educate clients and the general public on lifestyle approaches to the treatment of menopausal symptoms, such as dressing in layers, using a fan, consuming cold foods and beverages, exercise, weight loss, nonsmoking, and relaxation techniques (Weismiller, 2009). Similarly, nurses can assist patients with osteoporosis to make lifestyle changes related to weight bearing physical activity, fall prevention, and use of hip protector pads as well as refer them for pharmacologic treatment with calcium, vitamin D, bisphosphonates, raloxifene, and possibly estrogen replacement therapy barring other contraindications (e.g., a history of breast cancer) (Lash et al., 2009).

Menopause may cause vaginal dryness and discomfort during sexual intercourse. The nurse can counsel women concerning longer foreplay and the use of vaginal lubricants to relieve the problem.

Some women also experience decreased sexual desire. The population health nurse can help clients explore contributing factors in this experience such as depression, a feeling of being

at the end of the reproductive years, and acceptance of a new phase of life. Self-help groups for women who are having similar problems are extremely beneficial during this stage of life. If there is no such group in the local community, the nurse might start one by inviting clients to meet and begin discussions.

Intervention related to physical abuse of women has two dimensions. The first of these is dealing with the physical and psychological effects of physical abuse, and the second is dealing with the source of the problem itself. Recognizing the problem is a prerequisite to either dimension of treatment. Female clients should be asked in a caring and sensitive manner about any violence in their lives. Careful recording of the history and of information regarding old and new injuries is important in the diagnosis of abuse. Such a record may reveal a pattern the woman is unwilling or unable to admit to the nurse. If there is evidence of abuse, it is unethical for the nurse not to confirm this diagnosis with the client. Allowing the woman to describe what is happening to her through open-ended questions is therapeutic and can serve as the first step in stemming the cycle of abuse.

It is important that the nurse convey to the client that she does not deserve to be abused and that the nurse is concerned about her. These critical statements are needed to convey to the client that someone cares and that she is not worthless, helpless, or deserving of abuse.

It is not easy for a population health nurse to intervene in an abusive relationship. Inherent in such situations are reasons to fear that intervention will not be successful, that the woman may become depressed and suicidal or resent the nurse for interfering in a private family matter, or that the abuser may punish the woman or the nurse. Such fears have kept health care professionals from pursuing evidence and attempting to help women in abusive situations.

When the nurse is able to work through and conquer personal fear and is able to identify a client in an abusive relationship, the nurse should encourage the client to discuss the circumstances of her abuse. It is important that the client realize the danger inherent in her situation.

Once the diagnosis of abuse is made, the primary goal is to assist the woman to reestablish a feeling of control and to empower her to change the situation. Supportive counseling and reassurance are essential. The nurse should let the woman work out her problems at her own pace. Each woman has the capacity to change when she is ready. The nurse must realize that the victim will feel ambivalence in the relationship she has with her partner. The nurse should support realistic ideas for change and assist the client in altering unrealistic ideas. The nurse should help the client to clarify her beliefs about the situation. The nurse should also help to identify myths about abuse that the client may have internalized. For example, if the victim believes that she deserves the beatings, the nurse can assure the client that her partner is totally responsible for his or her own actions.

The nurse can help the client explore alternative plans for solutions to her problem. What are her personal supports? Is there anyone to whom she can go for help? The client may want to go home. If the client can do this without risk of suicide or homicide, the nurse can help her plan strategies for managing at home and provide her with resources for assistance or escape should the need arise. If necessary, however, the population health nurse can also help the woman to plan a quick getaway. The client needs to accumulate extra money, collect necessary documents like birth certificates and immunization records for children, pack a change of clothing, and carry a few emergency supplies. If the client has children, she should take them with her if she leaves or risk losing them to the abuser if he or she should claim that the client abandoned them.

The nurse should avoid becoming another controller in the life of the client. The physically abused woman needs every opportunity to develop independence. Nurses tend to want to rescue victims to stop the violence, but they cannot make decisions for the woman. Although nurses can provide information on shelters and other resources, they must allow the woman to make her own decisions.

Nurses should be familiar with the resources they recommend. Are they reliable? Will they assist the woman to become independent while providing a safe haven for her and her children? If the client is a lesbian, bisexual, or transgender woman, will her needs be effectively met in the shelter? Or will she be subjected to hostility and further abuse?

Population health nurses can also provide assistance in referrals for medical care for injuries and for counseling to deal with contributing factors and psychological effects of abuse. Such services may be needed for children as well as the woman. The woman should also be cautioned that her children may resist being removed from their home and other family members. If this should be the case, the population health nurse can help the client cope with grief and hostility on the part of the children. The client may also need help in dealing with her own grief over the loss of a significant relationship.

When adequate treatment facilities to meet the needs of women are not available, population health nurses can become actively involved in advocating for these services and in developing and implementing them. Population health nurses may also need to advocate for the availability of services for certain specific segments of the population, for example, low-income women or lesbian women.

HEALTH RESTORATION. As with all clients, health restoration interventions in the care of women focus on rehabilitation and preventing the recurrence of health problems. Areas in which interventions are particularly warranted for the female client include pregnancy, abuse, and STDs. Health restoration services may also be needed to deal with some of the effects of menopause, chronic illness, or abuse. Dealing with the long-term management of chronic illness is another

feature of health restoration that will be addressed in more detail in Chapter 27∞.

Health restoration with respect to pregnancy involves the use of an effective contraceptive to prevent subsequent pregnancies. Again, the nurse may be involved in education, counseling, and referral for contraceptive services. Health restoration might also involve assisting women and their families to adjust to the advent of a new baby or to deal with the psychological effects of a negative pregnancy outcome.

In the case of abuse, restoration necessitates the rebuilding of the woman's life and that of her family. This may involve developing new financial resources as well as ways of coping with problems. The woman needs to become self-sufficient. Again, referrals to a variety of agencies to help with employment skills and provide counseling may be of assistance. Nurses may also need to collaborate with other segments of the community to assure enforcement of protections for abused women and availability of services to assist them in rebuilding their lives.

Women can also be helped to prevent recurrence of STDs or to cope with the life changes necessitated by a diagnosis of HIV/AIDS or chronic hepatitis B or C. Health restoration related to STDs is discussed more fully in Chapter 26∞. Other restoration measures may be warranted for existing chronic health problems. For example, women may need to be assisted to adapt to lifestyle changes necessitated by chronic illness or to manage symptoms such as pain. Health restoration related to chronic physical and mental health conditions are addressed in Chapters 27∞ and 28∞, while issues of restoration related to substance abuse and violence are addressed in Chapters 29∞ and 30∞, respectively.

Evaluating Health Care for Women

Health care provided to women should be evaluated using the evaluative process described in Chapter 15∞. Once more, it is important to evaluate both the quality of the care given and its outcomes. Because of the dependent role of many women, it is particularly important that they play an active role in evaluating the health care they are given. At the national level, the 2020 objectives for the health of women can provide criteria for evaluating women's health care services. Evaluative information on selected national objectives related to women's health is presented in the *Healthy People 2020* feature on the next page. Information on other objectives that relate to women, as well as to other segments of the population, is included in relevant chapters of this book.

Women's health care needs are many and varied and are often poorly addressed by existing health care systems. Population health nurses may provide health care for women at all four levels of health care: health promotion, illness and injury prevention, resolution of existing health problems, and health restoration. Care may also be provided to individual women or to groups of women within the population, and often involves advocacy for services to meet women's needs.

Healthy People 2020

Selected Objectives Related to Women's Health

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
AHS-1.1 Increase the proportion of women with health insurance	84.6% (2008)	100%	82.8% (2011)	National Health Interview Survey (NHIS), CDC, National Center for Health Statistics (NCHS)
AHS-3 Increase the proportion of women 19–64 years with a usual primary care provider	79.9% (2007)	83.9%	80.5% (2010)	NHIS, CDC, NCHS
AHS-5.3 Increase the proportion of women 19–64 years with a source of ongoing care	87% (2008)	89.4	85.8% (2011)	NHIS, CDC, NCHS
AHS-6.1 Reduce the proportion of women unable to obtain or delay obtaining medical care, dental care, or prescription medications	10.8% (2007)	9%	11.7% (2010)	Medical Expenditure Panel Survey (MEPS), AHRQ
AOCBC-2 Reduce the proportion of women with doctor-diagnosed arthritis who experience a limitation in activity due to arthritis or joint symptoms	40.6% (2008)	35.5%	42.7% (2011)	NHIS, CDC, NCHS
AOCBC-10 Reduce the proportion of women with osteoporosis	8.9% (2005–2008)	5.3%	NDA	NHANES, CDC, NCHS
AOCBC-12 Reduce activity limitation due to chronic back conditions per 1,000 women	32.2 (2008)	27.6	34.9 (2011)	NHIS, CDC, NCHS
C-1 Reduce cancer deaths per 100,000 women	152.3 (2007)	161.4	146.7 (2010)	National Vitals Statistics System–Mortality (NVSS-M), CDC, NCHS
C-3 Reduce the female breast cancer death rate per 100,000 women	23.0 (2007)	20.7	22.1 (2010)	NVSS-M, CDC, NCHS
C-4 Reduce the cervical cancer death rate per 100,000 women	2.4 (2007)	2.2	2.3 (2010)	NVSS-M, CDC, NCHS
C-5 Reduce colorectal cancer deaths per 100,000 women	14.6 (2007)	14.5	13.4 (2010)	NVSS-M, CDC, NCHS
C-8 Reduce melanoma cancer deaths per 100,000 women	1.7 (2007)	2.4	1.7 (2010)	NVSS-M, CDC, NCHS
C-16 Increase the proportion of women who receive colorectal cancer screening	52.1% (2008)	70.5%	59.1% (2011)	NHIS, CDC, NCHS
D-3 Reduce diabetes deaths per 100,000 women	62.9 (2007)	66.6	58.9 (2010)	NVSS-M, CDC, NCHS
FP-1 Increase the proportion of pregnancies that are intended	51% (2002)	56%	51.3% (2006)	Guttmacher Institute Abortion Provider Survey, National Survey of Family Growth (NSFG), NVSS-N, CDC, NCHS

Continued on next page

Healthy People 2020 (Continued)

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
FP-6 Increase the proportion of females at risk of unintended pregnancy who used contraceptives or whose partners used contraceptives at last sexual intercourse	83.3% (2006–2010)	91.6%	NDA	Guttmacher Institute Abortion Provider Survey, National Survey of Family Growth (NSFG), NVSS-N, CDC, NCHS
HDS-2 Reduce coronary heart disease deaths per 100,000 women	98.8 (2007)	103.4	84.9 (2010)	NVSS-M, CDC, NCHS
HDS-3 Reduce stroke deaths per 100,000 women	42.7 (2007)	34.8	38.3 (2010)	NVSS-M, CDC, NCHS
HDS-5.1 Reduce the proportion of women with hypertension	28.7% (2005–2008)	26.9%	NDA	National Health and Nutrition Examination Survey (NHANES), CDC, NCHS
HDS-6 Increase the proportion of women who have had their blood cholesterol level checked in the past 5 years	76.8% (2008)	82.1%	NDA	NHIS, CDC, NCHS
HDS-7 Reduce the proportion of women with high blood cholesterol levels	16.1% (2005–2008)	13.5%	NDA	NHANES, CDC, NCHS
HIV-4 Reduce new cases of AIDs per 100,000 adult and adolescent women	7.3 (2007)	12.4	6.4 (2010)	National HIV Surveillance System, CDC, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention (NCHHSTP)
HIV-8.2 Reduce new cases of perinatally acquired AIDS	34 (2007)	31	18 (2010)	National HIV Surveillance System, CDC
HIV-17.1 Increase the proportion of sexually active unmarried females aged 15–44 years who use condoms	35.1% (2006–2010)	38.6%	NDA	National Survey of Family Growth (NSFG), CDC, NCHS
IVP-11 Reduce unintentional injury deaths per 100,000 women	26.1 (2007)	36.4	25.6 (2010)	NVSS-M, CDC, NCHS
IVP-29 Reduce homicides per 100,000 women	2.5 (2007)	5.5	2.3 (2010)	NVSS-M, CDC, NCHS
MICH-5 Reduce maternal mortality rate per 100,000 live births	12.7 (2007)	11.4	NDA	NVSS-M, NVSS-N, CDC, NCHS
MICH-6 Reduce maternal illness and complications due to pregnancy	31.1% (2007)	28%	NDA	National Hospital Discharge Survey (NHDS), CDC, NCHS
MICH-10.1 Increase the proportion of pregnant women who receive prenatal care in the first trimester	70.8% (2007)	77.9%	NDA	NVSS-N, CDC, NCHS
NWS-9 Reduce the proportion of adult women who are obese	35.3% (2005–2008)	30.5%	35.8% (2009–2010)	NHANES, CDC, NCHS

Continued on next page

Healthy People 2020 (Continued)

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
NWS-21.3 Reduce iron deficiency anemia among females aged 12–49 years	10.4% (2005–2008)	9.4%	NDA	NHANES, CDC, NCHS
PA-1 Reduce the proportion of adult women who engage in no leisure time physical activity	38.2% (2008)	32.6%	33.1% (2011)	NHIS, CDC, NCHS
SA-12 Reduce drug-induced deaths per 100,000 women	9.3 (2007)	11.3	10 (2010)	NVSS-M, CDC, NCHS
TU-1.1 Reduce cigarette smoking by adult women	18.5% (2008)	80%	16.8% (2011)%	NHIS, CDC, NCHS
TU-4.1 Increase smoking cessation attempts by adult women smokers	51.5% (2008)	80%	49.5% (2011)	NHIS, CDC, NCHS

CHAPTER RECAP

Women have unique health needs that arise from biological, psychological, environmental, sociocultural, behavioral, and health system factors that influence health. Population health nurses can influence the health of the female population by assessing their health needs, developing relevant population health nursing diagnoses, and planning, implementing, and evaluating programs of care that address those needs. Such programs of care may focus on health promotion, illness and injury prevention, resolution of existing health problems, and health restoration. Health promotion focused interventions include promoting healthy behaviors, promoting healthy interpersonal relationships, creating living conditions and work environments that foster health, assistance in developing effective

coping strategies, and promoting healthy pregnancies. Foci for illness and injury prevention among women include elimination of risk factors for disease, preventing osteoporosis, STD prevention, contraception, and immunization. Additional emphases in injury prevention include eliminating safety hazards at home and at work, promoting use of safety devices and practices, and preventing abuse. Resolution of existing health problems involves screening, diagnosis, and treatment for illnesses and other conditions including addressing psychosocial issues, such as poverty, that influence access to health care. Finally, health restoration foci include dealing with the long-term consequences of illness and injury and preventing recurrent health problems.

CASE STUDY

Preventing Gestational Diabetes Mellitus

You are a population health nurse in a small town in rural New Mexico. In conducting a comprehensive assessment of health needs in the area, you noted that the incidence of GDM is quite high. Nationwide incidence of GDM is about 2%, but approximately 6% of pregnant women in this community develop GDM each year. Approximately 10% to 15% of these women go

on to develop type 2 diabetes. The local population is about 60% Hispanic, 30% Anglo, and 10% Asian. Many of the Hispanic population are undocumented migrant families who work on the local farms and ranches. The Asian population tend to be recent arrivals to the community who work in a local high-tech industry. GDM is most prevalent among the Hispanic population

who often receive late or no prenatal care. Overweight and obesity are significant problems in the Hispanic and Anglo populations, but not in the Asian population.

1. What factors related to biological, psychological, environmental, sociocultural, behavioral, and health system determinants are influencing GDM (either positively or negatively)? What additional information would you want to obtain related to each category of determinants?
2. How would you word a related population health nursing diagnosis?
3. What evidence-based practice guidelines are available for preventing GDM?

4. What type of intervention, based on the evidence, might be implemented to decrease the incidence of GDM in this community?
5. What would be the target population for the intervention? How might the intervention need to be tailored to the target population?
6. What other segments of the community might you collaborate with in resolving this problem?
7. How would you evaluate the effectiveness of your intervention?

Care of the Older Population

Learning Outcomes

After reading this chapter, you should be able to:

1. Describe three categories of perspectives on aging.
2. Describe biological, psychological, environmental, sociocultural, behavioral, and health system determinants influencing the health of older populations.
3. Identify major considerations in health promotion in the care of older adults and analyze population health nursing roles related to each.
4. Discuss major foci for illness and injury prevention among older adults and describe related population health nursing roles.
5. Describe measures designed to resolve common health problems among older populations.
6. Identify at least three foci for health restoration with older clients and give examples of related population health nursing interventions.
7. Identify considerations that may influence population health nurses' approach to health education for older clients.
8. Identify foci for evaluating the care of older populations.

Promoting End-of-Life Care

Although the elderly are not the only ones to need end-of-life care, one often thinks of death as it relates to the culmination of a long life. Research indicates that many people experience significant pain. This is particularly true for patients with chronic illnesses and those who are approaching death. For example, an estimated 75% of patients with terminal illnesses experience pain as they approach death (Fink & Gates, 2010). One of nursing's primary functions is to address relief of such symptoms, yet for much of our history, there was no organized approach to addressing this function. Care of the dying and symptom relief received little attention until two women, Dame Cicely Saunders and Florence Wald, began movements to address these issues.

Dame Cicely Saunders was educated as a nurse, social worker, and physician (Cicely Saunders International, n.d.). She began her work with dying patients in 1948 and in 1967 founded the first hospice, radically altering approaches to care for the dying and their families (St. Christopher's Hospice, 2013). The mission of St. Christopher's and other hospices is to combine symptom management and compassionate care for the dying and their families, going beyond the commonly held belief of the time that there is nothing that can be done for the dying. Dame Cicely also pioneered research on interventions to control pain at the end of life. Her work led to the establishment of hospices around the world.

Beginning her nursing career at New York's Visiting Nurse Service (American Nurses Association, n.d.), which grew out of the Henry Street Settlement founded by Lillian Wald, Dr. Florence Wald believed that nurses should be community-focused and address the needs of patients across the lifespan from birth to death (Connecticut Women's Hall of Fame, n.d.). In 1965, Dr. Wald attended a presentation on palliative care by Dame Cicely at Yale University, where Wald was Dean of the Mental Health and Psychiatric Nursing Program. Frustrated with the conventional focus of medical care on cure, Wald incorporated concepts of end-of-life care into the nursing curriculum at Yale and founded the first U.S. hospice in Branford, Connecticut (Connecticut Women's Hall of Fame, n.d.). The hospice's services were based on a study of the needs of terminally ill patients. Wald went on to become a major proponent of end-of-life and palliative care in the United States (Adams, 2010).

Meeting the Needs of Elders in the Community

Located in central Taiwan, Fu-Kang Community Care Center's mission is "Health promotion and improved life style for people." In keeping with this mission, the staff have designed programs and activities to promote people's knowledge and health-related behaviors. A community assessment revealed diagnoses related to fall risk, insomnia, and chronic disease management. A retired nursing supervisor from the Health Bureau, the head nurse of the local health center, nursing professors from the local university, the pharmacist of a community drug store, and local seniors were invited to participate in designing programs to address these needs. These programs include: a tour to Ho-Li, a small town, and music therapy designed to promote body exercise matched to musical rhyme schemes. Other program foci include healthy eating, sleeping well, fall prevention using Tai Chi exercise, and coping with chronic disease. Blood pressure monitoring is included with each activity, and case management services are provided as needed.

Shin was one of the program participants. The first time she came to our care station, she was an 83-year-old woman in a wheelchair accompanied by her caretaker. She asked us for any elderly activity, and we invited her and facilitated her participation. Initially, she sat quietly in a corner, being assisted with all of her care.

Shin had been the midwife for Ho-Li, a small town in Taichung, Taiwan. People there are hard-working and simple. In the 1970s, most women chose to deliver their baby at home. Shin was the only midwife in the small town, and she had delivered most of its residents. She worked hard to take care of mothers and babies, sometimes day and night. Time passed, and she paid for her care with her health, at the age of 80, she had a stroke, and her husband passed away in the same year. She became a lonely old woman. Her children hired an assistant to care for her.

Although she was now confined to a wheelchair, she will never forget her career as a midwife. While talking with people delivered by her, her eyes brightened, and she would say “The value of a midwife is to create new lives and resources in this town. . . . The career of a midwife gave me a meaningful life. . . . Most of the people in Ho-Li were delivered by me. I can recognize every person in this town.” We could see the pride in her face when she talked about her career, but somehow, she still seemed shrunken and lonely. Her wheelchair emphasized the effects of the years on her body.

Each time, Shin was pushed by an assistant. She enjoyed her interactions with the other participants and volunteers. Sometimes, she made paper flowers, and she enjoyed the trips and the music therapy. She became more interactive, particularly when she would ask others: “Were you delivered by me?” Recently, Shin came into our care station through the front door. She asked for no wheelchair; she wanted to walk into the station. With our support, she walked in. And, we saw a brave new life in our town—Ho-Li.

Chen Chien Tzu-Chuan,
Hung Kuang University

According to U.S. Census Bureau figures (2013), people over the age of 65 years comprised 13.4% of the U.S. population in 2012. Nearly 6% of this group was over 75 years of age, and there were more than 53,000 people over 100 years of age in the United States in 2010 (Werner, 2011). By 2050, the elderly are expected to comprise more than 20% of the population. Similar figures are noted worldwide. In 1990, for example, people over 60 years of age constituted only 9% of the world’s population. By 2013, this figure had risen to 11.7% and is expected to climb to 21% by 2050. It is anticipated that developing countries will experience a faster aging process among their populations than developed countries, further burdening already strapped social, economic, and health resources (United Nations, Department of Economic and Social Affairs, Population Division, 2013).

Increased longevity and decreasing fertility are continuing to change the proportion of elderly people in relation to other age groups in the population. Worldwide life expectancy is anticipated to increase from 42 to 65 years in various parts of the world in 1950 to 68 to 78 years by 2015. By 2045 to 2050, life expectancy in more developed countries is expected to be 83 years, with a mean life expectancy of 78 years in less developed regions. Similarly, fertility is expected to decline from 6.6 children per adult woman in 1950–1955 to 2.2 by 2050 (United Nations, Department of Economic and Social Affairs, Population Division, 2013).

As the world’s population ages, there will be a growing demand for health care services that improve the quality of life as well as longevity. This emphasis on quality of life can be seen in the national health objectives for 2020 addressing the health needs of the elderly. A major thread throughout these objectives is to reduce activity limitations that impair the quality of life for older persons. These objectives can be viewed on the *Healthy People 2020* website and selected objectives are included at the end of this chapter. Concern for the health of the older population of the world also stems from a desire to minimize health care expenditures. Because of the prevalence of multiple chronic illnesses, the elderly account for a significant percentage of all health care expenditures worldwide. For example, based on Medical Expenditure Survey data, in 2010 people over 65 years of age had mean health care expenditures 2.6 times higher than those under 65. Medicare funded 63% of health care for those over 65 at a cost of \$6.9 billion (Agency for Healthcare Research and Quality [AHRQ], 2013a, 2013b). Similarly, mean prescription medication costs for the elderly in 2010 were more than twice as high as those for people under 65 years of age (AHRQ, 2013c), and the elderly accounted for more than \$19,000 per person in hospitalization costs, nearly 81% of which were funded by Medicare (AHRQ, 2013d).

Nurses have long provided care to individual older clients and to the elderly as a population group. The American Association of Colleges of Nursing and the John A. Hartford

Foundation Institute for Geriatric Nursing (2010) have developed a set of competencies required of baccalaureate nursing preparation for care of the elderly in the United States. For further information about the competencies, see the *External Resources* section of the student resources site. These competencies primarily address knowledge required for care of individual elderly clients, but can be adapted to the care of the elderly as a vulnerable population. This latter application to the health of the elderly population is the thrust of this chapter.

Theoretical Perspectives on Aging

From the perspective of gerontologic care, **aging** is defined as a complex set of physical, emotional, and social changes that contribute to increased risk for health problems and functional decline. Aging involves a gradual and progressive loss of function over time and is not a product of disease, although the effects of aging may place older people at higher risk for disease.

As many as 300 theoretical perspectives have been advanced to explain how and why aging occurs. Generally speaking, these perspectives can be divided into three categories: biological perspectives, psychological perspectives, and sociological perspectives. Biological theories posit that aging is a phenomenon experienced by all members of a given species, that it is a

process of physical decline, that it is progressive and gradual, and that it is irreversible.

Some of the current biological perspectives on aging include the cross-linking/glycation hypothesis, the evolutionary senescence theory, the genome maintenance hypothesis, the neuroendocrine hypothesis, the replicative senescence hypothesis, the oxidative damage/free radical hypothesis, and the rate of living theory. Table 19-1 • summarizes the basic premises of each of these perspectives.

Psychological theories of aging focus on psychological changes that occur with age and propose that effective aging requires development of effective coping strategies over time. Major theories in this area include Jung's theory of individualism, in which the individual's mental focus changes from the external to the internal world, and the developmental theories. Erik Erikson's stage theory of development proposed eight stages of life in which the individual needed to accomplish specific developmental tasks that would facilitate task accomplishment in later stages (Harder, 2012). Peck took Erikson's last two stages, which encompass the last 40 to 50 years of life, and subdivided them into seven more discrete stages that cover middle age and older adult life (Saxon & Etten, 2010). In Peck's final stage, the individual engages in life review in preparation for death. Table 19-2 • presents an overview of developmental theories and associated foci for task accomplishment.

TABLE 19-1 Underlying Premises of Selected Biological Perspectives on Aging

Theoretical Perspective	Underlying Premise
Cross-linking/glycation hypothesis	Proteins, DNA, and other structural molecules develop inappropriate affinities over time that decrease molecular mobility or elasticity inhibiting protein breakdown by proteases. Glycation is one form of cross-linking in which glucose molecules adhere to proteins inhibiting their normal function. Cross-linking has been shown to be related to wrinkling and other dermatologic changes in aging as well as cataract formation.
Evolutionary senescence theory	Aging may result from genetic mutations that manifest only after reproductive years and can be passed from one generation to another. Genetic effects that may enhance reproductive capacity may have negative effects later in life. This may reflect a need for balance between cell maintenance and reproduction.
Genome maintenance hypothesis	Regular damage to DNA that does not lead to cell death or is not corrected by normal physiologic processes may result in genetic mutations that may be passed on to future generations of cells. These insults may accumulate with age and lead to cellular functional decline. Similarly, cellular repair functions may deteriorate with age.
Neuroendocrine hypothesis	Declining function in the hypothalamus reduces hormonal control of major endocrine functions and regulatory systems for blood pressure, sleep, and sugar metabolism.
Oxidative damage/free radical hypothesis	Normal cell metabolism results in the production of free radicals that can damage DNA. Generally, the body eliminates free radicals, but over time missed radicals accumulate and result in cell changes related to aging.
Rate of living theory	Energy consumption may limit longevity and increased metabolic rates may influence the deleterious effects of free radicals.
Replicative senescence hypothesis	Cell reproduction is limited by the length of telomeres that must be split evenly with a full complement of genetic material going to each daughter cell. Small portions of telomeres are lost with each replication until a cell is no longer able to reproduce effectively.

TABLE 19-2 Stages and Foci of Erikson's and Peck's Developmental Theories

Life Stage	Erikson's Stages	Focus
Infancy	Stage 1: Trust vs. mistrust	Erikson: Development of a sense of trust in self and others
Childhood	Stage 2: Autonomy vs. shame and doubt	Erikson: Development of the ability to express oneself and cooperate with others
Childhood	Stage 3: Initiative vs. guilt	Erikson: Development of purposeful behavior and the ability to evaluate one's own behavior
Childhood	Stage 4: Industry vs. inferiority	Erikson: Development of belief in one's own abilities
Adolescence	Stage 5: Identity vs. role confusion	Erikson: Development of a sense of self and plans to actualize one's potential
Adolescence/early adulthood	Stage 6: Intimacy vs. isolation	Erikson: Development of one's capacity for reciprocal relationships
Middle age	Stage 7: Generativity vs. stagnation	Erikson: Promotion of creativity and productivity and development of the capacity to care for others Peck: Development of the ability to value wisdom over physical competence Shifting relationships to emphasize friendship and companionship over sexual satisfaction Development of flexibility in roles and relationships Development of mental and intellectual flexibility
Late adulthood	Stage 8: Ego identity vs. despair	Erikson: Acceptance of one's life as unique and worthwhile Peck: Development of the ability to value one's self outside of work roles Development of abilities to adapt to physical changes and effects of aging Maintenance of an active interest in the external world

Sociological theories of aging focus on changes in roles and relationships that occur with advancing age and are strongly influenced by cultural values and attitudes toward the aged and aging (Fung, 2013). Theories in this group tend to be mutually exclusive. For example, disengagement theory proposes that individuals disengage from life as a means of making way for a younger generation in preparation for death. Simultaneously, society stops providing useful roles for elders to play. Older persons may disengage, however, not because of their own desires but because they are forced to do so by societal expectations resulting from **ageism**, which is prejudice or discrimination based on chronological age or appearance of age. In activity and continuity theories, however, older persons maintain their interest in life, but their specific interests change. In activity theory, successful aging is dependent on one's ability to stay active and to find meaningful substitutes for prior roles. Successful aging, from the perspective of continuity theory, involves maintaining a balance between continuity and change in one's life. According to this theory, older people are often happiest in activities similar to those experienced in the past (VickyRN, 2013). Socioemotional selectivity theory suggests that the elderly have internalized sociocultural values that inform their actions as they age, and that this internalization accelerates with age.

In this theory, older people prioritize goals that contribute to development of emotional meaning in life, adjusting personal goals to fit situational constraints (Fung, 2013).

Population Health Nursing and Care of Older Populations

Population health nurses use the elements of the nursing process to identify needs for, plan, implement, and evaluate care for older populations. Each of these aspects of care will be addressed here.

Assessing the Health Status and Needs of Older Populations

Factors related to each of the six categories of health determinants influence the health of the older population, often with greater effects than on the health of people in younger age groups. Population health nurses would identify determinants that influence the health of specific older populations, assessing health status and needs and developing population health nursing diagnoses. Assessment of an older population can be conducted using the *Population Health Assessment and*

Intervention Guide included on the student resources site. A second tool to assess the health of an individual older client is also included on the site.

BIOLOGICAL DETERMINANTS Major biological determinants of health in the elderly include those related to gender and aging and physiologic function, including immunization status.

Gender and Aging. Gender and the effects of aging are two biological determinants in assessing the health status of older populations. According to 2012 census figures, 56% of the U.S. population over 65 years of age is female. Approximately 12%

of U.S. men and nearly 15% of women are over 65 years of age. The ratio of women to men is 1.26 women to every man at age 65, but increases to 1.46 to 1 after age 75 (U.S. Census Bureau, 2013). Because of lower incomes and other sociocultural factors that we will discuss later, older women may be at greater risk for poor health than men.

Although it may affect individual clients somewhat differently, aging results in a number of universal changes in physical structure and function. Normal changes occur in all body systems, but at different rates for different people. They may, however, increase the older client’s risk of developing illness and disability. Physical changes related to aging and their possible implications for health are summarized in Table 19-3.

TABLE 19-3 Common Physical Changes of Aging and Their Implications for Health

System	Changes Noted	Possible Health Implications
Integumentary		
Skin	Decreased turgor, sclerosis, and loss of subcutaneous fat, leading to wrinkles Increased pigmentation, cherry angiomas Cool to touch, dry Thinning, compromised thermoregulation Decreased perspiration	Lowered self-esteem Itching, risk of injury, insomnia Hypothermia, hyperthermia Hyperthermia, heatstroke
Hair	Thin, decreased pigmentation	Lowered self-esteem
Nails	Thickened, ridges, decreased rate of growth	Difficulty trimming nails, potential for injury
Cardiovascular	Less efficient pump action and lower cardiac reserves result in decreased ability to respond to increased cardiac demand Thickening of vessel walls, replacement of muscle fiber with collagen Valvular stenosis Impaired baroreceptor function	Decreased physical ability, fatigue, exercise intolerance, shortness of breath, intolerance of volume depletion Elevated blood pressure, varicosities, venous stasis, pressure sores, cool skin Murmurs, arrhythmias, atrial fibrillation Postural/orthostatic hypotension
Respiratory	Decreased elasticity of alveolar sacs, skeletal changes of chest Slower mucus transport, decreased cough strength, dysphagia Postnasal drip	Decreased gas exchange, decreased physical ability, dyspnea Increased potential for infection or aspiration
Gastrointestinal	Wearing down of teeth Decreased saliva production Loss of taste buds sense of smell Muscle atrophy of cheeks, tongue, etc. Thinned esophageal wall Decreased peristalsis Decreased hydrochloric acid and stomach enzyme production Decreased lip size, sagging abdomen Atrophied gums Weakening of the bowel wall Changes in carbohydrate metabolism Decreased gallbladder function Decreased bowel sounds Fissures in tongue Increased or decreased liver size (2–3 cm below costal border)	Difficulty chewing Dry mouth, difficulty digesting starches Decreased appetite, malnutrition Difficulty chewing, slower to eat Feeling of fullness, heartburn after meals Constipation, altered drug absorption Pernicious anemia, frequent eructation, increased risk of infection Change in self-concept Poorly fitting dentures, difficulty chewing, potential for mouth ulcers, loss of remaining teeth Diverticulosis and diverticulitis Manifestation of a genetic predisposition to diabetes Potential for gallstones Potential for misdiagnosis Potential for misdiagnosis

TABLE 19-3 (Continued)

System	Changes Noted	Possible Health Implications
Renal	Decreased number of nephrons and decreased ability to filter or concentrate urine	Fluid and electrolyte imbalance, drug toxicity, nocturia, increased potential for falls
Reproductive Female	Atrophied ovaries, uterus Atrophy of external genitalia, pendulous breasts, small flat nipple, decreased pubic hair Scant vaginal secretions Vaginal mucosa thinned and friable	Ovarian cysts Lower self-esteem Dyspareunia
Male	Decreased size of penis and testes, decreased pubic hair, pendulous scrotum Enlarged prostate	Lowered self-esteem Difficulty urinating, incontinence
Musculoskeletal	Decreased muscle size and strength Decreased range of motion in joints, affecting gait, posture, balance, and flexibility Kyphosis Joint instability Straight thoracic spine Breakdown of chondrocytes in joint cartilage Osteoporosis	Decreased physical ability, increased weakness, fatigue Increased risk of falls, decreased mobility Lowered self-esteem Increased risk of falls, injury Osteoarthritis, joint pain, reduced abilities for activities of daily living Increased risk of fracture
Neurological	Diminished hearing, vision, touch, and increased reaction time Diminished pupil size, peripheral vision, adaptation, accommodation Diminished sense of smell, taste Decreased balance Decreased pain sensation Decreased ability to problem-solve Diminished deep tendon reflexes Decreased sphincter tone Diminished short-term memory	Increased risk for injury, social isolation Potential for falls and other injuries Decreased appetite, malnutrition Increased risk of injury Increased risk of injury Difficulty adjusting to new situations Incontinence (fecal or urinary) Forgetfulness
Endocrine Thyroid	Irregular, fibrous changes	
Female	Decreased estrogen and progesterone production	Osteoporosis, menopause
Male	Decreased testosterone production	Fatigue, weight loss, decreased libido, erectile dysfunction, lowered self-esteem, depression

Aging also results in changes in patterns of disease that may make diagnosis or treatment of illness more difficult. These changing disease patterns include subtle symptoms such as anorexia, incontinence, changes in functional or mental status, and blunting or absence of fever as an indicator of infection (Smith & Cotter, 2012). The presence of comorbidities may also complicate diagnoses. **Comorbidity** is the coexistence of many chronic physical and/or mental illnesses in the same person at the same time. Drug therapies for one condition, for example, may interact with treatment of another condition, interfering with therapeutic effects or causing adverse effects. In addition, older people may not present with classic symptoms of a given condition, making diagnosis more difficult. For example, many older people do not experience the chest pain typical of myocardial infarction. Finally, older clients, family members,

and health care providers may inaccurately interpret abnormal symptoms as facets of normal aging (e.g., many people believe that pain and stiffness are normal concomitants of age).

Other effects of aging involve normal changes in sensory modalities. Changes related to vision include lagging eyelids, slowed pupillary accommodation, decreased lens elasticity leading to visual disturbances and possibly to falls or other injuries. Tear production diminishes causing dry itchy eyes and potential for infection, and diminished pupil size inhibits the ability to adjust to glare. Finally, visual fields are reduced increasing the potential for injury in complex environments (Cacchione, 2012).

Hearing changes include decreased cerumen removal and protection of the ear canal resulting in diminished hearing or potential for infection and contributing to social isolation.

Other changes include thickening of the ear drum and loss of high-frequency hearing as well as the ability to process sounds (Cacchione, 2012). The prevalence of hearing loss doubles with each decade of age, and an estimated two thirds of Americans 70 years of age and older have experienced significant hearing loss (Lustig & Olson, 2014).

Decreased sense of smell may diminish the ability to identify odors and reduce the ability to taste food, which may lead to decreased appetite and poor nutrition. Similarly, decreased numbers of taste buds decrease the ability to detect flavors and enjoy food. As noted in Table 19-3, decreased saliva production may impair digestion and lead to dry mouth, inhibiting swallowing. Tactile and temperature sensation may also decrease, as do the sense of balance and proprioception ability leading to increased injury potential. Finally, changes in pain sensation may also result in injury due to diminished protective reactions (Cacchione, 2012).

The goal of population health nursing in the care of the elderly is to foster healthy aging. The role of the population health nurse is to assist the elderly population to mitigate the adverse effects of aging, prevent unnecessary deterioration in function, and promote quality of life. This may be referred to as **successful aging**, which has been defined as continued physical, mental, and spiritual health and functional ability through middle and later adulthood. Elements of successful aging include absence of disease, continued physical activity, and the ability to live independently with good mental health and effective coping. A related concept is that of **balanced aging**, which is achievement of a balance between needs and abilities by adapting effectively to the exigencies of aging (Butler, Fujii, & Sasaki, 2011).

Physiologic Function. Older populations experience increased mortality and morbidity rates relative to younger groups of people. They also experience higher rates of many other problems that affect their quality of life, such as acute and chronic illnesses, falls and injuries, disability, pain, and incontinence. Immune levels are another consideration with respect to physiologic function in the elderly.

With respect to mortality, age-specific death rates increase with age for most diseases. For example, the U.S. coronary heart disease mortality rate in 2010 was 85 per 100,000 persons aged 45 to 64 years, but increased almost ninefold to 754.3 per 100,000 people over age 65 years of age, rising to 2,598.6 per 100,000 people over age 85. Similar escalation with age is noted in mortality rates for cerebrovascular disease, malignancies, chronic lower respiratory diseases, and other chronic illnesses (U.S. Department of Health and Human Services [USDHHS], 2014).

Acute and chronic illnesses. Older populations are even more prone to morbidity from acute and chronic illness than to death, and the bulk of the burden of many of these conditions is borne by the older segments of the population. Older adults experience a variety of chronic health problems. The

2012 American Association of Retired Persons (AARP, 2012b) member survey indicated that 28% of those surveyed had at least one chronic health problem, and 25% reported declining physical health. These figures probably underrepresent the extent of chronic health problems in the elderly population, since many low-income seniors and those with low education levels are unlikely to be members of AARP. Table 19-4• presents information on the incidence of some of the more common chronic conditions among the elderly in the United States. Overall, only about half of the population 65 to 74 years of age reported themselves as in excellent or very good health in 2012, and that percentage dropped to only 40% of those older than 75. On the other hand, nearly one fifth (18.4%) of those 65 to 74 years of age and 25% of those over 75 rated their health as fair or poor (National Center for Health Statistics [NCHS], 2014b).

According to the 2009 Behavioral Risk Factor Surveillance System (BRFSS), nearly 23% of people over age 65 were obese (CDC, Administration on Aging [AoA], AHRQ, & Centers for Medicare and Medicaid Services [CMS], 2011). In addition, the elderly are the fastest growing segment of the population with epilepsy. Elderly clients experience longer periods of confusion following seizures and have higher epilepsy-related mortality rates than younger people. Late adult onset seizures are often related to cerebrovascular disease, and treatment is complicated by a variety of comorbidities experienced by the elderly (Acharya & Acharya, 2014). Hypertension is another common chronic disease in the elderly. More women than men experience hypertension (77% and 63%, respectively), and men are more likely than women to have their blood pressure controlled (CDC, AoA, AHRQ, & CMS, 2011).

TABLE 19-4 Percentage of Adults over 65 Years of Age with Selected Health Conditions, 2012

Condition	Percentage of U.S. Older Adults Affected	
	Age 65–74 Years	Over 75 Years of Age
Coronary heart disease	16.2%	25.8%
Hypertension	52.3%	59.2%
Stroke	6.3%	10.7%
Current asthma	7.8%	6.0%
Emphysema	4.7%	4.7%
Diabetes mellitus	21.1%	19.8%
Kidney disease	3.1%	5.3%
Liver disease	2.1%	1.1%
Arthritis	46.8%	49.4%

Source: National Center for Health Statistics. (2014b). *Vital and health statistics: Summary health statistics for U.S. adults: National health interview survey, 2012*. Retrieved from http://www.cdc.gov/nchs/data/series/sr_10/sr10_260.pdf

Older people tend to experience chronic conditions at higher rates than younger people. For example, roughly 10% of the population over 65 years of age is affected by osteoporosis, compared to less than 2% of those aged 50 to 64 years. The proportion of people affected climbs to more than 20% of those over age 85.

Even for chronic diseases that do not have a higher incidence among older adults, the effects of disease may be more pronounced with age. For instance, only 24% of people aged 45 to 64 years with chronic obstructive pulmonary disease experience resulting activity limitations compared to 32% of those over 65 years of age and 46% of those over 85 (USDHHS, 2013).

Influenza and pneumonia are two acute health conditions that disproportionately affect the elderly. From 2008 to 2010, the U.S. mortality rate for influenza and pneumonia was 7.7 per 100,000 people 45 to 64 years of age, but rose to 110.1 per 100,000 for those over 65. The rate quadrupled for the population over 85 years of age (456.6 per 100,000) (Health Data Interactive, 2014).

HIV infection is also a consideration in the health status of older populations. Although a smaller proportion of the population is affected than in other age groups, the rate of diagnosis for HIV infection in 2011 was 2.3 per 100,000 people 65 years of age and older. In addition, nearly 900 older people were diagnosed with stage 3 AIDS. Older people with HIV infection are more likely than their younger counterparts to advance to stage 3 AIDS within a year of diagnosis of infection. In 2010, 1,886 older people with HIV infection in the United States died and nearly 20,000 people in this age group had died since the beginning of the epidemic (Division of HIV/AIDS Prevention, 2013). Although these figures are less than for other age groups, they are significant because many health care providers do not think of AIDS in the older population and because of the added complication posed by AIDS in the control of other health problems among the elderly.

Falls and injuries. In addition to increased risk related to acute and chronic illnesses, older populations often experience frequent falls and injuries. Worldwide, an estimated 28% to 35% of people over 65 years of age fall each year, and these figures increase to 32% to 42% for those over 70 years of age. Falls account for 40% of international injury mortality (World Health Organization [WHO], 2014).

Fall-related mortality increases with age. In 2010, for example, the rate of fall-related deaths was only 4 per 100,000 population for people aged 45 to 64 years but rose to 53.8 per 100,000 for those over 65 and to 207.7 per 100,000 for people over 85 years of age. Nonfatal injury data shows a similar increase with age. In 2008, the U.S. rate for emergency department visits for nonfatal injuries was 6,540.2 per 100,000 for the 45 to 64 age group, climbing to 7,201.8 per 100,000 for all persons over 65 and nearly doubling to 13,065 for those over 85 years of age (USDHHS, 2014).

One third of older U.S. adults fall each year, and nearly a third of those who fall require medical assistance or experience

activity limitations as a result (CDC, 2013a). In 2010, the overall nonfatal injury rate from falls in the elderly was 43 per 1,000 population but jumped to 115 per 1,000 in those over 75 years of age (CDC, 2012). Bathrooms are one of the most common locales for falls, and the 2008 rate of bathroom falls was 112.1 per 100,000 people aged 65 to 74 years, climbing to 241 per 100,000 for those aged 75 to 84 and 515.3 per 100,000 for those over 85 years of age (Stevens & Haas, 2011).

Falls increase the risk of death and disability. For example, 20% to 30% of falls result in moderate to severe injury, and fall-related traumatic brain injury accounts for 46% of fall fatalities. In 2010, falls resulted in 258,000 hip fractures. Falls also increase the risk of nursing home placement, particularly in people over 75 years of age. In addition, experiencing a fall may result in fear of falling, leading to reduced mobility and fitness and greater risk of a subsequent fall. Despite the number of falls that occur among elders each year, only about half of those involved inform their providers of the incident (CDC, 2013a) making it difficult for providers to engage in corrective education and action.

Falls also result in inordinate health care costs. In 2010, for example, the direct medical care costs for falls in the elderly amounted to \$30 billion. Costs are expected to rise to \$67.7 billion by 2020. The average cost for a fall-related hospitalization is \$34,924, and hip fractures account for a large proportion of fall-related hospitalization costs (CDC, 2014a). Costs increase with age, and in 2005, the cost of falls for women over 85 years of age was more than \$100 million. In the same year, the cost of falls among men over 65 years of age was \$160 million and \$189 million for women (CDC, 2012).

Disability. Chronic disease and injury in the elderly often lead to functional limitations and disability. **Functional status** reflects one's ability to perform tasks and fulfill expected social roles. Assessment of functional status includes exploration of abilities at three levels of task complexity: basic, intermediate or instrumental, and advanced activities of daily living. **Basic activities of daily living (BADLs)** are personal-care activities and include the ability to feed, bathe, and dress oneself, and toileting and transfer skills (getting in or out of a chair or bed). In 2011, 28% of Medicare beneficiaries living in community settings reported difficulty in at least one BADL. Activities most commonly affected included walking and bathing (Administration on Aging [AoA], 2013a).

Intermediate or **instrumental activities of daily living (IADLs)** are tasks of moderate complexity, including household tasks such as shopping, laundry, cooking, and housekeeping, as well as abilities to take medications correctly, manage money, and use the telephone or public transportation. In 2012, 12% of Medicare beneficiaries reported difficulties with one or more IADLs (AoA, 2013a). **Advanced activities of daily living (AADLs)** involve complex abilities to engage in voluntary social, occupational, or recreational activities.

The incidence of disability in the elderly increases with the number of chronic conditions. In 2012, 28% of people aged

Disability may result in social isolation for many older clients.

(Hunor Kristo/Fotolia)

65 to 74 years in the United States had difficulty with at least one physical activity, and the percentage increased with age to 45% of those 75 years and older (NCHS, 2014b). Based on the 2010 National Health Interview Survey, more than 23 million

Americans over 65 years of age (nearly 59%) had at least one basic activity limitation. Just over 3% of the noninstitutionalized population 65 to 74 years of age needed help with personal care, and that figure rose to 10.5% of those over age 75. An additional 21.5 million older adults had vision problems, and 37% had difficulty hearing (CDC, 2014b).

Research has shown that hearing loss, in particular, is associated with lower quality of life and physical and social dysfunction, but that these effects can be ameliorated with the use of hearing aids. Unfortunately, only 20% to 25% of those with hearing impairments use hearing aids (Fischer et al., 2011).

Population health nurses would assess for disability in individual older clients as well as the extent and types of disability prevalent in older populations. The *Focused Assessment* below provides guidance for assessing the extent of functional limitations and disabilities in the elderly population. The data included in the assessment will be collected primarily through community surveys. The guide can also be used to assess disability in individual elderly clients. A more detailed guide for assessing functional status in the elderly is included in the *Assessment Guidelines* on the student resources site.

FOCUSED ASSESSMENT

Assessing Disability in the Older Population

Basic Activities of Daily Living

What proportion of the population over 65 years of age has difficulty with

- Feeding (feeding self, chewing, or swallowing)?
- Bathing (getting into or out of a bathtub or shower, manipulating soap or washcloth, washing hair, effectively drying all body parts)?
- Dressing (remembering the order in which clothes are put on, dressing self, bending to put on shoes and socks, manipulating fasteners, putting on and removing sleeves, combing hair, applying makeup)?
- Toileting (ambulating to the bathroom, urinary urgency, removing clothing, positioning self on toilet, lifting from a sitting position on toilet, cleaning self after urination or defecation, replacing clothing)?
- Transfer (getting from lying to sitting position, standing from a sitting position, lying or sitting down)?

Instrumental Activities of Daily Living

What proportion of the population over 65 years of age has difficulty with

- Shopping (transporting self to shopping facilities, navigating within shopping facilities, lifting products from shelves, handling money, carrying purchases to and from car, storing purchases)?
- Laundry (collecting dirty clothing, sorting clothes to be washed or dry-cleaned, accessing laundry facilities,

manipulating containers of soap, etc., lifting wet clothing into dryer, hanging or folding clean clothes, putting clean clothing away)?

- Cooking (planning well-balanced meals, safely operating kitchen appliances and utensils, reaching dishes and pots and pans, cleaning and chopping foods, carrying food to the table)?
- Housekeeping (identifying the need for housecleaning, light housekeeping, doing heavy chores, doing yard maintenance)?
- Taking medication (remembering medications, opening medication bottles, swallowing medications, giving injections, etc.)?
- Managing money (budgeting effectively, writing checks, balancing checking account, remembering to pay, and recording payment of bills)?

Advanced Activities of Daily Living

What proportion of the population over 65 years of age has difficulty with

- Social activity (maintaining a group of people with whom to socialize, transporting self to social events, seeing and hearing well enough to interact with others, tiring easily, being fearful of incontinence or embarrassed over financial difficulties)?
- Occupation (carrying out occupational responsibilities, if any)?
- Recreation (having the physical strength and mobility to engage in desired recreational activities, maintaining a group of people with whom to pursue recreation, transporting self to recreational activities)?

Pain. Pain is a significant contributing factor in disability that accompanies a wide variety of acute and chronic illnesses and is a common problem among the elderly. Experience of daily pain has been reported by 35% to 48% of older adults, often resulting from conditions such as arthritis, back pain, cancer, and postherpetic neuralgia (Bruckenthal, Reid, & Reisner, 2009).

Unrelieved pain can diminish quality of life for the elderly through its functional, cognitive, emotional, and social effects. The normal effects of aging may lead to a slightly higher pain threshold for the elderly or differing descriptions of pain, making diagnosis more difficult. Pain is, however, prevalent and is often undertreated in older persons.

Barriers to effective pain management include lack of access to care or treatment, lack of use of adaptive resources, emotional distress and its effects on pain and pain management, knowledge deficits regarding pain management, age-related perceptions by clients and providers that pain is normal in old age, and poor communication with providers. Some patients, for example those with cognitive impairment, may be unable to express pain verbally.

Population health nurses would assess the extent of pain in individual clients as well as the adequacy of pain management for the older population in general. A variety of tools is available for assessing pain in individual clients (refer to Chapter 27 student resources). While verbal patients can be asked about their pain or to rate the level of pain experienced, nurses may need to rely on nonverbal indications of pain in nonverbal patients. Such indicators may include increased or diminished body movements; rigidity; changes in sleep and rest or dietary patterns; agitation, aggressiveness, or withdrawal; facial expression; changes in mental status or mood; and vocalizations such as grunting, gasping, calling out, sighing, moaning or groaning, and verbal abusiveness (Bruckenthal et al., 2009). Assessment of pain control at the aggregate level may rely on community surveys or other mechanisms for data gathering.

Incontinence. Incontinence is another common problem among the elderly that may lead to social disability. **Incontinence** is defined as involuntary leakage of urine or feces that may affect personal hygiene or social interaction. As many as 10% of community-dwelling older men and women may experience both fecal and urinary incontinence (International Foundation for Functional Gastrointestinal Disorders, 2013a), with 31% to 70% of those in residential care affected (Roe et al., 2011).

Possible causes of urinary incontinence include aging, bladder cancer or stones, neurological disorders, obstruction, smoking, chronic cough, kidney disease, and diabetes. Additional causes in men include prostatic enlargement due to benign prostatic hypertrophy (BPH) or prostate cancer, while past pregnancy may be a factor for women (Mayo Clinic Staff, 2011b). Older clients may experience several different types of urinary incontinence as indicated in Table 19-5.

Fecal incontinence may also result from a variety of causes. Some possible contributors include muscle damage or weakness, nerve damage, diarrhea or constipation, pelvic floor dysfunction, loss of bowel storage capacity (e.g., as a result

of bowel surgery), and irritable bowel syndrome with scarring of the bowel (International Foundation for Functional Gastrointestinal Disorders, 2014).

Incontinence may contribute to falls when those affected try to hurry to reach the toilet. Other physical consequences may include skin breakdown and urinary problems (Mayo Clinic Staff, 2011b). In addition, either urinary or fecal incontinence may lead to embarrassment and social isolation. Incontinence engenders feelings of incompetence and shame that is fostered by the stigma attached to being unable to control one’s bodily functions. Stigma has also been attached to related symptoms such as urgency and frequency (Elstad, Taubenberger, Botelho, & Tennstedt, 2010).

Both fecal and urinary incontinence are distressing to older clients because of the loss of control and feelings of reversion back to babyhood. Clients with incontinence may isolate themselves from others and become virtually housebound due to feelings of embarrassment and incompetence. They may also be reluctant to share problems of incontinence with health care providers. Population health nurses may need to advocate with older clients themselves to encourage them to seek treatment as well as assist them to minimize the effects of incontinence on their lives. They may also need to educate the public regarding incontinence and the potential for treatment.

Immune status. The immune status is another aspect of physiologic function that would be addressed in assessing the health status of individual clients or that of older populations. The Advisory Council on Immunization practices (ACIP) has made

TABLE 19-5 Types of Urinary Incontinence and Distinguishing Features

Type of Incontinence	Distinguishing Features
Stress incontinence	Periodic urine leakage due to pressure on the bladder (e.g., with coughing, sneezing, heavy lifting)
Urge incontinence	A sudden intense need to urinate followed by involuntary urination
Overflow incontinence	Inability to empty the bladder completely with subsequent leakage
Mixed incontinence	A combination of several types of incontinence
Functional incontinence	Physical or mental inability to get to the toilet in time
Total incontinence	Continuous leakage
Temporary incontinence	Due to alcohol use, overhydration, caffeine, bladder irritation (e.g., from coffee, tea, carbonated drinks, artificial sweeteners, acid juices, etc.), medication, urinary tract infection, constipation

Source: Mayo Clinic Staff. (2011b). *Urinary incontinence*. Retrieved from <http://www.mayoclinic.com/health/urinary-incontinence/DS00404/>

recommendations for the use of several vaccines for people over 65 years of age. Routine recommendations include annual influenza immunization; booster doses for tetanus, diphtheria, and pertussis; two doses of varicella vaccine, herpes zoster vaccine (HZV), and pneumococcal vaccine. For persons at high risk for disease, immunization for meningococcal disease, hepatitis A, and hepatitis B are also recommended (CDC, 2014d). For further information on immunization recommendations for the elderly, see the *External Resources* section of the student resources site. In spite of these recommendations, immunization coverage among older adults in the United States remains relatively low. Table 19-6• presents immunization coverage for selected agents as of 2011.

The immune status of the older population is also influenced by other physiological characteristics that may impede development of immunity following immunization. For example, malnutrition, low basal metabolic rate (BMR), loss of 5% or more of weight in 6 months, reduced upper arm circumference, and reduced ability to perform ADLs have all been associated with reduced vaccine efficacy in the elderly (Sagawa, Kojimahara, Otsuka, Kimura, & Yamaguchi, 2011). For this reason, population health nurses would also explore the extent of these traits in the older population as well as vaccination rates.

TABLE 19-6 Immunization Coverage Among U.S. Adults, 2011

Immunizing Agent	Coverage	Data Year
Tetanus	54.4%	2011
Pneumococcal	62.3%	2011
Herpes zoster	15.8%	2011
Influenza	72%	2009–2010

Global Perspectives

Influenza Immunization Rates Among Elders

Influenza immunization rates among elders throughout the world are less than desired. In 2009, for example, Mexico had the highest rate for influenza immunization among Organization for Economic Co-operation and Development (OECD) countries at only 88%. The lowest rate (1.4%) was noted in Estonia. Only 13 of the 21 countries reporting had immunization rates of 50% or more of the elderly population. The United States ranked 6th highest at 66.8% far below the *Healthy People 2020* target of 90% of community-dwelling elders (National Center for Health Statistics, 2012; USDHHS, 2013).

Population health nursing assessment of biological determinants influencing the health of the elderly may occur at either individual or population levels. The *Focused Assessment* below provides some questions that might be used in such assessments.

PSYCHOLOGICAL DETERMINANTS Psychological considerations that particularly influence the health of the older population include dementia and stress, coping, and depression. Although dementia has a number of biophysical causes and effects, it is addressed here because the majority of its effects are mental, with physiological effects arising from the mental deficits caused. Some other psychiatric illnesses will be noted in the elderly population, some of which may be superimposed on other physical illnesses or may result from physical illness.

Dementia. Dementia is a degenerative neurological condition that results in progressive loss of cognitive function leading to the inability to care for oneself and eventually to death. Given

FOCUSED ASSESSMENT

Assessing Biological Determinants Influencing the Health of Older Populations

- What is the age and gender composition of the elderly population?
- What are the primary causes of death in the elderly population?
- What is the incidence and prevalence of acute and chronic disease in the elderly population?
- What is the extent of disability in the elderly population? What types of disability are prevalent? What effect does disability have on other aspects of elder health?
- What is the prevalence of conditions such as pain and incontinence? How and to what extent do they influence the health status of the older population?
- What is the immune status of the elderly population? What proportion of the elderly population has received pneumonia vaccine? What proportion has received recent influenza, tetanus, and HZV immunizations? What is the extent of immunity to other diseases in the elderly population (e.g., pertussis, diphtheria)?

the current lack of definitive treatment, the average survival time for someone with severe cognitive impairment is 3.3 years (Mehta, Fung, Kistler, Chang, & Walter, 2010).

In 2011, Behavioral Risk Factor Surveillance System data indicated that nearly 12% of people 65 to 74 years of age in 21 U.S. states reported increased confusion or memory loss, rising to more than 15% of those over age 85 (Adams, Deokar, Anderson, & Edwards, 2013). Among those affected, 29% and nearly 38%, respectively, reported consequent functional difficulties. Alzheimer's disease (AD) is the leading cause of dementia. In 2013, there were an estimated 5 million Americans affected by AD, with projections of 13.8 million affected by 2050 without adequate intervention. Costs of care were \$203 billion in 2013 (Alzheimer's Association & CDC, 2013) and are projected to increase to \$1.1 trillion by 2050. In addition to the costs of personal care for those affected who cannot care for themselves, people with dementia are three times more likely than those with normal cognitive function to experience a preventable hospitalization (National Center for Chronic Disease Prevention and Health Promotion [NCCDPHP], 2011).

The Centers for Disease Control and Prevention (CDC) has developed the "Healthy Brain Initiative" in an effort to decrease the incidence of dementia in the U.S. population. The initiative has identified 44 action items, 10 of which have priority for immediate implementation. Foci of the initiative include surveillance for risk and incidence, support of policy change, advancing communication and awareness of dementia, and guiding applied prevention research. Additional areas of emphasis include improving the health of caregivers for persons with dementia and addressing depression in those affected (Alzheimer's Association & CDC, 2013; NCCDPHP, 2011). For further information about the initiative, see the *External Resources* section of the student resources site.

Population health nurses may assess cognitive function in individual elderly clients or in the overall older population. The *Focused Assessment* on the next page contains questions to guide assessment of cognitive function in individual clients. At the population level, the nurse would collect data regarding the extent of cognitive impairment within the older population as well as its effects on the overall health of the population and on society as a whole. A tool for assessing cognitive function in the elderly is also available on the student resources site.

Stress, Coping, and Depression. Like people in other age groups, older clients experience stress and have a broad range of abilities to cope with stress. Unlike others, however, older people may have fewer resources to allow them to cope effectively with stress. In 2012, for example, 2% of older community-dwelling elderly people expressed feelings of sadness, and another 2% reported feeling hopeless (NCHS, 2014b). Coping with the helplessness and loss of power often associated with chronic illness may be particularly difficult for older persons, who often need to achieve a balance between assistance and independence.

When older people cannot cope with the stress encountered in their lives, they may become depressed. Depression occurs in more than 6.5 million Americans over age 65. Depression in the elderly may go unrecognized because it is mistaken for the effects of other chronic illnesses. For example, problems with memory and slowed thought processes that may occur with depression might be interpreted as early dementia. Other people may interpret their feelings as sadness or fatigue and not equate them with depression (National Alliance on Mental Illness [NAMI], 2009).

Many older clients with depression have a previous personal history of depressive disorders; others develop depression for the first time late in life. Symptoms of depression in the elderly are often vague and nonspecific and may include lasting sadness or long-term anxiety, sleeping too much or too little or frequent awakening, decreased or increased appetite, loss of interest in previously valued activities, fatigue, restlessness, or difficulty concentrating. Additional symptoms may include thoughts of death or suicide and feelings of hopelessness or guilt (Madden-Baer, 2011).

In addition to diminished quality of life, depression in the elderly has been associated with diminished immunity and increased risk of substance abuse as a means of coping with depression. Depression increases health care use and costs and may lead to functional decline and dependence as well as self-neglect.

Depression may be difficult to diagnose in the elderly for several reasons. Comorbid depression is often missed in the presence of critical illness or undertreated when it is recognized. Providers and family members may miss symptoms of depression, attributing them to aging. At the same time, older clients may feel shame related to their perceived inability to cope and not voice their feelings of depression, or may fail to recognize them for what they are (Madden-Baer, 2011). Many medications used to treat chronic illness in the elderly may also contribute to feelings of depression. Depression may also contribute to lack of adherence to treatment regimens for other chronic health problems.

At its extreme, depression may lead to suicide, which is a significant problem among the elderly, particularly among older men. Suicide rates increase with age and are higher in older men than women (Crosby, Ortega, & Stevens, 2011). Older adults may be more successful in suicide attempts than younger people. In part, this is because suicide is more deliberate and carefully planned, whereas it tends to be more impulsive in younger persons (Demirçin, Akkoyun, Yilmaz, & Gökdoğan, 2011). Overall, older adults account for 16% to 20% of U.S. suicides each year (Madden-Baer, 2011).

Population health nurses would assess for the presence of dementia, depression, and other mental health problems as well as levels and sources of stress and coping skills in individual clients. They would also assess the prevalence of these conditions in the older population. A *Focused Assessment* related to psychological determinants of health in the elderly is

FOCUSED ASSESSMENT**Assessing Cognitive Function
in Older Clients****Attention Span**

- Does the client focus on a single activity to completion?
- Does the client move from activity to activity without completing any?

Concentration

- Is the client able to answer questions without wandering from the topic?
- Does the client ignore irrelevant stimuli while focusing on a task?
- Is the client easily distracted from a subject or task by external stimuli?

Intelligence

- Does the client understand directions and explanations given in everyday language?
- Is the client able to perform basic mathematical calculations?

Judgment

- Does the client engage in action appropriate to the situation?
- Are client behaviors based on an awareness of environmental conditions and possible consequences of action?
- Are the client's plans and goals realistic?
- Can the client effectively budget income?
- Is the client safe driving a car?

Learning Ability

- Is the client able to retain instructions for a new activity?
- Can the client recall information provided?
- Is the client able to correctly demonstrate new skills?

Memory

- Is the client able to remember and describe recent events in some detail?
- Is the client able to describe events from the past in some detail?

Orientation

- Can the client identify him- or herself by name?
- Is the client aware of where he or she is?

- Does the client recognize the identity and function of those around him or her?
- Does the client know what day and time it is?
- Is the client able to separate past, present, and future?

Perception

- Are the client's responses appropriate to the situation?
- Does the client exhibit evidence of hallucinations or illusions?
- Are explanations of events consistent with the events themselves?
- Can the client reproduce simple figures?

Problem Solving

- Is the client able to recognize problems that need resolution?
- Can the client envision alternative solutions to a given problem?
- Can the client weigh alternative solutions and select one appropriate to the situation?
- Can the client describe activities needed to implement the solution?

Psychomotor Ability

- Does the client exhibit repetitive movements that interfere with function?

Reaction Time

- Does the client take an unusually long time to respond to questions or perform motor activities?
- Does the client respond to questions before the question is completed?

Social Intactness

- Are the client's interactions with others appropriate to the situation?
- Is the client able to describe behaviors appropriate and inappropriate to a given situation?

presented on the next page and can be used to assess related factors in either individuals or population groups.

ENVIRONMENTAL DETERMINANTS. Conditions in the physical environment also affect the health of older populations. For example, living in neighborhoods with problems of traffic, noise, crime, trash and litter, poor lighting, and inadequate public transportation has been associated with increased risk of functional loss among elderly residents. Neighborhood

factors have also been linked to problems of social isolation, hearing impairment, cognitive impairment, and depression in the elderly.

Physical environmental conditions may also have a direct effect on physical health status. For example, many older persons in the United States live in areas with high levels of pollution. Both ozone and particulate matter pollution have an adverse effect on respiratory function, particularly in people with chronic respiratory diseases.

FOCUSED ASSESSMENT**Assessing Psychological Determinants
Influencing the Health of Older Populations**

- What sources of stress is the elderly population exposed to? What is the extent of their coping abilities?
- What is the prevalence of dementia and other forms of cognitive impairment in the elderly population? What levels of dementia are represented in the population (e.g., mild confusion, vegetative states)?
- What is the extent of depression and mental illness in the elderly population? What mental illnesses are prevalent in the population? What are the rates of suicide and attempted suicide in the elderly population?

Safety hazards are another major consideration with respect to the physical environment of the elderly. Older clients may live in older housing with multiple safety hazards. Or, given recent energy prices, older persons on fixed incomes may have significantly more difficulty heating or cooling their homes than in the past. Both heat and cold have more profound effects on elderly persons than on younger ones due to changes in heat-regulating mechanisms that occur with aging. For example, heat wave mortality has been associated with increasing age. The student resources site includes an inventory for assessing home safety for older clients.

Conversely, older people may live in settings that promote health and independence. Residential areas that provide opportunities for safe exercise by the elderly or assist with accomplishment of routine tasks can delay functional deterioration. Unfortunately many U.S. elderly do not live in such situations. The *Focused Assessment* below provides tips on assessing environmental determinants of health in older populations.

SOCIOCULTURAL CONSIDERATIONS. Sociocultural considerations that have a major impact on the health of the elderly population include living arrangements and family responsibilities; cultural considerations; social support; and education, economic, and employment factors. Abuse and violence are other sociocultural factors that have a profound influence on the health of this vulnerable population.

Living arrangements and family responsibilities. Living arrangements and family responsibilities both have significant influence on the health of the older population. Family configurations and the resulting roles and responsibilities change over time. Children grow up and marry or move away; spouses divorce or die. Older clients may need to adjust to a variety of changes in family roles and responsibilities, some of which are looked forward to and some of which are not. Older men are more likely than older women to be married due to greater longevity among women and the greater size of the older female population. More elders are living alone than in the past. Approximately three fourths of older persons live with other family members in developing countries, compared to only one fourth in developed nations. Even when children live close by, older people are more likely to need outside assistance than in the past due to the number of middle adult women in the workforce. In 2010, 4% of people over 65 years of age in the United States had never married, 72% were living with a spouse, and 27% were living alone (U.S. Census Bureau, 2012a, 2012b). Older women are more than twice as likely as older men to live alone (AoA, 2013a).

Most older Americans (81%) live in their own homes and 19% live in rental units. Nearly half of the older population in the United States spend more than a fourth of their income on housing costs. This is more likely to be true among renters, among whom 74% spent more than a quarter of their monthly income on housing in 2011. Older people

FOCUSED ASSESSMENT**Assessing Environmental Determinants
Influencing the Health of Older Populations**

- How adequate is housing available to the elderly population? What is the extent of home ownership in this population? What safety hazards are presented by housing for the elderly? Are rentals and taxes within the budgetary limitations of most of the elderly population?
- Does the physical environment of the community promote or impede physical activity in the elderly population?
- What health effects does environmental pollution have for the elderly population?

also tend to live in housing that is slightly older than that of the rest of the population with a median construction year of 1970 compared to 1976 for the general population. In addition, more than 3% of homes of the elderly had physical problems (AoA, 2013a).

Older people are accepting greater responsibility for raising grandchildren than in the past. In 2010, for example, an estimated 881,000 people over 60 years of age assumed at least partial responsibility for caring for their grandchildren (U.S. Census Bureau, 2012c). In a 2012 member survey, 12% of respondents were the primary caretakers for at least one grandchild (AARP, 2012a). These responsibilities often devolved on grandparents when their adult children died, were divorced, were mentally ill, or were incarcerated.

Caregiving responsibilities may also be undertaken by older persons in the care of aging spouses. In 2009, 42.1 million people in the United States provided care to an adult with functional limitations at any given point, and 61.6 million provided care at some time during the year. Most of these caregivers were women, and 85% were caring for someone over 50 years of age. The average number of hours of care per week was 20 hours, and the estimated economic value of this care was \$450 billion, almost as much as the total Medicare expenditure. Caregiving activities include providing companionship, helping with household tasks, personal care, dealing with financial concerns, administering medications, coordinating services, providing transportation, and communicating with professionals (Feinberg, Reinhard, Houser, & Choula, 2011).

A survey of elderly caregivers for family members with dementia revealed a concept of “role captivity,” a feeling of being trapped by the burdens of the caretaker role. Feelings of entrapment were associated with higher levels of depression (Givens, Mezzacappa, Heeren, Yaffe, & Fredman, 2014). In other studies, caregivers with higher perceived burdens have reported worse physical and mental health than non-caregivers (Buyck et al., 2011). Similarly, persons with hip fractures whose caregivers expressed needs for information achieved better long-term outcomes than those whose caregivers did not. Conversely, those whose caregivers reported greater needs for social services were less likely to recover their ability to walk and engage in ADLs (Shyu, Chen, Wu, & Cheng, 2010).

Caregiving by older people also imposes financial burdens on caregivers. Approximately one fourth of older caregivers experience moderate to severe financial hardships due to lost wages and out-of-pocket costs. For example, an estimated 42% of caregivers spend more than \$5,000 a year for unreimbursed expenses related to caregiving. As a result, caregivers may cut back on expenditures for their own needs further compounding the negative effects of caregiving on their health (Feinberg et al., 2011).

Social support. Social support is another major sociocultural influence on the health of the elderly population. Social support occurs at societal, neighborhood, and individual levels. At the societal level, social support is a function of the sense

of solidarity felt by subsegments of the population with other segments. In many European countries, for example, there is greater solidarity in which younger people feel a greater responsibility for the welfare of older generations than is usually the case in the United States. In stable neighborhoods, opportunities for social interaction increase social support available from neighbors who can be called upon at short notice because of their propinquity.

Social support may arise from either informal or formal social networks. A **social network** is the web of social relationships within which one interacts with other people and from which one receives social support. Social support includes emotional, instrumental, or financial assistance from the social network. The informal social network consists of friends, family members, and neighbors, whereas the formal network comprises health and social service providers. Religious affiliation may provide a form of social support that often bridges the formal and informal networks. For example, many congregations provide material and emotional support to their members.

Some authors have noted that examination of the health of elderly populations should include consideration both of the social support available and perceptions of its adequacy among recipients. Most older persons seek social support most often from family members, particularly spouses. The quality of support provided, however, is affected by several factors, including propinquity and past relationships. Provision of support may be reciprocal among family members, for example, when adult children provide assistance to aging parents and parents provide child care for grandchildren.

For immigrant families, intergenerational support may be transnational in nature, where some family members live in one country and some in another. **Transnationalism** is defined as a process by which family members living in different countries maintain ties and avenues of social support. Transnational social support may be made more difficult by monetary exchanges, immigration laws, and other forces that regulate movement of people and objects across international borders. Some refugee immigrant families may not even have transnational support available. Many refugee families have been separated or have had family members killed. In addition, family members left in the country of origin may not have the freedom to contact immigrant members or may have little in the way of support to offer. Population health nurses can be actively involved in linking these clients to other sources of support (e.g., churches or other organizations). They may also advocate for the availability of necessary support services for these older clients.

Education, employment, and economic status. Many older people are more likely than younger ones to have limited education. In 2009, 8.5% of people in the United States 65 to 79 years of age had not completed high school. This figure nearly doubled to 16.6% for those over 85 years of age (Beckles & Truman, 2011). Progress has been made, however, in the educational level of older Americans, with high school graduation

rates increasing from 28% in 1970 to 81% in 2012. In addition, nearly a fourth of those over 65 years of age had attained a bachelor's or higher degree in 2012 (AoA, 2013a).

Although older age is often believed to be a time of retirement, many older people in the United States are continuing to work beyond retirement age. In 2002, workers over 55 years of age constituted 14% of the U.S. workforce (Hughes et al., 2011); in 2009, this figure had risen to 19% (Wuellner et al., 2011). By 2015, those over age 55 years are expected to constitute 30% of the workforce (Hughes et al., 2011). In March of 2013, more than a third of people over 55 years of age were employed, and another 5.8% were unemployed and seeking employment (AARP Public Policy Institute, 2013).

Many older workers are forgoing retirement due to better health or a desire to enter another career field. A 2008 survey (MetLife Foundation & Civic Ventures, 2008) found that significant numbers of persons aged 40 to 70 years were involved in or hoped to pursue “encore careers.” **Encore careers** involve occupational changes in the second half of life focusing on meaningful work that makes a difference in the world. Between 6% and 9.5% of people between 40 and 70 years of age were already involved in encore careers, and nearly half of those not currently engaged in such work expressed interest in an encore career.

In other cases different factors are at work in continued employment among the elderly. For example, policy changes, such as the elimination of mandatory retirement ages for many occupations, may permit working into one's later years. At the

same time, the age for drawing Social Security benefits has been advanced, prohibiting retirement for many individuals who had planned to retire at age 65. Economic need and a lack of replacement workers are other factors contributing to the postponement of retirement for many older adults. Continuation of older workers in employment settings raises concerns for worker safety. Although older workers experience fewer injuries than younger ones, they may lose more work time when they are injured (Wuellner et al., 2011). In addition, absenteeism due to illness is higher in older than in younger workers (Hughes et al., 2011).

Both education level and employment affect the economic status of the older population. In 2012, using the traditional federal definition of poverty, an estimated 9.1% of people over 65 years of age in the United States had incomes at or below poverty level (Social Security Administration [SSA] 2014b). A revised supplemental poverty measure (SPM) has been developed, however, that better accounts for both income and necessary expenditures including resources from public assistance programs and geographic differences in housing costs, out-of-pocket medical costs, and so on (U.S. Census Bureau, 2011). When this revised measure is applied, the percentage of those over 65 years of age who live in poverty rises to 15.1% (Short, 2012). In 2012, 2.8% of people over 65 years of age in the United States had no income beyond Social Security, and the median household income for those over 65 was \$39,196 compared to annual incomes of \$65,000 for those 55 to 61 years of age and \$57,350 for the 62- to 64-year-old group (SSA, 2014b). In 2011, the largest group of U.S. elderly (24%) reported incomes of \$15,000 to \$24,999 (AoA, 2013a). The median Social Security benefit for people over 65 years of age in 2012 was \$16,799, with older persons (e.g., over 80 years of age) earning slightly less than younger ones (SSA, 2014b).

Approximately 90% of the U.S. older population receives at least a portion of their income from Social Security. Overall 39% of the income for this age group derives from Social Security funds. In 2013, more than half (52%) of older married couples and nearly three fourths (74%) of unmarried individuals over 65 years of age derived at least half of their income from Social Security, and nearly one quarter and one half, respectively relied on Social Security for 90% of their income (SSA, 2014a). Some older persons also receive income from other sources. For example, continued employment earned persons over 65 years of age a median of \$30,000 in addition to Social Security earnings in 2012 (SSA, 2014b).

Whatever the source of their income, many seniors do not have enough money to live on. In fact, approximately 16% of U.S. seniors over 60 years of age were food insecure in 2011. This amounts to 4.8 million people, more than twice as many as in 2001 (National Foundation to End Senior Hunger, 2013). An estimated one third of senior households have no money left after paying for essential expenses. In 2012 the average credit card debt among those over 65 years of age was more than \$9,283. A significant proportion of elders spend more than 30% of their income on housing and an estimated 16%

Older individuals may continue to be successfully employed beyond the typical retirement age. (Eldadcarin/Fotolia)

of older homeowners owe more on their homes than they are worth (National Council on Aging, 2014).

A growing proportion of the elderly cannot afford housing at all, and the number of elderly homeless persons is increasing. Contributing factors for homelessness in this population include poverty and lack of affordable housing. There are an estimated nine elders for every affordable senior housing unit, and the waiting list for subsidized housing may be as long as 3 to 5 years (National Coalition for the Homeless, 2009).

There is a great deal of concern lately about retirement funding. Much has been written in the United States about the Social Security and Medicare systems in particular. At present, most countries have set 65 years of age as the minimum age for drawing public pension benefits, and many employers have mandatory retirement at a specific age. Only Australia and the United States prohibit mandatory retirement except in certain age-dependent occupations. Because of increased longevity, many people can expect to spend a significant portion of their lives in retirement. The **old-age dependency ratio**, or the number of workers to nonworking elders, is expected to increase as the population continues to age. Another related concept is the **elderly support ratio** or the number of people over 65 years of age per 100 people aged 20 to 64 years. Changes in these two ratios result in a declining tax base from which to fund services to the elderly as well as other segments of the population. For example, in 2012, there were 2.8 workers for every Social Security beneficiary in the United States; by 2033, that ratio is expected to decrease to 2.1 workers per beneficiary (SSA, 2014a). Solvency in retirement was one of several concerns voiced

by AARP members in a 2012 member survey. Other areas of concern were increasing taxes, consumer fraud, continuing independence (e.g., being able to drive), and being able to age at home (AARP, 2012c)

Empowerment. Empowerment of older adults requires changes in attitudes toward aging and the elderly as well as affirmation of their rights. Disempowerment may stem from loss of autonomy and the ability to make decisions for oneself as well as assumptions that older people are incapable of decision making (Beales, 2012).

Empowerment is affected by both agency and an opportunity structure. Agency refers to the capacity of the individual to make meaningful decisions. Opportunity structure, on the other hand, involves the formal and informal contexts in which decisions are made. Empowerment results from a confluence of the existence of an opportunity to make choices, use of that opportunity by the individual, and the outcome of the choice.

Strategies that promote empowerment of the elderly include age-specific policies and budgets that support their rights and independence, maintenance of physical and mental health, incentives and opportunities for participation in decision making including political participation, age-friendly design of facilities and social structures, and legal recognition of rights. Empowerment is also fostered by access to knowledge of services and information providers, avenues to redress concerns and grievances, policies that promote income and health security, recognized societal roles, and capacity for self-advocacy (Beales, 2012).

Evidence-Based Practice

Promoting Health in the Elderly

The healthProelderly project conducted a review of best practices in health promotion among the elderly in 11 European countries (Lis, Reichert, Cosack, Billings, & Brown, 2008). The project began with a review of literature on health promotion for older people. The review was followed by identification of 170 best practice programs in participating nations, from which a set of 16 quality criteria were derived. These quality criteria were used to develop best practice guidelines, which were then used to evaluate three health promotion programs in each country. Evaluation results were used to create best practice guidelines for practitioners working with older clients.

The guidelines include recommendations for addressing the following aspects of health promotion program development:

- Identifying and accessing target groups for health promotion programs
- Addressing diversity in the target population
- Involving older people in program development

- Empowering participants and motivating them to take charge of their own health
- Designing evidence-based interventions
- Developing multifaceted and holistic interventions
- Employing strategies and methods appropriate to the target population
- Planning the setting for health promotion activities and assuring easy access
- Involving all stakeholders in planning and implementation
- Using an interdisciplinary approach
- Involving volunteers
- Ensuring effective financial management, quality assurance, and organizational structure
- Employing and learning from evaluation findings
- Ensuring program sustainability
- Making transferability of processes and outcomes evident
- Disseminating program results and accomplishments (Lis et al., 2008)

Abuse and violence. One final sociocultural consideration that affects the health of the older population is that of violence and abuse. The increase in the older population has been accompanied by a disproportionate increase in elder abuse or maltreatment. **Elder maltreatment** is defined as “any abuse and neglect of persons age 60 and older by a caregiver or other person in a relationship involving an expectation of trust” (National Center for Injury Prevention and Control [NCIPC], 2014a, para 1).

In a 2009 report to the Institute of Justice, a study of more than 5,000 persons over 60 years of age indicated that nearly 5% had experienced emotional mistreatment, 1.6% reported physical maltreatment, 0.6% reported sexual maltreatment, 5% reported neglect, and 5.2% reported financial exploitation (Acierno, Hernandez-Tejada, Muzzy, & Steve, 2009). Table 19-7 presents the percentage of elders reporting specific types of abuse and the most common perpetrators of each type. One additional type of elder maltreatment is self-neglect or failure or refusal of the older person to care for his or her own basic needs (NCIPC, 2014a).

At its extreme, elder maltreatment results in death. The 2008 homicide rate among people 65 years of age and older was 2.1 per 100,000 population. Elder abuse is discussed in more detail in Chapter 30. The *Focused Assessment* included below provides tips on assessing violence directed at the elderly as well as other sociocultural determinants of elder health.

BEHAVIORAL DETERMINANTS. Sociocultural and behavioral lifestyle factors can profoundly affect the health of older

TABLE 19-7 Categories of Elder Maltreatment and Common Perpetrators

Maltreatment Category	Percent Affected	Common Perpetrators
Emotional mistreatment	4.6% (overall) 14% (since age 60)	<ul style="list-style-type: none"> Spouse/partner (25%) Child/grandchild (19%)
Physical maltreatment	1.6%	<ul style="list-style-type: none"> Spouse/partner (57%) Child/grandchild (10%)
Sexual abuse	0.6%	<ul style="list-style-type: none"> Spouse/partner (40%) Acquaintance (40%)
Neglect	5.1%	<ul style="list-style-type: none"> Child/grandchild (39%) Spouse/partner (28%)
Financial exploitation	5.2%	Multiple possible perpetrators, no specific data available

Source: Acierno, R., Hernandez-Tejada, M., Muzzy, W., & Steve, K. (2009). *National elder mistreatment study*. Retrieved from <https://www.ncjrs.gov/pdffiles1/nij/grants/226456.pdf>

populations. Behavioral factors, such as diet and other consumption patterns, physical activity, sexuality, and medication use, have important influences on the health of the older population. Factors in each of these areas will be briefly addressed.

Diet. Diet figures significantly in many health problems experienced by older clients. Conversely, health problems such as

FOCUSED ASSESSMENT

Assessing Sociocultural Determinants Influencing the Health of Older Populations

- What are societal attitudes toward the elderly? To what extent does the society provide support services for its older members?
- What is the ethnic composition of the elderly population? What languages are spoken among the elderly population? How does culture influence the health of the elderly population?
- What religious affiliations are represented among the elderly population? What health and social services are provided to the elderly population by religious organizations in the community?
- What is the level of economic support available to the elderly population? What is the income distribution within the elderly population? What are the typical sources of income for members of the elderly population? What is the proportion of elderly living in poverty or near poverty?
- What is the typical education level in the elderly population? How does education level influence health?
- What proportion of the elderly population is working? What are the occupations typical of elderly members of the population?
- What retirement planning and assistance are available to older members of the population?
- What proportion of the older population is engaged in caretaking for other family members? What is the effect of caretaking on their health?
- What transportation resources are available to the elderly population? Are they accessible to older clients with mobility limitations? Are they affordable?
- What shopping facilities and other services are available to older members of the population? Are they accessible and affordable?
- What is the extent of social isolation in the elderly population? What resources are available in the community to limit social isolation?
- What is the level of empowerment among members of the older population? What societal factors promote or impede participation in decision making for older adults?
- What is the extent of violence and abuse against elders in the population? What factors are contributing to violence and abuse?

loss of teeth may affect dietary intake. Based on National Health Interview Survey data, in 2010 to 2012, 7.4% of the total U.S. population was edentulous (without any teeth), but this percentage increased to 23.1% of those over 65 years of age and to 32.2% over 85 years (CDC, n.d.). Presence or absence of teeth, diminished gastric secretion and motility, and diminished sense of taste or smell may affect older clients' ability or desire to eat a nutritious diet.

Some of the nutrition-related problems experienced by the older population include malnutrition, obesity, elevated cholesterol levels, dehydration, and deficiencies in certain specific nutrients. Approximately 1.1% of the U.S. population 65 to 74 years of age and more than twice as many (2.6%) of those age 75 and older were underweight in 2013 (NCHS, 2014b). As many as 1 million homebound community dwelling elderly may be malnourished (National Resource Center on Nutrition, Physical Activity, and Aging, n.d.a), and an estimated 3,000 U.S. adults die of malnutrition each year (Dray, 2011). Contributing factors include decreased appetite or difficulty eating, dietary restrictions that limit food choices, poverty, reduced social contact, dementia, depression, and substance abuse. Consequences of malnutrition include diminished immune system function and greater risk for infection, poor wound healing, and muscle weakness that may contribute to falls and injuries (Mayo Clinic Staff, 2011a).

In 2012, nearly 41% of the U.S. population aged 65 to 74 years was overweight, and another 29% was obese. Overweight and obesity prevalence among those over 75 years of age were slightly lower at 30% and 18%, respectively (NCHS, 2014b). Older individuals with disabilities are even more likely to be obese. Obese and overweight individuals may forgo health care due to embarrassment regarding their weight.

Chronic dehydration is another dietary problem that occurs frequently in older populations. Dehydration leads to loss of muscle function, depression, altered states of consciousness, renal failure, and increased potential for medication toxicity, hypo- or hyperthermia, and infection. Dehydration is often unrecognized in the elderly, and mortality may be as much as seven times higher in dehydrated elders than in the general elderly population.

Finally, older clients may be lacking in specific nutrients such as iron, protein, and calcium. Calcium, in particular, is needed to prevent or ameliorate the effects of osteoporosis. Many older women, however, do not know that they should continue calcium intake into their older years. Population health nurses would assess the nutritional status of individual clients as well as that of the general elderly population, including factors contributing to malnutrition, dehydration, and overweight/obesity in the population.

Other consumption patterns. Other consumption patterns that affect the health status of the older adult population include tobacco, alcohol, and drug use. In 2012, more than 11% of people aged 65 to 74 years in the United States reported current smoking, and 40.5% reported being former smokers. The

percentages of current and former smokers were slightly lower among people over 75 years of age at 5.7% and 41%, respectively (NCHS, 2014b). Elderly smokers are more likely than their younger counterparts to have health-related effects due to diminished respiratory function as a result of aging. Many older clients believe that smoking cessation will not make much difference with respect to their health. Smoking cessation at any age, however, can have beneficial effects, and population health nurses should promote smoking cessation among elderly clients who smoke.

Alcohol consumption may also affect the health of the older adult population. In 2012, current regular alcohol use was reported by 41.6% of Americans aged 65 to 74 years and 30% of those over 75 (NCHS, 2014b), and in 2009, binge drinking was reported by nearly 4% of those over age 65 (Kanny, Liu, & Brewer, 2011).

Misuse of other drugs may also occur among the elderly, and the negative effects of drug use accumulate over time. Opioids and benzodiazepines are among the mostly commonly abused drugs in the older population. Prescription drug abuse in the U.S. elderly is expected to increase by 190% from 911,000 people affected in 2001 to 2.7 million by 2020. Ten percent of people who sought treatment for substance abuse disorders in 2005 were over 50 years of age (Johns Hopkins Medicine, 2010). An estimated 4.4 million U.S. seniors are expected to need substance abuse treatment by 2020 compared to only 1.7 million in 2000. Treatment needs are expected to double in Europe (Roe, Beynon, Pickering, & Duffy, 2010). Unfortunately, treatment programs for older adults are often lacking and detoxification programs pose special hazards for the older population. Population health nurses would assess the older population for levels of substance use and abuse as well as the availability of smoking cessation and substance abuse treatment services targeted at this population.

Physical activity. As with their perceptions of the need for continued calcium intake, many older people do not believe they need to engage in much physical activity. Physical activity by older adults, however, has been shown to prevent disability and improve overall health and functional ability.

Physical activity provides both physical and psychological benefits for older clients. In the physical realm, exercise contributes to improved cardiovascular function, better control of hypertension and hyperlipidemia, and prevention of osteoporosis. Additional physical benefits include reduction in diabetes risk; increased muscle, bone, and joint strength; and decreased risk of falls. Psychologically, physical activity contributes to emotional well-being and improved self-assurance and self-concept and may be linked to improvements in cognition.

In spite of evidence regarding the benefits of physical activity, many older adults remain sedentary. According to 2012 figures, large numbers of people over 65 years of age failed to engage in recommended levels of physical activity. More than half met neither aerobic activity nor strengthening activity goals outlined in *Healthy People 2020* (NCHS, 2014b). In fact, research

Physical activity is an important element of physical and mental health. (Monkey Business/Fotolia)

suggests that older people engage in purposive self-limitation of activity, more often spending time socializing, relaxing, reading, or watching television than in physical activity such as sports, exercise, and recreational activities (Guo & Phillips, 2010).

Sexuality. Sexuality considerations related to the older population include knowledge, attitudes, values, and behaviors, as well as changes in anatomy and physiology due to the aging process. Primary health care providers often assume that older clients are asexual and rarely discuss sexual issues with members of the older adult population. Evidence suggests that, despite these perceptions, sexuality continues to be an area of importance for many older people.

Older clients may also have concerns regarding sexual dysfunction. Because most older people grew up in an era when sexuality was not a topic for discussion, they may find it difficult to talk about such concerns with health care providers. As we saw in Chapter 17, many of the medications used to treat chronic diseases common in the elderly cause impotence in men. Similarly, aging may decrease vaginal secretions, making intercourse painful for older women (Chapter 18). Both older men and women may experience diminished sexual interest, which may interfere with marital intimacy.

Medication use. Medication use and misuse are significant factors in the health of the older adult population. Medication use is increasing among the elderly. National data indicate that nearly 90% of all people over 65 years of age use at least one prescription drug, with greater use among women than men. In 2007–2010, 47.5% of people over 65 years of age used five or more prescription drugs. The most commonly used drug categories among the elderly were cardiovascular and cholesterol lowering medications (NCHS, 2014a).

In addition to taking multiple prescription medications, older adults may also use a variety of over-the-counter (OTC) medications and herbal therapies, compounding the potential for drug interactions and adverse reactions. A 2010 survey

by AARP and the National Center for Complementary and Alternative Medicine (NCCAM) indicated that half of respondents over 50 years of age had used some form of complementary or alternative medicine (CAM) at some point in their lives, and 47% had used CAM in the prior year. Among these people, 37% reported using herbal preparations. Frequent reasons given for CAM use included health promotion and illness prevention, pain relief, treatment of specific diseases, or to supplement conventional medicine. More than two thirds of the respondents did not inform their primary health care providers about their CAM use often because providers did not ask about CAM use and clients did not think to bring it up or feared provider disapproval (AARP & NCCAM, 2011).

In addition to the combination of multiple drugs, OTC medications, and herbal remedies, medication use in the elderly is complicated by the effects of aging. As age increases, changes occur in drug metabolism that increase the risk of adverse reactions and overdose.

Older clients may also have difficulty taking medications as recommended. An estimated 50% of the elderly have difficulty adhering to medication regimens. Medication misuse and non-adherence have been linked to poor control of many chronic health conditions and preventable hospital admissions and emergency department visits (American College of Preventive Medicine, 2011). Possible reasons for lack of adherence to treatment regimens are presented in Table 19-8.

The *Focused Assessment* provided on page 499 can guide evaluation of medication use in elderly clients.

Other health-related behaviors. Population health nurses should also assess the extent of other health-related behaviors by individual clients and within the older population. Behaviors of particular interest include safety practices, driving, and obtaining immunizations. Population health nurses would assess the extent of use of safety devices and practices. For example, do older clients wear good fitting footwear to help prevent falls? Similarly, do they use assistive devices as appropriate to foster mobility while minimizing the risk of falls?

As noted earlier, continued ability to drive a car is an area of concern for many older people. Driving helps older adults maintain their independence. In 2009, there were 33 million drivers over the age of 65 on U.S. streets and highways. Older adults are more likely than younger ones to sustain injuries in motor vehicle accidents, and in 2008, vehicular accidents killed 5,500 U.S. elders and injured another 183,000 (NCIPC, 2013a). Fortunately, most older adults engage in safe driving habits, wearing seatbelts, and driving only in safe weather conditions. In addition, older drivers are less likely to drive while under the influence of alcohol. Older people may not, however, recognize the risks posed by many medications in terms of drowsiness or dizziness. Population health nurses should assist older clients and their families to determine when continued driving is no longer safe. They can also assist older people in finding alternate forms of transportation and advocate for the availability of transportation services for this population.

TABLE 19-8 Categories of Factors Influencing Nonadherence Among Older Clients

Category	Influencing Factors
Patient-related factors	<ul style="list-style-type: none"> • Visual, hearing, or cognitive impairment (including developmental disability or dementia) • Limited dexterity • Difficulty swallowing • Difficulty remembering • Lack of disease knowledge and understanding of need for therapy • Denial of condition or need for therapy • Level of self-efficacy • Motivation • Fear or experience of adverse/side effects • Fear of dependence • Feelings of stigmatization • Anxiety, stress • Depression/mental health disorder • Substance abuse
Social factors	<ul style="list-style-type: none"> • Language barriers • Low health literacy • Lack of social support • Difficulty incorporating compliance into daily schedules • Lack of pharmacy access • Cultural beliefs and attitudes • Elder abuse
Economic factors	<ul style="list-style-type: none"> • Medication/copayment costs • Lack of health insurance/drug coverage
Condition-related factors	<ul style="list-style-type: none"> • Absence of symptoms • Lack of immediate benefit • Need for unwanted behavioral changes
Therapy-related factors	<ul style="list-style-type: none"> • Complexity of regimen • Need to master certain cognitive or psychomotor skills (e.g., dosage calculation, use of monitoring devices) • Duration of therapy • Frequent changes in therapy • Perceived social stigma attached to therapy
Health system-related factors	<ul style="list-style-type: none"> • Quality of relationships with providers • Extent of provider communication skills • Lack of positive reinforcement • Lack of educational capacity in health system • Failure to tailor educational materials to client literacy or education level, culture • Client frustration with quality of care, wait times, etc. • Lack of continuity of care

As noted earlier, population health nurses assessing the health of older populations should assess the immune levels within the population. They should also examine the extent to which older people avail themselves of recommended immunizations. In 2011, national coverage for pneumococcal disease among people over 65 years of age was only 62% (Williams et al., 2013), and during the 2012–2013 influenza season, only 66.7% of this population were immunized (National Center for Immunization and Respiratory Diseases, 2013). Similarly, only slightly over half of older Americans were up to date on tetanus immunizations (Williams et al., 2013). Behavioral determinants affecting the health of the older population can be assessed using the questions posed in the *Focused Assessment* on the next page.

HEALTH SYSTEM DETERMINANTS. The demand for health care services increases significantly in older people. Most of this increase is due to the multiple chronic illnesses experienced by older adults. For this reason, early diagnosis and effective treatment of chronic illness can help decrease the societal burden of care for the elderly.

The concept of “aging in place” was conceived as a way of improving the quality of life for older adults and of decreasing the cost burden of their care by maintaining older individuals in their homes whenever possible and providing care in the least expensive setting. **Aging in place** means being able to remain in one’s home despite challenges posed by aging or health-related conditions (MetLife, 2010). Based on a Metropolitan Life

FOCUSED ASSESSMENT**Assessing Medication Use in Older Clients**

- Is the client taking prescribed medications?
- Is the client taking over-the-counter (OTC) medications?
- Is the client using any complementary or alternative therapies? If so, is there potential for interactions with prescription medications?
- Are any of the client's medications contraindicated by existing health conditions?
- Do OTC medications potentiate or counteract prescription medications?
- Do prescription medications potentiate or counteract each other?
- Does the client take prescription and OTC medications as directed (e.g., correct dose, route, time)?
- Does the client comply with other directions regarding medications (e.g., not taking with dairy products)?
- Is the client aware of potential food–drug interactions or drug–drug interactions?
- Are medications achieving the desired effects?
- Is the client experiencing any medication side effects?
- What is the client doing about medication side effects, if any?
- Is the client exhibiting symptoms of any adverse medication effects?

Insurance Company Mature Market Institute report (MetLife, 2010), three foci are required for effective aging in place in the United States. The first is a focus on maintaining the independence of the older person. The second requires more economical use of available resources, and the third addresses the need for coordinated, comprehensive, collaborative relationships between providers and businesses to support aging in place. Provision of comprehensive coordinated services will require access to health care and other services, mechanisms for funding prescription and other coverage to meet health-related needs, and the availability of infrastructure support that allows older people, even those with multiple health problems to remain in their own homes. An additional health system determinant that influences the health of the older populations is the quality of interactions with health care providers.

Health care access. Access to health care services for older Americans has improved significantly since the advent of Medicare in the 1960s. In 2012, Medicare provided health insurance coverage for 93% of the U.S. population over 65 years of age, and 9% of the population also received Medicaid funded services. Overall, 98% of the population 65 years of age and older had some form of health insurance (AoA, 2013a).

The costs of health care to those without insurance can be prohibitive. Even with insurance, costs of care may impede access. For example, in 2011, the average out-of-pocket expenditure for health-related expenses was \$4,769, an increase of 40% from 2000 figures (AoA, 2013a). A couple retiring at age 65 in 2013 will need an estimated \$240,000 to cover health-related expenses over the remainder of their lives, and this figure does not even account for possible long-term care

FOCUSED ASSESSMENT**Assessing Behavioral Determinants Influencing the Health of Older Populations**

- What are the typical dietary patterns among the elderly in the population? What is the extent of obesity in the elderly population? What nutritional deficits are prevalent in the elderly population?
- What is the extent of smoking, alcohol, and drug use in the elderly population? What are the treatment rates for alcohol and drug abuse?
- To what extent do members of the elderly population engage in health-related behaviors such as testicular self-examination, mammography, and so on?
- To what extent do members of the elderly population employ safety precautions such as seat belt use?
- What proportion of the elderly population drives? What is the incidence of motor vehicle accidents among this population?
- What prescription and OTC medications are typically taken by elderly clients? What is the incidence of adverse events due to inappropriate medication use in the population?

expenses (Hamilton, 2013). More than three fourths of AARP members surveyed in 2012 indicated that paying for health care expenses was one of their biggest concerns (AARP, 2012b).

Some older adults also have no regular source of health care. In 2012, for example, nearly 4% of those aged 65 to 74 years and 2.8% of those over 75 had no usual source of care. Emergency departments were relied on for routine health care for 1.6% of those 65 to 74 years of age and 1.5% of those over age 75 (NCHS, 2014b). In 2012, 2.4% of older Americans reported failing to obtain needed health care services due to costs (AoA, 2013a).

Prescription drugs. Two elements of the health care system related to prescription drugs affect the health of older populations. The first is prescription of inappropriate drugs, and the second is the cost of medications.

A recent systematic review of related research (Opondo et al., 2012) indicated that more than 20% of prescriptions provided to elderly patients in primary care settings were inappropriate. Inappropriate medications most often prescribed included propoxyphene, doxazosin, diphenhydramine, and amitriptyline. The latter two medications have the greatest potential for adverse effects. The authors suggested that computerized clinical decision support systems could reduce the prevalence of inappropriately prescribed medications. Table 19-9• provides information on selected drugs that should be used with caution among older clients.

The cost of prescription drugs is one of the impediments to medication compliance among the elderly. Overall the cost of

drugs per Medicare beneficiary in the United States increased almost fourfold from 1992 to 2008, to an average per person cost of \$2,834 in 2008. Much of this increase can be attributed to increased prices of medications rather than increased numbers of prescriptions.

Drug costs vary significantly among older clients, with 6% of U.S. elders incurring no costs in 2008 and 15% incurring costs of \$5,000 or more. Costs also vary by health status. For example, in 2008 the average drug cost for persons with no chronic conditions was \$1,230, compared to \$5,300 for those with five or more chronic conditions (Federal Interagency Forum on Aging-Related Statistics, 2012).

Prior to 2006, prescription drug costs were born out-of-pocket by most elderly. In January 2006, however, Medicare Part D was initiated to subsidize prescription medications for part D subscribers. Part D included two options: enrollment in a stand-alone drug plan or enrollment in a Medicare Advantage managed care program that includes prescription drug benefits (Centers for Medicare and Medicaid Services [CMS], 2014). For further information about Medicare Part D drug coverage, see the *External Resources* section of the student resources site.

The advent of Medicare Part D prescription drug coverage substantially reduced out-of-pocket costs for medications, from 60% of costs in 1992 to 23% of costs in 2008. From June of 2006 to October 2011, the number of Medicare beneficiaries enrolled in Part D prescription drug plans increased from 18.2 million to 23.8 million people or 38% of all Medicare beneficiaries (Federal Interagency Forum on Aging-related Statistics, 2012).

TABLE 19-9 Hazardous Medications for Older Clients

Drug Classification	Specific Medications	Potential Hazard
Analgesics	Meperidine, pentazocine, propoxyphene	Confusion, hallucinations
Anticholinergics/antihistamines	Chlorpheniramine, diphenhydramine, hydroxyzine, cyproheptadine, promethazine, tripeleminamine, dexchlorpheniramine	Confusion, delirium, blurred vision, constipation, dry mouth, lightheadedness, urinary difficulty or incontinence, hallucinations, tachycardia
Anticoagulants	Warfarin, Coumadin	Bleeding, particularly with malnutrition, low albumin levels, interactions with Cipro, phenytoin, amiodarone, cephalosporins, high-dose penicillins, aspirin, barbiturates, cholestyramine, Lovenox, herbals (Ginkgo biloba, garlic), and high vitamin K foods Increased risk of serious injury with falls
Antihypertensives	Alpha-blockers, beta-blockers, diuretics	Orthostatic hypertension, sedation and depression, confusion, impotence, constipation
Cardiotonics	Digoxin	Increased risk of toxicity, arrhythmias
Diuretics	Potassium losing diuretics	Hypokalemia
Hypoglycemics	Insulin, Metformin	Hypoglycemia, vision changes
Nonsteroidal anti-inflammatory drugs (NSAIDs)	Naproxen, oxaprozin, piroxicam	GI bleeding, renal failure, high blood pressure, heart failure
Psychoactive drugs	Sedative/hypnotics, antidepressants, anxiolytics, antipsychotics, psychoactive stimulants	Increased risk of falls and other injuries, GI effects

Data from: Zwicker, D. A., & Fulmer, T. (2012). Reducing adverse drug events. In M. Boltz, E. Capezuti, T. Fulmer, & D. Zwicker (Eds.) *Evidence-based geriatric nursing protocols for best practice* (4th ed., pp. 324–362). New York, NY: Springer.

Initiation of Medicare Part D prescription drug coverage did not entirely eliminate the problem of high drug costs for seniors, however. Coverage provisions created a “doughnut hole” in which clients paid the bulk of the costs of prescription coverage. The doughnut hole was entered when the beneficiary had incurred \$2,250 in annual drug costs. Once total costs had exceeded \$5,100 in a year, Part D benefits resumed with a small copayment of approximately 5% of costs. In 2010 the Affordable Care Act (ACA) was enacted, provisions of which are intended to gradually reduce the effects of the doughnut hole and eliminate it entirely by 2020 (AARP, n.d.). From the passage of the act until October 2011, ACA resulted in more than \$464 million in savings on prescription drug costs for the American elderly (Reid, 2011). For 2014, Part D enrollees paid the basic premium for their specific Part D plan plus a maximum deductible amount of \$310, as well as a copayment (a flat fee for each prescription) or co-insurance (a percentage of the cost of the prescription) until total drug costs for the year reached \$2,850. From that point until drug costs for the year totaled \$4,550, the beneficiary paid 47.5% of the cost of brand-name drugs and 72% of the cost of generic drugs. Beyond the doughnut hole, the beneficiary pays only a small copayment for each prescription (CMS, 2014).

Infrastructure support. Infrastructure support factors that affect the health of older populations arise out of environment, sociocultural, and health system determinants. For example, housing modifications that accommodate diminished functional status (e.g., ramps versus stairs, home safety features) are environmental factors that can allow people to remain at home and continue to be independent. Similarly, transportation systems that meet the needs of the elderly who are no longer able to drive and policies that support in-home assistance are sociocultural determinants that foster aging in place. Within the health care system, the availability of home health and care management services, durable medical equipment, home telehealth services, and respite services for caretakers are examples of factors that can support aging in place (MetLife, 2010).

Client–provider interactions. Another major health system consideration that affects the health of older populations is the quality of interactions with health care providers. These interactions are shaped by knowledge and attitudes on the part of providers as well as clients. As reflected in the discussion of inappropriate prescriptions given to older adults, some providers do not have the knowledge or expertise to provide effective care to this population.

Difficulties in client–provider interactions may also arise from communication barriers and lack of empowerment of older persons. Health care providers may be particularly prone to attempting to make decisions for older clients based on perceptions of what is “in their best interests.” Empowerment of older clients was addressed earlier as a sociocultural determinant of health in older clients.

Barriers to effective communication between older clients and health care providers may stem from client attitudes and abilities or from provider characteristics. Client attributes that may impede communication include diminished communication abilities due to declining hearing, vision, or cognitive ability; diminished self-worth; and lack of knowledge about health-related issues. Provider-related barriers may include ageist attitudes and discrimination, as well as lack of knowledge and expertise regarding the needs of and interventions appropriate to older clients. Lack of health literacy on the part of clients and failure of providers to consider literacy issues may also impede communication.

Differences may also arise from the primary foci of providers and clients. Providers tend to focus on disease and its treatment, whereas the primary focus of many older clients is on quality of life. An additional barrier to communication between health care providers and older clients is a phenomenon called “elder speak.” Elder speak is an approach to communication with the elderly that conveys a message of incompetence and control and may take one of two forms: excessively nurturing communication and controlling communication. Elder speak may be characterized by a slow rate of speech, exaggerated intonation, elevated pitch and volume, frequent repetition, and the use of simple vocabulary and grammar. Other characteristics may include use of inappropriate terms of endearment (e.g., “honey” or “sweetie”), use of the plural pronoun “we,” and use of questions that prompt a specific answer (e.g., “you want to wear this pretty blue sweater, don’t you?”) such as one might use with a child. Research has indicated that a significant proportion of communication occurring in nursing home settings involves elder speak, and older clients in both institutional and home settings report they perceive the use of such speech as demeaning, patronizing, or implying incompetence. In one study, the use of elder speak was closely related to resistiveness to care among patients with dementia, while normal speech was related to cooperation with care (Williams, Herman, Gajwesi, & Wilson, 2009).

Information on access to health care as well as use of health care services can be obtained from local providers as well as community surveys of the elderly population. Community surveys and health institutions can also provide information on the extent or lack of health care insurance in the older population. Information on the quality of interactions between providers and older clients, however, is likely to be available only through community surveys or small-scale qualitative studies involving participant observation or interviews. *Focused Assessment* questions related to the health system determinants of health in older populations are provided on the next page.

Diagnostic Reasoning and Care of Older Populations

Once the population health nurse has determined the extent to which factors in each category of determinants of health are affecting the health of the older population and determined what those effects are, he or she would derive population nursing diagnoses related to the population’s health status. These

FOCUSED ASSESSMENT

Assessing Health System Determinants Influencing the Health of Older Populations

- What proportion of the elderly population has a regular source of health care?
- What is the level of insurance coverage among the elderly population (e.g., Medicare A and B, supplementary insurance)?
- To what extent are medication needs covered by insurance plans among the elderly population?
- What preventive and restorative health care services are available to members of the elderly population? To what extent are these services used by the population? How adequate are these services in meeting the needs of the elderly population?
- To what extent are palliative services, end-of-life care, and hospice services available and accessible to the elderly population?

diagnoses would reflect the problems identified in the elderly population as well as the availability of resources within the community to address these problems.

Nursing diagnoses may be either positive or negative. An example of a positive diagnosis might be: “community ability to maintain older clients in their own homes due to the availability and accessibility of assistance with ADLs.” Positive diagnoses usually indicate that no further nursing intervention is needed, but that the health status of the population in this area should continue to be monitored. A negative diagnosis might be “lack of assistance with ADLs for older persons with functional disabilities.” In this instance, the diagnosis would indicate the need for intervention by nurses and others in the community to resolve the identified problem.

Planning to Meet the Health Needs of Older Populations

Planning to meet the health care needs of older clients may involve health promotion, illness and injury prevention, resolution of existing health problems, or health restoration services. Major emphases in planning health care for older clients should be on successful aging and promotion of self-care. As noted earlier, aging can result in loss of functional abilities, stamina, and so on, but these losses can be balanced to achieve successful aging. Health care for older clients should be based on the standards for gerontological nursing practice developed by the American Nurses Association (2010). For further information about the standards, see the *External Resources* section of the student resources site.

General recommendations for addressing the health needs of the older population in the United States have been delineated in the *Guide to Community Preventive Services*. These recommendations include the following: (CDC, AoA, AHRQ, & CMS, 2011):

- Reducing out-of-pocket costs for care
- Increasing annual wellness visits
- Providing routine reminders for immunizations and recommended screening tests

- Using “small” media (e.g., newspapers, radio) to raise health awareness
- Tailoring health-related messages to individual needs and risk factors
- Initiating standing orders to prevent missed opportunities for preventive services
- Reducing structural barriers to access to care (e.g., distance, hours of operation, availability of respite services)
- Expanding access to care beyond traditional health care sites to community locations
- Providing “one-stop shopping” for health care services

Considerations related to each specific level of health care are discussed below.

HEALTH PROMOTION. Health promotion among the elderly is imperative for several reasons. First, they are the fastest-growing segment of the population. In addition, they exhibit the highest prevalence of chronic illness, and finally, they use the majority of health care services. Increasing longevity necessitates a focus on health promotion and illness prevention; however, these aspects of care are often neglected among the elderly in the mistaken belief that there is little benefit to be gained for people who may already have multiple chronic illnesses.

Health promotion often depends on changes in health-related behaviors. Although we often think about behavioral change as occurring at the individual-client level, behavior-related interventions should actually occur at three levels: individual, community, and national. Population health nurses can be particularly active in promoting activity at each of these levels. At the individual level, population health nurses can educate clients to take steps to modify dietary and physical activity behaviors to promote health. At the community level, initiatives can be undertaken to change environmental factors that influence health-related behaviors. These initiatives may include public policy interventions such as designing communities to promote safe opportunities for physical activity by all age groups, but particularly for the elderly. At the national level, comprehensive campaigns can be undertaken to address widespread behavior change among either clients (e.g., the

recent campaign on weight control and physical activity) or health care providers (e.g., the development of national guidelines for preventive activities).

Population health nurses may need to actively advocate for the availability of health promotion services to older clients. They may also need to advocate among the elderly population to foster use of these services. General aspects of health promotion in the older population include maintaining independence and life resolution. More specific considerations include nutrition, rest and physical activity, and health promotion for caregivers.

Maintaining independence. Because of physical and economic limitations, it is sometimes difficult for older persons to maintain their independence. Decreased income and physical inability to care for themselves sometimes force older clients to give up their own residence and live with family members. Whatever the living arrangements of older clients, population health nurses should assist them to maintain the highest degree of independence possible. Some older clients may be able to continue to live alone if referred to supportive services such as homemaker aides, transportation services, and Meals-on-Wheels.

Maintaining independence may demand new approaches to doing things. For example, when physical limitations prohibit typical self-care activities, such as bathing or washing dishes, due to inability to turn on stubborn taps, population health nurses can suggest replacing twist-type faucet controls with lever taps or using a dishcloth or nonslip material to grip the tap handle. Developing new approaches to self-care first involves identification of the underlying problem and development of alternative techniques to achieve one's goals. Elders should be encouraged to do as much as possible for themselves and have outside assistance provided only when needed. Modifications in storage facilities to place frequently used items in handy locations may help as will the use of assistive devices such as "grabbers." In other cases it may be helpful to simplify tasks (e.g., putting all tooth brushing needs in the same place). De-cluttering areas and placing items in the sequence in which they are usually used may also be helpful. In addition, spreading active tasks throughout the day or week with ample time for rest or when pain is at a minimum may help to conserve client's energy and minimize discomfort. Environmental adaptations such as raised toilet seats, ramps rather than stairs, or moving to single-level housing may also promote continued independence (Swann, 2010).

When older persons are living with family members, the nurse can encourage family members to foster independence in the client. This may mean encouraging families to assign specific roles within the household to the older family member. Population health nurses can also be actively involved in designing and implementing programs intended to assist older clients to age in place.

Life resolution. Creating meaning for one's life is one of the developmental tasks to be accomplished by older adults. This

entails developing a personal set of goals and the ability to view one's life as having been productive. Reminiscence is one way of accomplishing life resolution and achieving positive feelings about one's own life. The population health nurse must recognize and foster older clients' need to reminisce and should encourage family members to do so as well. This is sometimes difficult given the nurse's busy schedule and the number of clients who need to be seen; however, nurses should be able to find some time during interactions with older clients to listen to these reminiscences and to help clients reflect on their lives. In spite of cognitive losses, reminiscence or "life review" has also been shown to be effective with some clients with Alzheimer's disease (Chao, Chen, Liu, & Clark, 2008).

Nutrition. Adequate nutrition is important for the older population to maintain health, prevent disease, and prevent further effects of existing chronic conditions. Adequate nutrition for health promotion frequently entails a reduction in caloric intake. Despite reduced caloric needs, older adults continue to require a balance of all other nutrients. Nutritional deficits are most frequently noted for calcium; iron; vitamins A, D, and C; the B vitamins riboflavin and thiamine; and dietary fiber. Population health nurses can promote the health of older clients by educating this population regarding their nutritional requirements.

Other, more general interventions may also be needed to improve older clients' nutritional status by eliminating impediments to good nutrition. For example, social isolation may need to be addressed because people tend to eat better in company with others. Older clients can be referred to senior nutrition centers, or family members can be encouraged to drop by at mealtimes to eat with older clients who live alone. Interventions may also be required to deal with nausea, poorly fitting dentures, or other factors that may impede good nutrition. Population health nurses may also need to be active in the development and implementation of programs to meet the nutritional needs of the older population where these services do not already exist, or in increasing access to existing services for underserved segments of the population.

As noted earlier, a significant proportion of the U.S. elderly population is obese and another group is undernourished. Worldwide, malnutrition is a common problem among seniors. The Older Americans Act nutrition program has been designed to provide an integrated diet and exercise program for the older population. The program serves a threefold purpose: to reduce hunger and food insecurity among older Americans, to promote socialization, and to promote health and well-being through access to nutrition and other health promotion and illness prevention services (AoA, 2013b).

The Older Americans Act (OAA) funds three types of nutrition programs for the elderly: congregate nutrition services (e.g., lunches in senior centers or other locales), home-delivered services, and the Nutrition Services Incentive Program (NSIP) that provides additional funds to states and territories and eligible tribal organizations for the purchase of food for senior

nutrition programs. NSIP funds can be used only for food purchase and not for preparation or other nutrition-related services, such as nutrition education (AoA, 2013b). The National Resource Center on Nutrition, Physical Activity, and Aging (n.d.b) has developed a two-part guideline to assist communities in developing senior nutrition programs. For further information about the guidelines, see the *External Resources* section of the student resources site.

Physical activity and rest. Many people believe that the need for exercise decreases with age; however, older people need exercise as much as their younger counterparts. CDC (2014c) recommendations for physical activity among older adults include muscle strengthening that works all major muscle groups on 2 or more days a week and either 150 minutes of moderate intensity aerobic activity or 75 minutes of vigorous-intensity aerobic activity or an equivalent combination of moderate and vigorous activity per week. Older clients can be encouraged to spread their activity over the day or week to avoid fatigue and discomfort.

Unfortunately, members of the older adult population often fail to engage in recommended physical activity. Barriers to physical activity among the elderly include lack of time, pain, boredom, fatigue, unsafe environments, fear of injury, lack of awareness of the need to exercise, environments not conducive to physical activity, and failure to set reasonable exercise goals. Population health nurses can help design and provide physical activity programs for older adults that address these barriers. Community-based exercise programs can have positive effects on physical activity among older clients.

The quality of rest is another consideration in caring for the older adult population. Many older adults experience insomnia that may be due to underlying disease states, medications, or use of alcohol, tobacco, or caffeine. Interventions that may assist clients with insomnia include treating underlying diseases, keeping a sleep log to determine possible triggers to wakefulness, adjusting medication regimens as needed, and promoting good sleep hygiene. The last can be accomplished by promoting exercise (particularly outdoor activity); increasing exposure to light; avoiding alcohol, tobacco, and caffeine after midafternoon; avoiding daytime naps if possible; and not working in bed. Other possible interventions include developing a relaxing bedtime routine, promoting pain control, and reducing ambient lighting an hour or so before bed (Hulisz & Duff, 2009). Population health nurses can educate clients with sleep problems regarding these strategies. They should also caution clients regarding the potential adverse effects of the use of over-the-counter sleep aids and herbal supplements because of their interactions with many prescription medications. Nurses may also refer clients for medical care of underlying diseases or for changes in medications that may be contributing to wakefulness.

Caregiver health promotion. Health promotion interventions may also be required for caregivers of older clients. The Family

Caregiver Alliance (2012) has developed several foci and action steps to enhance caregiver health and well-being as presented in Table 19-10. Population health nurses can assist caregivers to attend to their own needs and engage in the suggested activities. Population health nursing interventions related to health promotion for caregivers as well as for the older population are summarized in Table 19-11. For information on sources of assistance for caregivers, see the *External Resources* section of the student resources site.

ILLNESS AND INJURY PREVENTION. The second level of health care involves strategies to prevent specific illnesses and injuries. Several barriers to illness and injury prevention in older populations have been identified (Ogden, Richards, & Shenson, 2012). These include lack of insurance coverage and out-of-pocket costs for preventive services, although this has been somewhat minimized by preventive health provisions of the Affordable Care Act. For example, in 2011, 17 million older Americans received preventive services funded without copayments under ACA (Reid, 2011). Other barriers to preventive services include lack of providers knowledgeable about geriatric prevention needs, lack of coordination of services, and low health literacy and education levels including language difficulties. Another barrier is the existence of multiple comorbidities that require complex management (Ogden et al., 2012). For example, limited ability to stand and move makes it difficult to obtain a mammogram without specialized equipment. Major considerations in illness and injury prevention for the elderly to be addressed here include elimination or modification of risk factors and prevention of specific diseases, injury and abuse prevention, prevention of incontinence, and immunization.

Risk factor modification. Population health nurses assist older individuals and population groups to modify or eliminate risk factors for disease. This may involve interventions like

TABLE 19-10 Activities to Promote Caregiver Health

Caregiver Health Promotion Activities

- Reduce personal stress
- Set achievable goals
- Seek solutions to problems
- Communicate constructively
- Ask for and accept help
- Share personal concerns with primary care providers
- Engage in exercise
- Get adequate rest and nutrition
- Accept and deal with emotions
- Attend to personal health needs
- Participate in nurturing activities
- Change negative views
- Seek counselling as needed

TABLE 19-11 Health Promotion Strategies for Older Populations

Area of Focus	Health Promotion Strategies
Maintaining independence	Participate in the development of services that allow clients to live independently as long as possible. Promote environments that support independent living by the older population.
Life resolution	Encourage reminiscence.
Diet and nutrition	Educate public regarding nutritional needs of older adults. Assure access to nutritional foods. Eliminate social and environmental barriers to good nutrition.
Physical activity and rest	Educate the older population on the need for exercise. Participate in the development of physical activity programs that address the most common barriers to exercise among older clients. Develop programs to deal with insomnia in the elderly.
Caregiver health promotion	Assist caregivers with adjustment to caregiving. Promote caregiver independence and personal life. Educate caregivers for needed skills. Educate and encourage caregivers regarding nutrition, physical activity, and rest. Educate and assist caregivers to adapt to the effects of aging on their own abilities. Educate caregivers regarding fall prevention and medication safety. Refer caregivers for hearing and vision checks and correction services. Promote social interaction by caregivers. Refer caregivers to social support networks. Advocate for and initiate caregiver support networks. Advocate for and refer to respite care. Assist caregivers with stress management, referring for professional care as needed. Assist caregivers to develop good coping skills. Provide positive reinforcement for caregiver activities. Assist caregivers with emergency planning and execution of power of attorney. Assist caregivers in navigating the Internet and judging the credibility of information found; refer for assistance with computer literacy skills.

smoking cessation or effective management of existing health conditions, such as obesity, diabetes, or hypertension, that are risk factors for other conditions like cardiovascular disease and stroke. Treatment for diseases that increase older adults risk of subsequent health problems will be addressed in the section on resolution of existing health problems.

Smoking cessation may be beneficial for the older population in preventing smoking-attributable health problems. In fact, the U.S. Preventive Services Task Force (USPSTF, 2013) has recommended asking all adults about tobacco use and referring current users to tobacco cessation programs. In addition to the obvious cardiovascular and respiratory effects, not smoking has been associated with decreased risk for colorectal and other cancers. A 5As model has been developed to assist with smoking cessation in older adults. Elements of this model include:

1. Asking about smoking behaviors
2. Advising clients regarding the need to stop smoking
3. Assessing clients' willingness to stop smoking
4. Assisting them with smoking cessation strategies or referral to smoking cessation programs
5. Arranging for follow-up to support smoking cessation and monitor its effectiveness (AHRQ, n.d.).

Research in nine HMOs has indicated that incorporating more than just advising clients to stop smoking is associated with better success rates. Unfortunately, older clients are frequently not even advised to stop smoking much less assisted with referrals or pharmacotherapy to assist cessation. From 2002 to 2007, for example, 24% of men and 30% of women over 65 years of age reported not being counseled to stop smoking (CDC, AoA, AHRQ, & CMS, 2011). Population health nurses can refer older clients who smoke to smoking cessation programs or assist in the development of such programs. They can also campaign for access to such programs and coverage of smoking cessation under health insurance plans.

USPSTF has also made a few other recommendations for preventive interventions among older clients (as well as screening recommendations, which will be discussed later in

this chapter). Preventive recommendations include the use of aspirin to prevent myocardial infarction in men 45 to 79 years of age, and women aged 55 to 79 years. Similarly, all sexually active adults should be counseled regarding prevention of sexually transmitted diseases (STDs) whatever their age. In addition, exercise or physical therapy has been recommended along with the use of vitamin D in people over 65 years at risk for falls, but the task force recently rescinded its long-standing recommendation to combine supplemental calcium and vitamin D to prevent fractures citing a lack of sufficient evidence of efficacy. Other recommendations include dietary counseling for adults with hyperlipidemia. Finally, USPSTF has recommended against the use of hormone replacement therapy to prevent osteoporosis and cardiovascular disease in postmenopausal women (USPSTF, 2013). Recommendations change, however, with advances in knowledge. For information on current prevention recommendations for the elderly, see the *External Resources* section of the student resources site.

Injury and abuse prevention. Safety and injury prevention are areas of significant concern in the care of the older population. As we saw earlier, falls and other injuries are major contributors to disability in older populations. Risk factors for falls in the elderly include arthritis, problems with gait or balance, poor muscle strength, and vision problems. The risk of falls also increases with the number of medications taken.

Fall prevention education alone has not been particularly effective in reducing falls in the elderly. One reason is that, while older people may accept fall prevention messages, they often do not view them as relevant to themselves. Instead, older clients may be more receptive to messages that emphasize health and independence. Elements of fall prevention programs include assessment for fall risk and tailored interventions based on risk factors identified; exercise, such as tai chi; medication review for drugs that cause dizziness, drowsiness, or postural hypotension, and use of corrective lenses for vision problems (CDC, 2013a). Tai chi and other similar exercise programs for older populations have been shown to reduce falls by as much as half (NCIPC, 2013b). Elimination of safety hazards also serves to prevent falls and may include installing handrails and lights on stairs and grab bars and nonslip mats in showers and tubs; removing throw rugs, cords, and other trip hazards; providing adequate lighting; using shades and curtains to reduce glare; and wearing sturdy shoes, rather than slippers, inside and outside (CDC, 2013b).

Safe driving is another area of concern among older clients, particularly those with sensory impairments or diminished reaction times. Strategies for motor vehicle accident prevention in this age group include exercise to promote flexibility and strength, medication review, and vision assessment. Population health nurses can also encourage older clients to drive during the day and in good weather, find and plan the safest routes ahead of time, and avoid distractions while driving. They can also encourage unsafe drivers to use public transit or ride with others (NCIPC, 2013a). Unfortunately, transportation services

for the elderly are often lacking, leaving older populations with decreased mobility and diminished opportunities for social interaction.

Motor vehicles are also problematic when older people are pedestrians. In many areas, the bulk of pedestrian fatalities occur among elderly individuals. In areas where there are large numbers of elderly, nurses can campaign for traffic signals at heavily used crossings, strict enforcement of speed limits, and public awareness of the presence of older adults.

Population health nurses can initiate and participate in education campaigns related to safety issues for the older population. In addition, they can support initiatives that promote safe environments for the elderly. Finally, they may need to engage in activity to promote access to public transportation to meet the needs of the elderly, particularly those with disabilities that may limit their ability to use existing transportation systems.

Home and neighborhood safety and prevention of elder abuse are two other safety concerns with older populations. Population health nurses can be active in promoting police activity to make neighborhoods safe for older clients to move about in them. They may also be involved in the development of neighborhood watch programs and in programs to alert public safety officials that older clients are residing in particular places. This is particularly important for older disabled individuals in the community. For example, nurses can participate in the development of programs to identify homes with older residents so fire and police personnel can meet their special needs in the event of an emergency.

The last area of concern in promoting the safety of older clients is preventing abuse and neglect. Risk factors for abuse occur at the individual, relationship, community, and societal level. Individual level factors related to perpetrators of abuse include the presence of mental illness, substance abuse, high levels of hostility, poor preparation for caregiving activities, assumption of caregiving responsibilities at an early age, inadequate coping, and exposure to maltreatment as a child. Relationship factors include financial or emotional dependence on the elder, disruptive behavior on the part of the elder, and lack of formal and informal support systems. At the community level, limited or unavailable formal support services may contribute to abuse. Finally, societal factors include social tolerance for aggressive behavior, a culture in which individuals are given great freedom to make decisions for others, social expectations related to family caregiving responsibility, stoic beliefs, philosophies, and negative attitudes toward aging and elders (NCIPC, 2014b). Population health nurses can assess for the presence of these risk factors in individual situations as well as their prevalence within the population. They can also make referrals for assistance to modify risk factors and advocate for the availability of services to prevent abuse. Specific interventions for preventing abuse are discussed in more detail in Chapter 30∞.

Immunization. The Advisory Committee on Immunization Practices (ACIP) currently recommends one dose of tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis

(Tdap) vaccine for all adults, followed by tetanus and diphtheria toxoid (Td) boosters every 10 years. Other vaccines recommended for routine administration for people over 65 years of age include annual influenza immunization, two doses of chickenpox vaccine, one dose of herpes zoster vaccine (HZV) after 60 years of age to prevent shingles, and one dose of pneumococcal vaccine. Additional recommendations for older adults at particular risk of disease include meningococcal, hepatitis A, and hepatitis B immunization (CDC, 2014d). Immunization recommendations are updated, and population health nurses can obtain the most recent ACIP recommendations from the CDC website.

Immunization is an important component of prevention for older adults. (Gabriel Blaj/Fotolia)

Population health nurses can be active in providing immunization services for older adults as well as in educating the older population regarding the need for immunizations. Nurses may also be involved in the design of programs and services to meet the immunization needs of the older population, making sure that all segments of the population have access to services. Such services may be provided under standing orders in nontraditional settings, such as pharmacies, senior centers, and so on, improving the proportion of the older population that has access to immunization services.

Incontinence prevention. The last aspect of prevention to be addressed here is prevention of incontinence. Urinary incontinence may be prevented by maintaining a healthy weight, refraining from smoking, performing Kegel exercises to strengthen pelvic floor muscles, preventing constipation, and avoiding bladder irritants such as alcohol or caffeine (Mayo Clinic Staff, 2011b). Preventing fecal incontinence may involve ingesting adequate fiber and preventing constipation, avoiding foods that irritate the gastrointestinal tract, establishing a regular time for defecation, and stimulating bowel emptying on a regular basis (International Foundation for Functional Gastrointestinal Disorders, 2013b). Interventions for preventing incontinence, as well as other illness and injury prevention strategies are summarized in Table 19-12.

RESOLUTION OF EXISTING PROBLEMS. Resolution of existing health problems in the older population involves screening, diagnosis, and treatment of disease. Because of the prevalence of chronic illness, self-management of disease is another important area of emphasis in health problem resolution.

TABLE 19-12 Illness and Injury Prevention Strategies for Older Populations

Area of Focus	Strategy
Risk factor modification	Educate the older population on the need for and benefits of smoking cessation. Assist in the development of programs to assist older clients with smoking cessation.
Injury and abuse prevention	Educate public regarding safety issues for older adults. Promote exercise to strengthen muscles, bones, and joints. Eliminate environmental safety hazards. Educate older drivers regarding the hazards of driving. Promote alternative forms of transportation for older adults. Initiate or promote programs to alert fire and police personnel to older clients in specific residences. Promote family coping abilities and relieve stress to prevent abuse of older persons.
Immunization	Educate older populations regarding the need for immunizations. Provide immunization services and assure their accessibility to all segments of the older population. Develop immunization programs in places where older clients are frequently found.
Incontinence prevention	Educate older populations regarding diet and physical activity to maintain healthy weight. Encourage smoking cessation. Refer for smoking cessation assistance. Teach clients to perform Kegel exercises. Encourage avoidance of bladder irritants such as alcohol and caffeine. Encourage fiber consumption to prevent constipation.

Screening. Screening is another aspect of care that is often neglected among older clients. Many people believe that it is not necessary to engage in early detection of disease because the benefits of treatment are minimal among the elderly. A number of disease conditions can still be effectively treated in the older population, however, if found early enough. For example, older adults are perceived to have a poor prognosis for colorectal cancer, yet surgery is quite effective following early detection of disease. Screening procedures recommended by USPSTF (2013) for older adults are summarized in Table 19-13.

Population health nurses can educate older clients regarding the need for routine screening and refer them for screening services. Clients with particular risk factors or symptoms of possible disease should also be referred for screening and diagnostic services as appropriate. For example, a population health nurse might refer an older immigrant woman with a persistent productive cough for tuberculosis screening or refer a client with an elevated blood pressure for possible diagnosis and treatment of hypertension. Population health nurses may also need to advocate for access to screening services for older clients. For example, a nurse might advocate expanding breast cancer education and screening programs to target older women.

Other authorities recommend additional screening for the older population. For example, although the USPSTF has found insufficient evidence for the effectiveness of in-depth fall risk assessment, geriatric specialists have recommended a brief routine screening for fall risk, followed by in-depth assessment in those who are deemed at risk. Risk factor modification is then directed toward individual risk factors. Medicare includes fall

risk screening in annual preventive care visits (Renfro & Fehrer, 2011). A tool for fall risk screening and other screening tools for use with older clients have been developed by the Hartford Institute for Geriatric Nursing (2013). For information about geriatric fall risk assessment and other best practice interventions, see the *External Resources* section of the student resources site.

Dealing with common health problems. As noted earlier, older clients experience a variety of health problems related to the effects of aging. They are also subject to problems stemming from chronic and communicable diseases. Resolution of problems related to communicable diseases and chronic conditions is addressed in detail in Chapters 26 and 27. Here we will address interventions for some of the routine health problems commonly found in older populations. Population health nurses can assist individual clients in dealing with these problems or educate the older population in general. Some of the common problems encountered in caring for older clients include skin breakdown, constipation, urinary and fecal incontinence, sensory loss, mobility limitations, pain, and cognitive impairment. Additional problems that may be encountered by population health nurses working with this population include depression, social isolation, abuse and neglect, and substance abuse. Inadequate financial resources and the need for advocacy at individual and population levels are also areas that may be addressed by means of population health nursing interventions.

Some problems, like fecal and urinary incontinence, chronic pain, and cognitive impairment, are particularly distressing to clients and their caregivers and warrant specific consideration. Generally speaking, behavioral approaches have proven more

TABLE 19-13 Routine Screening Recommendations for Older Populations

Type of Screening	Recommendation
Abdominal aortic aneurysm	One-time screening in men aged 65 to 75 years who have ever smoked
Alcohol misuse	All adults, with referral for those with drinking problems
Colorectal cancer	All adults aged 50–75 years (fecal occult blood, sigmoidoscopy, and/or colonoscopy)
Depression	Older adults in practice settings where follow-up is available
Diabetes mellitus	Older adults with blood pressures > 135/80
Elder abuse	Insufficient evidence for or against routine screening
Hearing impairment	Insufficient evidence for routine screening of asymptomatic persons
Hypertension	All older adults
Lipid disorders	Men over age 35 and women over age 45 if at risk (total cholesterol and HDL-C)
Mammogram	Every 2 years for women aged 50–74 years Insufficient evidence for routine screening after age 75
Obesity	All older adults with referral for those with BMIs over 30 kg/m ²
Osteoporosis	Women over age 65
Papanicolaou smear	Not recommended for women over age 65 with prior normal smears and no risk factors
Prostate cancer	Not recommended because potential harm outweighs possible benefit of early detection
Tobacco use	All adult men

Source: U.S. Preventive Services Task Force. (2013). *Recommendations for adults*. Retrieved from <http://www.uspreventiveservicestaskforce.org/adultrec.htm>

effective than medication in reducing urinary incontinence. Recommended interventions include decreasing fluid intake after the evening meal, Kegel exercises, and eliminating constipation. Additional approaches may include treatment of underlying physical causes, use of prescription drugs, or modification of existing drug regimens. Bladder training may also be helpful, including withholding urination to build bladder capacity, double voiding (urinating once and then trying to urinate again a short while later) to assist with complete emptying of the bladder, and scheduled toileting. More invasive therapies are also available, such as urethral inserts and vaginal pessaries, injection of bulking agents into tissues surrounding the urethral meatus, and nerve stimulators to strengthen pelvic muscles, as well as surgical intervention (Mayo Clinic Staff, 2011b). Population health nurses may refer individual clients to such services or advocate for their availability to members of the older population.

Population health nurses may also engage in interventions to prevent consequences of urinary incontinence, such as use of absorbent pads and protective garments. Additional considerations include skin protection through good hygiene and use of barrier creams (e.g., petroleum jelly), maintaining a clear path to the toilet, and using an elevated toilet seat. In some cases structural modifications to living arrangements may be needed, such as the addition of another bathroom, or widening the bathroom doorway to permit wheelchair or walker access (Mayo Clinic Staff, 2011b).

Treatment of fecal incontinence may also employ a variety of strategies depending on its cause and severity. Population health nurses should encourage clients with incontinence to be examined by their primary care provider to identify any underlying medical conditions. In addition, population health nurses can suggest several dietary changes that may improve continence. For example, if incontinence is due to watery stools or constipation, increasing bulk in the diet may contribute to stools that are more formed and easier to control. Conversely, for some people, high-fiber diets may have a laxative effect, increasing the problem of incontinence. Specific foods that relax the internal anal sphincter (e.g., caffeine-containing beverages and foods such as coffee, tea, and chocolate) may need to be avoided. Other food and that may contribute to fecal incontinence include fatty meats, fried foods, alcohol, dairy products, cured or smoked meat, some fruits and fruit juices (e.g., apples, pears, peaches), and artificial sweeteners (National Digestive Diseases Information Clearinghouse [NDDIC], 2013; Norton, 2011).

Keeping a food diary may also allow the client to identify other foods that cause problems. Population health nurses can educate clients about other dietary strategies that may help, including ingesting an appropriate amount of fiber and drinking approximately 64 ounces of fluid per day unless fluids are otherwise contraindicated. Fluid intake should consist primarily of water; milk and drinks with caffeine, alcohol, or carbonation should be avoided (National Digestive Diseases Information Clearinghouse, 2013).

Medications may also be used in the control of fecal incontinence, but clients should be encouraged to consult their primary care providers rather than use over-the-counter remedies. Bowel training, involving development of regular bowel patterns and going to the bathroom when the urge is felt, has also been found to be helpful in dealing with fecal incontinence (Norton, 2011). Other procedures similar to those described for urinary incontinence may also be used, and population health nurses can refer clients for evaluation for these procedures as needed. They can also advocate for their availability to older clients.

Population health nurses can also assist older clients with fecal or urinary incontinence to address the psychological effects of these problems. Some easy suggestions are to carry a backpack with cleanup supplies and a change of clothing whenever one leaves the house, locate restrooms before they are needed, use the toilet before leaving home, wear disposable undergarments or sanitary pads if needed, or use oral fecal deodorants for frequent episodes of incontinence.

Chronic pain in the elderly is often overlooked or undertreated. As we saw earlier, a significant proportion of older clients experience ongoing pain that is perceived by them and by their providers and caretakers to be a normal part of aging. Others experience pain as a result of a variety of chronic illnesses. A number of barriers exist to effective pain control in the older population. These barriers may relate to providers, to clients and/or their families, or to the health system in general. Provider-related barriers include lack of expertise in pain assessment and management with older clients, concerns related to potential addiction, inability to assess pain in clients with cognitive impairment, and the previously mentioned perception that pain is normal in the aged. Client/family barriers include fear of medication side effects and addiction, reluctance to complain of pain, and, again, the fatalism exemplified in the belief that pain is a part of aging that must be accepted. Health system barriers include the cost of pain medication, insufficient time to adequately assess pain and its management during client encounters, and cultural biases in the health professions against opioid use.

Population health nurses can help educate the general public, as well as health care providers, regarding the need for appropriate pain control in the elderly. In addition, they can assist in the development of alternative options for pain control (e.g., development of and insurance coverage for acupuncture, guided imagery, and other pain relief services). Population health nursing advocacy may be required with health care providers, with family members, or within the health system to develop attitudes and services that support effective pain control for older clients. For example, the population health nurse might educate family members, or even clients themselves, regarding the improbability of addiction. Or, the nurse may need to advocate for access to pain-control services for low-income elderly clients.

Shortness of breath characteristic of advanced COPD can also be very disabling for older clients. In addition to

referring clients for medical evaluation and possible therapy with bronchodilators, steroids, and oxygen, population health nurses can assist clients with COPD in implementing a variety of strategies that may improve lung function and limit disability. The primary intervention among smokers is, of course, smoking cessation. Population health nurses can refer clients who smoke to smoking cessation programs. They may need to advocate with insurance plans for coverage of such services as necessary therapy for COPD. Other foci for COPD care include avoiding lung irritants, such as second-hand smoke, air pollution, and dust; medication compliance and follow-up care, recognizing and preparing for respiratory emergencies, and emotional support from family, friends, and health care professionals (National Heart, Lung and Blood Institute [NHLBI], 2013a, 2013b).

Population health nurses can also suggest that clients refrain from excessive use of cough medicines to control the chronic cough characteristic of COPD because they decrease clearance of secretions, making clients more susceptible to respiratory infection (Rennard, 2014). The nurse can also refer clients for pneumonia vaccine as well as annual influenza immunization to prevent infection. Nutrition is another important aspect of COPD control. Suggestions for improving the nutritional status of clients with COPD include the following:

- Resting before meals
- Eating slowly and taking small bites that are chewed thoroughly
- Choosing foods that are easy to prepare and to chew
- Asking family members to help with meal preparation
- Eating smaller, more frequent meals
- Drinking fluids at the end of the meal instead of before or with food
- Sitting up straight while eating and using pursed-lip breathing during the meal
- Obtaining meals from a local Meals-on-Wheels program
- Eating the main meal early in the day to provide energy for the rest of the day (Cleveland Clinic, 2011).

Pulmonary rehabilitation is another approach to controlling the debilitating effects of COPD. Comprehensive pulmonary rehabilitation may include education, exercise, psychosocial support, and the use of specific breathing techniques such as pursed-lip breathing, diaphragmatic breathing, and controlled coughing (Cleveland Clinic, n.d.). For information on easy-to-follow client instructions for these breathing techniques, see the *External Resources* section of the student resources site. Population health nurses can teach these strategies to clients with COPD as well as advocate for access to necessary diagnostic and treatment services.

As we saw earlier, the number of older adults with cognitive impairment is expected to increase significantly in the next few decades. In older clients, it is particularly important to distinguish among depression, dementia, and delirium, as each of these conditions may produce similar effects. Depression, as we will see in Chapter 30∞, can be effectively treated in most older clients. Treatment goals for depression in the elderly

include reduction of suicide risk, improved level of function, and improved quality of life. Older antidepressant medications (e.g., tricyclic antidepressants, or TCAs) are cardiotoxic and may be less well tolerated in the elderly than newer drugs, leading to increased risk of overdose and mortality. For this reason, these drugs should not be routinely used to treat depression in older clients. Instead, “novel antidepressants” (e.g., selective serotonin reuptake inhibitors, SSRIs) are recommended with close monitoring of treatment and adverse effects. Older clients may also be more likely than younger ones to experience “discontinuation syndrome,” a temporary condition that may include severe cognitive impairment, so they should be cautioned against abruptly stopping their medications. Population health nurses may advocate with health care providers for recognition and treatment of depression in elderly clients. They may also engage in political advocacy to assure access to treatment services for the older population. The principles of political advocacy were discussed in Chapter 9∞.

Delirium is usually characterized by a sudden onset and is generally reversible if the underlying cause is identified and treated. Some possible causes of delirium in the elderly include drug toxicity, infectious diseases, problems with elimination, exacerbation of chronic illness, or development of new disease processes. Other potential causes of delirium include changes in the psychosocial context such as a recent loss, a move to a new residence, or hospitalization. Dementia, on the other hand, is characterized by a gradual onset, progressive decline, and irreversibility.

Recently, there has been progress in the development of drug therapies to retard the progression of Alzheimer’s disease. Until a truly effective treatment is found, however, early detection and advance planning for progressive decline are the best modes of control for this condition. The most effective approaches to care of individual clients with Alzheimer’s disease combine medication, lifestyle changes, and supportive services for both clients and their families.

The goal of treatment in the face of cognitive impairment is to maintain the client’s quality of life as much as possible. Some medications may be helpful in slowing cognitive decline in clients with Alzheimer’s disease, particularly when initiated early in the disease process. Antidepressants, mood stabilizers, and antipsychotics may also be warranted for some clients although, as we saw earlier, use of these medications may lead to accidental injury in some clients. Activities that enhance cognitive capabilities may also be of some help (Chao et al., 2008; Spector, Orrell, & Woods, 2010; Yuill & Hollis, 2011). Consistent routines, reduction of environmental stimulation and triggers for agitated or aggressive behavior, and adequate rest are other interventions that may assist the cognitively impaired client.

In the past, reality orientation was recommended as a strategy for dealing with confusion in older people, particularly those with dementia. Reality orientation was a practice of reminding the client of “reality” when they strayed too far from it. For example, the nurse might persistently inform a client

with dementia that her husband would not be coming to visit her because he died 3 years ago or that she cannot find the closet because she is no longer living in her old home. Research has indicated, however, that reality orientation may result in anxiety and distress.

A more recent approach is termed **validation therapy**, a therapeutic approach to dealing with dementia by *validating* and accepting what the client perceives as reality, focusing on the emotional foundation for the belief or behavior (National Health Service, 2013). Validation therapy is based on the theory that people attempt to resolve unfinished life issues and that retreat into a specific *unreality* is an attempt to do that. It also presupposes that there is a reason for the behavior exhibited. Validation classifies dementia behaviors into four progressive stages: malorientation, time confusion, repetitive motion, and vegetation (Validation Training Institute, 2013b). In the malorientation stage, the client expresses past conflicts in “disguised forms.” For example, a client may believe that her daughter is her mother and reenact conflicts from the past. In the time confusion stage, the client retreats inward and may not be in touch with reality, but still attempts to resolve old life issues. In the repetitive motion stage, movements replace words in the attempt to resolve past conflicts, and finally, in the vegetation stage, the client gives up trying to resolve life issues and retreats from the world. In the validation approach, the caregiver (nurse or family member) accepts what the client perceives as reality and tries to redirect them without engaging in confrontations aimed at orienting them to reality. For example, a confused client may be asking when her dead husband will arrive. Rather than reminding her that he will never arrive because he is dead, the caretaker might just say, “It sounds like you really miss him,” thus exploring the emotion underlying the question.

Although validation therapy was developed between 1963 and 1980, there has been limited research examining its effectiveness in addressing the problems of dementia until recently. In the last few years, several studies have demonstrated its effectiveness in dealing with elders with dementia (Validation Training Institute, 2013a).

Advocacy may be required to be sure that treatment and supportive services are available in the community for older clients with impaired cognitive function and their families. Advocacy is also needed to support continuing research on the effectiveness of therapeutic approaches in dealing with the issues of dementia and cognitive impairment in the elderly.

Support for caregivers is another area for intervention in dealing with cognitive impairment and other problems in the elderly. A number of policy recommendations have been formulated to address the needs of caregivers. These include caregiver friendly workplace policies that promote flexibility in hours worked and time to deal with care recipients’ needs, modifying family medical leave legislation to provide better coverage, and providing funding for support services, including respite services. Additional recommendations address the need to modify Social Security requirements for persons

who leave work to care for ill family members, paying family members for care, integrating them into care planning, developing a standard definition of family care giving, and promoting research on caregiving (Feinberg et al., 2011). Population health nurses may be actively involved in advocating for these policy changes at local, state, and national levels.

The National Family Caregiver Support Program (NFCSP), funded by the Administration on Aging, has identified five core services needed by caregivers. These include information on available resources; referral to needed services; counseling, group support, and caregiver training; respite; and supplemental services (AoA, 2012). Caregivers need information regarding the older client’s condition and treatment regimen as well as the availability of services in the local community and how to obtain them. Information may also be needed on managing life changes and on dealing with financial and legal issues, particularly in the face of increasing cognitive impairment in the recipient of care. Caregivers may also benefit from counseling services that help them to cope with the physical and emotional burdens of caregiving. Counseling may prevent caregivers from being “entrapped” by their caregiving role as noted earlier. **Respite**, the provision of temporary relief from caregiving responsibilities, is often lacking for many caregivers who have 24-hour, 7-day-a-week responsibilities for the care of their aging family members. When available, respite may be provided by informal (other family members and friends) or formal support networks. Finally, caregivers may need help with obtaining needed supplies and assistive devices or in dealing with the financial burden of caregiving.

Specific intervention to address the psychological stress experienced by caregivers may also be needed. A systematic review of research on dealing with stress among caregivers identified two general approaches to dealing with caregiver stress: psychoeducational skill building and psychotherapy or counseling. Psychoeducational skill building may involve development of skills to reduce stress, behavior management skills training, depression management, anger management, or progressive lowering of caretakers’ stress threshold. Psychotherapy programs tended to focus on the use of cognitive behavioral therapy. Programs targeted toward promoting caregiver quality of life and providing combinations of skill building, education, and support services were found to be more effective than single focus programs (Gallagher-Thompson, & Coon, 2007).

Disease self-management. Effective chronic disease control requires a combination of supportive care, self-management, maintenance of function, and prevention of further disability. Over time, chronic illness requires an increasing burden of self-management.

Self-management of chronic disease requires the presence of physical, environmental, mental, and socioeconomic factors that promote effective disease management. For example, one must have the cognitive ability, economic resources, and knowledge of and access to a variety of community services

needed to manage the chronic condition. Depression is an emotional factor that may preclude an environment conducive to self-management of disease.

Effective self-management of disease is also dependent on possessing the knowledge and skills required to engage in self-management behaviors. For example, the client with hypertension will need to monitor his or her blood pressure as well as correctly take medications prescribed.

Self-management of chronic disease involves a number of activities, including symptom response and monitoring, compliance with complicated medical and lifestyle regimens, and developing the skills needed for self-management. Effective self-management of disease among older clients includes establishing treatment goals, identifying alternative methods to achieve these goals, planning short-term interventions to achieve goals, implementing the plan, and evaluating and revising the plan.

Managing medications is an important element of self-management of chronic illness. Adherence to medication regimens is affected by a variety of factors related to the condition and the complexity of therapy, physical and emotional client-related factors, social and economic factors, and health system factors. Physical client-related factors may include visual or cognitive impairment, impaired dexterity, or difficulty swallowing. Perceptions of risk and consequences and depression are examples of emotional factors that may influence adherence. Social and economic factors may include low health literacy, language difficulties, or the inability to afford medications or fit treatment elements into one's daily schedule. Finally, examples of health system factors include provider lack of effective communication skills or restricted formularies that preclude ordering medications that foster adherence (e.g., monthly injections for osteoporosis rather than daily pills or injections) (American College of Preventive Medicine, 2011).

The American College of Preventive Medicine (2011) has developed the mnemonic SIMPLE to reflect several adherence promoting strategies that can be used to foster adherence. The elements of the system and examples of related strategies are presented below:

S—Simplify the regimen as much as possible, breaking it into simple steps that fit with the client's lifestyle. Use adherence aids such as pill dispensers or organizers.

I—Impart knowledge that will foster adherence, such as the purpose of the regimen, potential consequences of nonadherence, and so on, and involve the client and family in decision making.

M—Modify client beliefs and behaviors if possible, focus on positive benefits of adherence and address fears and concerns honestly. Provide positive reinforcement.

P—Provide communication and trust. Make sure that clients understand the treatment regimen and related instructions and provide emotional support for needed lifestyle changes. Engage in active listening and allow time for questions.

L—Leave one's bias aside. Examine attitudes toward clients of different backgrounds and their effects on provider–client

relationships. Develop an understanding of clients' cultural beliefs and attitudes. Use culturally appropriate interventions.

E—Evaluate adherence. Ask about adherence at each encounter and identify and address barriers to adherence. Periodically review medication containers and prescription renewal dates (American College of Preventive Medicine, 2011).

Population health nurses may assist with this task by encouraging providers to simplify medication regimens as much as possible for older adults. Targeted interventions that assist older adults with medication adherence may also be helpful. Technological interventions such as prompting devices, electronic dispensers, monitoring devices, and data management systems may be effective for clients who can afford them, but research is needed to test their effectiveness in practice. Unfortunately, many elderly clients cannot afford these technological advances. Other, less expensive, strategies include pill organizers and telephone reminders, and population health nurses can advocate the use of such strategies with low-income clients.

With increasing drug advertising, clients may request specific drugs, and population health nurses need to be knowledgeable in answering clients' questions about drugs for their conditions. Population health nurses can also refer clients to websites that provide comparisons of the effectiveness of specific medications. Effectiveness comparisons for multiple categories of drugs can be made using an online tool developed by AARP (n.d.). For more information about the tool, see the *External Resources* section of the student resources site.

Clients may also have questions about Medicare part D prescription drug coverage benefits, and population health nurses can either educate clients themselves or refer them to other sources of information. Population health nurses may also need to advocate for effective drug coverage for older clients and assist them to select prescription drug plans that best meet their personal needs. At the national level, population health nurses also need to advocate coverage for a set of drugs most commonly used by older clients under all Medicare-approved prescription drug plans. The provisions of Medicare part D were discussed in more detail in Chapter 7.

The effectiveness of self-management of chronic illness may be evaluated based on symptom assessment and physical examination, direct indicators of disease processes (e.g., blood glucose levels), or indirect indicators of medication compliance (e.g., pill counts, prescription refills). Additional measures of effectiveness include subjective reports of clients or family members or the frequency of visits to primary health care providers or emergency departments. Interventions for addressing disease self-management and resolving other problems common among older clients are presented in Table 19-14.

HEALTH RESTORATION. Health restoration activities for older clients include restoring health and functional status as much as possible and providing palliative and end-of-life care.

Rehabilitation. Health restoration for the individual client may involve rehabilitation services, but the type of service

TABLE 19-14 Strategies for Resolving Existing Health Problems in Older Populations

Client Problem	Resolution Strategies
Screening	Refer for routine screening procedures. Refer for additional screening as needed. Advocate for coverage for disease screening. Interpret screening results and refer for diagnostic and treatment services as needed.
Skin breakdown	Inspect extremities regularly for lesions. Keep lesions clean and dry. Apply skin protectants to prevent irritation with fecal or urinary incontinence. Eliminate pressure by frequent changes of position. Refer for treatment as needed.
Constipation	Encourage fluid and fiber intake. Discourage ignoring urge to defecate. Encourage regular exercise. Encourage regular bowel habits. Use mild laxatives as needed; discourage overuse. Administer enemas as needed; discourage overuse. Administer bulk products or stool softeners as indicated.
Urinary incontinence	Refer for urological consult or treatment of underlying physical causes. Refer for modification of medication regimen as needed. Encourage frequent voiding and double voiding. Teach Kegel exercises. Decrease fluids after the evening meal. Assist with bladder training. Encourage use of sanitary pads, panty liners, etc., with frequent changes of such aids. Keep skin clean and dry; change clothing and bed linen as needed. Offer bedpan or urinal frequently or assist to bedside commode at frequent intervals.
Fecal incontinence	Refer for medical treatment of underlying causes as needed. Educate for dietary changes to address contributing factors. Encourage avoidance of caffeinated beverages and chocolate. Suggest smaller, more frequent meals. Suggest eating and drinking at different times. Encourage consumption of soluble fiber. Encourage sufficient fluid intake. Teach Kegel exercises or assist with bowel training. Suggest strategies to decrease embarrassment.
Sensory loss	Provide adequate lighting. Keep eyeglasses clean and hearing aids functional. Eliminate safety hazards. Use large-print books or materials. Use multisensory approaches to communication and teaching. Avoid using colors that make discrimination difficult. Speak clearly and slowly, at a lower pitch, avoid “elderspeak.” Eliminate background noise. Assist clients to obtain voice enhancers for phone. Use additional herbs and spices in food, but use with discretion. Purchase small amounts of perishable foods. Check pilot lights on gas appliances frequently. Encourage the use of smoke detectors.

(Continued)

TABLE 19-14 (Continued)

Client Problem	Resolution Strategies
Mobility limitation	<p>Provide assistance with ambulation, transfer, etc.</p> <p>Assist clients to obtain equipment such as walkers and wheelchairs.</p> <p>Install ramps, tub rails, etc., as needed.</p> <p>Promote access to public facilities for older persons.</p> <p>Assist clients to find alternative sources of transportation.</p> <p>Make referrals for assistance with personal care or instrumental activities as needed.</p>
Pain	<p>Plan activities for times when pain is controlled.</p> <p>Encourage warm soaks.</p> <p>Encourage adequate rest and exercise to prevent mobility limitations.</p> <p>Encourage effective use of analgesics.</p> <p>Refer for assistance with alternative pain control measures.</p>
COPD (shortness of breath)	<p>Refer for medical therapy (e.g., bronchodilators, steroids, oxygen), as needed.</p> <p>Educate regarding safety precautions with oxygen therapy.</p> <p>Encourage smoking cessation, as needed.</p> <p>Advocate for coverage of smoking cessation under health insurance plans.</p> <p>Encourage and refer for pneumonia and influenza immunization.</p> <p>Promote adequate nutrition.</p> <p>Encourage small, easily prepared and eaten meals or ask for assistance in meal preparation from family members.</p> <p>Discourage use of cough suppressants.</p> <p>Suggest taking fluids at the end of the meal rather than before or with foods.</p> <p>Refer to Meals-on-Wheels, if appropriate.</p> <p>Suggest sitting upright to eat.</p> <p>Educate client for pursed-lip breathing, diaphragmatic breathing, and controlled coughing.</p> <p>Promote physical activity as tolerated.</p> <p>Advocate for access to necessary diagnostic and treatment services.</p>
Cognitive impairment	<p>Apply principles of validation therapy, if helpful.</p> <p>Refer for Alzheimer's drug therapy as indicated.</p> <p>Refer for antidepressant, mood-stabilizing, or antipsychotic medications as needed.</p> <p>Promote exercise (register wanderers with national registry if appropriate).</p> <p>Promote activities to enhance memory (e.g., discussion of current events, games, puzzles, etc.).</p> <p>Educate families and caregivers regarding the progression of disease.</p> <p>Provide hand massage or therapeutic touch services or teach these interventions to caregivers.</p> <p>Establish consistent daily routines.</p> <p>Reduce environmental stimulation and triggers for aberrant behavior.</p> <p>Provide adequate rest.</p> <p>Promote reminiscence therapy.</p>
Depression	<p>Accept feelings and reflect on their normality; encourage client to discuss feelings.</p> <p>Refer for counseling or medications as needed.</p>
Social isolation	<p>Compensate for sensory loss; enhance communication abilities.</p> <p>Improve mobility; provide access to transportation.</p> <p>Assist clients to obtain adequate financial resources.</p> <p>Refer clients to new support systems.</p> <p>Assist clients to deal with grief over loss of loved ones.</p>
Abuse or neglect	<p>Assist caretakers to develop positive coping strategies.</p> <p>Assist families to obtain respite care or day care for older members.</p> <p>Refer families for counseling as needed.</p> <p>Arrange placement in temporary shelter.</p> <p>Assist families in making other arrangements for safe care of older clients.</p> <p>Advocate for laws and protective services systems that protect older clients from abuse.</p>

TABLE 19-14 (Continued)

Client Problem	Resolution Strategies
Substance abuse	Identify problem drinking by older clients. Refer for therapy, Alcoholics Anonymous, or Al-Anon as appropriate. Observe for toxic effects of alcohol ingestion. Maintain hydration and nutrition.
Inadequate financial resources	Refer for financial assistance. Assist with budgeting and priority allocation. Educate for less expensive means of meeting needs. Function as an advocate as needed.
Caregiver stress	Educate for needed caregiving skills. Promote behavior management skills. Promote coping skills. Refer for counseling as needed. Refer for or promote availability of respite services. Advocate policy changes and legislation to support family caregiving.
Disease self-management	Educate older clients/caregivers for disease self-management (procedures, medication management, etc.). Promote symptom management and educate for appropriate response. Promote adherence to therapeutic regimens. Promote lifestyle modification, as needed. Educate clients to recognize the need for professional assistance.

needed depends on the problems experienced by the client. For example, intervention for an abused older client may include long-term counseling for family members to prevent subsequent abuse as well as counseling for the older client to address the psychological effects of abuse. Restoration related to financial inadequacies may involve assistance with budgeting. Rehabilitation following a fracture may involve physical therapy, while recovery from a myocardial infarction will require cardiac rehabilitation. Similarly, pulmonary rehabilitation for clients with COPD may involve education for exercise training, social support, and teaching breathing techniques (Rennard, 2014). The role of the population health nurse with respect to rehabilitation for individual clients may involve referral for rehabilitation services, encouraging clients to participate fully in rehabilitation programs, and monitoring the effects of rehabilitation. At the aggregate level, population health nurses may need to advocate for the availability of or assist in designing rehabilitation services needed by members of the community as well as for adequate funding for such services.

Palliative care. Palliative care is another important consideration in health restoration with the older adult population. Because of the incurability of many chronic conditions, the only avenue open for intervention is symptom management. Palliative care addresses pain and symptom relief and maintenance of quality of life without attempting to cure an underlying disease process. The intent of palliative care is to decrease suffering and improve quality of life for both clients and families (Meier, 2010). Although often viewed in the context of end-of-life

care, palliative care is also warranted when symptom control is the primary goal of care. Important features of palliative care include relief of pain and other symptoms, effective communication with health care providers, and achievement of a sense of completion. Characteristics of palliative care include a client-centered perspective, focus on symptom relief, safety, and decreased resource utilization. Palliative care focuses on meeting the needs of clients and their families, particularly on minimizing the experience and effects of distressing symptoms such as pain, anxiety, confusion, and so on. Such care is safe in that it does not hasten death, but promotes physical and psychological comfort as death approaches. Finally, palliative care decreases resource utilization by minimizing the use of expensive technologies that offer little potential benefit for the client (Meier, 2010). Palliative care services need to be initiated in a timely fashion irrespective of disease prognosis.

Unfortunately, such services are not equitably available to older clients in the population. Population health nurses can refer individual clients to palliative care services and monitor their effectiveness. They also need to advocate for the availability and affordability of such services for all segments of the population.

Palliative care often takes place in hospice settings. Unfortunately, Medicare's requirement for hospice care includes forgoing all further curative measures and a projected life expectancy of less than 6 months (Centers for Medicare and Medicaid Services, 2012a). The need for palliative care services affects a broader population than those in the terminal stages of life-threatening illnesses. Medicare Part B and Medicaid

also cover some palliative medications and treatments (Caring Connections, n.d.; CMS, 2012b). Some hospices, particularly those in managed care systems, are now instituting separate palliative services that may be initiated prior to actual hospice care. Some managed care organizations also cover the cost of palliative care.

Population health nurses may be involved in providing palliative care to older clients and others with incurable conditions but more often provide referrals to palliative care services and monitor their effectiveness. Population health nurses may be actively involved in developing palliative care services and in advocating coverage of these services under both public and private health insurance programs.

End-of-life care. Three specific considerations must be addressed in providing effective end-of-life care to older clients. These include formulation of advance directives, personal preparation for death, and actual care of the dying client.

Advance directives are legal statements of one's wishes regarding health care in the event of incapacitation. Advance care planning may result in specific documents such as living wills or health-related powers of attorney. These documents specify circumstances in which life-sustaining treatment is or is not to be provided and appoint a surrogate to make decisions regarding life-sustaining treatments in the event of the client's incapacitation. **Life-sustaining treatment** is medical intervention to forestall death that has no appreciable effect on underlying disease processes or injuries.

To be effective, advance care planning documents must be supported by state policies, usually legislation, that promotes their implementation. The National Hospice and Palliative Care Organization (2013) provides information on the development of advance directives and its website contains links to information on execution of advanced directives in specific states. For more information about advance directives, see the *External Resources* section of the student resources site.

Population health nurses may need to encourage older clients and their families to engage in advance health care planning and to execute the appropriate documents. They may also need to advocate for compliance with advance directives by family members or health care providers when these directives have been written.

Preparation for death usually also entails a number of practical activities involved in getting one's affairs in order. Older clients may need to make decisions about funeral arrangements or the disposition of their belongings. Both nurses and family members should be encouraged to listen to clients in their reflections on such matters, rather than put them off with assurances that they "won't die for a long time yet." Population health nurses may need to advocate with family members to encourage them to address older clients' concerns about dying. Nurses may also need to refer clients for legal assistance with wills, burial plans, and other financial arrangements. Many communities have low-cost legal aid services available to elderly clients. Population health nurses should keep in mind,

however, that clients may exhibit cultural differences in their preparation for death. For example, in many cultures, such decisions are believed to be the responsibility of children, and the dying client should not be bothered. In others, discussion of death is believed to hasten its occurrence, so clients are not willing to explore plans related to their deaths.

End-of-life care begins when the focus of care shifts from cure and restoration of health to promoting a peaceful death and may occur over differing periods of time based on the "dying trajectory" in a particular situation. Dying trajectories may be of three general types. In the first trajectory the client experiences a short period of rapid decline followed shortly by death. The second trajectory involves a slow decline with periodic acute crises requiring medical intervention. In the third trajectory, the client experiences a prolonged decline and lingering death (Gabrielle, 2011).

Major considerations in end-of-life care include dealing with preparatory grief, management of pain and other symptoms, dealing with anxiety and depression, meeting spiritual needs, and assisting family members with mourning (Strada, 2013). Both clients with terminal conditions and their families engage in preparatory or anticipatory grief as a natural preparation for approaching death. At this time, population health nurses may need to assist clients and family members to deal with feelings of guilt and focus on positive aspects of life. As noted earlier, clients may also need help in getting their affairs in order. Pain management may involve both pharmacologic and nonpharmacologic therapies, and clients and families may need to be encouraged to use analgesics and other modalities to promote comfort. Similarly, medications and counseling may be needed to address issues of anxiety and depression, and population health nurses can make referrals for these services as needed. Meeting spiritual needs may mean referring client and family members to religious counselors or assisting them to address spirituality in their own ways. Finally, family members may need assistance to deal with grief after the death, again possibly requiring referral to counseling or bereavement groups. Interventions for end-of-life care and other aspects of health restoration for older adult populations are summarized in Table 19-15.

Implementing Care for Older Populations

Two major considerations in implementing care for older populations are health education directed at this group and political advocacy. Health education initiatives are based on the general principles of teaching and learning discussed in Chapter 11, but there are also some unique considerations in implementing education programs for the older adult population.

Older adults may exhibit some decline in linguistic skills with age. Auditory communication may be too fast-paced for comprehension or contain too much information to be easily comprehensible. As we saw earlier, many older adults experience hearing and vision impairments as well as cognitive impairments that may impede learning. Strategies to circumvent hearing loss include using a lower-pitched voice; facing

TABLE 19-15 Strategies for Health Restoration and End-of-Life Care in Older Populations

Area of Focus	Intervention Strategy
Rehabilitation	<ul style="list-style-type: none"> Refer clients for rehabilitation services. Encourage clients to participate fully in rehabilitation programs. Monitor the effects of rehabilitation. Advocate for available and affordable rehabilitation services. Advocate for adequate insurance coverage of rehabilitation services.
Palliative care	<ul style="list-style-type: none"> Provide palliative care to individual clients or refer them to palliative care services as needed. Monitor the effectiveness of palliative care. Advocate for the availability and affordability of palliative care services.
End-of-life care	<ul style="list-style-type: none"> Assist individual clients and families with advance care planning. Advocate for adherence to advance directives within health care systems. Assist clients and families to deal with preparatory grief. Assist clients and families to deal with feelings of guilt. Help dying clients come to some life resolution. Assist dying clients to get their lives in order. Refer for legal or other assistance as needed. Provide culturally sensitive and appropriate end-of-life care to individual clients. Provide or refer for pharmacologic and nonpharmacologic pain management. Assist with management of other symptoms. Refer for assistance with anxiety and depression. Refer for spiritual counseling if desired. Refer survivors to counseling or bereavement groups as needed. Advocate for effective state and national policies related to advance directives. Advocate for access to hospice and other end-of-life services. Advocate for changes in reimbursement for end-of-life services.

the listener while speaking; employing nonverbal teaching techniques; using clear, concise terminology; and having the client use a hearing aid if needed. The effects of hearing loss can also be minimized by limiting background noise, reemphasizing important points, and supplementing verbal with written materials.

The use of glasses, a magnifying glass, and large print may help to minimize visual deficits. Learning can also be enhanced by visual materials using black lettering on white or yellow paper, providing adequate lighting, and eliminating glare in the learning environment.

In implementing health education plans for older adults, the nurse may need to repeat material more frequently. Because of decreases in short-term memory, it may take longer for some older clients to learn new material. Once material is learned, however, older clients retain it as well as younger ones. Multisensory presentation, multiple repetitions, reinforcement of verbal content with written materials, and use of memory aids (e.g., a calendar for taking medications) may also assist learning in older clients.

Because response times are longer for older people than for their younger counterparts, lessons should proceed at a slower pace, and the nurse should allow more time for responses

on the part of the client. Self-paced instruction is helpful. Motivation to learn can be heightened by increasing client participation in the lesson and by setting easily attainable, progressive goals that enhance success and satisfaction. Irrelevant material can confuse clients and should be eliminated from the presentation.

Endurance may be somewhat limited in older clients, so teaching sessions should be kept short (10 to 15 minutes per session). Lessons should be scheduled at times of the day when learners are rested and comfortable. Health education for older clients should not be time limited, as they may need more or less time to learn specific material. Again, learning should be broken down into small, progressive steps so that periodic success will continue to motivate older learners. The teaching-learning process should also allow for rest periods as needed.

Political advocacy may be needed to implement strategies at all levels of care. Political advocacy is based on the general principles discussed in Chapter 9 but may require more effort than advocacy for other population groups in countries like the United States that are affected by pervasive ageism. Advocacy efforts may need to start at local levels, with research that documents the cost savings of health promotion strategies and effective end-of-life care. For example, it has been demonstrated

that money spent on hospice services decreases hospitalization costs. Similarly, the cost savings associated with family caregiving versus formal care can be used as justification for services to support caregivers.

Evaluating Health Care for Older Populations

Evaluating the effectiveness of health care for older members of the population can occur at the individual or aggregate level. At the individual level, the population health nurse would assess the client's health status and the effects of interventions at each level of health care (promotion, prevention, resolution, and restoration) in improving health status. On occasion, the effectiveness of care would be measured in terms of a peaceful death and the physical and emotional health of family members and caregivers.

At the aggregate level, evaluation of the effects of care on the health of the elderly can be measured, in part, by the level of accomplishment of relevant national health objectives. The status of selected national objectives for the year 2020 related to the health of older clients is found in the *Healthy People 2020* feature below.

Another approach to evaluating health care for older populations is to examine the achievement of key indicators of well-being among the elderly developed by the Federal Interagency Forum on Aging-Related Statistics (2012). Areas of focus within the indicators include population composition, health status, health risks and behaviors, health care (including access, utilization, cost, residential services, and personal assistance and equipment), and end-of-life issues. For more information about indicators, see the *External Resources* section of the student resources site.

Healthy People 2020

Selected Objectives for the Health of Older Adults (65 years or older unless otherwise indicated)

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
AHS-3 Increase the proportion of people over 65 with a usual primary care provider	90.6% (2007)	83.9%	90.2% (2010)	National Health Interview Survey (NHIS), CDC, National Center for Health Statistics (NCHS)
AHS-6 Reduce the proportion of people over 65 unable to obtain or delay obtaining medical care, dental care, or prescription medications	8.6% (2007)	9%	10.3 (2010)	Medical Expenditure Panel Survey (MEPS), AHRQ
AOCBC-2 Reduce the proportion of older adults with Dr. diagnosed arthritis who experience a limitation in activity due to arthritis or joint symptoms	48.5% (2008)	35.5%	46.7% (2011)	NHIS, CDC, NCHS
AOCBC-10 Reduce the proportion of older adults with osteoporosis	10.3% (2005–2008)	5.3%	NDA	NHANES, CDC, NCHS
AOCBC-11 Reduce hip fracture hospitalizations among older adults 11.1 per 100,000 women 11.2 per 100,000 men	823.5 (2007) 464.9 (2007)	741.2 418	NDA NDA	National Hospital Discharge Survey (NHDS), CDC/NCHS
AOCBC-12 Reduce activity limitation due to chronic back conditions per 1,000 older adults	54.0 (2008)	27.6	63.3 (2011)	NHIS, CDC, NCHS
C-1 Reduce cancer deaths per 100,000 older adults	1030.3 (2007)	161.4	985.1 (2010)	National Vitals Statistics System –Mortality (NVSS-M), CDC, NCHS

Healthy People 2020 (Continued)

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
C-3 Reduce the female breast cancer death rate per 100,000 older women	107.8 (2007)	20.7	103.7 (2010)	NVSS-M, CDC, NCHS
C-4 Reduce the cervical cancer death rate per 100,000 older adults	6.3 (2007)	2.2	5.7 (2010)	NVSS-M, CDC, NCHS
C-5 Reduce colorectal cancer deaths per 100,000 older adults	101.3 (2007)	14.5	90.9 (2010)	NVSS-M, CDC, NCHS
C-8 Reduce melanoma cancer deaths per 100,000 older adults	12.9 (2007)	2.4	13.6 (2010)	NVSS-M, CDC, NCHS
C-16 Increase the proportion of adults 65–75 years who receive colorectal cancer screening	60.4% (2008)	70.5%	67.8% (2010)	NHIS, CDC, NCHS
C-18.1 Increase the proportion of women aged 65–74 years counseled regarding mammograms	69.6% (2008)	76.8%	NDA	NHIS, CDC, HCHS
D-3 Reduce diabetes deaths per 100,000 older adults	466.5 (2007)	66.6	439.8 (2010)	NVSS-M, CDC, NCHS
DH-17 Increase the proportion of older adults with disabilities who report sufficient social and emotional support	76.6% (2008)	76.5%	76.1% (2010)	Behavioral Risk Factor Surveillance System (BRFSS), CDC, PHSP0
ENT-VSL 4.2 Increase the proportion of adults 70 years or older who have had a hearing exam in the last 2 years	38.5% (2003–2004)	42.4%	NDA	NHANES, CDC, NCHS
HDS-2 Reduce coronary heart disease deaths per 100,000 older adults	867.9 (2007)	103.4	745.3 (2010)	NVSS-M, CDC, NCHS
HDS-3 Reduce stroke deaths per 100,000 older adults	306.6 (2007)	34.8	273.1 (2010)	NVSS-M, CDC, NCHS
HDS-5.1 Reduce the proportion of older adults with hypertension	70.3% (2005–2008)	26.9%	NDA	National Health and Nutrition Examination Survey (NHANES), CDC, NCHS
HDS-6 Increase the proportion of older adults who have had their blood cholesterol level checked in the past 5 years	94.6% (2008)	82.1%	NDA	NHIS, CDC, NCHS
HDS-7 Reduce the proportion of older adults with high total blood cholesterol levels	15.3% (2005–2008)	13.5%	NDA	NHANES, CDC, NCHS
HDS-11 Increase the proportion of older adults with hypertension taking medication to lower their blood pressure	79.4% (2005–2008)	69.5%	NDA	NHANES, CDC, NCHS
IID-4.4 Decrease the rate of invasive antibiotic pneumococcal infection per 100,000 older adults	12.2 (2008)	9	10.9 (2010)	Active Bacterial Core Surveillance, CDC, NCIR
IID-13.1 Increase the percentage of older adults who receive pneumococcal vaccine	60.1% (2008)	90%	NDA	NHIS, CDC, NCHD

Continued on next page

Healthy People 2020 (Continued)

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
IID-14 Increase the percentage of adults 60 years and older who receive zoster vaccine	6.7% (2008)	30%	NDA	NHIS, CDC, NCHD
IVP-1.1 Reduce the rate of fatal injuries per 100,000 older adults	118.6 (2007)	53.7	120.6 (2010)	NVSS-M, CDC, NCHS
IVP-1.2 Reduce the rate of hospitalization for nonfatal injury per 100,000 older adults	1,878.4 (2007)	555.8	1,991.9 (2010)	National Hospital Discharge Summary (NHDS), CDC, NCHS
IVP-11 Reduce unintentional injury deaths per 100,000 older adults	101.2 (2007)	36	102.6 (2010)	NVSS-M, CDC, NCHS
IVP-23.2 Reduce the rate of fall related deaths per 100,000 older adults	47.0 (2007)	47.0	52.4 (2010)	NVSS-M, CDC, NCHS
IVP-29 Reduce homicides per 100,000 older adults	2.0 (2007)	5.5	2.0 (2010)	NVSS-M, CDC, NCHS
IVP-41 Reduce the rate of nonfatal intentional self-harm injuries per 100,000 older adults	23.5 (2008)	112.8	24.0 (2010)	NVSS-M, CDC, NCHS
NWS-9 Reduce the proportion of older adults who are obese	37.8% (2005–2008)	30.5%	37.8% (2009–2010)	NHANES, CDC, NCHS
OA-2 Increase the proportion of older adults who are up to date on a core set of clinical preventive services 2.1 Men 2.2 Women	46.3% (2008) 47.9% (2008)	50.9% 52.7%	48.5% (2010) 48.5% (2010)	BRFSS, CDC, PHSP0
OA-5 Reduce the proportion of older adults with moderate to severe functional limitations	29.3% (2007)	26.4%	30.8% (2010)	Medicare Current Beneficiary Survey (MCBS), CMS
OA-11 Reduce the rate of emergency department visits due to falls per 100,000 older adults	5,235.1 (2007)	4,711.6	6,083.2 (2010)	National Hospital Ambulatory Medical Care Survey (NHAMCS), CDC, NCHS
OH-3.2 Reduce the proportion of adults 65–74 years with untreated coronal caries	17.1% (1999–2004)	15.4%	NDA	NHANES, CDC, NCHS
OH-3.3 Reduce the proportion of adults 75 years and older with untreated root surface caries	37.9% (1999–2004)	34.1%	NDA	NHANES, CDC, NCHS
OH-4.2 Reduce the proportion of adults 65–74 years who have lost all of their natural teeth	24% (1999–2004)	21.6%	15.3% (2009–2010)	NHANES, CDC, NCHS
PA-1 Reduce the proportion of older adults who engage in no leisure time physical activity	50.4% (2008)	32.6%	45.2% (2010)	NHIS, CDC, NCHS
RD-1.3 Reduce asthma deaths per 100,000 older adults	43.4 (2008)	21.5	37.7 (2010)	NVSS-M, CDC, NCHS

Healthy People 2020 (Continued)

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
RD-10 Reduce COPD deaths per 100,000 older adults	283.1 (2007)	102.6	287 (2010)	NVSS-M, CDC, NCHS
SA-12 Reduce drug-induced deaths per 100,000 older adults	4.4 (2007)	11.3	4.9 (2010)	NVSS-M, CDC, NCHS
TU-1.1 Reduce cigarette smoking by older adults	9.3% (2008)	12%	7.9% (2011)	NHIS, CDC, NCHS
TU-4.1 Increase smoking cessation attempts by older adult smokers	41.6% (2008)	80%	41.6% (2011)	NHIS, CDC, NCHS
V-5.4 Reduce the rate of visual impairment due to cataracts per 1,000 older adults	110.0 (2008)	99	NDA	NHIS, CDC, NCHD
V-5.5 Reduce the rate of visual impairment due to age-related macular degeneration per 1,000 older adults	34.0 (2008)	14	NDA	NHIS, CDC, NCHD

CHAPTER RECAP

Myriad theories attempt to explain aging, but these theories can be grouped into three main categories. Biological theories address physiologic changes that occur over time leading to the physical changes exhibited in older adults. Psychological theories focus on psychological changes that occur with age and propose that effective aging requires development of effective coping strategies over time. Sociological theories of aging focus on changes in roles and relationships that occur with advancing age.

Factors related to each of the six categories of determinants of health influence the health of older individuals and populations. Biological determinants include the age and gender composition of the older population, physical effects of aging, chronic conditions, and resulting functional limitations, as well as the immune status of the population. Some important psychological determinants include the prevalence and effects of dementia, sources of stress, coping abilities, and depression and other mental health problems. Environmental determinants reflect the fit of older individuals and populations with their environment and include housing and physical safety hazards, neighborhood characteristics, environmental pollution, and so on. Several sociocultural determinants affect the health of older populations including living arrangements and family responsibilities; social support;

education, employment, and economic status; level of empowerment, and the prevalence of abuse and violence against the elderly. Behavioral determinants to be considered in assessing the health of the older population include diet and other consumption patterns, physical and sexual activity, medication use, and other health-related behaviors, such as safety practices and use of preventive services. Finally, health system determinants affecting the health of older populations include access to and use of health care services, prescription drug use, infrastructure support, and relationships with providers.

Population health nursing interventions for older clients and populations address health promotion, illness and injury prevention, resolution of existing health problems, and health restoration. Health promotion foci include maintaining independence, fostering life resolution, promoting a healthy diet and adequate physical activity and rest, and fostering caregiver health. Illness and injury prevention center on risk factor modification, injury and abuse prevention, immunization, and preventing incontinence. Resolution of health problems may involve a wide variety of population health nursing interventions depending on the problems experienced, but can be grouped into strategies related to screening, care for common

health problems in the older population, and disease self-management strategies. Intervention foci in health restoration may involve return to a prior state of health or preparation for dying and address rehabilitation, palliative care, and end-of-life care for older clients and their families.

Special considerations in implementing care for older clients focus on strategies for health education that address the charac-

teristics of the older population and advocating for policies that support the health and well-being of the elderly. Finally, evaluation of the effectiveness of care for older populations addresses resulting changes in health status for individual clients as well as determination of population level effects. Either *Healthy People 2020* objectives or key indicators of well-being can be used to frame evaluation at the aggregate level.

CASE STUDY

Promoting Physical Activity in Older Adults

A small non-profit community center in a large metropolitan area strives to meet the needs of its population of approximately 70,000 people. About 6% of the population is elderly, and like most of the community, they have very low incomes. The community is home to people who speak more than 30 different languages, and providing care for seniors in the community is a challenge. Fortunately, the agency staff include a number of multilingual individuals, so translation is not often a problem. For several years, the community center has provided a senior lunch program and employed a population health nurse who assists elderly clients with a variety of health needs.

One of the nurse's routine tasks is blood pressure monitoring for the seniors who attend the lunch program. Over time, the nurse became aware of the high prevalence of hypertension and obesity in the population. As a result, in addition to

the lunch program, the center added an exercise program for seniors several days a week. Grant funds were obtained to hire an exercise coach and now 50 to 60 seniors gather for each session. The exercise program has provided another avenue for social interaction for often isolated seniors as well as for improving their weight, flexibility, and blood pressures.

1. What biological, psychological, environmental, socio-cultural, behavioral, and health system determinants are evident in this situation? What additional factors in each category might be influencing the health of these seniors?
2. What levels of health care are represented by the exercise program, the senior lunch program, and blood pressure monitoring activities?
3. How might you evaluate the effects of the exercise program? Of the nutrition program?

20 Care of Gay, Lesbian, Bisexual, and Transgender Populations

Learning Outcomes

After reading this chapter, you should be able to:

1. Discuss concepts related to gender identity and sexual orientation.
2. Identify determinants of health affecting gay, lesbian, bisexual, and transgender individuals.
3. Describe health promotion and illness/injury prevention measures appropriate to the care of the GLBT population and population health nursing roles in each.
4. Identify areas of focus in resolving existing health problems in the GLBT population and related population health nursing roles.
5. Describe considerations relevant to restorative health care for the GLBT population and the population health nursing roles related to each.

Key Terms

biphobia

cisgender

coming out

disclosure

gender dysphoria

gender expression

gender identity

gender nonconforming individual

gender role conformity

hate crimes

heterosexism

homophobia

minority stress

second-parent adoption

serosorting

sexual orientation

syndemic

transgender individuals

transphobia

transsexuals

Lesbian Health Care

The 1970s saw an emphasis on gay liberation, coming out, and demands for equitable treatment. Access to culturally sensitive health care for lesbians (and other members of the gay, lesbian, bisexual, and transgender [GLBT] population) lagged significantly behind other social changes. Joan Waitkevicz, a lesbian physician, teamed with several other lesbian health activists to establish the St. Mark's Women's Health Collective. The intent of the clinic was to provide a source of safe comfortable care for lesbians in New York City. Subsequently, Dr. Waitkevicz became involved in the Gay Women's Focus at Beth Israel Medical Center, the first hospital-based health center for lesbian women (Labaton, 2012).

Winning Freedom from Discrimination

Members of the GLBT population have been subjected to continuing discrimination in large and small ways. For years, the Boy Scouts of America (BSA) expressly forbade gay boys from membership in the organization. In May of 2013, however, a grassroots coalition of organizations campaigned for and won a removal of the prohibition on gay scouts. Petitions were initiated on websites such as change.org and were signed by more than 300,000 people and the campaign was covered by major news media and magazines. Contacts were made with prominent BSA board members who were CEOs of major U.S. companies. In addition, major corporate donors to BSA, such as Intel and UPS, were convinced to suspend their funding to the organization until the ban was lifted, and *National Geographic* called for change. Gay Eagle Scouts also persuaded the band Train to refuse to perform at a scheduled Boy Scout concert. In addition, seven members of the U.S. House of Representatives signed a letter advocating for the reform. Despite this success, however, BSA still prohibits GLBT adults from functioning as Boy Scout leaders, and further advocacy is needed to achieve complete equality within the organization (Scouts for Equality, 2013).

Variations in sexual orientation and gender identity have been present throughout recorded human history, but, until recently, they have been deemed aberrations and have rarely been considered in terms of their implications for health and health care delivery. Collectively, people who exhibit these variations are referred to as the GLBT community or population. Despite some similarities among different elements of the GLBT population, they display a diverse range of age, racial/ethnic, and socioeconomic characteristics as well as variation in sexual orientation (Institute of Medicine [IOM], 2011). Members of this population experience health issues that are both similar to and different from their heterosexual or "straight" counterparts, and population health nurses must be prepared to provide health care to effectively meet their needs. In addition, population health nurses may be actively involved in advocacy to assure provision of service to this population.

Sexual Orientation and Gender Identity

Before examining the health-related needs of the GLBT population, it is important to define some related concepts. **Sexual orientation** refers to one's preferred choice of sexual or romantic partners or the gender(s) of people to whom one is attracted. Attraction may be to people of one's own sex, the opposite sex, or both sexes. Sexual orientation comprises three aspects: attraction, behavior, and identity (IOM, 2011, p. 27). Commonly used terms for different sexual orientations include *heterosexual*, *homosexual*, and *bisexual*. Heterosexual or straight individuals are primarily attracted to members of the opposite biological sex, while homosexual individuals are attracted primarily to members of their own biological sex. Bisexual individuals are attracted to members of both sexes. These preferences constitute the attraction aspect of sexual

orientation. The behavioral aspect reflects one's actual sexual behavior or activity with members of one sex or the other. The identity aspect of sexual orientation reflects one's sense of self as a member of a particular social group based on a shared orientation (IOM, 2011). For example, women who identify themselves as lesbian share a sexual or romantic preference for other women, while gay men prefer other men.

There is no general consensus on the use of the terms *heterosexual*, *homosexual*, and so on, primarily because the terms are defined differently by different groups. Sexual orientation is culturally defined, and what is considered homosexual in one culture may not be in another, even if it involves same-sex sexual activity (Martinez-Donate et al., 2010). For example, some men who self-identify as straight have sexual intercourse with other men, and are commonly referred to as "men who have sex with men" or MSM. Sometimes such same-sex behavior is situational, as in the case of prisoners who do not have access to members of the opposite sex. In other cases, it may involve casual sexual encounters with members of the same sex.

Similar lack of clarity occurs in definitions of bisexuality. For instance, men who self-identify as gay may also have sexual interactions with women, but do not consider themselves bisexual. Similarly, women who self-identify as lesbian may also have sexual encounters with men. For the purposes of this book, self-identification as a gay, lesbian, bisexual, or transgender individual will be used as the primary means of distinguishing membership in these groups. Readers should be aware, however, that different definitions have been used in some of the research that will be reported here. Where relevant, the terms "men who have sex with men" (MSM) or "women who have sex with women" (WSW) will be used since they encompass both gay/lesbian and bisexual individuals as well as some who self-identify as straight despite occasional same-sex sexual activity.

Synnott (2009) described four perspectives on sex or gender: anatomical, chromosomal, hormonal, and psychological. The anatomical perspective relies on sex-specific internal and external organs (e.g., a uterus, penis, prostate, etc.); the chromosomal perspective is based on the number of X and Y chromosomes one possesses. In the hormonal perspective, one's sex is defined by the balance of male and female hormones. The final perspective involves one's felt identity or gender identity.

Gender identity differs from sexual orientation in that it reflects one's perception of self as a man or woman, boy or girl. One's gender identity may or may not correspond to one's biological sex. Transgender individuals are born anatomically one gender, but identify with the other, with both genders (bigender individuals), or neither (Synnott, 2009; Wilson et al., 2010). Transgender individuals are a diverse group whose members do not conform to culturally defined gender expectations (Bockting, Miner, Romine, Hamilton, & Coleman, 2013). They may differ in terms of their gender identity, gender presentation or expression, or sexual orientation. Transgender individuals may or may not exhibit **gender role conformity**,

the extent to which one adheres to cultural norms for his or her anatomical sex. Depending on circumstances, they may conform to their birth sex, their self-perceived gender, or both at different times. **Cisgender** refers to an individual whose self-perceived gender is congruent with his or her assigned birth gender (National Coalition of Anti-Violence Programs, 2013). **Gender expression** is how one presents oneself as masculine or feminine (or possibly neither) in terms of personality, appearance, and behavior (IOM, 2011). A **gender-nonconforming individual** is one who by nature or choice does not conform to societal gender expectations (Parents, Families, and Friends of Lesbians and Gays [PFLAG], n.d.a). **Transgender individuals** are persons whose gender identity does not match their assigned birth gender (PFLAG, n.d.b). Members of the transgender community view this as an all-encompassing term that includes cross-dressers, drag kings and queens, and transsexuals although not all of these individuals self-identify as members of the other gender. For example, a drag queen may be a biological male who dresses as a female, but still considers himself male. **Transsexuals** are persons who believe they were born into the "wrong" body and are actually members of the opposite gender. Transsexual is sometimes used to distinguish those who have undergone sexual reassignment surgery (SRS) to change their anatomical appearance to that of members of the opposite gender. In the transgender community, the preferred term for this surgical procedure is "gender recognition surgery" denoting recognition of their appropriate gender identity. Women who have surgical procedures to become men

Transgender individuals identify as members of the opposite gender and dress and act accordingly. (Karen Struthers/Fotolia)

are known as female-to-male (FTM) transgenders, transmen, or transguys. Men who undergo SRS may be known as male-to-female (MTF) transgendered individuals or transwomen (UC Berkeley Gender Equity Resource Center, n.d.). Transgender individuals may exhibit different sexual orientations as well. For example, MTF transgender persons may be attracted to men, other women, or both. On occasion, MTF transgender individuals may be labeled as MSM, although they consider themselves women who have sex with men. Similarly, FTM transgender individuals who have sex with transwomen consider themselves straight.

Additional definitions describing the diversity of gender identity and sexual orientation are presented in Table 20-1.

Determining the Size of the GLBT Population

Although differences in sexual orientation and sexual identity are becoming more socially acceptable, continuing stigma may preclude many people from living openly or acknowledging

membership in the GLBT population. This makes it difficult to accurately determine the size of the gay, lesbian, bisexual, and transgender populations. Inferences regarding the extent of sexual and gender diversity are often drawn from related data. For example, 2005 Census Bureau data included more than 770,000 same-sex couples in households throughout the United States, many of whom are probably gay or lesbian couples. Census data, however, probably underrepresent the GLBT population due to fear of exposure or differences in definitions. In an American Community Survey, an estimated 8.8% of the U.S. residents self-identified as gay or bisexual. In other estimates, as many as 7% of women may self-identify as lesbian, and 8% of men as gay or bisexual (Buffie, 2011). In the 2010 National Survey of Sexual Health and Behavior, 6.8% of men, and 4.5% of women self-identified as homosexual, gay, lesbian, or bisexual, while the estimated size of the transgender population varies from 1 person per 2,900 men in Singapore to 1 per 100,000 in the United States. Comparable ratios for women are 1:8,300 for Singapore and 1:400,000 U.S. women (IOM, 2011).

TABLE 20-1 Definitions of Terms Related to Gender Identity and Sexual Orientation

Gender Identity Terminology	Definition
Bigender person	One who identifies as both man and woman. May take hormones and live part-time in the cross-gender role.
Cisgender/gender-straight/gender-normative	A person who by nature or choice conforms to social gender-based expectations for his or her anatomic sex.
Cross-dresser (previously transvestite)	One who adopts the clothing and behaviors of the opposite sex for emotional or sexual gratification. May live part-time in the cross-gender role.
Drag kings or queens	Persons who dress in the clothing of the opposite gender and adopt a hyperfeminine or hyper-masculine presentation. May live part-time in the cross-gender role often in the context of a performance. Does not necessarily indicate sexuality or gender identity.
Gender diverse	One who does not conform to societal gender-based expectations
Gender fluid	One whose gender identification shifts with time and circumstances.
Gender nonconforming individual	One who, by nature or by choice, does not conform to normative gender expectations
Gender queer/two spirit	One who possesses both masculine and feminine characteristics, who may or may not desire hormones or surgery and may or may not live full- or part-time in the cross-gender role.
Pangender	One whose gender identity involves multiple gender expressions.
Transgenderists	Persons who live full-time in the cross-gender role. They may take hormones, but do not desire surgery.
Transsexuals	Persons who desire to or actually engage in masculinization or feminization of the body by means of hormones and/or surgery and live full-time in the cross-gender role.
Sexual Orientation Terminology	Definition
Asexual	One who is not sexually attracted to either gender.
Bisexual	One who is sexually or romantically attracted to two sexes (man and woman, transsexual, or any combination of them). The attraction may not be simultaneous or of equal intensity.
Gay/gay man	A man who is sexually or romantically attracted to other men.
Homosexuality	Sexual, emotional, or romantic attraction to persons of one's same sex.
Lesbian	A woman who is sexually or romantically attracted to other women.
Pansexual	One whose sexual orientation or gender identity is fluid.
Straight	One attracted to a gender other than his or her own.

Based on: Institute of Medicine. (2011). *The health of lesbian, gay, bisexual, and transgender people: Building a foundation for better understanding*. Washington, DC: National Academies Press; UC Berkeley Gender Equity Resource Center. (n.d.). *Definitions of terms*. Retrieved from http://geneq.berkeley.edu/lgbt_resources_definition_of_terms

From 2001 to 2009, only nine sites participating in the Youth Risk Behavior Surveillance System asked questions about sexual orientation, with a median of 93% of teens reporting a heterosexual orientation, 1.3% gay or lesbian, and 3.7% bisexual. An additional 2.5% of youth were unsure regarding their sexual orientation. Twelve sites assessed only sexual contact, for which 53.5% reported intercourse with the opposite sex only, 2.5% with the same sex only, and 3.3% with both sexes (Kann et al., 2011). The Guttmacher Institute (2014), on the other hand, has reported estimates of 3% of 18- to 19-year-old males and 8% of females self-identifying as homosexual or bisexual. The number of women who have sex with women may be particularly hard to determine as they tend to be a more hidden population than MSM, and women living together are less likely to be viewed in a sexual relationship than men in similar circumstances.

Population Health Nursing and Care of GLBT Populations

Population health nurses may find that they need to design and implement health care programs to meet the needs of the GLBT population in their area. They may also be involved in advocating for this population at local, regional, national, or international levels. In doing so, they will make use of the elements of the nursing process, assessing the needs of the population, planning and implementing care, and evaluating the effects of interventions in terms of GLBT health.

Assessing the Health of GLBT Populations

Assessing the health status of gay, lesbian, bisexual, and transgender populations involves determining factors related to the six categories of determinants of health that promote or impede health and healthy behaviors.

BIOLOGICAL DETERMINANTS. Biological determinants related to the health of the GLBT population include maturation and aging and the presence of physical illnesses. Although GLBT culture emphasizes youth, there is a significant older population among members of the population. There are an estimated 1 to 3 million older sexual minority group members in the United States (Wight, LeBlanc, de Vries, & Detels, 2012), and the older GLBT population is expected to increase to 6 million members by 2030. Because of their marginal status in society, older GLBT persons may have more difficulty than others in obtaining assistance in old age, creating a population of particular concern to population health nurses. All of the health problems typical of old age are compounded by the stress of sexual minority status and resulting stigmatization and discrimination (IOM, 2011). Older gay men, who lived through the early stages of the HIV epidemic, may be at particular risk of lack of social support in old age due to having outlived many of their peers. Similarly, GLBT adolescents may experience more health problems than their straight counterparts due to the added stress of stigma and discrimination.

Members of the GLBT population also tend to be at greater risk for a number of physical health problems than the general population. In part, this is due to the greater prevalence of high-risk behaviors in this population, as well as to reluctance to seek medical care. Much of the attention given to health issues in this population to date has focused on the extent of sexually transmitted infections (STIs). For example, MSM account for most of the new syphilis diagnoses in many health department jurisdictions (Mayer, 2011). Many MSM with primary and secondary syphilis are co-infected with HIV (Cohen et al., 2012), but MSM often do not perceive themselves to be at risk for HIV infection. For example, in the 2008 National Health Behavior Survey, the prevalence rate of HIV infection among young MSM in 21 cities was 19%, yet nearly half of these men (44%) were unaware of their infection. Lack of awareness was even more likely in young MSM from ethnic minority groups (Smith et al., 2010). From 2001 to 2006 there was a 93% increase in new HIV infections among young Black MSM in 33 states and a 144% increase in the state of Wisconsin between 2000 and 2008 (Biedrzycki et al., 2011). More recently, up to 28% of African American MSM have been reported to be HIV-positive compared to 16% of White MSM, and the rate of incidence among this group is growing faster than among other high-risk groups (Fields et al., 2013). MSM accounted for 53% of all new HIV diagnoses in 2006 (Parsons, Grov, & Golub, 2012). HIV incidence is also high among MTF transgender women (Wilson et al., 2010). Women who have sex with women and bisexual women have also been found to be at greater risk for *Chlamydia trachomatis* infection than those who are exclusively heterosexual (Singh, Fine, & Mrazek, 2011).

Members of the GLBT population experience other health problems at higher rates than the general population. For example, lesbian women have been found to be twice as likely to be obese as other women, placing them at greater risk for cardiovascular and other weight-related problems (Boehmer et al., 2011). Similarly, transgender individuals have higher rates of obesity than the general population (Conron, Scott, Stowell, & Landers, 2012). Gay men, on the other hand, are less likely than their straight counterparts to be obese or overweight (Conron, Mimiaga, & Landers, 2010). In addition, lesbian women are less likely than other women to bear children, increasing their risk of breast cancer (Allina, 2012).

Membership in dual minority groups may also adversely affect physical health status. For example, Hispanic lesbian and bisexual women were found in one study to have higher rates of asthma and disability, and Hispanic bisexual women reported more arthritis and poorer overall health than either Caucasian lesbian and bisexual women or straight Hispanic women (Kim & Fredriksen-Goldsen, 2012). Based on Behavioral Risk Factor Surveillance System (BRFSS) data for Massachusetts, members of sexual minority groups, in general, were more likely than others to report activity limitations, tension, smoking, drug use, and asthma. No differences were noted, however, with respect to the incidence of diabetes or heart disease (Conron et al., 2010).

In addition to higher rates of disability, gay, lesbian, and bisexual individuals have been found to experience disability at younger ages than the general population (Fredriksen-Goldsen, Kim, & Barcan, 2012). Mortality rates, however, are no higher for MSM than for other men, when HIV-related mortality is excluded (Cochran & Mays, 2011).

For transgender individuals, measures to modify anatomical structures may have health consequences as well as benefits. For example, feminizing hormones may increase one's risk of venous thrombosis and pulmonary embolism. Other potential adverse effects include gallstones, liver disease, pancreatitis, and glucose intolerance. Conversely, although estrogen therapy may increase stroke and coronary heart disease risk in straight women, it does not seem to do so in transgender MTF women and may actually shift lipid profiles to a more typical female pattern resulting in a protective effect. Masculinizing hormones used by FTM transgender individuals may lead to acne, weight gain, possible polycythemia, liver disease, insulin resistance, fluid retention and edema, and increased risk of cardiovascular disease due to a shift to a typically masculine lipid profile. Finally, FTM transgender individuals may experience bone mineral loss following oophorectomy without regular testosterone use (Gender Centre, 2013). Population health nurses should be alert to these problems in individual transgender clients and to increased incidence in the transgender population. Another problem is that hormones may be perceived as a cause of medical problems when there is some other underlying disease process involved.

Immunity is another consideration related to biological determinants of health in the GLBT population. In addition to routine immunizations suggested for adults, sexually active gay, bisexual, and transgender men and women should also receive immunization for hepatitis A and B. Population health nurses should assess immunity among individual clients as well as levels of immunity in the gay, bisexual, and transgender population at large.

PSYCHOLOGICAL DETERMINANTS. Homosexuality, or same-sex attraction, was considered a psychiatric disease by the American Psychiatric Association from 1952 until 1973. The 1952 *Diagnostic and Statistical Manual of Mental Disorders* (DSM) included homosexuality as a sociopathic personality disorder leading to widespread laws that criminalized homosexuality activity and prohibited employment and licensure in several occupations. Although homosexuality was removed as a psychiatric disorder from later versions of the DSM, gender identity disorder and gender dysphoria were added as psychiatric diagnoses (IOM, 2011). **Gender dysphoria** has been defined as serious discomfort or distress related to one's biologically defined sex. Gender dysphoria has been retained as a diagnosis in the DSM-5 (American Psychiatric Association, 2013), but has been separated from the sexual dysfunction section of the manual. The reported intent of the diagnosis and related chapter is to promote care for individuals who experience severe distress related to the incongruence between their self-perceived gender identity and their biological sex. Relabeling of the diagnosis as

gender dysphoria versus gender identity disorder is also intended to diminish the perception of pathology related to gender-atypical behavior (Moran, 2013). Generally, gender dysphoria is diminished in most individuals who experience sexual reassignment surgery. In the interim, however, population health nurses may need to be particularly alert to suicidal ideation in individuals who exhibit severe gender dysphoria.

Although GLBT individuals do not appear to be any more intrinsically susceptible to mental illness than their straight counterparts, there is some evidence to suggest that they have a slightly higher prevalence of mental illness, possibly as a result of "minority stress." **Minority stress** is the stress associated with being a member of any stigmatized minority group (Buffie, 2011). Many mental health problems in the GLBT population are linked to the discrimination experienced in interactions with the straight world. For example, meta-analysis of related research has indicated a lifetime prevalence of depression and anxiety disorders one-and-a-half times higher in gay, lesbian, and bisexual individuals than in the straight population (Choi, Paul, Ayala, Boylan, & Gregorich, 2013).

A person who realizes that he or she is gay, lesbian, bisexual, or transgender has three basic choices. She or he can live openly as a member of a sexual minority group risking potential rejection by family, loss of one's job or professional reputation, and societal labeling and abuse. Denial is a second option that requires considerable expenditure of energy in fulfilling the accepted gender. Finally, he or she can live a sexually diverse life but maintain a straight appearance.

GLBT individuals who do not live their identities openly must deal, on a daily basis, with the fear that others will discover who they really are. This involves the complex task of vigilance about how they look and act, where they are, who they are with, and what they say. This may mean constantly monitoring responses and changing pronouns to misrepresent the identity of partners. They must hide from coworkers, family, or friends important life events such as a new relationship or the breakup of an old one. Although they grieve such losses, their grief is not sanctioned by society and is another source of hidden stress. Transgender individuals also run the risk of rejection and physical assault if their biological gender is discovered or, if they continue to maintain a cross-gender role in some venues, if their transgender activities are discovered. Recently, members of the GLBT community have also had to deal with increased fears of being "outed" by other, more militant individuals. *Outing* involves publicizing another's sexual orientation without their consent.

GLBT individuals may internalize societal discrimination and prejudice leading to low self-esteem and depression. The phenomenon of internalization is supported by findings that enactment of legislation limiting marriage to a man and a woman in 14 states resulted in significant increases in the incidence of psychiatric problems in the GLBT population in those states, compared to no increase in states without such bans (Buffie, 2011). Internalization among young MSM may lead to risky sexual behaviors and increased potential for sexually transmitted infections (Halkitis et al., 2013).

Members of the GLBT population are subject to overt discrimination as well as to the stress of inadvertent or insensitive comments by others who do not recognize them as gay, lesbian, bisexual, or transgender individuals. Due to the stigma of membership in a sexual minority group and the potential for retaliation, they are also faced with the quandary of whether to actively work for equality or remain hidden from public view (Buffie, 2011). Data from the National Transgender Discrimination Survey, for example, indicated that transgender individuals were routinely subjected to discrimination in educational, employment, public service, and health care settings (Grant et al., 2011). Mental health problems are also associated with stigmatization among transgender individuals. In one study, for example, 44% of transgender individuals reported depression, 33% reported clinical anxiety, and 27.5% reported somatization (Bockting et al., 2013).

Members of sexual minorities are more likely than the general population to be exposed to violence and

traumatic events at earlier ages and may be at greater risk for posttraumatic stress disorder (Roberts, Austin, Corliss, Vander Morris, & Koenen, 2010). Suicide is a significant problem in GLBT populations, particularly among youth. The lifetime risk of suicide for gays, lesbians, and bisexuals is nearly two-and-a-half times greater than that of the straight population (Choi et al., 2013), and risks are even higher for ethnic minority gay, lesbian, and bisexual youth (O'Donnell, Meyer, & Schwartz, 2011). Similarly, three fourths of Caucasian transgender individuals reported suicidal ideation, and 64% of those had attempted suicide (Nemoto, Böedeker, & Iwamoto, 2011). Population health nurses should be alert to the presence of mental health problems in GLBT individuals as well as to a high incidence of problems in this population. As we will see later, they can make referrals for mental health services as needed as well as work to minimize factors that contribute to mental health problems among GLBT individuals.

Global Perspectives

Protecting the Rights of Sexual Minorities

In December of 2008, Senegal hosted the International Conference on AIDS and Sexually Transmitted Infections in Africa. Later that same month nine members of a non-governmental agency focused on HIV prevention and support for those with AIDS were convicted of homosexuality and given 5-year prison terms (Moody, 2009). Although the convictions were later overturned due to international outcry, they are representative of the circumstances faced by GLBT individuals throughout the world.

Several authors have noted the need for both research and policy formation related to global issues of sexual minority populations. The Global Research and Advocacy Group (2013) has included sexual minority issues as one element of its global

research agenda. Similarly, Fabrice Houdart, the country officer for the Central Asia arm of the World Bank, has called for research into the economic and societal costs of homophobia and transphobia as a precursor for action to support development to assist poor sexual minority group members, and has suggested mobile telephone applications as a means of collecting data from, educating, and mobilizing sexual minorities throughout the world (Houdart, 2012a, 2012b).

With respect to global policy, a diverse group of human rights experts developed the Yogyakarta Principles, applying the principles of international human rights law to the support of members of sexual minority groups. These principles and their application to the GLBT population are summarized in the following table.

Application of International Human Rights Law to Sexual Orientation and Gender Identity

Principle	Application to Sexual Orientation and Gender Identity
1. The right to universal enjoyment of human rights	<ul style="list-style-type: none"> • Incorporate GLBT rights into national constitutions • Amend legislation that impinges on human rights for GLBT individuals • Educate people to promote enjoyment of human rights irrespective of sexual orientation or gender identity • Recognize all aspects of human identity including sexual orientation or gender identity in policy making
2. The right to equality and nondiscrimination	<ul style="list-style-type: none"> • Embody principles of nondiscrimination based on sexual orientation or gender identity in national constitutions • Repeal criminal or other legal provisions that prohibit consensual same-sex activity • Prohibit or eliminate discrimination based on sexual orientation or gender identity • Take measures to ensure equal advancement of persons of diverse sexual orientation or gender identity • Take action to eliminate prejudicial or discriminatory attitudes or behaviors based on sexual orientation or gender identity

(Continued)

Principle	Application to Sexual Orientation and Gender Identity
3. The right to recognition before the law	<ul style="list-style-type: none"> • Assure abilities of GLBT persons to enter contracts or own property • Take legal measures to respect and recognize each person's self-defined gender identity • Take legislative action to assure that legal documents reflect the person's self-defined gender identity • Ensure that such procedures respect the privacy of GLBT individuals • Ensure that changes to identity documents are recognized in all contexts where gender identification is required by law • Provide social support for persons undergoing gender transition or reassignment
4. The right to life	<ul style="list-style-type: none"> • Repeal all legislation that prohibits consensual sex, and in the interim refrain from imposing the death penalty for such actions • Remit existing death sentences for consensual same-sex activity • Cease state condoned attacks on the lives of persons based on sexual orientation or gender identity and assure that such attacks are vigorously investigated and prosecuted
5. The right to security of the person	<ul style="list-style-type: none"> • Prevent and provide protection from harassment and violence based on sexual orientation or gender identity • Enact legislative measures to impose appropriate criminal penalties for violence and harassment based on sexual orientation or gender identity, including within the family • Investigate and prosecute all allegations of violence against persons based on sexual orientation or gender identity and provide support for victims • Educate the public to combat the prejudices underlying such actions
6. The right to privacy	<ul style="list-style-type: none"> • Ensure the right to privacy of actions, including same-sex consensual activity without undue interference • Repeal any law that prohibits or criminalizes gender expression in dress, speech, or mannerisms or through bodily changes • Ensure the right to decide when, how, and to whom to disclose information related to sexual orientation or gender identity and protect individuals from unwanted disclosure
7. The right to freedom from arbitrary deprivation of liberty	<ul style="list-style-type: none"> • Assure that sexual orientation or gender identity is not used as a basis for arrest or detention • Educate police accordingly • Maintain accurate records of arrests motivated by sexual orientation or gender identity
8. The right to a fair trial	<ul style="list-style-type: none"> • Prohibit or eliminate prejudicial criminal or civil judicial treatment based on sexual orientation or gender identity • Protect persons from prosecution based on sexual orientation or gender identity • Train judges and other court personnel on international human rights
9. The right to treatment with humanity while in detention	<ul style="list-style-type: none"> • Avoid further marginalization or violence against detained persons based on sexual orientation or gender identity • Provide access to medical care and counseling for detained GLBT individuals • Put protective measures in place to prevent violence against prisoners based on sexual orientation or gender identity • Where permitted, ensure equal conjugal visits for same-sex couples in detention settings • Provide for independent monitoring of detention facilities with respect to treatment of GLBT individuals • Train detention facility staff regarding international human rights
10. The right to freedom from torture and cruel, inhuman, or degrading treatment or punishment	<ul style="list-style-type: none"> • Prevent or protect GLBT individuals from torture and cruel, inhuman, or degrading treatment or punishment based on sexual orientation or gender identity • Identify persons subjected to torture and cruel, inhuman, or degrading treatment or punishment based on sexual orientation or gender identity and offer support, redress, and reparation
11. The right to protection from all forms of exploitation, sale, and trafficking of human beings	<ul style="list-style-type: none"> • Prevent or protect individuals from sexual exploitation based on actual or perceived sexual orientation or gender identity • Establish measures to protect vulnerable individuals from trafficking or exploitation based on sexual orientation or gender identity

Principle	Application to Sexual Orientation and Gender Identity
12. The right to work	<ul style="list-style-type: none"> • Eliminate and prohibit employment discrimination based on sexual orientation or gender identity • Provide training to counter discriminatory attitudes based on sexual orientation or gender identity in employment settings
13. The right to social security and other social protection measures	<ul style="list-style-type: none"> • Ensure equal access to social security and other social benefits to all regardless of sexual orientation or gender identity
14. The right to an adequate standard of living	<ul style="list-style-type: none"> • Ensure equal access to food, safe drinking water, adequate sanitation, and clothing without regard for sexual orientation or gender identity
15. The right to adequate housing	<ul style="list-style-type: none"> • Ensure security of tenure and access to affordable, habitable, accessible, culturally appropriate, and safe housing, including shelter accommodation, regardless of sexual orientation or gender identity • Prohibit evictions not in conformity with international human rights that are based on sexual orientation or gender identity • Ensure equal rights to land and home ownership and inheritance regardless of sexual orientation or gender identity
16. The right to education	<ul style="list-style-type: none"> • Ensure equal access to education and equal treatment by teachers regardless of sexual orientation or gender identity • Ensure that education is directed to respect for human rights including those of GLBT individuals • Provide protection for staff, students, and teachers from violence and harassment based on sexual orientation or gender identity • Ensure that discipline is enacted without regard for sexual orientation or gender identity
17. The right to the highest attainable standard of health	<ul style="list-style-type: none"> • Provide access to health care goods and services without regard for sexual orientation or gender identity • Facilitate access to competent gender reassignment services • Ensure that health care providers treat all clients and their partners without discrimination based on sexual orientation or gender identity • Train health care personnel to provide quality care regardless of sexual orientation or gender identity
18. Protection from medical abuses	<ul style="list-style-type: none"> • Ensure that no child's body is irreversibly changed to impose a gender identity without free, full informed consent by the child • Protect persons from involuntary participation in research on the basis of sexual orientation or gender identity • Ensure that medical or psychological treatment does not expressly treat sexual orientation or gender identity as a condition to be treated, cured, or suppressed
19. The right to freedom of opinion and expression	<ul style="list-style-type: none"> • Promote full freedom of expression and opinion without regard for sexual orientation or gender identity • Ensure that notions of public morality, health, or security do not restrict expression of opinion regarding sexual orientation or gender identity • Ensure that exercise of the right to freedom of expression does not violate the rights of GLBT individuals • Ensure that all persons, regardless of sexual orientation or gender identity, have access to information and participation in public debate
20. The right to freedom of peaceful assembly and association	<ul style="list-style-type: none"> • Ensure rights to organize around and advocate for sexual orientation or gender identity issues • Ensure that notions of public morality, health, or security are not used to restrict freedom of assembly related to sexual orientation or gender identity issues
21. The right to freedom of thought, conscience, and religion	<ul style="list-style-type: none"> • Ensure that the expression, practice, and promotion of different opinions and beliefs regarding sexual orientation or gender identity is not undertaken in a manner incompatible with human rights
22. The right to freedom of movement	<ul style="list-style-type: none"> • Ensure that the right of freedom of movement and residence is guaranteed regardless of sexual orientation or gender identity

(Continued)

Principle	Application to Sexual Orientation and Gender Identity
23. The right to seek asylum	<ul style="list-style-type: none"> • Ensure that a well-founded fear of persecution based on sexual orientation or gender identity is accepted as grounds for granting asylum • Prohibit discrimination regarding asylum based on sexual orientation or gender identity • Prohibit extradition to a country or state where one could be subjected to torture, persecution, or cruel and inhuman treatment or punishment based on sexual orientation or gender identity
24. The right to found a family	<ul style="list-style-type: none"> • Ensure the right to found a family through adoption or assisted procreation regardless of sexual orientation or gender identity • Ensure that laws and policies recognize diverse family forms and protect families from discrimination based on sexual orientation or gender identity • Prohibit consideration of a parent's sexual orientation or gender identity as incompatible with a child's best interests in court proceedings • Permit children who are capable of exercising decisions to make decisions on their own behalf • Where same-sex marriage is recognized, ensure that same-sex couples have equal benefits to different-sex couples • Ensure that marriages and other legally recognized partnerships are entered only voluntarily
25. The right to participate in public life	<ul style="list-style-type: none"> • Ensure full enjoyment of the right to participate in public life and levels of government service regardless of sexual orientation or gender identity • Take measures to eliminate stereotypes and prejudices that prevent or restrict participation in public life based on sexual orientation or gender identity • Ensure the right of each person to participate in policy formation that affects his or her life regardless of sexual orientation or gender identity
26. The right to participate in cultural life	<ul style="list-style-type: none"> • Ensure opportunities to participate in cultural life regardless of sexual orientation or gender identity • Foster dialogue among cultural groups, including groups that hold different views of sexual orientation or gender identity
27. The right to promote human rights	<ul style="list-style-type: none"> • Take measures to combat activities or campaigns against human rights defenders working on issues of sexual orientation or gender identity • Ensure the protection of human rights defenders working on sexual orientation or gender identity issues from violence, threat, or discrimination • Support recognition and accreditation of human rights organizations that work on sexual orientation or gender identity issues at national and international levels
28. The right to effective remedies and redress	<ul style="list-style-type: none"> • Establish legal procedures that ensure victims of human rights violations based on sexual orientation or gender identity have full redress • Ensure that remedies are enforced and implemented in timely fashion • Establish effective institutions for redress of violations of human rights based on sexual orientation or gender identity and effectively train personnel • Ensure access to knowledge of procedures for redress of violations based on sexual orientation or gender identity • Ensure financial aid for persons unable to afford legal processes related to redress
29. Accountability	<ul style="list-style-type: none"> • Establish criminal, civil, and administrative procedures and monitoring mechanisms to ensure accountability of perpetrators of human rights violations based on sexual orientation or gender identity • Ensure that allegations of violations of rights based on sexual orientation or gender identity are thoroughly investigated and when substantiated, penalties enacted • Establish independent institutions and procedures to monitor formation and enforcement of laws to eliminate discrimination based on sexual orientation or gender identity • Remove obstacles preventing perpetrators of human rights violations based on sexual orientation or gender identity from being held accountable

ENVIRONMENTAL DETERMINANTS. Members of the GLBT population are exposed to many of the same environmental health hazards as the general population. In addition, environmental factors, such as population density, may affect the availability of support services. For example, rural areas may lack access to services and to health care providers who are comfortable dealing with GLBT individuals. Rural populations have also been shown to be less accepting of sexual diversity and may contribute to diminished family support of GLBT individuals. Urban settings, particularly those with large GLBT populations, may provide more supportive environments and better access to needed services (IOM, 2011).

SOCIOCULTURAL DETERMINANTS. Sociocultural factors have a profound impact on the health status and health-related behaviors of GLBT individuals. Sociocultural elements that may negatively affect the health and well-being of the GLBT population include homophobia and heterosexism, stigmatization, discrimination, and violence. Social relationships and socioeconomic status are additional areas for consideration in assessing sociocultural determinants of health in GLBT populations.

Homophobia and heterosexism. Discrimination and violence against gay men, lesbians, bisexuals, and transgender individuals has been attributed to **homophobia**, an irrational fear or hatred of people who exhibit a nonheterosexual sexual orientation or rejection of one's own homosexual feelings. Related terms include **biphobia**, which is defined as fear and intolerance of persons who are bisexual (UC Berkeley Gender Equity Resource Center, n.d.), and **transphobia**, defined as fear or hatred of people who do not conform to traditional gender norms (Trans Respect Versus Transphobia, n.d.). Some authors note, however, that the use of the term *homophobia* restricts responses to gay men and lesbians to an individual phenomenon, when it is evident that it is in reality a societally constructed

entity that influences many aspects of the sociocultural environment. For that reason, many authors prefer the term **heterosexism**, which is defined as the assumption that all people are heterosexual and belief that heterosexuality is “normal” and superior to other sexual orientations (UC Berkeley Gender Equity Resource Center, n.d.). Heterosexism results in oppression, stigmatization, discrimination, and violence against members of GLBT populations.

Heterosexism is a cultural phenomenon in which opposite sex attraction and behavior are the expected cultural norms. Heterosexism may be more deeply embedded in some cultures than others. MSM who are members of cultural minority groups with strong heterosexist beliefs may be faced with less tolerance than others. For example, some authors have noted that Latino gay and bisexual men in Southern California are simultaneously exposed to more relaxed attitudes to homosexual behavior in the majority culture and strict cultural attitudes. Similarly, many Asian cultures attach significant stigma to sexually diverse individuals as well as to their families.

Among young urban, African American men, a subculture exists among persons who have sex with other men and women, but do not consider themselves either gay or bisexual. This subcultural group is sometimes referred to as “down low.” Members of the group tend to divorce sexual behavior from sexual identity and pride themselves on their masculinity (Heath & Goggin, 2009). For these reasons, health promotion and illness campaigns designed to reach gay and bisexual men may not be effective in this subpopulation.

Cultural conflicts similar to those experienced by Latinos and Asians may also be encountered by older gay men who developed their sexual identities in an age when it was more prudent to keep one's sexual orientation hidden. This group may be at particular disadvantage in dealing with the effects of societal heterosexism as well as ageism (Wight et al., 2012).

Stigmatization and discrimination. Societal attitudes toward what many consider deviant behavior may lead to prejudice, discrimination, harassment, and victimization. As noted by the Institute of Medicine (2011), members of the GLBT community have a common experience of stigmatization and have historically been marginalized by a heterosexual society.

In various studies, two thirds to three fourths of sexual minority group members report lifetime experience of discrimination (Choi et al., 2013; McCabe, Bostwick, Hughes, West, & Boyd, 2010), and more than 20% reported experiencing discrimination in the prior year (Choi et al., 2013). Similarly, approximately two thirds of transgender individuals report being subjected to gender-identity-based discrimination, which is compounded when people are members of more than one stigmatized group. In one study, 56% of transgender individuals had experienced verbal harassment, 37% reported employment discrimination, and 19% reported being subjected to physical violence (Bockting et al., 2013). Multiple sources and experiences of discrimination have an additive

Same-sex couples may experience discrimination in a variety of settings, including health care settings. (Francesco83/Fotolia)

effect on psychological health in GLBT populations (McCabe et al., 2010).

Stigmatization and discrimination are linked to psychological distress and psychopathology for members of minority groups, including those of sexual minorities. Experience of discrimination has been associated with mood, anxiety, and substance abuse disorders. Discussion of experiences of discrimination, however, seems to have a protective effect (McLaughlin, Hatzenbuehler, & Keyes, 2010), and population health nurses can encourage GLBT individuals to reveal and discuss their experiences, providing both emotional support and assistance in redressing discriminatory practices.

Responses to stigmatization and discrimination are varied among the GLBT population. Some individuals may resist “coming out” or disclosure. **Coming out** involves openly living as a gay, lesbian, bisexual, or transgender individual, while **disclosure** involves revelation of one’s sexual orientation or gender identity to selected individuals in one’s life. Both responses bring the risk of discrimination and rejection by family and friends. Being “out” may relieve internal stress at the risk of the loss of important social connections.

Other GLBT individuals strive to create new relationships with people who will accept their sexual diversity. Some GLBT youth turn to the Internet to meet other sexual minority group members. Initial interaction online provides a sense of anonymity and safety from the associated stigma. A review of research from the 1990s through 2013 provided evidence of

increasing use of the internet for making sexual connections. Some studies indicated increased sexual risk behaviors related to use of the Internet to meet other GLBT individuals and some did not find such associations. The Internet has also been used increasingly to conduct research with GLBT populations and to disseminate health-related information (Groves, Breslow, Newcomb, Rosenberger, & Bauermeister, 2014).

In addition to individual experiences of discrimination, GLBT individuals as a group are discriminated against by societal policies. One major area of societal discrimination lies in bans on same-sex marriage that exist in many states. Being married conveys a number of advantages not available to members of same-sex relationships. For example, employment-based partner health insurance benefits are often restricted to married individuals. Similarly, tax breaks afforded by joint tax returns are available to married couples, but not to those in relationships that do not have the legal status of marriage. Differences also occur for both partners and children in terms of survivor benefits under Social Security (Buffie, 2011). In fact, denial of Social Security spousal benefits costs same-sex couples an estimated \$124 million annually (Fredriksen-Goldsen, 2012).

Due to the general lack of recognition of same-sex marriages, same-sex couples are not eligible for more than 1,000 benefits accorded by the federal government to married couples. For example, in addition to the tax and survivorship benefits noted above, the federal Medical Leave Act does not

Evidence-Based Practice

Basing Evidence on Real People

To be of use in directing practice, evidence derived from research needs to reflect the population targeted for care. Unfortunately, with many stigmatized conditions such as membership in sexual minority groups, members of the target population may be difficult to reach using traditional approaches to subject recruitment. Some authors have suggested peer ethnography as a means of targeting special populations of interest for whom evidence-based interventions are lacking.

Ethnography is a research methodology in which the researcher becomes immersed in the population being studied and derives information from direct observation and face-to-face interactions with members of the target population. Gaining entrée to specific groups may be difficult for outsiders, particularly when the group has a history of discrimination. In peer ethnography, however, members of the target group are trained in ethnographic methods and can provide an insider’s view of group member’s beliefs and behaviors (Mutchler, McKay, Davitt, & Gordon, 2013). In what other stigmatized groups might peer ethnography be of use in developing a sound evidence base for practice?

Additional recommendations for research to build an evidence base for care of the GLBT population have been advanced by the Institute of Medicine (2011). These recommendations include the following:

- Development of a research agenda by NIH to advance understanding of GLBT health issues.
- Inclusion of data collection regarding sexual orientation and gender identity in federally funded surveys.
- Inclusion of data on sexual orientation and gender identity in electronic health records.
- Development of standardized measures of sexual orientation and gender identity.
- Support of methodological research related to GLBT health.
- Comprehensive research training related to GLBT health at NIH.
- Encouragement of NIH grant applicants to explicitly address inclusion or exclusion of sexual and gender minorities in study samples.

cover domestic partners or same-sex relationships, although some employers extend coverage to all employees. In 2011, only nine states and the District of Columbia included same-sex spouses and domestic partners under state medical leave legislation. Similarly, same-sex couples are not protected from loss of their home in order to spend down to be eligible for long-term care services under Medicaid. Heterosexual spouses, however, are protected from home loss in these circumstances (Fredriksen-Goldsen, 2012).

In the recent past, there has been considerable legislation designed to foster or impede bans on same-sex marriage. California's proposition 8 and other similar legislation legally defined marriage as occurring between a man and a woman. The 9th U.S. Circuit Court of Appeals ruled proposition 8 unconstitutional, and in July 2013, the U.S. Supreme Court failed to rule on the issue, thus upholding the unconstitutionality of the act and its provisions and supporting federal benefits for same-sex married couples in the states that permit same-sex marriage. It remains unclear, however, if federal marriage benefits will be based on the ruling only in states that legalize same-sex marriage, or will apply throughout the country. The ruling also fails to settle the question of whether or not any state has the right to ban marriage between same-sex couples. As of mid-2013, 12 states plus California permit same-sex marriage, and public opinion has slowly been turning in favor of same-sex marriage (Mintz, 2013).

In June of 2013, the U.S. Supreme court ruled that provisions of the Defense of Marriage Act that deny same-sex couples the same federal legal protections as any other married couple are unconstitutional. At its inception, the ruling applied to states and territories that recognize same-sex marriages. For those living in states that do not recognize their marriages, additional work is needed to promote equity (Freedom to Marry, 2013). Population health nurses can advocate for changes in state laws that promote equity for all married couples.

Some authors have maintained that same-sex marriage is another facet of the ongoing evolution of the societal concept of marriage. They cite as evidence former laws and social mores that defined marriage as occurring between a man and woman of the same race, social status, or religion (Buffie, 2011). Legalization of same-sex marriage has been associated with improved health among gay and lesbian individuals. For example, in one study, legalization was associated with a decrease in medical and mental health care visits and lower health care costs among gay men, both those who had committed relationships and those who did not, again suggesting population as well as individual benefits of minimizing stigma and discriminatory practices (Hatzenbuehler et al., 2012).

A number of groups and organizations have been established to advocate for policies and legislation that prohibit discrimination against members of the various GLBT populations. For example, the Transgender Law Center in San Francisco works on behalf of transgender individuals to create a society

that recognizes freedom of gender expression as a basic right of the individual (Transgender Law Center, 2013). Similarly, the New England-based Gay & Lesbian Advocates & Defenders organization (GLAD) works through litigation, public policy advocacy, and education to eliminate discrimination related to gender identity and expression, sexual orientation, or HIV status (GLAD, 2013).

Social relationships. Interactions within families beyond the legality of marriage are another element of the sociocultural dimension that affects the health of the GLBT population. Disclosure of a nonheterosexual orientation or transgenderism to family members and their response, homosexual relationships, and homosexual parenting are the three primary aspects of family interaction to be assessed by the population health nurse.

Two different themes occur in families' responses to disclosure of a family member's homosexuality: loving acceptance or rejection. All families who come to know of GLBT members need to deal with feelings of grief, guilt, and fear for their child or sibling. GLBT youth who experience family rejection are more likely to experience a variety of psychological and behavioral problems. Family acceptance, on the other hand, has been strongly correlated with higher levels of self-esteem, social support, and overall health in GLBT adolescents and young adults. Acceptance also seems to be a protective factor for depression, substance abuse, suicidal ideation, and lifetime

Marriage between same-sex couples should entail the same rights and responsibilities as those accorded to heterosexual couples.

(Lisa F. Young/Fotolia)

suicide attempts (Ryan, Russell, Huebner, Diaz, & Sanchez, 2010).

For those families that are able to accept homosexuality, bisexuality, or transgenderism in one of their members, acceptance appears to come about in stages similar to the stages of grief experienced with the loss of a loved one. The first stage is one of grief, followed by a period of denial during which parents may see their child's professed sexual identity as a "phase" that he or she will grow out of. This stage is followed successively by stages characterized by guilt and anger and, finally, loving acceptance. For some families, acceptance is followed by advocacy (Broad, 2014). Unfortunately, some families never achieve the stage of acceptance of their loved one's sexual orientation or gender identity.

Parental response to the disclosure of homosexuality is strongly influenced by a variety of factors: the strength of traditional gender role conceptions, perceptions of the probable attitudes of significant others in the family's social network, and parental age and education level. Affiliation with conservative religious ideologies and intolerance of other stigmatized groups are other factors that affect parental resolution of grief over the lost image of their child (Broad, 2014).

GLBT individuals may face decisions about disclosure to spouses and friends as well as parents and siblings. Many GLBT individuals are or have been involved in committed heterosexual relationships, and many of them have children. Some individuals do not become aware of or accept their sexual diversity until after marriage. Others marry in an attempt to deny or hide their sexual orientation or gender identity. Responses of spouses to the disclosure of homosexuality, bisexuality, or transgenderism vary considerably and may include feelings

of living with a "stranger," guilt, development of an asexual friendship or a semi-open relationship in which partners are free to take outside lovers, or a desire for divorce. Transgender identity changes can be particularly devastating to marital relationships, as the spouse questions not only the partner's sexual identity but his or her own as well. Population health nurses should assess the extent of clients' disclosure of their sexual identities and the effects of the responses received. Nurses should also assess the needs of family members for assistance in dealing with the disclosure. The Family Acceptance Project has created a screening tool to identify GLBT youth who are experiencing serious family rejection. Information and training on the screening tool are available at the website, and a source for further information is included in the *External Resources* section of the student resources site. Table 20-2• provides examples of accepting and rejecting behaviors that population health nurses can share with families of GLBT individuals.

Disclosure to family members is usually not a one time event. As families grow and change, both the GLBT family member and others face decisions regarding disclosure to other family members and friends. In other words, families engage in their own "coming out" regarding the sexual diversity of family members, although this process is framed somewhat differently than the coming out experienced by members of the GLBT population (Broad, 2014). Disclosure of one's sexual orientation or gender identity to children is another dilemma faced by gay, bisexual, and transgender men. Depending on when and how disclosure occurs, children may exhibit the same range of responses shown by other family members. Some considerations in disclosure of sexual orientation or gender identity to children are provided on the student resources site.

TABLE 20-2 Accepting and Rejecting Behaviors by Families of GLBT Individuals

Accepting Behaviors	Rejecting Behaviors
Discussing with a GLBT family member their identity and feelings	Engaging in physical punishment of expressions of GLBT identity
Expressing affection for the GLBT family member	Engaging in verbal abuse or name-calling related to a family member's GLBT identity
Supporting the GLBT family member's identity	Excluding GLBT member from family activities
Advocating for fair treatment of the GLBT family member	Prohibiting access to GLBT friends, information, or support resources
Requiring respect of the GLBT family member by other family members	Blaming GLBT family members when they are subjected to discrimination related to their identity
Connecting the GLBT family member with relevant resources and organizations	Attempting to change a GLBT family member's appearance or behavior
Assisting the GLBT family member to identify appropriate GLBT role models	Informing a GLBT family member of their "sinfulness" and likelihood of divine punishment
Welcoming the GLBT family member's friends and partners	Indicating that you are ashamed of the GLBT family member or the unwanted attention they draw to the family
Supporting the GLBT family member's gender expression	Refusing to allow a GLBT family member to disclose or discuss their identity with others
Expressing the belief that a GLBT family member can have a happy and productive life	

Based on: Ryan, C. (2009). *Supportive families, healthy children: Helping families with lesbian, gay, bisexual & transgender children*. Retrieved from http://familyproject.sfsu.edu/files/English_Final_Print_Version_Last.pdf

Parenting by GLBT families brings its own stresses, many of them similar to those experienced by straight parents. GLBT individuals may become parents in a number of ways: in heterosexual relationships prior to coming out, as foster parents or through adoption, or in cooperation with a sperm donor or surrogate mother. Data cited in the IOM (2011) report on the health of the GLBT population indicated that 35% of lesbians, 8% of gay men, 67% of bisexual women, and 36% of bisexual men had at least one child. In addition, key findings of a study by the Urban Institute and Williams Institute indicated that half of gay men and 41% of lesbian women want to have children, and approximately 2 million GLBT individuals are interested in adopting children. In 2010, 65,000 children had been adopted by a gay or lesbian parent, and gay/lesbian parents were caring for an estimated 14,000 foster children (Sudol, 2010).

Adoption or foster parenting by GLBT individuals may pose more difficulties than for straight couples. Although 60% of adoption agencies surveyed in a national study accepted applications from prospective GLBT parents, only 40% had actually placed children in GLBT households, and only 19% of agencies actively sought out GLBT individuals as adoptive parents. Federal law does not address adoption by GLBT individuals, and some states, particularly those that do not recognize same-sex marriage, prohibit adoption by members of the GLBT population. In 2010, only six states had laws prohibiting adoption discrimination against GLBT individuals, three had laws restricting GLBT adoption, and three others had laws or policies that restricted adoption. Even fewer states (only four) have laws or legislation that prohibit exclusion of GLBT individuals from serving as foster parents, and one state (Nebraska) actively prohibited foster parenting by gay individuals. A study by the Children's Bureau and AdoptUSKids recommended inclusive practices by all adoption and foster child agencies that emphasize sexual orientation and gender identity in their nondiscrimination policies, include information about GLBT

families in recruiting materials, and use inclusive language on paperwork (Sudol, 2010). GLBT families have been described as an untapped resource for foster and adoptive families and assessment guidance for agencies considering placement of a child in a GLBT family have been developed (Mallon, 2011). Population health nurses can assess state and local policies and legislation related to adoption and fostering by GLBT families and advocate for equitable treatment of these populations. For further information about GLBT foster parenting, adoption, and family life, see the *External Resources* section of the student resources site.

Other GLBT individuals may choose to have children through surrogate parent arrangements in which a woman is impregnated either through intercourse or artificial insemination by sperm from a donor male. Conversely, a gay or bisexual man, or an FTM transgender individual who has not had an orchiectomy may impregnate a surrogate mother or a female partner. Both arrangements have the potential for legal risks and challenges, particularly if the donor or surrogate is known. For example, sperm donors may later sue for access to interaction with the child or be held liable for child support. Similarly, surrogate mothers may sue for custody. Such eventualities can be minimized by being knowledgeable regarding state laws related to donor status and surrogacy, working with a physician or women's health practitioner, and having an attorney execute a detailed contract regarding the rights and responsibilities of all parties (Forman, n.d.).

The parental rights of same-sex partners may also be called into question if a same-sex partnership dissolves or with the death of the biological or adoptive parent of any children. This can be forestalled by a second-parent adoption. **Second-parent adoption** is a legal procedure in which a same-sex parent formally adopts his or her partner's biological or adoptive child as a second, legally recognized parent. As of 2014, 23 states and the District of Columbia provided for second-parent adoption by same-sex couples; in 8 states various obstacles exist with respect to adoption by same-sex couples or unmarried individuals. In the remaining states, decisions are made on a case-by-case basis, but in Florida legislation prohibiting adoption by "homosexuals" was declared unconstitutional in 2010 (Human Rights Campaign, 2014).

The mistaken societal view that sexual orientation or transgenderism can be transmitted to children has motivated a great deal of research on the effects of GLBT parenting on children. Research has indicated, however, that being raised by a GLBT parent does not have adverse effects for children. They have not been shown to face greater stigma and are not more likely to be abused or to exhibit sexual diversity than other children. In addition, they seem to develop more secure parental attachments and grow up as successfully as children in heterosexual families (Sudol, 2010).

GLBT couples' relationships are subjected to the same kinds of stress as straight relationships, but this stress may be exacerbated by the absence of social support for the marital role. Therapists who work with gay and lesbian couples have

More same-sex couples are choosing to have and raise children.

(Zoomyimages/Fotolia)

identified several additional issues that threaten the stability of their relationships. These issues include differences in the stages of coming out between partners, differences with respect to extended family involvement, inequalities of power, and financial conflict and disparity in income. With the exception of the stage of coming out, these same issues may also affect the stability of relationships among straight couples.

Another aspect of family relationships that affects GLBT individuals more so than straight members of the population is that of informal caregiving. Societal and health system policies often create restrictions on who can provide family caregiving that do not recognize the rights of same-sex partners, particularly in states that do not recognize same-sex marriages or formal unions. For example, partners may be restricted from visiting, being involved in care decisions, and making funeral arrangements. In addition, as noted earlier, partners may face challenges to or denial of fiscal rights related to Social Security, property ownership, and custody of minor children. In one study, 13% of people caring for sick or disabled spouses or partners were in same-sex relationships, yet these individuals are frequently not eligible for caregiving assistance and lack legal protections to support caregiving (Fredriksen-Goldsen, 2012).

When the support of a GLBT individual's family of origin is lacking, many people turn to associations with other GLBT individuals for support. Affinity with the GLBT community has been linked to better health and, in the past, to safer sexual practices among MSM. This may be changing, however, as younger MSM engage in more socially acceptable practices such as unprotected sexual intercourse (Halkitis et al., 2013). In some studies, for example, condom use is less likely in interactions with one's main partner than with casual sexual partners (Wilson et al., 2010), and in one study in New York City, 19% of MSM reported unprotected anal intercourse (Halkitis et al., 2013).

Socioeconomic status. Some members of the GLBT community tend to be of higher socioeconomic status than the general population, and some are of lower status. Sexual minority youth tend to leave home earlier and are more likely to be homeless than other young people. For example, in one study of Massachusetts high school students, 25% of lesbian and gay teens and 15% of bisexual teens were homeless compared to only 3% of heterosexual students. Homelessness may be a result of victimization and abuse at home and places GLBT youth at high risk for violence, substance abuse, and mental health problems (Corliss, Goode-Now, Nichols, & Austin, 2011). Similarly, transgender individuals have been found to be more likely to be unemployed and poor than nontransgender people (Conron et al., 2012). Some transgender individuals lack education and career training or may be discriminated against with respect to employment. For many of them, sex work becomes an economic alternative that is linked to high risk situations and behaviors, such as substance abuse, unsafe sexual practices, and the potential for physical and sexual abuse. In addition, the stigma and social isolation associated

with sex work may increase their vulnerability to mental illness and sexually transmitted infections (Nemoto et al., 2011). Older GLBT individuals are at particular risk for poverty and its effects on health (LGBT Movement Advancement Project [MAP] & Services and Advocacy for Gay, Lesbian, Bisexual and Transgender Elders [SAGE], 2010).

Conversely, California Health Interview survey data indicated that lesbian women tend to be better educated and have higher incomes than women in general. The same is true for gay men, but bisexual men tended to have lower incomes than straight men (Boehmer, Miao, Linkletter, & Clark, 2012). Socioeconomic status has implications for health. For example, although self-reported health status does not differ between people with same-sex partners and those with different-sex partners in general, people with same-sex partners with lower incomes, particularly young women, in one study rated their health as worse than those with different-sex partners (Thomeer, 2013). Similarly, financial concerns and independence issues have been associated with depression in older gay men (Wight et al., 2012).

Violence and hate crimes. One additional sociocultural factor that has implications for health in the GLBT population is that of violence and hate crimes. **Hate crimes**, also known as bias crimes, involve criminal violence based on sexual minority or other stigmatized status (e.g., race, religion). In 2009, 1,482 victims were subjected to hate crimes related to gender orientation in the United States, a number that probably far underrepresents actual occurrence since not all jurisdictions report hate crimes. Hate crimes against gay men are more common than among lesbian women or bisexuals (U.S. Census Bureau, 2012). A meta-analysis of studies of sexual minority adolescents published in 2011 indicated they were 3.8 times more likely to experience sexual abuse, 1.2 times more likely to be subjected to parental physical abuse, 1.7 times more likely to be assaulted at school, and 2.4 times more likely to miss school due to fear than straight youth (Friedman et al., 2011).

A systematic review and meta-analysis indicated that men who have sex with men who experience sexual abuse as children were at higher risk for HIV infection and engaged in several high-risk sexual behaviors. Such behaviors included having multiple partners and frequent casual partners, engaging in unprotected sexual activity, and having sex while under the influence of alcohol or other drugs (Lloyd & Operario, 2012). Risk for violence is also high among transgender individuals. A report on hate-related violence by the National Coalition of Anti-Violence Programs indicated that half of hate-motivated homicides were perpetrated against transgender women. Similarly, transgender individuals were more likely than others to be subjected to discrimination, threats, intimidation, and police violence. Violence victimization was even more likely for GLBT individuals of color than for the overall GLBT population (National Coalition of Anti-Violence Programs, 2013).

GLBT families may also experience intimate partner violence (IPV) just as heterosexual couples do. Bureau of

Justice Statistics data (Catalano, Smith, Snyder, & Rand, 2009) indicated that approximately 7% of IPV against men is perpetrated by other men, and 1% of women are subjected to IPV by other women. A review of literature indicated that IPV among men who have sex with men is at least as high or higher than in the heterosexual population (Finneran & Stephenson, 2012).

Most IPV-related social services are designed to assist abused women, so men may not be able to find assistance when needed. Victimization may not even be acknowledged as IPV in jurisdictions that do not recognize same-sex marriage, making it difficult for abused men to obtain protective orders. In addition, GLBT individuals may be reluctant to report IPV for fear that it will be used as ammunition against same-sex relationships and support for prejudicial attitudes.

BEHAVIORAL DETERMINANTS. Behavioral factors are also important influences on the health of the GLBT population. Specific areas to be assessed include sexual practices, substance use and abuse, and health-promoting and illness preventive behaviors.

Sexual practices. Unsafe sexual practices exhibited by some GLBT individuals include unprotected anal intercourse (UAI) or failure to use condoms and sexual activity for pay. Some MSM and transgender individuals may engage in sex work and may also engage in substance use during sex to “clock coin,” exchanging sexual favors for money or substances (Mutchler et al., 2013). A far more common practice, however, is unprotected anal intercourse, which increases the risk of spread of STIs.

Some GLBT individuals may engage in **serosorting**, limiting sexual partners to persons of the same HIV status or use of condoms with HIV discordant partners (Eaton, Cherry, Cain, & Pope, 2011; Wilson et al., 2010). Many gay and bisexual men are less likely to use condoms with their primary partners than with casual or commercial partners. Failure to use condoms with main partners may reflect a sense of intimacy and safety or partners’ negative attitudes toward condom use (Wilson et al., 2010). In addition, some MSM may use female insertive condoms for anal intercourse. Insertive condoms, however, have only been approved by the Food and Drug Administration for vaginal intercourse, and their effectiveness in preventing STI with anal intercourse is unknown (Kelvin et al., 2011).

Although serosorting may have a protective effect, its effectiveness is undermined if the partner’s serostatus is unknown, if either party has relationships outside of the main partnership, or with frequent changes in main partners or multiple serial partnerships over time (Halkitis et al., 2013). In one large survey of MSM, 54% reported UAI with a male partner, 37% with their main partner, and 25% with casual partners. UAI has been associated with use of Viagra and other sex-related drugs, a greater number of partners, use of crystal methamphetamine and amyl nitrites, and a belief that HIV infection is less of a threat now

due to effective treatment (Schwarcz et al., 2007). Chronic alcohol use and use of marijuana, cocaine, and club drugs have also been linked to UAI (Mutchler et al., 2013). Unsafe sexual practices among MSM have been predicted to result in the possibility that as many as 40% of MSM may be HIV-infected by 40 years of age (Parsons et al., 2012). Use of sex toys and group sex as well as UAI have also been implicated in increased risk of hepatitis C among MSM (Fierer et al., 2011).

Bisexual women may also be at risk for STIs. In one study, bisexual women had a greater number of male partners, were less likely to use condoms, and engaged in more drug and alcohol use than women with only male partners. WSW and bisexual women may also have more new partners, more than one partner, or symptomatic sexual partners than straight women (Singh et al., 2011).

Unsafe sexual practices such as UAI may, in some individuals, be part of a “syndemic” that increases HIV risk in sexual minority populations. A **syndemic** is a situation in which multiple epidemics interact to enhance the adverse effects of each. Elements of a suggested syndemic related to sexual risk taking include compulsive sexual behavior, depression, childhood sexual abuse, intimate partner violence, and polydrug use, all of which (except childhood sexual abuse) have been linked to HIV seropositivity (Parsons et al., 2012). Population health nurses will assess GLBT individuals for unsafe sex practices. They will also assess the extent of such practices or evidence of a syndemic in the population.

Substance use and abuse. Generally speaking, members of the GLBT population are more likely to smoke, drink, and use drugs than the general population. For example, in the California Health Interview Survey, lesbians and bisexual women were found to be twice as likely as straight women to be current smokers and 2.5 times more likely to engage in binge drinking. Gay and bisexual men were more likely to be current smokers, but less likely to engage in binge drinking than straight men. Differences in findings for many behaviors included in the survey varied by age group, suggesting that interventions should be age-specific (Boehmer et al., 2012).

Similarly, Massachusetts Behavioral Risk Factor Surveillance System data from 2001 to 2008 suggested that sexual minority group members were more likely to report smoking and drinking than the rest of the population. Bisexual women were also more likely to engage in binge drinking. On a positive note, gay, lesbian, and bisexual individuals were also more likely to participate in HIV testing. Transgender individuals in Massachusetts also reported greater prevalence of smoking (Conron et al., 2012). Smoking is approximately twice as prevalent among GLBT individuals as in the overall population, partly due to specific targeting of the GLBT community by tobacco marketing strategies (Levinson, Hood, & Mahajan, 2012).

Illicit drug use may also be more prevalent in some GLBT populations than in the general public. For example, sexual minority youth have been found to be more likely than other

youth to use a number of illicit drugs (Newcomb, Birkett, Corliss, & Mistanski, 2014). An area of growing concern among gay men is the use of methamphetamines. Heavy methamphetamine use began in this population in the 1970s and has escalated to become the most common illicit drug used by gay and bisexual men (Rozsa, 2013).

Many factors contribute to extensive substance use, both licit and illicit. The stress of being part of a stigmatized and marginalized population may be a significant contributing factor. With respect to methamphetamine, some people use it to heighten sexual pleasure or as part of social interactions. Methamphetamine use among HIV-infected individuals is of particular concern because it contributes to increased viral load and decreased immune response, and decreases medication adherence (Parsons, Kowalczyk, Botsko, Tomassilli, & Golub, 2013). Population health nurses should assess the extent of tobacco, alcohol, and drug use in GLBT populations and the prevalence of related health problems.

Other health-related behaviors. Members of the GLBT population may also engage in other behaviors that support health or contribute to health problems. For example, some MTF transgender individuals may resort to injecting silicon oil, often in the buttocks or hips, to create a more feminine body image. Such injections were banned by the Food and Drug Administration (FDA), but are still provided by “black market” providers, who may or may not adhere to appropriate infection control measures. The silicon itself may contribute to pulmonary emboli or pneumonia, and facial injections may result in cellulitis and loss of vision. In addition, silicon is gravity dependent and may migrate within the body, causing deformity and disability (Sanchez-Ponte et al., 2012).

Transgender individuals may also self-inject non-prescription hormones, often at higher than usual treatment doses. For example, large proportions of transgender individuals in Washington, DC, San Francisco, Chicago, Virginia, and Ontario, Canada reported use of hormones from nonmedical sources. In addition, a few respondents in the Canadian study reported attempting surgical orchiectomies or mastectomies on themselves (Rotondi et al., 2013). The health effects of high-dose hormone injections are not yet known, but needle sharing for both hormone injection and intravenous drug use pose health risks for the transgender population.

GLBT individuals may also engage in health promoting and illness preventive behaviors. For example, according to the 2008 National HIV Behavioral Surveillance System (NHBS), 90% of MSM had been tested for HIV in their lifetimes and 62% were tested in the prior year. Similarly, 35% had been tested for syphilis, and 51% received hepatitis vaccine (Finlayson et al., 2011). In addition, based on California Health Interview Survey data, bisexual men have been found to be more likely than their gay or straight counterparts to eat five or more fruits and vegetables per day; however, lesbian and bisexual women are less likely to do so. Lesbians, gays, and bisexual individuals were more likely than straight individuals to engage in

vigorous physical activity and muscle strengthening, and gay men were more likely than straight or bisexual men to obtain colon cancer screening (Boehmer et al., 2012).

HEALTH SYSTEM DETERMINANTS. Factors related to the health care system also influence the health of the GLBT population. Two main assessment considerations in this area are barriers to health care and the availability of culturally sensitive health care services.

Barriers to health care. Members of the GLBT population may encounter homophobia and heterosexism among health care workers and care delivery systems. In addition, the perception of homophobia represents a significant barrier to health care that may lead people to forego health care unless absolutely necessary.

According to the Institute of Medicine (2011), barriers to health care may be personal or structural. Personal barriers include enacted stigma on the part of providers, felt stigma, and internalized stigma. Enacted stigma involves explicit behaviors on the part of health care providers that express stigma, such as denial of care, provision of inadequate care, or verbal abuse. Felt stigma is a perception that stigma is likely to be experienced in a given situation (IOM, 2011) that may lead to delay in seeking care, failure to disclose sexual orientation or gender identity, or concerns for confidentiality and disclosure of one’s status through employment-based health insurance. Internalized stigma may be expressed by straight individuals in the health care system as prejudice against sexual minority group members, or by members of the GLBT population who have internalized homophobic attitudes as described earlier (IOM, 2011).

Structural barriers to health care are the result of institutional stigma, which is the manifestation of stigma within social institutions. Failure to provide health insurance coverage for same-sex spouses and lack of legal recognition of partners and inclusion in health decision making are examples of institutional stigma. Another example of institutional stigma is insurance companies that discontinue coverage of transgender individuals when their gender identity is disclosed. Such practice will be prohibited under the Affordable Care Act. Lack of health care provider knowledge and expertise in addressing the needs of sexual minority group members is another structural barrier to effective health care (IOM, 2011).

In one study, roughly 4% of gay, lesbian, and bisexual respondents reported discrimination in obtaining health care and in their treatment by health care providers (McLaughlin et al., 2010). In the California Health Interview Survey, bisexual men and women were less likely than straight individuals to have health insurance, yet gay and bisexual men utilized health care services more often than straight men. Gay, lesbian, and bisexual individuals were also more likely to make emergency department visits than their straight counterparts (Boehmer et al., 2012). Transgender individuals have also reported lack of access to health care as well as transphobia among providers (Nemoto et al., 2011).

Even when individual health care providers are devoid of homophobia, various circumstances may threaten GLBT clients and act as health barriers. For example, assessment questions about birth control practices, if answered truthfully, might have the effect of requiring that a client disclose his sexual identity. For the client who fears loss of health care benefits (due to assumed higher risk of HIV/AIDS), this is a situation to be avoided. Confidentiality issues may also prevent GLBT individuals at risk for HIV infection from being tested, and when HIV infection is diagnosed, provisions of the Ryan White Care Act HIV/AIDS program vary from state to state, so access to necessary care may be restricted.

Health care providers are often poorly educated with respect to the needs of and care for members of GLBT populations. Although major health professional organizations, such as the American Medical Association (AMA, n.d.), American Psychiatric Association (2014), and American Psychological Association (2009), have developed policy statements affirming the normality of same-sex sexual orientations and the right of GLBT individuals to quality health care, incorporation of GLBT issues in health professional education is often confined to discussion of HIV infection and other STIs. The World Professional Association for Transgender Health (2011), however, has established standards that can assist professionals in the care of transgender individuals. For further information about the standards, see the *External Resources* section of the student resources site.

Culturally sensitive health care. The Institute of Medicine (2011) has recommended education of health care professionals to effectively provide culturally sensitive health care to GLBT individuals and groups. Health care systems should also be revamped to remove sources of institutional stigma. For instance, substituting gender-neutral pronouns for gender-specific terms on all forms has been suggested. Examples of gender-neutral pronouns are provided in Table 20-3. Gender-neutral pronouns, however, have not been widely endorsed or adopted in the transgender community.

The Transgender Law Center (2011) has developed a set of principles for designing health care services to meet the needs

of the transgender community that can be adapted to creating culturally sensitive services for the GLBT population in general. These principles are as follows:

- Involve a diverse group of leaders from the GLBT community in designing effective services to assure that they meet the needs of the target population.
- Build leadership from all elements of the community, particularly hidden segments that are often underrepresented and underserved.
- Focus on the motivations of the community.
- Recruit people for specific activities and functions.
- Clarify roles and responsibilities that respect the expertise of community members and minimize the role of officials or providers.
- Enlist the support of policy makers.
- Assess the health care issues of the GLBT community and fully understand the underlying factors.
- Analyze the policy environment and its effects on health care for GLBT individuals.
- Develop specific goals for care and policy formulation.
- Develop systems that provide routine primary care and also address GLBT-specific health care issues.
- Create culturally tailored literature for the GLBT population.

Common issues to be addressed in developing culturally sensitive health care delivery programs for the GLBT population include training providers for cultural competency, using inclusive terminology in intake forms, promoting a medical home, and funding access to care. An additional, often neglected issue is the provision of gender-neutral bathrooms (Transgender Law Center, 2011).

Population health nurses should assess factors related to each of the six areas of determinants of health as a precursor to planning and implementing health care services for this population. The comprehensive target group assessment tool included on the student resources site can be used as the basis for such an assessment.

Planning and Implementing Health Care for the GLBT Population

Health care services to address the needs of the GLBT population will occur at each of the four levels of health care. Selected population health nursing interventions related to health promotion, illness and injury prevention, resolution of existing health problems, and health restoration will be addressed here.

HEALTH PROMOTION. Members of the GLBT population are in need of the same health promotion interventions as the general public. For example, adequate nutrition and physical activity can be promoted in this population. Because of the potential exposure to minority stress, members of the GLBT population may need assistance in developing effective coping strategies. Population health nurses can teach coping strategies

TABLE 20-3 Substituting Gender-neutral for Gender-specific Pronouns

Gender-specific Pronoun	Gender-neutral Pronoun
She/he	Ze (pronounced “zee”)
Her/him	Hir (pronounced “here”)
Her/his	Hir (pronounced “here”)
Hers/his	Hirs (pronounced “heres”)
Herself-himself	Hirself (pronounced “herself”)

Based on: UC Berkeley Gender Equity Resource Center. (n.d.). *Definitions of terms*. Retrieved from http://geneq.berkeley.edu/lgbt_resources_definition_of_terms

to individual members of the GLBT population. They can also advocate for equitable treatment to reduce the potential for minority stress. For example, improved mental health can be promoted through advocacy for recognition of same-sex marriage for gay and lesbian couples and promoting access to hormone therapies and sexual reassignment surgery for transgender individuals.

ILLNESS AND INJURY PREVENTION. Effective illness and injury prevention strategies for the GLBT population include measures to prevent HIV infection and other STIs as well as immunization for illnesses such as hepatitis A and B for those at risk of infection. Population health nurses can promote safe sexual practices, including strengthening partner relationships and norms for monogamy, elimination of unprotected anal intercourse, use of condoms, and promotion of serosorting strategies. In addition, nurses can assist members of the GLBT population to develop skills related to discussion of HIV status and negotiation for safer sexual practices. Other illness and injury prevention strategies would be similar to those for the general population and include promoting safety and eliminating risk behaviors (e.g., use of safety devices, smoking cessation, and so on).

Programs to prevent UAI among men who have sex with men have yielded mixed results. For example, a social marketing strategy targeted toward men who self-identified as straight, but engaged in sex with men was successful in motivating condom use (Martinez-Donate et al., 2010). In other populations, however, campaigns to promote condom use have not been very effective (Halkitis et al. 2013). Population health nurses can be actively involved in educating MSM for safer sexual practices and in advocating these practices in venues that reach MSM. For example, a population health nurse might advocate for a condom dispenser in a prominent location in a gay bar or convince gay publications to include articles advocating safer sexual practices. Nurses might even volunteer to write health-related articles for these publications. Table 20-4 • summarizes relevant health promotion and illness and injury prevention strategies for GLBT populations.

RESOLVING EXISTING HEALTH PROBLEMS. As with the general population, resolution of existing health problems in the GLBT population focuses on screening and treatment. Lesbian and bisexual women require the same screening interventions as straight women (e.g., mammography, cervical cancer screening). Similarly, gay and bisexual men should receive the screenings recommended for all men. Transgender individuals, however, may require screening services related to both genders. For example, MTF transgender individuals need regular mammograms due to the use of female hormones and risk of breast cancer, but they will usually still need regular prostate examinations as well. Similarly, most FTM transgender individuals continue to need regular cervical cancer screening. Because lesbian women typically do not use contraceptive services (a common route to health care services for straight

TABLE 20-4 Health Promotion and Illness/Injury Prevention Strategies for GLBT Populations

Focus	Strategy
Health promotion	<ul style="list-style-type: none"> Promote adequate nutrition Promote physical activity Promote effective coping Advocate for environments that promote health Advocate for equitable treatment
Illness/Injury prevention	<ul style="list-style-type: none"> Promote safe sexual practices Strengthen relationships and promote monogamy Encourage routine and risk-specific immunizations Promote general safety practices Assist with development of abilities to discuss HIV status and negotiate safer sexual practices Promote serosorting strategies and condom use Discourage unprotected intercourse Encourage risk factor elimination

women), they may miss opportunities for routine breast and cervical cancer screening.

Members of the GLBT population at risk for sexually transmitted infections such as HIV infection, syphilis, gonorrhea, *Chlamydia trachomatis*, or hepatitis should also be screened for these conditions. In addition, because of the greater prevalence of smoking, problem drinking, and drug use in the GLBT population, sexual minority group members may need to be screened and referred for problems in these areas. Depression screening may also be warranted. Population health nurses may provide or make referrals for relevant screening services. They may also need to advocate for provision of needed services and their coverage under health insurance plans.

Treatment strategies will depend on the type of health problems experienced by members of the GLBT population. General considerations in treatment of existing health problems among GLBT individuals include assuring access through health insurance coverage, reforming the health insurance market to cover needed services, promoting trusting relationships and disclosure of sexual orientation and gender identity to health care providers, educating providers to give effective care, developing GLBT-friendly health care systems, and ensuring confidentiality.

Effective treatment for transgender individuals often involves feminizing or masculinizing genitoplasty as well as hormone therapy. Feminizing genitoplasty for MTF transgenders usually includes orchiectomy, penectomy, vaginoplasty, and vulvoplasty and may also include breast augmentation and electrolysis of facial and body hair. Surgery for FTM transgender individuals often includes chest reconstruction or reduction mammoplasty (reduction of breast tissue) and creation

of an artificial penis. Feminizing genitoplasty is often quite successful, but no completely satisfactory techniques have yet been developed for masculinizing surgery, and both may result in possible surgical complications. Population health nurses may refer clients for sexual reassignment surgery and/or hormone therapy and may also advocate for coverage for these services under health insurance plans. Surgical procedures are often not covered under health insurance plans and many transgender individuals have to pay for surgery out-of-pocket and attempt to get reimbursement or forgo surgery.

Another area for resolution of existing health care problems is the need for assistance and support for caregiving in the GLBT population (Fredriksen-Goldsen, 2012). There is also a need to recognize and make referrals for treatment related to intimate partner violence among same-sex couples and bisexual and transgender individuals. Population health nurses may refer individual GLBT clients for treatment services or assist in the development of services available to this population. They may also need to advocate for available services or for insurance coverage of needed services. For further information about sources of assistance to which population health nurses might refer GLBT clients, see the *External Resources* section of the student resources site.

HEALTH RESTORATION. Health restoration services for members of the GLBT population would be similar to those for the general population. In addition, transgender individuals may need assistance in recovering from sexual reassignment surgery and with legal issues surrounding gender identification (e.g., legal name changes, change of gender on identification or birth certificates, etc.). Population health nurses can moni-

tor the effects of surgery and recovery. In addition, population health nurses should help monitor transgender individuals for effects related to hormone therapy such as increased risk of heart disease, stroke, and breast cancer. If clients are dissatisfied with the results of surgery, nurses can refer them for psychological assistance in dealing with their disillusionment. Population health nurses can also refer transgender clients for assistance with legal issues. Strategies for resolution of existing health problems and health restoration for GLBT populations are summarized in Table 20-5.

Evaluating Health Care for the GLBT Population

Healthy People 2020 includes two developmental objectives related to GLBT health. The first objective is to increase the number of population-based data systems that include questions related to the health of the gay, lesbian, and bisexual population. The second is similar and reflects the needs for data about the health status of the transgender population (U.S. Department of Health and Human Services [USDHHS], 2013). No current status data is available for either objective so they are not useful in evaluating the effects of care on the health of the GLBT population.

Another approach to evaluating care for the GLBT population lies in the Healthcare Quality Index created by the Human Rights Campaign Foundation (Snowden, 2013). Although the index does not provide information on health status, it does provide data related to the quality of health care provided to members of the GLBT population by 718 health care establishments in 2013, a 153% increase over participation in 2012.

TABLE 20-5 Strategies for Resolving Existing Health Problems and Health Restoration in the GLBT Population

Focus	Strategy
Resolving existing health problems	<ul style="list-style-type: none"> Provide or refer members of the GLBT population for relevant screening services Provide or refer for STI screening (including HIV screening) for members of the GLBT population at risk for STIs Conduct brief screenings for smoking, problem drinking, and drug use behaviors as needed Conduct or refer for screening for depression Assist in the design and implementation of culturally appropriate screening and treatment services for members of the GLBT population Advocate for the availability of needed screening services (particularly dual gender screenings for transgender individuals) Advocate for insurance coverage for needed screening services Refer members of the GLBT population for needed treatment services Advocate for the availability and coverage of necessary treatment services (particularly for SRS and hormone therapy for transgender individuals) Advocate for access to and funding for necessary treatment services Refer transgender individuals for SRS and/or hormone therapies as needed Advocate for the availability and coverage of treatment services for transgender individuals Refer for treatment of psychological health problems (including substance use and abuse)
Health restoration	<ul style="list-style-type: none"> Assist with and monitor recovery after SRS Monitor effects of hormone therapy Refer for assistance in dealing with legal issues related to transgenderism

Areas addressed include four core criteria such as inclusion of sexual orientation and gender identity in patient and employee nondiscrimination policies, explicit GLBT-inclusive visitation policies, and provision of staff training in GLBT-centered care. Information is also obtained about 31 additional best policies and practices related to areas such as GLBT patient services and support, transgender-specific services and support, options for patient self-identification, medical decision making, employee benefits and policies, and community engagement (Snowden, 2013). Table 20-6 provides some of the major

findings from 2013. As indicated in the table, some progress has been made in the creation of GLBT-friendly health care organizations, particularly with respect to the core criteria. Much work remains to be done, however, especially in regard to the additional best practices and policies.

With respect to evaluation of health care effects on the health of GLBT populations, population health nurses will need to obtain locality-specific data. The same data categories included in the *Assessment Guidelines* on the student resources site can be used to collect evaluative data.

TABLE 20-6 Findings from the 2013 Healthcare Quality Index

Criterion	2013 Findings	2012 Findings
Inclusion of sexual orientation in patient nondiscrimination policies	93%	90%
Inclusion of gender identity in patient nondiscrimination policies	87%	76%
Explicit GLBT-inclusive visitation policy	90%	75%
Inclusion of sexual orientation in employee nondiscrimination policies	97%	96%
Inclusion of gender identity in employee nondiscrimination policies	85%	75%
Staff training in GLBT patient-centered care	80%	67%
Communication of nondiscrimination policies	91%	
Equal visitation policies	90%	
Provision of information regarding GLBT services and issues on organization's website	21%	
Publication of GLBT-specific educational material	18%	
Potential for identification of data from GLBT clients in:		
Care surveys	9%	
Satisfaction surveys	6%	
Review of services to identify GLBT-related gaps	25%	
Provision of transgender-focused staff training	42%	
Creation of unisex bathrooms	59%	
Explicit communication to patients regarding possible designation of a same-sex partner as a medical decision maker	81%	
Provision of health care benefits to same-sex spouses of benefits-eligible employees	55%	
Provision of at least one health insurance plan option that covers medically necessary health services for transgender employees, including gender transition-related treatment	6%	
Provision of opportunities to record same-sex marital relationships in medical records	30%	
Inclusion of different gender identity options in medical records	15%	
Inclusion of sexual orientation options in medical records	13%	
Explicit staff training regarding confidentiality of patient sexual orientation/gender identity information	30%	
Conduct of a formal needs assessment of the GLBT population served by the organization	11%	
Inclusion of an openly GLBT person on a governing or advisory board	50%

CHAPTER RECAP

Members of the GLBT population have health needs similar to those of other men and women, but they also have many unique health needs that are frequently not met by the health care system due to personal and structural barriers to health care access. Personal barriers may derive from enacted stigma, perceived stigma, or internalized stigma. Structural barriers are created by discriminatory social and institutional policies that reflect the dominant heterosexism of society.

Factors related to each of the six determinants of health affect the health status of the GLBT population. Population health nurses may employ health promotion, illness and injury prevention, resolution, or health restoration strategies to deal with the effects of determinants on the health of the GLBT population. Evaluation of care for members of sexual minority groups focuses on resulting group health status as well as the quality of health care provided. Health care quality may be evaluated using criteria included in the Healthcare Quality Index.

CASE STUDY

Access to Health Care

In the course of investigating an outbreak of hepatitis B in a group of young ethnic minority men who have sex with men in a large city, you discover that the majority of them have not seen a health care provider in the past 2 years. Many of them have health insurance, but some do not. Similarly, those affected vary widely in terms of their educational levels.

1. What biological, psychological, environmental, socio-cultural, behavioral, and health system factors might be contributing to their failure to use health care services?
2. What population health nursing interventions might promote more effective use of services?

21 Care of Poor and Homeless Populations

Learning Outcomes

After reading this chapter, you should be able to:

1. Analyze factors contributing to poverty and homelessness.
2. Identify biological, psychological, environmental, sociocultural, behavioral, and health system determinants that influence the health of poor and homeless populations.
3. Describe approaches to health promotion among poor and homeless populations and related population health nursing roles.
4. Discuss interventions related to the prevention of homelessness and illness and injury prevention in poor and homeless populations. Analyze potential roles of population health nurses with respect to each.
5. Identify strategies to resolve the problems of homelessness and poverty and analyze the roles played by population health nurses.
6. Identify restoration strategies for poor and homeless populations.
7. Identify potential foci for evaluating care for poor and homeless populations.

Key Terms

affordable housing

criminalization

deindustrialization

deinstitutionalization

gentrification

homeless individual

means-tested income transfers

poverty

safe havens

single room occupancy unit (SRO)

structural unemployment

worst-case needs households

Promoting the Health of New York City's Poor

Organized health services for the poor in New York City were initiated by Lillian Wald and her cohorts at the Henry Street Settlement; however, in the early days of this effort African American nurses were actively involved in improving the lot of poor Black residents of New York. In 1900, Jessie Sleet Scales was hired as the first Black community health nurse in the city by the Charity Organization Society. Her role was to promote tuberculosis treatment in the Black community of New York City. Her appointment as a district nurse was controversial and was only made on the condition that her salary not be paid by the Society, but by a private philanthropist. A trial period of 2 months was agreed upon. In addition to her identified role of tuberculosis care, Scales provided direct care, dressing wounds, bathing patients and newborns, and caring for their mothers. She identified and dealt with numerous other diseases and provided education for hygiene and health promotion. She was so successful that her position was made permanent and she is credited with opening the field of community health nursing to African American nurses (Mosely, 1996).

Another African American nurse, Elizabeth Tyler, was hired by the Henry Street Settlement as the first Black nurse in the organization. Because the Settlement had no Black clients at the time, Tyler actively sought out those in need by soliciting referrals from apartment house janitors. Within 3 months, she had acquired a sufficient clientele to require the employment of another Black nurse, Edith Carter. Tyler later established the Stillman House Branch of the Henry Street Settlement to meet the needs of the Black community in the San Juan Hill area, so named because of fighting between Blacks and Irish and among U.S.- and foreign-born Black residents (Mosely, 1996).

Tyler's and Carter's efforts were initially viewed as intrusive by area residents, and they tended not to be receptive, so the nurses solicited referrals from local physicians. They also visited churches, following obviously ill members to their homes and attempting to persuade them to accept care. Tyler later was employed by the Delaware State Health and Welfare Commission where she was instrumental in developing child health and tuberculosis clinics. Both Tyler and Carter struggled to correct misconceptions and lack of health knowledge, particularly in efforts to combat harmful traditional health practices and the allurements of quack practitioners in the community. Carter, in particular, was well known for her success with patients deemed "incurable" by the medical establishment. According to a supervisor at Henry Street, "to the people in this area Miss Carter *is* Henry Street" (Mosely, 1996, p. 78).

Providing Permanent Housing for the Chronically Homeless

The aim of the 100,000 Homes Campaign in communities throughout the nation is to provide permanent housing for the more than 110,000 chronically homeless individuals in the United States. The chronically homeless are those who are without housing for extended periods of time or experience multiple episodes of homelessness. The approach taken is one of "housing first" which focuses first on providing permanent housing and then on addressing factors that contribute to homelessness such as mental illness or substance abuse.

Such strategies are actually less expensive and more effective than traditional approaches such as temporary shelters and transitional housing. The average cost of housing first strategies is about \$15,000 per person per year, far cheaper than a year's stay in a shelter. In addition, approximately 85% stayed housed rather than returning to the street. Since 2010, more than 12,000 people have been served by the campaign (Tucker, 2012).

As we have seen in several previous chapters, socio-cultural factors play a significant role in determining the health status of population groups. The health-related effects and population health nursing roles with respect to two interrelated sociocultural factors, poverty and homelessness, are explored in detail in this chapter.

Overview of Poverty and Homelessness

In 1948, the United Nations General Assembly adopted the Universal Declaration of Human Rights, Article 25 of which indicates that all people have rights to a standard of living that promotes health and includes access to food, clothing, housing, health care, and necessary social services and security in the event of adversity (United Nations, 1948). The following year, in the United States, the Housing Act of 1949 proposed the achievement of decent housing for every American family (Choldin, n.d.). To further the objectives of these two pieces of legislation, the World Health Organization developed the 11 *Health Principles of Housing* presented in the *Highlights* box at right.

Unfortunately, many of the world's societies do not achieve these principles of justice in housing. United Nations (UN) estimates include more than 100 million homeless people worldwide and another 1 billion people (17% of the world's population) living in inadequate housing (U.N., n.d.). Adequate housing is of concern because of its effects on the health of the population. These effects occur in three ways: through poor physical conditions of housing, through the absence of affordable housing, and through location of housing in unhealthy places.

Defining Poverty and Homelessness

Both poverty and homelessness are defined in multiple ways. **Poverty** is having an income or means of support insufficient to meet one's basic needs; what is considered *sufficient* may vary from one definition to the next. In the United States, poverty is defined in terms of a household income less than the identified threshold based on the number of persons in the household. This official definition of poverty is based on monetary income before taxes, but excluding capital gains and noncash benefits (such as food stamps, Medicaid, or housing subsidy) (U.S. Census Bureau, 2013).

In 2014, the poverty threshold for a single individual was an annual income of \$11,670 or less; for a family of four the threshold was an annual income of \$23,850 (U.S. Department of Health and Human Services [USDHHS], 2014a). The "near poor" have incomes 100% to 199% above the federal poverty level, while middle-income and high-income levels are 200% to 399% of the poverty threshold and greater than 400% of the poverty threshold (National Center for Health Statistics [NCHS], 2014).

Highlights

The World Health Organization's Health Principles of Housing

1. "Adequate housing provides protection against exposure to agents and vectors of communicable diseases through safe water supply, sanitary excreta disposal, disposal of solid wastes, drainage of surface water, personal and domestic hygiene, safe food preparation, and structural safeguards against disease transmission" (World Health Organization, 1989, p. 2).
2. "Adequate housing provides protection against injuries, poisoning and thermal and other exposures that may contribute to chronic disease and malignancies; special attention should be paid to structural features and furnishings, indoor air pollution, chemical safety, and use of the home as a workplace" (World Health Organization, 1989, p. 9).
3. "Adequate housing helps people's social and psychological development and reduces to a minimum the psychological and social stresses connected with the housing environment" (World Health Organization, 1989, p. 14).
4. "Suitable housing environments provide access to places of work, essential services and amenities that promote good health" (World Health Organization, 1989, p. 15).
5. "Only if residents make proper use of their housing can its health potential be realized to the full" (World Health Organization, 1989, p. 18).
6. "Housing should reduce to a minimum hazards to the health of groups at special risk from the conditions they live in, including women and children, those who live in substandard housing, displaced and mobile populations, and the aged, chronically ill and disabled" (World Health Organization, 1989, p. 20).
7. "Health advocacy, carried out by health authorities and bodies in related fields, should be an integral part of public and private decisions about housing" (World Health Organization, 1989, p. 24).
8. "Economic and social policies that affect the state of housing should support the use of land and housing resources to maximize physical, mental and social health" (World Health Organization, 1989, p. 27).
9. "Economic and social development, as it affects human shelter, should be based on appropriate processes of planning, the formulation and implementation of public policy, and the provision of services, with intersectoral collaboration in: development planning and management; urban and land use planning; housing legislation and standards and their enforcement; the design and construction of housing; the provision of community services; and monitoring and surveillance of the situation." (World Health Organization, 1989, p. 29).
10. "Education—public and professional—should actively foster the provision and use of housing to promote health" (World Health Organization, 1989, p. 36).
11. "In dealing with the needs and problems of the human habitat, community involvement at all levels should support the processes of self-help, help between neighbors, and communal cooperative activities" (World Health Organization, 1989, p. 38).

Global Perspectives

World Poverty

Poverty and its consequences are not unique to the United States, and incomes at poverty level would be considered wealth in many nations throughout the world. According to World Health Organization (WHO) figures, more than one fifth of the world's population has an income equivalent to one U.S. dollar per day, and more than half of the populations of 10 countries have incomes at this level. The extent of poverty ranges from less than 2% of the population of many affluent countries to 83.7% of Liberia's total population. The African region has the greatest percentage of people in poverty at 42.6%, followed by the South-East Asian region at 38.4%. Gross national per capita income in 2011 ranged from \$1,313 per year in the lowest income countries to \$38,690 in the most affluent countries (WHO, 2013).

Poverty may also be defined in terms of the percent of one's income spent on essential goods and services (e.g., food, shelter, and clothing) or one's income relative to the median income in the local area. In the context of the U.S. Rural Rental Housing Loan Program, very low income is defined as an income 50% below the area median income (AMI), and low-income households are below 50% to 80% of the AMI (National Coalition for the Homeless, 2012e). Measurable definitions of poverty are important because they often determine clients' eligibility for assistance programs. For example, eligibility may be restricted to individuals or families with incomes at or below the defined poverty level. In some programs, eligibility may be set at 100% or 150% above poverty level.

Homelessness also has multiple definitions, depending on the purpose of the definition. One of the most commonly used definitions is that posed by Title 42 of the Stewart B. McKinney Homeless Assistance Act of 1987, the first federal legislation in the United States dealing with the problem of homelessness. In a 2009 revision of the McKinney Act, a **homeless individual** is defined as (a) an individual or family without a regular, adequate nighttime residence; (b) an individual or family sleeping in public or private places not designed as a regular sleeping accommodation (c) an individual or family living in a publicly or privately operated shelter; (d) a previously homeless individual who is being discharged from an institution where he or she has been housed; (e) an individual or family who are about to lose their housing with no subsequent residence identified and without the resources or needed to obtain housing; (f) homeless youth or families with children who have a history of housing instability and are likely to continue in this state due to physical, emotional, or social circumstances; and (g) individuals fleeing situations of abuse or dangerous housing conditions (U.S. Department of Housing and Urban Development [HUD] 2009).

The McKinney-Vento Act expands on this definition with respect to homeless children as follows:

Homeless child and youth (A) means individuals who lack a fixed, regular, and adequate nighttime residence . . . and (B) includes: (i) children and youth who lack a fixed, regular, and adequate nighttime residence, and includes children and youth who are sharing the housing of other persons due to loss of housing, economic hardship, or a similar reason; are living in motels, hotels, trailer parks, or camping grounds due to lack of alternative adequate accommodations; are living in emergency or transitional shelters; are abandoned in hospitals; or are awaiting foster care placement; (ii) children and youth who have a primary nighttime residence that is a private or public place not designed for or ordinarily used as a regular sleeping accommodation for human beings . . . (iii) children and youth who are living in cars, parks, public spaces, abandoned buildings, substandard housing, bus or train stations, or similar settings, and (iv) migratory children . . . who qualify as homeless for the purposes of this subtitle because the children are living in circumstances described in clauses (i) through (iii). (U.S. Department of Education, n.d.)

Other federal agencies include persons on the streets, those in shelters, and those who face imminent eviction (within a week) from a private dwelling or institution (National Coalition for the Homeless, 2011b). The United Nations Committee on Human Rights defined absolute homelessness as "the condition of people without any physical shelter who sleep outdoors, in vehicles, or in abandoned buildings or other places not intended for human habitation" (Substance Abuse and Mental Health Services Administration, n.d., para 1). Other related terms are the "unsheltered homeless" and chronic homelessness. The unsheltered homeless are people living in places not meant for human habitation. Chronic homelessness is defined as having a disability and being continually homeless for more than a year or experiencing four or more episodes of homelessness in the prior three years (Henry, Cortes, & Morris, 2013). Unfortunately, these definitions fail to recognize the large

Due to overcrowding in shelters, many homeless individuals have no choice but to sleep outside. (Giuseppe Porzani/Fotolia)

segment of the population who are virtually homeless but are living doubled and tripled up with friends or family or who are living in substandard housing (National Coalition for the Homeless, 2012i). This situation is sometimes referred to as “relative homelessness” (SAMHSA, n.d.).

The Magnitude of Poverty and Homelessness

There are no exact figures on the number of poor or homeless persons in the United States. From 2010 to 2011, the median household income in the United States declined by 1.3%, and the national poverty rate increased from 15.3% to 15.9% of households. In 2011, more than 48 million individuals had incomes below the poverty level (National Alliance to End Homelessness, 2013). In 2009, nearly 15% of families and 18.7% of individuals were considered near poverty, at 125% of the poverty level (U.S. Census Bureau, 2012a, 2012e). Also in 2009, 14.7 million children, more than 20% of U.S. children and youth, were living in poverty (U.S. Census Bureau, 2012b).

Both individual poverty among adults and poverty among children is more common among ethnic minority groups than among White Americans. For example, Black children were more than twice as likely as White children to live in poverty. Hispanic children also experience high levels of poverty (U.S. Census Bureau, 2012b). Among individual adults, Blacks had slightly higher poverty rates than Hispanics (25.8% vs. 25.3%), and both had higher rates than Whites (12.3%) or Asians (12.5%) (U.S. Census Bureau, 2012c). American Indian and Alaska Native populations also experienced high rates of poverty at 20.4% (Beckles & Truman, 2011).

The relationship between poverty and homelessness is well established and is best conveyed by the following statement: “If you are poor, you are essentially an illness, and accident, or a paycheck away from living on the streets” (National Coalition for the Homeless, 2011c, p. 1). As with poverty, the exact number of homeless persons is unknown and, in fact, varies from one day to the next. The best estimate is that approximately 13.5 million people in the United States will be homeless at some point in their lives, and on any given night 250,000 to 3.5 million people are homeless (O’Connell et al., 2010). These figures probably underrepresent the true extent of homelessness, since homeless counts are often based on the number of people in shelters or seeking assistance from homeless service providers. Due to shelter overcrowding, fear, and other factors, many homeless people may not seek assistance, and, as noted earlier, many virtually homeless individuals and families are living temporarily with family members or friends (National Coalition for the Homeless, 2011a).

On one night in January 2013, 610,042 homeless people were identified (Henry et al., 2013); this “point-in-time” estimate includes those in shelters and transitional housing or on the streets, but does not include persons in family households (SAMHSA, 2011). From 2011 to 2012, the size of the homeless population in the United States decreased by 0.4% or slightly

more than 2,000 people. The rate of homelessness in the general population was 20 homeless per 10,000 people, with a higher rate among veterans (29 per 10,000 veterans) (National Alliance to End Homelessness, 2013). Approximately 85% of the homeless population in the United States in 2013 consisted of single individuals and 15% was homeless as part of a family constellation. In addition, nearly 18% are chronically homeless. Overall, the extent of homelessness declined by nearly 4% from 2012 to 2013, and unsheltered homelessness declined by 7%. Declines in homelessness occurred for all population subgroups (individuals, families, the chronically homeless, and veterans. Most homeless people were staying in shelters or transitional housing, but 35% were “unsheltered,” living on the street, in vacant buildings, in cars, or other places not intended for human habitation (Henry et al., 2013).

Although homelessness occurs throughout the nation, five states (California, New York, Florida, Texas, and Georgia) account for more than half of the homeless population. California alone accounts for 22% of the U.S. homeless population (Henry et al., 2013). Families with children make up one of the fastest growing segments of the homeless population, and the effects of homelessness are particularly severe for children and adolescents. An estimated 1.3 million people from 600,000 families will experience homelessness over time, and an additional 3.8 million families live in “precarious housing” and are at high risk for homelessness. Among children, three of every 200 U.S. children will be homeless at some point and more than twice as many will be at risk of homelessness (National Coalition for the Homeless, 2012c). As indicated by these and other figures, the risk for homelessness in the U.S. population is higher than previously thought (National Coalition for the Homeless, 2011a).

Another rapidly increasing, but often overlooked, segment of the homeless population is the elderly. For example, in 2008, 16.8% of the homeless population was over 50 years of age. There is some debate regarding the age at which a homeless person should be considered elderly. Generally, however, 50 years of age is used as a cut-off because homeless people tend to age faster than the general population and a 50-year-old homeless individual may have a health status similar to that of a 70-year-old in the general population (National Coalition for the Homeless, 2012l). The increase in homelessness among the elderly is due, in large part, to the loss of affordable housing in the context of fixed incomes.

Older householders and poor families have a high probability of being part of *worst-case needs households*. **Worst-case needs households** are defined by HUD as “very low income renters who do not receive government housing assistance and who either paid more than one half of their income for rent or lived in severely inadequate conditions or who faced both these challenges” (HUD, 2013, p. 1). Worst-case needs are the result of excessively high rents relative to household income. Approximately 48 million U.S. households were in worst-case situations in 2011, a figure that increased 43.5% from 2007 to 2011. Very low-income households with disabled members were even more likely to be considered worst-case needs households (HUD, 2013).

Population Health Nursing and Care of Poor and Homeless Populations

Population health nurses may encounter homeless clients in a number of venues. They may work in or with shelters for homeless people. Or they may encounter virtually homeless people during home visits to other clients with whom homeless individuals may be staying. Population health nurses may also encounter homeless clients who seek services from other agencies where nurses are employed. Finally, homeless clients may be referred to population health nurses by other agencies and providers.

Homeless individuals may be reluctant to admit to their homelessness for a variety of reasons. They may feel embarrassed about their condition or may want to forestall intrusion into what they may feel is their own affair. Population health nurses should be alert to indicators of possible homelessness in clients they encounter. For example, a population health nurse may note that a client has not taken a shower or washed his or her clothes in some time. Or the client may be hesitant when asked for a home address or may give the address of a known homeless shelter. Clients who report living with other family members or friends may also be virtually homeless. When faced with these indicators, the population health nurse can tactfully explore if the client is indeed homeless and if assistance is desired.

In other instances, clues may be more subtle. For example, in a hearing related to a college academic integrity violation related to plagiarism, the student explained his purchase of a paper from an Internet source as a result of not being able to work in his dorm room because his roommate was using drugs and he was afraid to be associated with him. When a population health nurse faculty member, who happened to be a member of the hearing committee, asked where the student was staying if he was not living in the dorm, he reported that he was living in one of the student lounges on campus. In addition to dealing with the academic integrity violation, the committee took immediate steps to obtain adequate housing for the student. However, his homeless plight would not have been identified if the population health nurse had not caught the cue buried in his defense of plagiarism.

Assessing the Health of Poor and Homeless Populations

The first step in the care of poor and homeless segments of the population is assessing their health status and identifying the factors that influence their health. The population health nurse examines factors that contribute to homelessness in the population as well as the effects of homelessness on health. Factors related to each of the six categories of determinants of health should be examined.

BIOLOGICAL DETERMINANTS. Biological factors, in conjunction with factors in other areas, may lead to poverty

and homelessness. Conversely, poverty and homelessness have serious consequences for physical health that vary with gender, age, and prior health status.

With respect to gender, the majority of single homeless individuals are men (67.5%). Women, on the other hand, make up a similar proportion of heads of homeless families, often as a result of domestic violence (National Coalition for the Homeless, 2011b). Among homeless veterans, the bulk of the population is male. In addition, this population is apt to be younger than the rest of the homeless population with 50% of homeless veterans under 51 years of age. Approximately 40% of homeless veterans are African American or Hispanic (National Coalition for Homeless Veterans, n.d.).

People of certain age groups may be more likely than other groups to become homeless or have more negative consequences as a result of homelessness. As we noted earlier, significant numbers of young children are homeless or at risk for homelessness. As many as one in 50 U.S. children may be homeless at any given time, amounting to 800,000 to 1.2 million homeless children, at least half of whom are under 5 years of age (National Coalition for the Homeless, 2012i). Poverty and housing insecurity among children has been associated with poor health, lower weight, and risk for developmental delays (Cutts et al. 2011), and homeless children are at higher risk for increased mortality and lead poisoning than housed children (Kerker et al., 2011). Asthma prevalence rates are also higher for poor children than for the near poor and non-poor child populations (Moorman, Zahran, Truman, & Molla, 2011). In addition, homeless children with asthma are more likely than their housed counterparts to have severe disease and frequent emergency departments for care and less likely to be on controller medications (Cutuli, Herbers, Rinaldi, Masten, & Oberg, 2010).

There are generally two categories of children among the homeless population, children who are part of homeless families and unaccompanied minors (Corliss, Goodenow, Nichols, & Austin, 2011). Unaccompanied minors may make up as much as 2% of the homeless population (National Coalition for the Homeless, 2011a). Unaccompanied minors are youth under 18 years of age without parental, foster parent, or institutional supervision (National Coalition for the Homeless, 2012k). Reasons for homelessness among adolescents tend to fall into three categories: family problems, economic problems within the family, or residential instability. Family problems may include strained relationships with parents, addiction in a family member, or parental neglect or outright abuse (National Coalition for the Homeless, 2012k). In some studies, sexual minority youth, who often leave home due to abuse or other family problems, may range from 4 to 5% to 50% of homeless unaccompanied youth (Corliss et al., 2011).

Economic problems in the family that may lead to youth homelessness include housing foreclosure leading to separation of adolescents, particularly boys, from other family members due to shelter rules or child welfare policies. Residential instability among youth usually stems from a history of foster

care and outgrowing foster care with no other place to go. In some studies, one in five unaccompanied youth arrived at homeless shelters directly from foster care, and one in four had been in foster care within the prior year. In addition to other health risks, homeless youth have been found to be 2 to 10 times more likely to be HIV-infected than their housed age mates as a result of sexual abuse and exploitation and the practice of engaging in sex for money (National Coalition for the Homeless, 2012k).

Certain health conditions may contribute to poverty and homelessness due to limited ability to work. For example, people with HIV/AIDS are at greater risk for homelessness than the general population for a number of reasons. Hospitalization and excessive fatigue may interrupt employment, leading to loss of income and consequent inability to pay for housing. They may also experience discrimination and job loss due to their condition. For other individuals, serious illness, with the attendant medical bills may precipitate homelessness for individuals or families. For example, approximately 40% of people evicted by foreclosures indicated that medical problems played a role in the foreclosure (National Coalition for the Homeless, 2012f). Approximately half of all personal bankruptcies in the United States are the result of serious health problems. As noted by the National Coalition for the Homeless (2012h), serious illness or disability can precipitate loss of employment and savings, eventually resulting in homelessness.

Being poor or homeless also contributes to or complicates other health problems. Homeless individuals are sick more often and have 1.5 to 3.5 times the risk of mortality of their housed counterparts (National Coalition for the Homeless, 2012h; O'Toole et al., 2010). Life expectancy for homeless individuals is approximately 30 years less than for those who do not experience homelessness (National Coalition for the Homeless, 2012f). Mortality rates for HIV/AIDS and substance abuse deaths in New York City were three and five times higher, respectively, in homeless individuals than in the general population and substance abuse deaths were also higher than in the housed low-income population (Kerker et al., 2011). Health problems common among homeless adults include asthma, bronchitis, hypertension, heart disease, cancer, liver and kidney disease, diabetes, and sexually transmitted infections and other infectious conditions. Skin infections and pneumonia are also common.

Other frequently noted problems include malnutrition, TB, and other respiratory diseases resulting from the lack of housing and overcrowding in shelters (National Coalition for the Homeless, 2012h). In addition, homeless individuals are more likely to self-report poor health than either the housed poor or non-poor.

As we can see from this list of common conditions, poor and homeless persons often suffer multiple acute and chronic conditions that require long-term treatment and monitoring that is difficult in circumstances of poverty and homelessness (National Coalition for the Homeless, 2012h). Inadequate diet and lack of access to medications and health care supplies

make disease management difficult. For example, hypertension is less likely to be controlled among the poor than the non-poor. Paradoxically, control may be even worse among the near poor (Keenan & Rosendorf, 2011); perhaps because they are less likely than the truly poor to have publicly funded health insurance. Similarly, diabetes prevalence is higher among the poor than the non-poor (Beckles, Zhu, & Moonesinghe, 2011), and glycemic control among diabetics is considerably less likely in the poor than in higher income individuals (NCHS, 2012).

Poor and homeless individuals are also more likely to have physical disabilities (National Coalition for the Homeless, 2011a) and activity limitations. For example, in 2012, 42% of people aged 18 to 64 years in poverty experienced basic activity limitations compared to 21% of those with incomes 400% of poverty level or higher. Similarly, complex activity limitations were found in 28% of the poor versus 8% of high-income individuals. Differences in activity limitations by income level were even more striking among the elderly (NCHS, 2014). In 2012, limitations in activities of daily living (ADLs) and in instrumental activities of daily living (IADLs) were three times more common among the poor than the non-poor (Adams, Kirzinger, & Martinez, 2012). In addition, survival stress experienced by many homeless persons may lead them to put health needs at a lower priority than basic survival needs (O'Connell et al., 2010).

The elderly are at particular risk of health problems stemming from poverty and homelessness. All of the usual problems of the elderly discussed in Chapter 19 are intensified by poverty and homelessness. The homeless elderly are particularly susceptible to the effects of communicable diseases, exposure, burns, and trauma due to alcohol use, physical or mental impairment, or assault. The elderly homeless population is also more likely than younger groups to experience chronic disability due to physical, mental, or emotional impairment.

PSYCHOLOGICAL DETERMINANTS. Psychological problems can stem from poverty and homelessness. In 2011–2012, for example, more than 8% of people with incomes below 100% of the federal poverty level reported experiencing severe psychological distress in the prior 30 days, compared to 4.9% of the near poor, 2.6% of middle-income individuals, and only 1.1% of those with incomes more than 400% above the poverty threshold (NCHS, 2014).

Psychological factors can lead to homelessness when people are unable to cope with the demands of daily life and have limited support systems. Mental illness, in particular, is associated with homelessness. An estimated 20% to 25% of the homeless experience severe mental illness and mental illness is the third most common cause of homelessness for single adults (National Coalition for the Homeless, 2012m). In one study 15% of all the people in the California mental health system reported being homeless at one point in their lives. Mental illness may disrupt one's ability to care for oneself, including managing a residence. In addition, mental illness may prevent

formation or maintenance of interpersonal relationships or contribute to paranoia and mistrust of others. Mental illness also makes it difficult to obtain and keep a job and may also impede care of one's physical needs. Many mentally ill homeless individuals may attempt to self-medicate themselves in an effort to deal with their symptoms, and many have resulting dual diagnoses of substance abuse and mental illness (National Coalition for the Homeless, 2012m).

Homeless veterans, in particular, have a history of mental illness, with up to 50% of this population affected. Post-traumatic stress disorder (PTSD) is a common diagnosis among homeless veterans, and an estimated 70% have substance disorders (National Coalition for Homeless Veterans, n.d.; National Coalition for the Homeless, 2012j).

In the past, many authors cited the move to deinstitutionalize the mentally ill in the 1950s and 1960s as the cause of increasing homelessness among this population. **Deinstitutionalization** was the process of discharging large numbers of mentally ill persons from mental institutions in an attempt to enable them to live in the least restrictive environment possible. This move was prompted by recognition of the appalling conditions prevalent at the time in many institutions for the mentally ill. Although the intent of deinstitutionalization was laudable, the results were not. Unfortunately, there was no concurrent move to provide the community services needed for the mentally ill to live in noninstitutional settings, leaving them to fend for themselves. Other authors, however, point out that the increase in homeless mentally ill persons did not actually occur until the 1980s, when income and housing assistance programs for this population were withdrawn. Most mentally ill persons do not need to be institutionalized, but they do require access to a variety of supportive services, including housing support, in order to function effectively in society and maintain residential status (National Coalition for the Homeless, 2011c).

Some homeless persons without preexisting mental illness exhibit psychological problems as a result of their homelessness. For example, housing insecurity and frequent moves have been associated with mental health and behavior problems, substance abuse, poor school performance, and increased risk of pregnancy in adolescents (Cutts et al., 2011). Homeless youth have also been found to have higher rates of depression, anxiety, low self-esteem, and conduct disorder than their housed age mates. In addition, rates of PTSD are three times higher in this population than among adolescents who are not homeless (National Coalition for the Homeless, 2012k). Younger children's mental health is also affected by homelessness, and homeless children are more likely than their housed age mates to experience anxiety, depression, and behavior problems.

ENVIRONMENTAL DETERMINANTS. Environmental factors also contribute to the effects of homelessness on health. Exposure to cold, even in the mildest climates, can lead to hypothermia. This is particularly true when people are lying on concrete or are clothed in wet garments. Increased exposure risk for

frostbite, immersion foot, and hypothermia occurs primarily in persons who are homeless and living on the streets. Immersion foot, also known as trench foot, occurs when the feet are wet for prolonged periods of time. Although these conditions do not, of themselves result in death, they may contribute to an eightfold increased risk of mortality from other causes (National Coalition for the Homeless, 2012h). Another weather-related environmental phenomenon that has been found to affect migrant farmworkers is the heat index in their often substandard housing. For example, one study of 170 North Carolina farmworker camps found dangerously high heat indexes in most housing units (barracks-style housing, trailers, and houses). High heat indexes in housing units limit recovery from the negative effects of heat exposures during daily work in hot, humid conditions contributing to a high incidence of heat-related deaths in the migrant farmworker population (Quandt, Wiggins, Chen, Bischoff, & Arcury, 2013).

Overcrowding and poor sanitary conditions in homeless shelters contribute to the spread of communicable diseases among a population that is already debilitated by exposure and poor nutritional status. TB, in particular, is rapidly spread in overcrowded shelters (Dobbins et al., 2012; Samuel et al., 2012) and other settings where homeless individuals may congregate. For example, TB transmission in one outbreak also involved two local bars frequented by shelter residents and a local jail, suggesting the potential for spread of the disease to the general public as well as to other shelter residents (Samuel et al., 2012). Crowding in shelter environments is also associated with poor mental health, diminished coping ability, poor parent-child interactions, stressful social relationships, and difficulty sleeping. Crowding has also been associated with food insecurity in shelter residents, particularly homeless families (Cutts et al., 2011).

Another environmental aspect of shelter life lies in the actual physical structure of some shelter facilities. Many shelters are located in older buildings that may have stairs, making it difficult for the elderly and others with limited mobility to access emergency shelter and other services. Access to services in other organizations may also entail long periods of standing in line, which may be difficult for elderly and disabled individuals (National Coalition for the Homeless, 2012l).

Unsafe physical environments also present health hazards for young children. In addition to the potential for physical injury, the restrictions placed by parents on children's activities in unsafe surroundings may result in developmental delays. Prolonged sun exposure and the attendant risk for skin cancer are other environmental factors affecting the homeless of all ages.

Aspects of rural versus urban environments also affect homelessness and access to assistance for poor and homeless individuals. Several authors have noted that even the definition of homelessness "does not fit well with the rural reality" (National Coalition for the Homeless, 2012n, p. 1). Because of the unavailability of shelters in many rural areas, homeless individuals are more likely than their urban counterparts

to move in with family members or friends in crowded and substandard conditions. These individuals, however, do not qualify for assistance, and the rural communities that house them are not eligible for federal funding for homeless services (National Coalition for the Homeless, 2012n), leading to a need for a more flexible definition of rural homelessness (National Coalition for the Homeless, 2012f). Based on current definitions, approximately 9% of homelessness in the United States occurs in rural areas, and an estimated 70,000 rural individuals may be homeless on any given night (National Coalition for the Homeless, 2011a).

Even the factors contributing to homelessness differ substantially between urban and rural environments. For example, rural states experience significantly more foreclosures, a frequent cause of homelessness, than urban areas (National Coalition for the Homeless, 2012f). Rural homeless populations are more likely to consist of families, particularly single women with children, with a larger proportion of Native Americans and migrant workers than urban populations (National Coalition for the Homeless, 2012n). Homeless veterans, on the other hand, are more likely to be found in urban than suburban or rural areas (68% and 32%, respectively) (National Coalition for Homeless Veterans, n.d.).

Domestic violence and poverty are also more common precursors to homelessness in rural than urban environments. In fact, rural residents are 1.2 to 2.3 times more likely to be poor than their urban counterparts, and 20% of nonmetropolitan counties are classified as high poverty counties compared to only 5% of metropolitan counties. One third of rural renters (1.9 million households) are “cost burdened,” spending more than 30% of their incomes for housing (National Coalition for the Homeless, 2012e).

More rural homelessness is found in agricultural areas and those with declining extractive industries (e.g., coal mining). Paradoxically, increased homelessness in rural areas is also linked to rural areas experiencing economic growth as burgeoning industry and outsiders earning higher incomes create a demand for scarce housing that drives housing costs beyond the budgets of long-time residents.

The greater visibility and population density of urban than rural homeless populations leads to inequities in the availability of and access to needed services, and rural housing needs are often overlooked in policy formation. Even when housing is available in rural areas, it is often substandard, and 30% of nonmetropolitan households experience at least one problem, including high costs, physical deficiencies, or overcrowding (National Coalition for the Homeless, 2012e). In fact, homelessness is often precipitated by substandard housing conditions that make structures uninhabitable. In such cases, relocation to safer housing is often more expensive and beyond the ability of many rural families to afford it. For these reasons, many authors have suggested redefining rural homelessness to include people living in substandard housing, making them eligible for services available to those living on the streets or in shelters (National Coalition for the Homeless, 2012f).

Other contributing factors in rural homelessness include distances between affordable housing and work settings, lack of transportation, restrictive land use regulations and housing codes, rising rent burdens, and insecure tenancy due to changes in real estate markets. For example, inexpensive trailer parks may be replaced by more expensive upscale housing unaffordable to local residents (National Coalition for the Homeless, 2012n).

Homelessness in urban areas brings its own set of difficulties, and some authors have suggested that homeless individuals are “warehoused” in densely populated urban areas. Although temporary shelter and other assistance services may be more accessible in urban than rural areas, there may be a lack of affordable housing and widespread economic distress in the community that limits the availability of work and other supports (Eitzman, Pollio, & North, 2013).

SOCIOCULTURAL DETERMINANTS. Sociocultural factors play a major role in the development of poverty and homelessness and in their effects on health. Lack of affordable housing and available shelter; poverty, inadequate social support and welfare reform; employment; and housing assistance are some of the societal conditions that influence poverty and homelessness. Other considerations to be addressed include education, homelessness among military veterans, domestic violence, mega events and their effects on housing and homelessness, and considerations related to criminal justice, civil rights, and violence against homeless individuals.

Lack of affordable housing and available shelter. Housing is a basic human need. The World Health Organization incorporates four aspects into its definition of housing: house, home, neighborhood, and community. A house is a physical structure or dwelling used, or intended to be used, for human habitation (WHO, 2010). A house, in this context, may include a freestanding dwelling, apartment, condominium, or single room occupancy unit. A **single room occupancy unit (SRO)** is a building that provides single rooms as sleeping accommodations for individuals (City of South San Francisco, n.d.). Bathrooms, kitchens, and other living spaces are shared by tenants in SROs (National Coalition for the Homeless, 2012e). The term “home” encompasses the economic, social, and cultural structure established by a given household. The neighborhood aspect includes streets, shops, places of worship, recreation, green space and transportation surrounding where people actually live, and the community includes those living, working, and providing services in the neighborhood (WHO, 2010). Interventions to address population housing needs must address all four aspects of this definition.

Lack of affordable housing is one of two trends that have contributed to the alarming rise in homelessness in the United States (National Coalition for the Homeless, 2011b). **Affordable housing** is defined as housing that costs no more than 30% of one’s income (National Coalition for the Homeless, 2012d). In the United States, approximately

Thrift stores help the poor and homeless to stretch their resources, but still may not meet all their needs. (rekandphoto/Fotolia)

6.5 million families spent more than 50% of their income on housing in 2011 (National Alliance to End Homelessness, 2013). Housing costs have escalated tremendously making housing unaffordable for many individuals and families. For example, there was a 41% increase in the fair market rent for a two-bedroom apartment between 2000 and 2009 resulting in high rent burdens—rents that take a large proportion of one’s income (National Coalition for the Homeless, 2011c). High rent burden is the result of the lack of affordable adequate housing units relative to the population demand for housing, creating increased competition for available housing, which is worse among low-income individuals and families than those with higher incomes (HUD, 2013). Subsequent increases in the average fair market rents have also occurred. For example, average rents rose by 1.5% just from 2010 to 2011, and the number of rental vacancies also decreased (National Alliance to End Homelessness, 2013).

In 2011, there were an estimated 65 housing units available for every 100 low-income renters and 35 units per 100 extremely low-income renters. From 2011 to 2009, the median renter income decreased by 1.5% whereas the median rent increased by 4.1%. Conversion of formerly resident-owned properties to rental units increased the affordable housing by 3.33 million units, but this gain was offset by the advent of 3.47 million new renter households resulting in a continuing dearth of affordable housing for low-income households (HUD, 2013). In 2009, a worker would have needed to earn \$14.97 per hour to be able to afford a one-bedroom apartment and \$17.84 per hour for two bedrooms, nearly twice the minimum wage (National Coalition for the Homeless, 2011c).

In addition to low-income workers, the elderly are at an economic disadvantage with respect to affordable housing. The majority of older adults live on fixed incomes and for many, Social Security income, even when augmented by Supplemental Security Income, a subsidy for low-income seniors and disabled persons, is insufficient to afford housing. There are an estimated nine seniors waiting for every occupied unit of

affordable elderly housing, and the waiting list for housing assistance may be 3 to 5 years. In addition, households headed by elderly individuals have a one in three chance of being worst-case needs households (National Coalition for the Homeless, 2012l).

Part of the loss of affordable housing stems from **gentrification**, which is defined as a process in which deteriorated low-income housing and businesses are renovated and occupied by higher income individuals (Briney, 2013). It usually involves displacement of low-income housing by higher-income space use such as luxury apartments, condominiums, or office buildings. When gentrification occurs, the ethnic composition of neighborhoods often changes with in-migration of middle-income White families, younger individuals, and couples seeking to be closer to their work. Renovation of older, run-down housing leads to increased rents and property taxes for former residents who choose to remain in the neighborhood. Because of these changes, gentrification may also significantly alter the character and culture of an area (Briney, 2013).

Some authors have described attempts at “positive” gentrification, which often involves the demolition of deteriorating public housing and its replacement by mixed-income housing in which people from different socioeconomic groups buy or rent in the same area. The intent of such efforts is to “deconcentrate” poverty, by placing the poor among others of higher socioeconomic status (Chaskin & Joseph, 2013). Such redevelopment often greatly improves the local infrastructure in terms of open space and streets. It may also result in cultural clashes regarding what constitutes acceptable behavior (e.g., parking cars on the road, accumulation of unused items in yards, and so on) in the reconstituted community (Drew, 2011). In addition, the demolition and rebuilding process forces prior residents to find other housing, and may result in their not returning to their prior neighborhood. In some redevelopment initiatives, efforts are made to enforce inclusion of a certain percentage of low-income housing, but in many jurisdictions, developers can buy their way out of such requirements by paying nominal fines, resulting in many more high-priced than low-income units. In reality, rather than returning to the new and improved housing, many former residents relocate in other nearby disadvantaged neighborhoods. National estimates are that no more than 14% to 25% of former residents return to gentrified neighborhoods. Relocation often disrupts social ties among neighbors, thus decreasing the social capital available to the displaced residents (Goetz, 2010).

Another aspect of the problem is the loss of many SROs, or residential hotel units in inner city areas. Much of this loss is the result of gentrification and conversion of SROs and rooming houses to upscale rentals.

People who are homeless require shelter, and the first step to meeting their needs is the provision of emergency shelter. Shelter, however, may not be available. According to 2012 HUD data, there were 476,119 total shelter beds across the nation in 2012, only 90% of which were available year round (HUD, 2012b). 2012 housing inventory counts (HICs) from

Gentrification of older neighborhoods reduces housing availability for low-income groups. (Kim Seidl/Fotolia)

continuum of care, local planning agencies throughout the country that coordinate services in geographic areas, indicated a total of 114,237 units available for families including emergency shelter units, safe havens, transitional housing units, rapid rehousing units, and permanent supportive housing units. An additional 349,277 family beds and 376,318 adult-only beds were available. In addition, slightly more than 28,000 overflow vouchers were available for use at local hotels when other forms of shelter were not available (HUD, 2012a). Despite these numbers, however, on a given night in January as many as 1,740 people could not be provided emergency shelter, and 1,422 could not be provided transitional shelter (National Coalition for the Homeless, 2012b).

Lack of affordable housing and lack of shelter space have led to an increase in the size of the literally homeless population as well as those living doubled-up in the homes of friends and families. From 2010 to 2011, for example, the number of doubled-up households increased by 9.4% (National Alliance to End Homelessness, 2013).

Poverty, social support, and welfare reform. Poverty is the second most major cause of homelessness in the United States, and increasing poverty is the result of eroding employment opportunities and the decreased availability and value of public assistance (National Coalition for the Homeless, 2011b, 2011c). The relationship of employment to poverty and homelessness is addressed later in this chapter.

A large percentage of the homeless are people who are employed, but employment does not protect them from poverty. In 1967, the minimum hourly wage was sufficient to raise a family of three above the federal poverty level. However, the minimum wage was frozen at \$3.35 per hour from 1981 to 1990, while the cost of living increased by 48%, resulting in a far from livable wage. As of July 24, 2009, the minimum hourly wage in the United States was set at \$7.25 (U.S. Department

of Labor, Wage and Hour Division, n.d.). As of June 2014, 22 states and the District of Columbia had minimum wage levels above that set by the federal government, with the highest set at \$9.32 per hour (National Conference of State Legislatures, 2014).

The federal minimum wage has not changed since 2009, although a few states have automatic adjustments to their minimum wage rate based on the consumer price index, the local average wage, or some other cost of living formula (National Conference of State Legislatures, 2014). At the minimum wage, a full-time 40-hour-per-week worker would earn \$13,624, which is 25% below the 2009 poverty level for a family of three and even further below the current poverty threshold. A household of that size would need to include more than one minimum wage worker to be able to afford a two-bedroom apartment at fair market rent anywhere in the country. In states with the median fair market rent, a minimum wage worker would need to work 87 hours per week to be able to afford a two-bedroom apartment. Because of high rates of inflation, the real purchasing power of the minimum wage has decreased by 26% since 1979, and the current \$7.25 minimum wage is actually worth only \$4.42 in buying power. In addition, rising costs for food and gasoline take a greater percentage of household income than in the past, further limiting the funds available for housing (National Coalition for the Homeless, 2012d). The poor simply cannot afford most housing without assistance.

Assistance to low-income individuals and families, however, may not be available or is insufficient to meet their basic needs. In the past, low-income families received cash assistance through the Aid to Families with Dependent Children (AFDC) program. The AFDC program was repealed in 1996 and replaced by the Temporary Assistance to Needy Families (TANF) program as part of a sweeping welfare reform program. The intent of welfare reform was to assist persons on the welfare rolls to become employed and fend for themselves. In 2005, however, TANF assisted only half of the families formerly receiving AFDC, and federal appropriations for TANF have not kept up with inflation levels, leading to significant increases in extreme poverty, particularly among young children. In addition, federal support for housing assistance declined by 49% from 1980 to 2003, while approximately 200,000 low-income housing units were destroyed each year (National Coalition for the Homeless, 2011c). In the end, welfare reform was successful in getting many families off the welfare rolls and into paying jobs, but these jobs often do not pay sufficient wages to afford available housing. In addition, there is little assistance to these families for expenses related to work, such as transportation or child care (National Coalition for the Homeless, 2012i).

Financial assistance is available to some segments of the poor population. For example, many low-income senior citizens are eligible for Supplemental Security Income (SSI) in addition to Social Security. For most of these individuals, even the addition of SSI does not raise them above the poverty level (National Coalition for the Homeless, 2012l). Housing

subsidies have been shown to assist the poor to remain housed, but many people do not receive subsidies.

Foreclosure is another effect of the current economic crisis that contributes to homelessness. A survey of organizations providing services for the homeless indicated that approximately 10% of their clients were homeless as a result of foreclosure. More than 342,000 foreclosures occurred in the single month of April 2009, an increase of 32% from the same month in 2008. Although one usually thinks of foreclosures affecting home owners who fall behind on mortgage payments, 20% of foreclosures in 2008 were on rental properties, and 40% of families facing eviction due to foreclosures were renters. Many of these families found shelter with family or friends, in homeless shelters, and in hotels or motels, but 26% were reduced to living on the street (National Coalition for the Homeless, 2012f).

A small proportion of low-income individuals and families and some other groups receive federal housing assistance. Housing assistance programs exist for disabled persons and

the elderly, as well as veterans, and those in rural areas. Some public housing is also available to low-income individuals and families. Federal housing assistance programs are summarized in Table 21-1 •. Unfortunately, these assistance programs may have long waiting lists or lengthy selection processes, and all of them are underfunded to meet the needs of the homeless population. For example, the average waiting period for Section 8 vouchers is 35 months, and only about a third of poor renter households ever receive housing assistance (National Coalition for the Homeless, 2011c). In addition, housing vouchers, if obtained, may not be of much use in areas where low-income housing is scarce.

Employment and homelessness. Unemployment and underemployment are other major social factors contributing to homelessness. Although many people remain employed, there has been a shift in the job market from relatively well-paid manufacturing jobs to lower-paid employment in service indus-

TABLE 21-1 Federal Housing Assistance Programs

Program	Focus	Eligibility/Requirements
Section 811. Supportive Housing for Persons with Disabilities Program	<ul style="list-style-type: none"> • Small group homes, independent living projects, multifamily housing developments 	<ul style="list-style-type: none"> • Very low-income persons 18 years of age or older with physical or developmental disabilities
Section 202. Supportive Housing for the Elderly Program	<ul style="list-style-type: none"> • Provision of housing with supportive services for low-income elderly 	<ul style="list-style-type: none"> • Very low-income persons aged 62 years and older • 20% to 25% of funding mandated for nonmetropolitan areas
Section 8. Housing Choice Voucher Program	<ul style="list-style-type: none"> • Rental assistance through a voucher system administered by state, regional, or local housing authorities that permits renters access to privately owned housing • Recipients find their own housing that meets criteria • Also provides a homeowner's voucher that assists with the purchase of a home by first-time very low-income persons 	<ul style="list-style-type: none"> • Very low-income families, elderly, and disabled individuals • Income cannot exceed 50% of median income of area • Renters pay 30% of monthly income for rent and utilities, voucher covers difference in rental costs
Section 8. Single-Room Occupancy	<ul style="list-style-type: none"> • Rehabilitation of existing structures to provide SRO units • Rental assistance to meet difference between housing costs and 30% of income • Rental assistance provided for a 10-year period • Provides a single room with communal bathrooms, kitchen, living spaces, laundry facilities, possibly meeting rooms 	<ul style="list-style-type: none"> • Very low-income homeless individuals (income below 50% of area median income) • Renters pay approximately 30% of income for rent, public housing agencies pay landlord the difference in cost
HOPE VI	<ul style="list-style-type: none"> • Provision of funds to local public housing agencies to destroy and replace or dramatically rehabilitate deteriorated public housing units, including physical and managerial changes and some social and community services • Integration of low-income renters in middle-income areas • Provision of employment support services 	<ul style="list-style-type: none"> • Intensive screening • Agreement to counseling and employment services
Public Housing	<ul style="list-style-type: none"> • Provision of federally owned and administered rental housing to low-income families and individuals 	<ul style="list-style-type: none"> • Low-income family, elderly, or disabled individual

TABLE 21-1 (Continued)

Program	Focus	Eligibility/Requirements
HOME: Home Investment Partnerships Program	<ul style="list-style-type: none"> • Funding grants to states or communities to build, buy, or rehabilitate housing units for rental or ownership • Provision of rental assistance for occupants 	<ul style="list-style-type: none"> • Local jurisdictions must contribute 25% match for funds • Income below 80% of area median
Section 502. Rural Home Ownership Direct Loan Program	<ul style="list-style-type: none"> • Loans to build, repair, renovate, or relocate houses (including mobile/manufactured homes) • Assistance with site purchase and water and sewage disposal arrangements 	<ul style="list-style-type: none"> • Low-income and very-low-income rural families without adequate housing (below 80% of area median) • Able to afford mortgage payments, taxes, and insurance • 40% of funds must be used to serve families with incomes less than 50% of area median income
Section 515. Rural Rental Housing Loans	<ul style="list-style-type: none"> • Competitive mortgage loans to provide affordable rental housing • Provision of funds to buy and improve land and water and waste disposal systems 	<ul style="list-style-type: none"> • Very low-, low-, and moderate-income families, elderly, and disabled individuals • Renters pay higher of 30% of income or basic rent
Veterans Administration	<ul style="list-style-type: none"> • Temporary housing funding including emergency shelter and transitional housing, long-term care, and skills training 	<ul style="list-style-type: none"> • Low-income military veterans
HUD-VA Supportive Housing Program	<ul style="list-style-type: none"> • Vouchers for housing subsidization 	<ul style="list-style-type: none"> • Low-income military veterans
VA Compensated Work Therapy/Transitional Residence Program	<ul style="list-style-type: none"> • Supervised group home residence • Recipients work for the VA about 33 hours/week and receive salary and maintenance payment

tries (e.g., janitorial work). This phenomenon is referred to as **structural unemployment**, which is unemployment caused by a mismatch between the skills and abilities of persons available to work and the jobs needing to be filled, rather than an absence of jobs. Deindustrialization is a related phenomenon that contributes to structural unemployment. **Deindustrialization** is a shift in economic and occupational structure from a heavy focus on manufacturing to service, technology, and other forms of employment. In structural unemployment, jobs may be available, but those who are unemployed do not have the skills needed to qualify for them. The emergence of high-technology occupations requires new sets of skills that many displaced workers do not have. Such changes in the structure of the job market have resulted in the current relatively high levels of unemployment.

The percentage of homeless people who are jobless varies from group to group. Overall, 44% of the homeless are employed, but many homeless individuals work at low-paying jobs that do not provide sufficient income to meet basic survival needs. Many poor and homeless individuals are underemployed, a measure of those who are unemployed plus those who desire full-time work, but can only find part-time employment. Using this measure, in 2009, 15.8% of the U.S. workforce was underemployed (National Coalition for the Homeless, 2012d). Others who worked full-time remained below the poverty level (U.S. Census Bureau, 2012d).

In addition to declining real wages noted earlier, job security and stability have also declined, and displaced workers may have difficulty finding another job. Even when they do find work, however, many take jobs that pay an average of 13% less than former salaries. People are experiencing more long-term unemployment than in prior years, and the unemployed includes those formerly employed in professional and managerial jobs as well as unskilled workers. These workers often engage in what is termed non-standard work, such as temporary work, day labor, and part-time employment. For example, temporary work has increased by 11% since 1972, but even temporary jobs are being lost, with about 73,000 temporary positions lost per month in 2009 (National Coalition for the Homeless, 2012d). Non-standard work usually does not provide health insurance and other benefits that accompanied many people's prior employment.

Finding employment is difficult for most homeless individuals. Those with mental illness find it hard to maintain a job, if they can get one, because of their instability. Homeless single women with children, who account for almost half of homeless families, have problems of child care while they work. Former prisoners are also at a disadvantage in seeking employment as are young people who often have few employable skills. Similarly, employment is unlikely among elderly homeless people (National Coalition for the Homeless, 2012d, 2012k, 2012l)

Even homeless persons with employable skills in areas where jobs are available may have difficulty negotiating the employment process. Lack of transportation may make it difficult to go to an interview or to get to work when a job is found. In addition, job application and interviews take time, which may prevent the individual from securing food or shelter for the night when these are obtained only after long waits in line in competition with many other homeless persons. Moreover, the homeless person may also find that he or she is penalized for working by reduction or even loss of assistance benefits and publicly financed health care coverage. Homeless individuals who cannot find regular work may engage in day labor or “shadow work.” Shadow work may involve selling junk, personal possessions, or plasma; begging or panhandling; scavenging for food, salable goods, or money; and theft, all of which may carry criminal penalties in some jurisdictions.

Other sociocultural factors. Education, veteran status, domestic violence, “mega events,” and considerations related to criminal justice, civil rights, and violence are other sociocultural factors related to poverty and homelessness. Education both contributes to and is affected by poverty and homelessness. Many of the poor are from low socioeconomic backgrounds. For example, a third of adults with incomes below poverty level did not complete high school, compared to 29% of those below 125% of the poverty threshold and only 10% of those 150% above poverty level (Beckles & Trumann, 2011). Lack of education results in an absence of employable skills in today’s job market, which contributes to poverty and eventually leads to homelessness for many people.

Homelessness also influences educational performance among children and youth. As noted by the National Coalition for the Homeless (2012c), schools provide one of the few avenues for poor and homeless children to develop the skills needed to escape poverty. Unfortunately, the stability of the school environment is complicated by residency requirements, delay in the transfer of records, lack of transportation, and, often, lack of immunization records. Additional problems lie in getting children and youth assessed for special education needs, providing counseling, and promoting participation in before- and after-school activities. Unaccompanied youth also face problems with guardianship and liability. Homeless children are less likely than their housed counterparts to be enrolled in school. An estimated 87% of homeless children are enrolled in school, and only 77% of those attend school regularly. Some effort has been made to promote education among this population. For example, the McKinney Act’s Education of Homeless Children and Youth program provides grants to state education agencies to support the education of homeless children, including preschool education. This initiative resulted in a 17% increase in school enrollment from the 2006–2007 academic year to 2007–2008.

Multiple factors, however, continue to impede school attendance by homeless children and youth. Residency requirements

to attend local schools, lack of immunization records, delay in transfer of school records, and lack of transportation make school enrollment and attendance difficult. Poor health and lack of food, clothing, and school supplies are other impediments to attendance and good school performance. Although the reauthorization of the McKinney Act in 2001 addressed some of these issues, funding for homeless education programs has not kept up with the need or with the inflation in costs of ancillary services such as food and school supplies. At one point, for example, states receiving funds were unable to provide assistance to 41% of enrolled homeless students. Finally, family mobility due to shelter time limits, domestic violence, or the search for work or affordable housing leads to frequent changes of schools. Students who change schools frequently are nine times more likely to repeat a grade, four times more likely to drop out of school, and three times more likely to be put in special education classes (National Coalition for the Homeless, 2012c), and adolescents with more than two school changes are 50% less likely to graduate than other teens (Cutts et al., 2011).

Military veterans comprise 12% of the homeless population (National Coalition for Homeless Veterans, n.d.). As many as 130,000 to 200,000 veterans may be homeless at any given time, with estimates of 400,000 homeless veterans in the course of a year. As many as three times more veterans experience heavy rent burdens and are at high risk for homelessness. Veterans with disabilities, particularly related to PTSD and traumatic brain injury, are more likely than other veterans to become homeless (National Coalition for the Homeless, 2012j).

Compared to other homeless individuals, veterans are likely to be younger and better educated (National Coalition for the Homeless, 2012j). They are also twice as likely to be hospitalized as homeless individuals who are not veterans (O’Toole et al., 2010). Homeless veterans tend to be found in central city areas (79%) rather than suburban or rural areas (16% and 5%, respectively) (National Coalition for the Homeless, 2012j). In addition to the mental health problems common among homeless veterans, unemployment is a contributing factor in their homelessness. Many veterans are discharged from the military without employable skills useful in the civilian economy making them less able to compete for available jobs (National Coalition for Homeless Veterans, n.d.).

Some efforts have been made to address the needs of homeless veterans. In addition to the programs described in Table 21-1, the Veterans Administration (VA) provides a variety of services to veterans, including those who are homeless. For example, the VA provides health care to 150,000 veterans and other services to 112,000 people annually. In addition, partnerships with community service providers have provided 15,000 residential rehabilitation and transitional beds and more than 30,000 permanent beds, reducing the number of homeless veterans by 70% since 2005 (National Coalition for Homeless Veterans, n.d.). Despite these successes, however, the VA serves only about 25% of the veterans in need, leaving approximately 300,000 veterans without assistance (National Coalition for the Homeless, 2012j). Homeless veterans need a

wide variety of coordinated services related to housing, nutrition, health care, substance abuse and mental health treatment, and personal development and job training and placement services (National Coalition for Homeless Veterans, n.d.).

Domestic violence is another factor that contributes to homelessness, particularly among women and children. An estimated 63% of homeless women are victims of domestic abuse and 28% of families are homeless as a result (National Coalition for the Homeless, 2012b). Homeless youth may also be fleeing physical or sexual abuse. Some studies have reported 46% of runaway and homeless youth as physically abused and 17% as sexually abused (National Coalition for the Homeless, 2012k).

Many homeless women and youth have minimal resources and face the choice of remaining in an abusive situation or becoming homeless. They often have nowhere to go. Homeless youth have few employable skills and abused women may have poor work histories and credit ratings as a result of abuse. Homeless women with children often stay in shelters, transitional housing, or permanent supportive housing longer than single homeless men and women because it is often harder for them to find permanent housing. In addition, landlords may discriminate against abused women if they have protective orders in place and may evict families if violence occurs in rental properties (National Coalition for the Homeless, 2012b). Cash assistance, housing, job training, child care, and transportation are some of the needs of abused homeless women with children.

The effect of “mega events” on housing and homelessness is another factor that is often overlooked in an assessment of poor and homeless populations. A special report to the United Nations General Assembly (Rolnik, 2009) highlighted the effects of such mega events in the context of the right to adequate housing. Mega events are large, one time events, often large sporting events that prompt changes in local infrastructure and economies. Examples are the summer and winter Olympic Games and the World Cup of soccer. Such events have both positive and negative effects for the poor and homeless.

On the positive side, mega events lead to the rapid construction of housing as well as improvements in waste management and sanitation capabilities, cleansing of contaminated areas, beautification and environmental upgrading, transportation improvement, and so on. After the event, the surplus housing may be available for local residents. In the interim, however, massive redevelopment initiatives often lead to displacement of the poor and demolition of low-income housing. In many instances, the wealthy developers and governments benefit from increased revenue, tourism, and increased tax revenues, but little of this money filters into programs for the local poor. Evictions are often not accompanied by plans for relocation of displaced individuals and families, and those displaced rarely return to the renovated areas (Rolnik, 2009).

Residents of “informal settlements,” such as shanty towns or tent cities, are frequently among the first to be displaced when land is required for redevelopment or construction of enhanced sports facilities. Frequently, these communities are

disrupted with community ties broken and people displaced to areas far from employment opportunities or other services. Preparation for mega events also frequently entails cleaning up “unsightly” elements of the city’s image through removal and relocation of homeless individuals and criminalization of homelessness. **Criminalization** is the development of laws and regulations and application of criminal penalties to activities such as sleeping on the streets, begging, and so on, that would be perfectly acceptable if performed in private. Criminalization may also affect other activities such as prostitution or sidewalk vending. Offenders may be jailed, and in some instances, may be relocated to large camps with minimal facilities out of sight of event participants and fans (Rolnik, 2009).

Population health nurses may be actively involved in advocacy for human rights in cities where mega events are planned. They and others in the environment should assure that sufficient attention has been given to meeting the needs of the populations most likely to be negatively affected by the event. For example, they should insist on protection of vulnerable populations from forced evictions and on community participation in event planning and decision making (Rolnik, 2009).

Criminalization of homelessness and related activities is only one aspect of criminal justice as it applies to the poor and homeless. Homelessness and lack of basic necessities to support life may lead to crime, as well as prostitution, to obtain money. More often, however, homeless individuals are arrested for actions that, if conducted in private, would be perfectly acceptable. The homeless are overrepresented in jail, and recently released prisoners are at high risk of homelessness due to disruption of family and community ties. Mentally ill inmates have an even more difficult time reintegrating into society and have an even higher risk of homelessness.

Earlier, we saw that the number of available shelter beds is insufficient to meet the need in many jurisdictions. Another barrier to shelter that keeps people on the street and vulnerable to arrest for *nuisance* crimes is the cost of shelter, which may be beyond the means of the most destitute homeless. Fines imposed for *illegal* activities further deplete the money available to homeless individuals for obtaining housing. In addition, mental health and drug courts may also reserve shelter beds for sentencing purposes, further restricting the availability of shelter for many homeless individuals.

Many communities have laws against camping or sleeping in public areas, yet most of these communities lack sufficient shelter beds to meet local needs. Police often conduct sweeps of areas where homeless people congregate prior to major political, entertainment, or sports events, and homeless people are banned outright from some high-income residential and tourist areas. In many places, public parks have been designated as “family” parks, making them off-limits for people without children. Similarly, bars have been placed in the center of public benches to prevent people from lying down on them. Increased policing of gentrified areas and tourist centers effectively removes the homeless from the sight of the more affluent members of the community.

Discrimination in terms of civil rights violations is not the only form of discrimination encountered by homeless individuals and families. In some cases, discrimination in housing markets may actually cause homelessness. Despite legislation to the contrary, Black individuals and families, elderly poor, people with HIV/AIDS, and those with psychiatric disorders frequently encounter discrimination in their efforts to obtain housing. In addition, exclusionary zoning ordinances prohibit construction of multifamily units or high-density housing in many high-income neighborhoods. Requirements for significant acreage upon which to build further restrict development of affordable housing and increase the price of what housing is available.

Discrimination against the poor and homeless, at its extreme, results in violence and victimization in the form of hate crimes. The National Coalition for the Homeless (2012g) identified three types of perpetrators of *hate crimes*: mission offenders, scapegoat offenders, and thrill seekers. Mission offenders perceive themselves to be on a mission to cleanse the world of certain types of undesirable people. Scapegoat offenders engage in violence in response to feelings of frustration with circumstances (e.g., unemployment) that they attribute to members of a particular group. Thrill seekers act violently to derive pleasure from hurting others. The Coalition noted that most violence against homeless persons is committed by thrill seekers, most of whom are young people. In fact, 72% of hate crimes against homeless persons in 2010 were perpetrated by people under 30 years of age and 50% be people under age 20 (National Coalition for the Homeless, 2012g). The elderly and homeless youth are most likely to be victimized (National Coalition for the Homeless, 2012k, 2012l).

Some actions have been taken in many jurisdictions to deter hate crimes against the homeless. For example, several states have added homelessness to their hate crime legislation. Other jurisdictions have initiated training programs for local police in dealing with hate crimes against the homeless and education in schools regarding homelessness. Finally, in some locales, sanctions for intimidation and harassment have been made more severe if these activities are directed against homeless individuals (National Coalition for the Homeless, 2012g).

BEHAVIORAL DETERMINANTS. Behavioral considerations that are particularly relevant to poor and homeless populations include diet and nutrition, rest, substance abuse, and sexual activity. Inadequate nutrition among poor and homeless individuals is a lifestyle factor leading to ill health. As housing and heating costs increase for poor families, food expenditures tend to decrease. One in ten U.S. adults and one in four children are considered food insecure. Food insecurity is defined as a lack of affordable food that supports health (Bruening, MacLehose, Loth, Story, & Neumark-Sztainer, 2012). Family food insecurity is associated with parental overweight, consumption of less health foods, and higher rates of binge eating than in non-insecure families. Food insecure families are particularly likely to be unable to afford fruits and vegetables.

The homeless, even those housed in shelters, rarely have access to kitchen facilities. Some shelters do provide meals, but they are rarely adequate to meet the nutritional needs of those served. This is particularly true in the case of homeless children, who frequently exhibit anemia or serious growth failure, and who often go hungry. The poor and homeless may also have difficulty meeting special dietary needs posed by chronic illness and pregnancy.

Homeless individuals may also have difficulty obtaining adequate rest. Because of increased crime and victimization at night, many homeless individuals may attempt to sleep in the daytime when they are less vulnerable to attack. This further limits their ability to obtain many services that are offered only during the day. The inability to rest frequently places homeless individuals at greater risk for a variety of health problems and worsens existing health conditions. For example, the inability to lie down to rest may lead to venous stasis and contribute to leg and foot ulcers. These adverse effects on circulation are made worse if the homeless individual smokes. Smoking also intensifies the effects of respiratory infections contracted from others in crowded shelters.

Substance abuse is a behavioral factor that may contribute to homelessness when the abuser is unable, because of his or her addiction, to meet, or even care about, needs for shelter. Substance abuse may also lead to expenditure of money for alcohol or drugs that could be used for shelter. On the other hand, homelessness may lead to use and abuse of alcohol and drugs as a form of escape, or alcohol or drugs may be used to relieve symptoms of psychiatric illness. The precise connection between homelessness and substance abuse, however, is unclear. Competition for scarce housing resources may put those with drug and alcohol abuse problems at a disadvantage relative to other homeless individuals. An estimated 38% of homeless individuals are alcohol dependent, and 26% abuse other drugs. Alcohol and drug abuse among the homeless tend to vary with age, with older individuals more likely to abuse alcohol and younger ones to have problems with other substances. Many substance abusing individuals, not surprisingly, put greater emphasis on survival than on treatment for addictions. Continued sobriety is difficult on the streets where substances are widely used. In addition, many substance abuse treatment programs focus on abstinence only strategies rather than harm-reduction strategies that might be more effective in homeless populations. Another barrier to treatment lies in the fact that many treatment facilities for substance abuse do not accept those who are mentally ill and vice versa. Given the prevalence of dual diagnoses in this population, these restrictions make improvement difficult (National Coalition for the Homeless, 2012o). Homeless veterans are particularly likely to suffer from dual diagnoses of mental illness and substance abuse disorders, with 70% being affected by substance abuse (National Coalition for Homeless Veterans, n.d.).

High rates of substance abuse do not explain the overall increase in homelessness. However, substance abuse increases the risk of displacement and homelessness among precariously

housed individuals (National Coalition for the Homeless, 2011c). Distinct differences are found in the drinking behavior between high-income (over \$50,000 a year) and low-income individuals (less than \$15,000). For example, overall binge drinking is more prevalent among higher income individuals, but the frequency of episodes of binge drinking and the number of drinks consumed per episode are higher for low-income persons (Kanny, Liu, & Brewer, 2011).

Smoking is another behavioral determinant that affects the health of poor and homeless populations. According to the Office on Smoking and Health (2014), smoking prevalence was highest among people with incomes below the federal poverty threshold, 29% compared to 17% for adults at or above poverty level.

Sexual minority group membership may be a precursor to homelessness, particularly among young people. Sex trading, or the exchange of sex for money or food, is a lifestyle that may arise as a result of homelessness. Sex trading is particularly prevalent among adolescent runaways who find no other way to earn enough money to support themselves. Sex trading and injection drug use among some members of the homeless population place this group at risk for communicable diseases such as HIV infection and hepatitis B and C.

Homelessness and poverty may also affect other health-related behaviors. For example, homeless children are less likely than other children to have been tested for lead poisoning, but are more likely to have elevated blood lead levels (Kerker et al., 2011). Poverty and homelessness may also make it more difficult for people to engage in health-promoting and illness-preventing activities. Similarly, in 2012 people in poverty were less likely to obtain influenza immunization, pneumococcal vaccine, and colorectal screening than those with higher incomes (NCHS, 2014). For example, people with incomes over \$75,000 per year were roughly one-and-a-half times more likely than

those with annual incomes under \$15,000 to obtain colorectal cancer screening (Rim, Joseph, Steele, Thompson, & Seeff, 2011). In addition, poor women are less likely to receive mammograms and Papanicolaou smears (NCHS, 2014).

HEALTH SYSTEM DETERMINANTS. Health system factors may contribute to homelessness or limit access to care for poor and homeless persons. For example, medical bills for catastrophic illness, particularly for those who do not have health insurance, may catapult individuals and families into homelessness. Catastrophic illness in this population could easily lead to depletion of any existing savings, inability to make rent or mortgage payments, and eventually homelessness.

Lack of treatment services and supportive housing and other services for the mentally ill and substance abusers may also contribute to homelessness. Often, particularly in urban areas, people with mental illness or substance abuse disorders do not receive treatment until they have deteriorated to the point where they are a danger to themselves or others. Such tolerance of deviant behavior prevents these individuals from obtaining help when they need it and when they could most easily benefit from it. Long waits for treatment may prevent individuals with mental illness or substance abuse disorders from obtaining help in a timely fashion and may lead to subsequent homelessness as they become less and less able to cope with life. Even when treatment becomes available, homeless individuals with no contact address cannot be reached and may be dropped from long waiting lists.

More often than causing homelessness, however, health care system factors make it more difficult for poor and homeless individuals to obtain health care and to prevent or resolve health problems. Financial costs are one barrier to health care for this population. In the 2011 National Interview Survey, 19.9 million people or 6.5% of the U.S. population did not receive

Evidence-Based Practice

Dealing with Homelessness Among the Mentally Ill and Substance Abusers

A systematic review of the literature examining 16 studies of housing and support interventions for people with mental illness who have been homeless indicated that interventions that combined permanent housing, assertive community treatment, and intensive case management support resulted in significant reduction in homelessness and hospitalization, and improved well-being (Nelson, Aubry, & Lafrance, 2007). Unfortunately, many assistance programs for persons with mental illness or substance abuse are predicated on enrollment and completion of psychiatric therapy or substance abuse treatment. More recent studies, however, are indicating that “housing first” programs that focus on providing stable housing for this population without such requirements result in sustained housing as well as reduction in alcohol use and participation in therapy (Tucker, 2012).

Project-based Housing First initiatives provide immediate permanent housing in a single housing project. Despite concerns that such programs enable alcohol or drug use, findings of one study indicated that participants actually decreased their alcohol use. In addition, longer residence in the project was correlated with additional decreases in alcohol use (Collins et al., 2012). Another housing first project resulted in 97% housing retention in the first year and 84% in the second year among chronically homeless individuals with co-occurring mental health and substance abuse diagnoses. Other results included a decrease in psychiatric symptoms and a reduction in the demand for assertive community treatment services (Tsemberis, Kent, & Respress, 2012).

needed medical care due to cost, and another 27.3 million delayed obtaining care. Not surprisingly failure to receive care occurs more often among the poor than the non-poor (13.6% versus 3.7%) (Adams et al., 2012). Similar differences in access to dental care and ability to fill prescriptions were noted between poor and non-poor individuals (NCHS, 2014). For example, in 2011, 12.6 million people aged 18 to 64 years did not take a prescription due to costs. Figures are somewhat lower among those over age 65 (5.8%) due to Medicare prescription benefits. Poor individuals also reported skipping doses, taking less medication than prescribed, using alternative therapies, delaying filling a prescription, and purchasing drugs from other countries (Cohen, Kirzinger, & Gindi, 2013). The latter practice has implications for drug purity and effective dosing. From 2003 to 2012, the number of people who did not seek needed medical care or who failed to fill a prescription increased from 63 million to 80 million people (Stempniak, 2013).

In 2011, more than 10% of the poor, 11% of the near poor, and 4.2% of the non-poor lacked health insurance coverage at some point in the year, and more than 30% of the poor had been without health insurance for more than 36 months (Adams et al., 2012). Provisions of the Affordable Care Act have improved matters somewhat. For example, 48% of people 19 to 64 years of age in 2013 had health insurance compared to only 41% a few years earlier (Stempniak, 2013), but a significant proportion of the population remains uninsured.

Lack of health insurance coverage and frequent moves among the poor and homeless population limits their ability to establish a medical home and to receive health promotive and illness preventive services (Cutts et al., 2011). For example, from 2011 to 2012, roughly a third of persons with incomes below 100% of the poverty threshold had no regular source of care compared to only 10% of those with high incomes (NCHS, 2014). In general, the poor and homeless use more health care services than their housed counterparts, but do so in more expensive venues such as emergency departments. For example, 55% of homeless women, including those with health insurance, reported emergency service use. Percentages were even higher among women with a history of intimate partner abuse (Vijayaraghavan et al., 2012). In another study, homeless children with asthma were more likely than housed children to use emergency department services for exacerbations of their disease (Cutuli et al., 2010).

Some assistance is provided to help homeless individuals and families obtain needed health care. Under the Health Care for the Homeless (HCH) program, for example, more than 740,000 homeless people received services in 2008, but the need far outstrips capability (National Coalition for the Homeless, 2012h). Some homeless individuals, particularly children, may also be eligible for Medicaid; however, enrollment processes are complex, and lack of a permanent address or personal identification may make enrollment difficult. Homeless individuals and families may also lack the expertise or the energy to complete the processes involved in registration or application for services. In 2012, for example, just over half of

people with incomes below poverty level were covered under Medicaid (NCHS, 2014).

In addition, health care often takes lower priority than meeting daily survival needs among the poor and homeless. For example, in Toronto, with universal health insurance coverage, competing priorities and barriers like lack of transportation, long waits for services, and feelings of stigmatization and embarrassment were found to prevent use of health care services among the homeless (Hwang et al., 2010). Other problems include lack of personal identification, lack of medical records, fragmentation of services, and lack of continuity of care (National Coalition for the Homeless, 2012h). Lack of child care for other children may also prevent homeless parents from obtaining care for themselves or their children. Provider barriers include insensitivity to the needs and circumstances of the homeless and unwillingness to provide care to those with no means of payment.

Compliance with treatment recommendations may also be difficult. Homeless clients may be unable to afford prescribed medications or may not have a watch to time doses correctly. They may not have access to water to take oral medications, and syringes for insulin may be lost, sold, or stolen. Other difficulties include retaining potency in medications exposed to frequent temperature changes and obtaining prescription refills. Treatment for HIV/AIDS and tuberculosis is particularly difficult among the homeless due to the complexity of treatment regimens (National Coalition for the Homeless, 2012h).

Mental health services for poor and homeless populations are also lacking. Some observers have noted a mismatch between traditional community mental health services and the needs of the homeless population. Comprehensive services are seldom offered at one location, and mental health services seldom address the social factors contributing to homelessness. Availability of integrated mental and physical health services with assistance with social needs, on the other hand, has been found to promote access to behavioral and medical care and foster treatment compliance among the homeless mentally ill and those with substance abuse disorders (Colorado Coalition for the Homeless, 2013).

Population health nurses assess factors related to each of the six categories of determinants of health in identifying the health status and needs of poor and homeless populations. The *Focused Assessment* on the next page provides some questions that can be used in assessing the health of the poor and homeless populations. The assessment tools related to Chapters 16∞, 17∞, 18∞, and 19∞ included in the student resources site can be used to assess the health of poor and homeless children, men, women, and older persons, respectively.

Assessment data for poor and homeless populations may be somewhat more difficult to obtain than data about other, more easily observed populations. Population health nurses working with poor and homeless individuals or groups of people would be particularly alert for commonly encountered health problems. In addition, they would assess individual clients for the presence of any other chronic or communicable diseases,

as well as for high prevalence rates for these conditions in the poor and homeless populations. Information regarding prevalent conditions can be sought from health professionals and agencies that care for poor and homeless people. Some data on the age, gender, and ethnic composition of the homeless

population may be available from shelter sites and social service agencies. Local churches may also have a sense of the number and types of homeless people served. Local government agencies may also have data on the extent of the homeless population and its composition.

FOCUSED ASSESSMENT

Assessing Poor and Homeless Populations

Biological Determinants

- What is the age composition of poor/homeless populations? The ethnic and gender composition?
- What developmental effects have poverty and/or homelessness had on members of the population? What acute and chronic health problems are prevalent? What is the prevalence of pregnancy?
- What is the immunization status of the poor/homeless populations (particularly children)?

Psychological Determinants

- What is the extent of mental illness in the poor/homeless population? What is the extent of depression, anxiety, and suicide?
- What stresses are experienced by this population? How does the poor/homeless population cope with stress?
- What are individual and group responses to poverty/homelessness? To seeking help?

Environmental Determinants

- What are the effects of climatic conditions on the poor/homeless population?
- Where do homeless individuals in the community seek shelter? How adequate are shelter facilities? What hygiene facilities are available to homeless persons?
- Do environmental conditions pose other health hazards for poor/homeless individuals (e.g., flooding under bridges used for shelter)?

Sociocultural Determinants

- What is the community attitude to homelessness? To poor or homeless individuals?
- What is the extent of family support available to the poor/homeless individual? What is the extent of community support available to the poor/homeless population?
- To what extent does family violence contribute to homelessness in the community?
- What effects do education, economic, and employment factors have on poverty/homelessness in the community? What proportion of the eligible poor/homeless population is receiving financial assistance? What proportion of the poor/homeless is employed? In what kind of work?
- What child care resources are available to poor/homeless women with children?

- What education programs are available for homeless children?
- What transportation resources are available to the poor/homeless population?
- What is the availability of low-cost housing in the community? What is the availability of shelter for homeless persons? For individuals with special needs?
- What proportion of the poor/homeless population consists of families? What proportion of poor/homeless families are headed by women?
- What is the extent of crime victimization among homeless individuals?

Behavioral Determinants

- What food resources are available in the community for poor/homeless individuals? What nutritional deficits do poor/homeless individuals exhibit? What is the nutritional value of food available to poor/homeless individuals and families?
- What is the extent of drug and alcohol abuse in the poor/homeless population?
- What is the prevalence of smoking in the poor/homeless population?
- Are there facilities available in the community for homeless individuals to rest during the day? What health effects does lack of rest have on the homeless individual?
- What is the extent of prescription medication use among the poor/homeless population? Do poor/homeless individuals have access to resources to help with medication expenses?
- What is the extent of sex trading and unsafe sexual activity in the population?

Health System Determinants

- What health care services are available to poor/homeless persons in the community? To what extent are these services integrated with other services needed by the population? What is the availability of mental health services for poor/homeless individuals? Drug and alcohol treatment services? To what extent are preventive health services available to and utilized by the poor/homeless population?
- Where do poor/homeless persons usually obtain health care? What are the attitudes of health care providers toward poor/homeless individuals?
- How is health care for poor/homeless persons financed?

Information on the prevalence of specific conditions and immunization status can be obtained in surveys of the poor and homeless population. Surveys of homeless individuals will need to be conducted in places where they congregate. For example, a population health nurse might survey individuals living in a shelter or those who take advantage of community meal programs. Because of the time needed to complete surveys, the lack of resources available to them (e.g., pens or pencils for completing written surveys), and varied levels of education among the homeless population, surveys will be most effective if conducted verbally in the context of other services. For example, the nurse might survey clients as they wait in line at a local soup kitchen or approach them for a few minutes of their time after they finish a meal. Privacy is often lacking in the lives of homeless individuals, and population health nurses should refrain from asking for highly personal information in public settings. Homeless individuals with substance abuse problems may also be wary of admitting these and other illicit behaviors (e.g., theft of food) unless assured of confidentiality. Population health nurses should endeavor to ask survey questions in language appropriate to the client's understanding and in ways that do not imply value judgments. Homeless individuals themselves may be involved in the development of survey tools that address their perceived needs in a sensitive and culturally appropriate manner. Population health nurses can also advocate for the involvement of poor and homeless individuals in data collection and analysis and payment for temporary employment in these activities.

Surveys can also be a mechanism for collecting information on the extent of mental illness and the level of coping skills in the population. Psychiatric treatment facilities may also have data on the number of homeless individuals served and the types of diagnoses seen.

Environmental conditions and their effects on the poor and homeless are often best assessed through observation. What is the local weather and how does it affect the population, particularly the homeless? The adequacy of shelter facilities can be observed by visits to existing shelters. Other places where homeless people congregate can also be observed. At the same time, observations in public places can provide some information on the attitude of others toward obviously homeless individuals as well as on the extent of police activities related to the homeless. Local police records can also provide information on arrests for nuisance crimes.

The extent of family violence as a precursor to homelessness can best be determined by surveys of homeless individuals, particularly women and youth. Police and other protective services agencies are another source of information on family violence. These agencies may also provide information on the availability of shelters for victims of abuse. Shelter personnel can likewise be a source of information on the homeless population.

Educational and employment information can be obtained in a similar manner. Local social service agencies or employment offices may have information on places where poor and

homeless individuals may go to seek day labor. Observation and questioning of people in these locations can provide information on the kinds of jobs available and wages paid, as well as potential job hazards faced by the population. Perusal of the local newspaper can also provide a sense of the job opportunities that may be available to poor and homeless individuals. General community employment and economic data may be available from local chambers of commerce or government employment offices. Census data also include this information but may be outdated, depending on the recency of data collection.

Social service agencies and telephone books are potential sources of data regarding child care availability. In addition, the population health nurse can contact local child care providers to determine the availability of care for children in low-income families. Similarly, school districts can provide information on the availability of public preschool programs. School districts can also provide information on the number of homeless children enrolled in local schools, as well as the services available to meet their needs.

Information on shelter availability would most likely be obtained from social service agencies, local churches, or local government offices. These organizations may also have information regarding food resources and other services available to poor and homeless populations. Information on specific nutritive intake, however, is best obtained by observation in shelters or surveys of poor and homeless individuals. Surveys could also be used to determine the extent of health-related behaviors such as smoking, alcohol and drug use, and sex trading, as well as the use of prescription medications. Crime victimization data would be available from local police departments.

General information on the availability of health services can be obtained from telephone directories and the Web, and specific agencies can be contacted to determine the type and extent of services provided to poor and homeless individuals. Emergency departments (EDs), in particular, may have information on the frequency with which uninsured poor and homeless individuals use ED services as a substitute for primary care. Local officials and health care agencies can also be contacted to determine how health care services for poor and homeless individuals are funded.

Diagnostic Reasoning and Care of Poor and Homeless Populations

Based on the assessment of the health status of poor and homeless individuals and populations and factors contributing to that status, nursing diagnoses may be derived at several levels. At the individual client level, the population health nurse may make diagnoses related to the existence of poverty or homelessness. As discussed before, the diagnostic statement includes underlying factors if identifiable, for example, "homelessness due to inability to pay for shelter" or "homelessness due to mental illness and inability to care for self."

Other kinds of diagnoses made at the individual or family level might relate to specific health problems resulting from or intensified by poverty or homelessness. As an example, the nurse might make a diagnosis of “stasis ulcers due to excessive walking and standing and inability to lie down at night” or “malnutrition due to inability to afford food and lack of access to cooking facilities.”

Nursing diagnoses may also be made at the population level. For example, the population health nurse may diagnose a significant problem of homelessness in the community. Such diagnoses might be stated as “an increase in the homeless population due to recent closure of major community employer” or “an increase in the number of homeless families due to unemployment and reductions in public assistance programs.” Diagnoses may also be made at the aggregate level relative to specific problems engendered by poverty or homelessness, for example, “increased prevalence of tuberculosis due to malnutrition and crowding in shelters for the homeless” or “increased incidence of anemia among poor and homeless children due to poor nutrition.”

Planning and Implementing Health Care for Poor and Homeless Populations

Planning to meet the needs of poor and homeless populations should focus on long-term as well as short-term solutions to problems. Planning should also reflect the factors contributing to the needs of the poor and homeless in a particular locale. For example, if most of the homelessness in one community is due to unemployment, long-term interventions would most likely be directed toward improving employment opportunities in the area or increasing the employability of those involved. If, on the other hand, a significant portion of homelessness in the area is due to mental illness and inability to care for oneself, attention would be given to providing supportive services for the mentally ill.

Planning should address the underlying factors contributing to poverty and homelessness as well as their health consequences. For example, providing shelter on a nightly basis may decrease the risk of exposure to cold for homeless persons but does nothing to relieve homelessness. In planning to meet the health needs of individual poor and homeless clients, population health nurses may work independently or in conjunction with other health care and social service providers. When planning to address factors contributing to poverty and homelessness, however, the population health nurse frequently is part of a group of government officials and concerned citizens who have assumed responsibility for dealing with the overall problems of poverty and homelessness. The principles of coalition building, discussed in Chapter 9, will be helpful to population health nurses working with others to address problems of homelessness and poverty in the community.

Efforts to alleviate homelessness and its consequences may take place at the promotion, prevention, resolution, or restoration levels of care. Population health nurses may be involved in

activities at any or all of these levels. As is true in caring for any client, planning care for a poor or homeless client or population begins with prioritizing health needs. In many instances, the first priority would be obtaining shelter, a measure related to resolution of an existing problem of homelessness. Other health needs could then be addressed in terms of their priority. For each of the health care needs identified for the homeless client or population, the population health nurse would develop specific outcome objectives and design relevant interventions. Planning efforts should be a joint function of the population health nurse, poor or homeless clients, who best know their situation and the kinds of interventions that are likely to be successful in that situation, and other concerned organizations and individuals.

HEALTH PROMOTION. Health promotion for poor and homeless individuals or populations involves the same strategies that might be used with any person or group. Population health nurses might be involved in educating clients or populations regarding good nutrition, rest, and exercise as well as the development of effective coping strategies. At the aggregate level, population health nurses might need to advocate for health promotion services for poor and homeless populations and encourage their use. In addition, they might need to advocate for health insurance and coverage of health promotion services for poor and homeless individuals and populations.

PREVENTION. Prevention strategies for poor and homeless individuals and populations occur at two levels: prevention of poverty and/or homelessness and prevention of illness and injury among poor and homeless individuals and populations.

Preventing poverty and homelessness. Preventing poverty requires the ability to earn incomes sufficient to meet basic human needs, including the need for housing and shelter. Population health nurses can advocate for increases to minimum wage limits to create livable wages. In addition, they may refer individual clients for financial assistance and job training and employment services.

Some homeless individuals may be reduced to scavenging in trash cans for food or items to sell. (rus09/Fotolia)

Prevention of homelessness can occur at the individual or family level or at community levels. Population health nurses can help prevent individuals and families from becoming homeless by assisting them to eliminate factors that may contribute to homelessness. For example, if a family is threatened with eviction because of a parent's unemployment, the nurse can assist family members to obtain emergency rent funds from local social service agencies. The nurse can also encourage the family to apply for ongoing financial aid programs or assist the parent to find work.

As noted earlier, some people become homeless because of underlying psychiatric illness and an inability to deal with the requirements for maintaining shelter. Severely disturbed people may just wander away from home and take up residence on the streets. Homelessness in this group can be prevented by referrals for psychiatric therapy and counseling. Case management in the transition from hospital or prison to community may help to prevent homelessness in mentally ill or inmate populations. Nurses may also provide support services to families caring for mentally ill members to prevent these persons from becoming part of the homeless population. Placement in a sheltered home might also be an approach to preventing homelessness in the mentally disturbed person when family members either cannot or do not wish to care for the client. In addition, the population health nurse can monitor the effectiveness of therapy and watch for signs of increasing agitation or disorientation that may precede wandering. The nurse can also assist the disturbed person by giving concrete direction in such tasks as paying rent.

Runaway children and teenagers are another segment of the homeless population for whom homelessness may be prevented through intervention. Efforts of population health nurses to promote effective communication in families and enhance parenting skills may prevent young people from feeling a need to run away. Similarly, efforts to prevent or deal with child abuse may prevent runaways.

Prevention strategies to reduce the incidence of poverty and homelessness at the community level require major changes in societal structure and thinking. Some suggested avenues for intervention include federal support for low-cost housing, increases in the minimum wage, and access to supportive services for the mentally and physically disabled to allow them to function effectively in society. Another suggestion aimed at reducing the incidence of poverty in families with children to prevent their homelessness is to provide child care assistance and paid parental occupational leaves as needed.

Creating employment opportunities and programs to train people in employable skills is another possible preventive measure for both poverty and homelessness. Current public job training programs, however, have been criticized for their failure to facilitate job placement for those who complete the programs. Job training programs directed specifically toward the local job market have been suggested as more appropriate approaches to unemployment. Another societal intervention could be to provide a guaranteed annual income to all citizens.

Such an approach is exemplified in part by social insurance programs such as Social Security and unemployment insurance that are not restricted to the poor but available to all eligible participants. Other social programs that may help to prevent homelessness include legal assistance to prevent evictions as well as increased housing subsidies (National Coalition for the Homeless, 2012f, 2012g). Strategies that might prevent evictions and foreclosures or mitigate their effects include counseling to prevent foreclosure, free or pro-bono legal assistance, cash assistance with housing costs, relocation assistance, and purchase of properties by communities for use by low-income persons (National Coalition for the Homeless, 2012f). Changes in housing codes and tax laws to prevent loss of welfare benefits or allowing tax credits in shared housing situations may also be helpful. There is also a need for "discharge planning" for housing assistance for people displaced by building condemnation or renovation or release from prisons and other institutions.

Population health nursing involvement in such activities occurs primarily through advocacy and political action. As advocates, population health nurses can make policy makers aware of the needs of the poor and homeless and can contribute to efforts to plan programs that prevent homelessness. Nurses can also engage in political activities such as those described in Chapter 9 to influence policies that help to eliminate conditions that contribute to poverty and homelessness. For example, comprehensive legislation was introduced before the U.S. Congress in November 2005 as part of the Bringing America Home Act (H.R. 4347). Defeated several times, the Bringing America Home Act is being reintroduced. This legislation addresses four main areas of concern: housing security, economic security, health security, and civil rights (National Coalition for the Homeless, 2012a).

Housing security provisions of the act include increasing Section 8 housing vouchers by more than 1.5 million over 10 years, dedicating a proportion of vouchers for special populations such as homeless veterans and youth, authorizing use of surplus federal properties for permanent housing, requiring that federal dollars used for demolition result in the creation of an equal number of low-income housing units, and establishing a Rent Relief Fund within the U.S. Department of the Treasury for emergency assistance to tenants facing eviction. Additional provisions address protection for tenants facing eviction due to foreclosures, providing tax credits for rehabilitation of homes owned by low-income individuals, preventing discrimination by landlords against persons receiving federal housing assistance, and provision of community development block grants to enforce housing codes and provide relocation assistance to people living in uninhabitable dwellings (National Coalition for the Homeless, 2012a).

Economic security provisions of the Bringing America Home Act include establishing a universal livable income indexed to the cost of living, providing the same economic protections enjoyed by permanent workers to temporary workers, establishing training and apprenticeship programs for those with barriers to employment and establishing apprenticeships

in skilled trades for homeless persons, repealing statutes that limit SSI income for shelter residents, increasing the allowable asset limit for SSI to \$3,000 for an individual or \$4,500 for a couple, and providing homeless individuals with access to food stamps. The health security provisions of the act would establish universal health insurance under a single-payer model and strengthen homeless access to mainstream addiction and mental health service programs. Finally, the proposed civil rights provisions would remove barriers to obtaining personal identification for people with no fixed residence, require communities receiving homeless assistance funds to certify that they do not criminalize homelessness or related activities, and add the homeless as a protected category to hate crime legislation (National Coalition for the Homeless, 2012a). Population health nurses can be actively involved in promoting passage of this and similar legislation. For further information about the Bringing American Home Act, see the *External Resources* section of the student resources site.

Population health nurses can also work to promote adoption of sound housing policies and advocate for the creation of more affordable housing and provision of housing assistance for low-income individuals and families.

Preventing illness and injury. Illness and injury prevention strategies may also be undertaken with respect to specific health problems experienced by poor and homeless persons. Here, population health nurses may work with individuals, families, or groups of people. For example, population health nurses working with homeless substance abusers might advocate a program providing clean syringes to injection drug users. If such an approach is not successful, the nurse might provide a simple bleach solution for injection equipment to minimize the risk of blood borne diseases such as hepatitis and HIV/AIDS. Similarly, nurses may provide assistance to families with budgeting and meal planning to provide nutritious meals on limited incomes.

Community-based avenues for preventing homelessness among the mentally ill include providing access to services within the community that enable these persons to care for themselves adequately without institutionalization. Efforts may also be needed to ensure hospitalization for those persons who cannot be adequately maintained in the community. Treatment for substance abuse and secure places for convalescence after hospital discharge might also serve to prevent homelessness in this subgroup.

Also at the group level, nurses may engage in prevention of specific problems by encouraging community groups to provide shelters for homeless individuals. Nurses may also provide basic health care for the homeless, focusing particularly on preventive measures such as influenza vaccine and routine immunizations for children. For example, immunization and other health-related services may be provided in nontraditional settings such as soup kitchens, shelters, and so on. Adequate ventilation, reduced crowding, and use of ultraviolet lights in shelters may also help to prevent the spread of communicable disease.

Another area for prevention of the health consequences of homelessness is adequate nutrition. Population health nurses can advocate for food programs for the needy, including the homeless. They can also serve as consultants to existing food programs to ensure that meals are nutritionally adequate to meet the needs of the population served. Population health nursing activities in this area may also include attempts to arrange diets for homeless clients with special needs (e.g., assisting a diabetic client to select foods from those prepared in a shelter that approximate a diabetic diet as closely as possible).

Population health nurses can also work with other concerned citizens to initiate programs to provide adequate clothing and shoes for homeless clients. Efforts may also be needed to arrange for the homeless to bathe and wash their clothing. In some cities, day shelters that do not provide sleeping accommodations often provide homeless individuals an opportunity to shower and wash their clothing. These shelters may also provide a clean change of clothing on a periodic basis.

Another aggregate approach to preventing specific health problems among the homeless is providing universal access to health care through national health insurance or similar programs at the state level. Nurses can promote such programs through political activity and advocacy and may also be involved in implementing them by providing direct services to the homeless.

In addition, population health nurses can advocate against regulations that criminalize homelessness. They can also campaign for the addition of homelessness to existing hate crimes legislation and advocate for strict enforcement of such laws. Population health nurses may also be involved in educating local law enforcement, youth, and the general public about homelessness to prevent bias, discrimination, and hate crimes against the homeless. Foci and related population health nursing strategies associated with health promotion and prevention for poor and homeless populations are summarized in Table 21-2.

RESOLUTION OF EXISTING PROBLEMS. Resolving existing health problems among poor and homeless individuals involves addressing both poverty and homelessness. As indicated by the National Coalition for the Homeless provision of housing constitutes “treatment” for homeless persons with health problems, and eliminating homelessness will require the development of affordable housing that fits people’s incomes (National Coalition for the Homeless, 2012d; 2012h). Population health nurses working with homeless individuals must first address their priority concerns for shelter and basic necessities before other health needs can be addressed. At the individual level, interventions may include referral for financial assistance via “means-tested income transfers.” **Means-tested income transfers** involve the distribution of cash or noncash assistance to individuals and families who meet a test of need based on income and assets. Population health nurses may need to function as advocates to assist clients through the bureaucratic process frequently involved. This is particularly true for elderly

TABLE 21-2 Health Promotion and Prevention Strategies for Poor and Homeless Populations

Focus	Strategy
Health promotion	Promote adequate nutrition Advocate for access to healthy and nutritious foods for low-income and homeless individuals Refer individuals and families to sources of food supplementation Promote physical activity and rest Advocate for the provision of facilities that allow effective rest Promote effective coping Advocate for insurance coverage for health promotion services for poor and homeless populations
Preventing homelessness	Advocate for a livable minimum wage Refer poor individuals and families to sources of financial assistance Make referrals for legal assistance with foreclosures and evictions Advocate for safeguards for individuals and families facing foreclosure and eviction Refer individuals and families for relocation assistance Refer individuals for job training and employment assistance and advocate for the availability of such services as needed Advocate for or refer to mental health or substance abuse treatment services Provide or refer clients to case management services for transitions from hospital or prison to community. Advocate for the availability of such services as needed Promote effective parenting and prevent child abuse and runaways Support the Bring Home America Act and similar legislation Promote adequate consideration of the effects on poor and homeless populations of mega event planning.
Preventing illness and injury	Educate poor and homeless clients for injury and illness prevention Provide or make referrals for preventive services (e.g., immunizations) Advocate for access to preventive services Educate poor and homeless substance abusers for harm reduction Advocate for appropriate ventilation and ultraviolet light in shelter settings Assist poor and homeless individuals in obtaining special dietary requirements Assist homeless clients to meet hygiene needs (e.g., bathing and clean clothes) Advocate against laws and regulations that criminalize homelessness or related activities Advocate for expansion of hate crime legislation to include victimization of the homeless

clients and those with mental health problems. At the community level, nurses can advocate a review of eligibility criteria for means-tested income transfer programs so that a greater proportion of the poor and homeless population is served.

Shelter is an immediate need for homeless individuals. The population health nurse can assist the homeless client to locate temporary shelter. This may be accomplished by means of referrals to existing shelters. If the nurse is not aware of homeless shelters provided in the community, he or she can contact a local YMCA or YWCA, a Salvation Army service center, or local churches for information on shelter availability. When organized shelter facilities are not available, the nurse may try contacting local houses of worship to see if members of religious congregations can provide shelter for a homeless person on a short-term basis. In making a referral for emergency shelter, the population health nurse would consider the needs of the particular client. Ideally, for example, the elderly and women

and children would be referred to shelters where they are protected from victimization. Similarly, homeless persons with chronic health problems should be referred to shelters where health services are available and their conditions can be monitored on an ongoing basis.

At the aggregate level, population health nurses can work with government officials and other concerned citizens to develop shelter programs for homeless individuals or families. Avenues that might be pursued include school gymnasiums, churches, and public buildings. Many cities have used these and other buildings as temporary nighttime shelters for the homeless during cold weather. Plans might also be developed for more adequate shelters that provide other services as well as a place to sleep. In designing a shelter program, the population health nurse and other concerned individuals would employ the principles of program planning presented in Chapter 15∞.

For homeless persons with significant mental health problems, it may be necessary to create specialized shelters called **safe havens**, which are secure stable places of residence that place few demands on those receiving help. Many mentally ill homeless individuals are not able to deal with the behavioral restrictions and other policies imposed by many typical homeless shelters. They need a place with limited restrictions that offers the same bed each night, a place to stay during the day, and a place to store their belongings. Because of the special needs of this segment of the homeless population, safe havens do not limit the length of stay for those served. Safe havens then become a stage in clients' progressive movement toward permanent housing in which they can learn to trust and relearn skills needed to maintain a permanent residence while unlearning the distrust required for survival on the streets. Safe havens serve the same function for abused women, allowing them to remain in a secure environment unknown to the abuser where they are protected from abuse by, and often from interaction with men.

Integrated programs that provide shelter with a variety of other needed services have been shown to be more effective in resolving the problems of homelessness, than those that focus on limited aspects of the situation (e.g., the provision of shelter). A comprehensive program for the homeless in Boston incorporates the three core functions and essential services of public health in efforts to address the problems of homelessness in the city. For example, in addition to providing housing assistance and other services for homeless clients, the program has been credited with obtaining health insurance for 75% of its clientele (O'Connell et al., 2010). Similarly, a population-focused primary care approach has been shown to be effective in meeting the needs of homeless veterans. The program provided open access to primary care services as well as on-site integration of housing and benefits assistance, job referral, and so on. In addition to helping resolve the immediate problem of homelessness, the program increased primary care service use and resulted in improved health outcomes such as improved hypertension and diabetes control (O'Toole et al., 2010). Another program that focuses on "Vets helping Vets" provides an integrated set of services in the context of transitional housing. The program includes role modeling of successful coping by formerly homeless veterans and provides the camaraderie previously enjoyed by many former military personnel (National Coalition for Homeless Veterans, n.d.).

Shelters are an emergency resource, not a solution to the problem of homelessness. Population health nurses should help homeless clients find ways to meet long-term shelter needs. For individual clients, this may mean referrals for employment assistance or other services to eliminate factors that resulted in homelessness. At the community level, nurses can participate in planning long-term solutions to the problems of homelessness. Unfortunately, such planning has not often been the focus of community attempts to deal with the problem. Population health nurses can advocate and participate in planning efforts to provide low-cost housing, employment

assistance, job training, and other services needed to resolve community problems of homelessness. Initiating these planning activities may require political activity on the part of the population health nurse.

Planning for long-term resolution of the problem of homelessness for runaways involves a different set of strategies. The population health nurse can explore with the youngster his or her reasons for running away from home. Nursing interventions are then directed toward modifying factors that led the child to run away. For example, if the child was abused, the nurse can institute measures to prevent further abuse if the youngster returns to the home, or foster home placement can be arranged. If problems stem from poor family communication, the nurse can make a referral for family counseling or other therapeutic services. The nurse can also serve as a liaison between the child and his or her family, negotiating for changes that make the child's return possible.

Particular care should be taken to involve the child in planning interventions to resolve his or her situation. A child returned to his or her family unwillingly will probably run away again. In addition, such actions on the part of the population health nurse may also destroy any faith the child may have had in health care providers as a source of assistance.

At the aggregate level, population health nurses should alert community policy makers to the need for coordinated services for the homeless offered in a single location to meet the health and social needs of homeless clients. They should also make sure that planning groups in which they participate plan services to address the needs of the homeless for housing, food, clothing, employment, child care services for working parents, and adequate preventive and therapeutic health care services. Planning should also include avenues for outreach and follow-up services, particularly for the homeless who may be lost to service. Such comprehensive programs require changes in health care and social systems that may necessitate legislation and public policy formation that can be guided by nursing input.

Population health nurses can also provide curative services for a variety of health problems experienced by the homeless. For example, they may make referrals for food supplement programs or provide treatment for skin conditions or parasitic infestations. They will also be actively involved in educating clients for self-care. Homeless clients may have difficulty with simple aspects of treatment regimens. For example, if the homeless client does not have access to a clock or watch, it may be difficult to take medications as directed. Nurses can suggest the use of medications that can be taken in conjunction with set activities, such as on arising or at bedtime. As another example, outbreaks of tuberculosis in shelters have been contained, in part, by a new process of a 12-week course of therapy for asymptomatic residents with latent tuberculosis infection as opposed to the traditional therapy prolonged over 6 months (Dobbins et al., 2012). Population health nurses will probably be responsible for such treatment programs for tuberculosis in the future.

The special needs of homeless children and older persons require particular attention. One suggestion is age-segregated shelters or services specifically designed for older persons and families with children to prevent their victimization by other subgroups within the homeless population. Special attention also needs to be given to meeting the nutritional needs of these vulnerable groups as well as those of pregnant women.

HEALTH RESTORATION. Health restoration strategies may be aimed at preventing a recurrence of poverty and homelessness for individuals, families, or groups of people affected. Conversely, the emphasis may be placed on preventing the recurrence of health and social problems that result from conditions of poverty and homelessness. Interventions may also be geared toward long-term maintenance of housing status as well as management of chronic conditions among the poor and formerly homeless.

Population health nursing involvement in health restoration may entail political activity to ensure the provision of services to relieve poverty and homelessness on a long-term basis. This means involvement by nurses in efforts to raise minimum

wages or to design programs to educate the homeless for employment in today's society. Advocacy and political activity may also be needed to ensure the adequacy of community services for the mentally ill to allow them to care for themselves or to support their families as caregivers.

At the individual or family level, population health nurses may be involved in referral for employment assistance or for educational programs that allow homeless clients to eliminate the underlying factors involved in their homelessness. Moreover, nurses might assist clients to budget their incomes more effectively or engage in cooperative buying efforts to limit family expenses. Population health nurses may also be actively involved in monitoring the status of mentally ill clients in the home and in assisting families of these clients to obtain respite care and other supportive services needed to prevent the mentally ill client from returning to a state of homelessness. In such cases, nurses also monitor medication use and encourage clients to receive counseling and other rehabilitative services. Strategies for resolving existing health problems and for health restoration in poor and homeless populations are summarized in Table 21-3•.

TABLE 21-3 Strategies for Resolving Existing Health Problems and Health Restoration in Poor and Homeless Populations

Focus	Strategy
Resolving homelessness	<ul style="list-style-type: none"> Refer for emergency shelter and advocate for needed shelter and transitional beds and permanent housing Refer to housing assistance for permanent housing Advocate for housing assistance for poor and homeless individuals and families Advocate for means-tested income transfer programs for the poor and homeless Assist homeless individuals and families to obtain housing subsidies and other services Assist in the development of community resources for the poor and homeless, including integrated emergency shelter, transitional housing, job training and placement, mental health and substance abuse treatment, etc. Refer homeless individuals and families to safe havens, as needed Advocate for affordable housing Mediate between homeless youth and their families, as needed Advocate for incorporation of poor and homeless people into service and resource planning
Resolving existing health problems	<ul style="list-style-type: none"> Provide or refer poor and homeless individuals and families for relevant screening services Provide or refer for treatment services for existing health problems tailored to the circumstances of the poor and homeless population Advocate for the availability of screening and treatment services for the poor and homeless Advocate for insurance coverage for needed screening and treatment services Refer for treatment of psychological health problems (including substance use and abuse)
Health restoration	<ul style="list-style-type: none"> Refer poor and homeless individuals for maintenance therapy for mental health problems Educate poor and homeless clients for self-management of chronic health conditions Monitor mental health status and medication use in poor and homeless populations Monitor treatment effectiveness for chronic physical health conditions Refer for job training and employment services Assist with money management and budgeting skills development

Evaluating Care for Poor and Homeless Populations

Evaluating the effects of nursing interventions with poor and homeless clients can take place at two levels: the individual level and the population level. At the individual level, evaluation of the effectiveness of interventions reflects the client care objectives developed by the nurse and client in planning care. For example, if an objective for a homeless family was to provide them with an income sufficient to meet survival needs, the nurse and family would determine whether this objective has been achieved. Does the family now have sufficient income to provide adequate housing, appropriate nutrition, and other needs? If the objective was to find employment for the mother or father, has this been accomplished?

Evaluation of aggregate-level interventions must also be undertaken. For example, nurses and other concerned individuals will want to determine whether the extent of poverty and homelessness in the population has decreased or whether shelter programs are sufficient to meet the needs of the homeless population. Evaluation of health restoration programs focuses on the extent to which interventions prevent people

from returning to poverty and again becoming homeless. Are job training programs effective in increasing the income of participants above the poverty level? Criticism of current welfare programs seems to indicate that such programs do not effectively relieve the problems of the poor and homeless. If current programs are not effectively alleviating the problem, other solutions must be sought; population health nurses must be actively involved in developing those solutions.

One approach to evaluating care for poor and homeless populations is the achievement of national health objectives as they relate to low-income individuals and families. The current status of some of the *Healthy People 2020* objectives for people with incomes less than 100% of poverty is presented below. As we can see from the data, none of the objectives have reached the targets and little progress has been made with respect to many of them. Some of the objectives have actually moved away from the target, indicating that considerable work yet remains to protect the health of the poor. No national objectives have been developed for the homeless population, but objectives related to the poor can also be used to evaluate the effectiveness of care for homeless populations.

Healthy People 2020

Selected Objectives Related to the Health of the Poor

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
AHS-1.1 Increase the proportion of people under 65 years of age <100% of poverty with medical insurance	71% (2008)	100%	71.6% (2011)	National Health Interview Survey (NHIS), CDC/NCHS
AHS-3 Increase the proportion of people <100% of poverty with a usual primary care provider	70.5% (2007)	83.9%	70.8% (2010)	Medical Expenditure Panel Survey (MEPS), AHRQ
AHS-6.1 Reduce the proportion of persons <100% of poverty who are unable to obtain or delay obtaining necessary medical care, dental care, or prescription medications	14.7% (2007)	9%	15% (2010)	Medical Expenditure Panel Survey (MEPS), AHRQ
AOCBC-2 Reduce the proportion of adults <100% of poverty with diagnosed arthritis who experience an activity limitation due to arthritis or joint symptoms	57.8% (2008)	35.5%	61.5% (2011)	NHIS, CDC/NCHS
CDK-1 Reduce the proportion of the U.S. population <100% of poverty with chronic kidney disease	19.8% (1999–2004)	13.6%	NDA	National Health and Nutrition Examination Survey (NHANES), CDC/NCHS
D-5.1 Reduce the proportion of persons with diabetes <100% of poverty with A1c values >9	23.7% (2005–2008)	16.1%	23.5% (2009–2010)	NHANES, CDC/NCHS

Continued on next page

Healthy People 2020 (Continued)

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
DH-17 Increase the proportion of adults <100% of poverty with disabilities who report sufficient social and emotional support	54.2% (2008)	76.5%	NDA	Behavioral Risk Factor Surveillance System (BRFSS), CDC/PHSPO
HC/HIT-6.1 Increase the proportion of persons with incomes <\$20,000 who have access to the Internet	43% (2007)	75.4%	63.9% (2012)	Health Information National Trends Survey (HINTS), NIH/NCI
IID-8 Increase the proportion of children aged 19–35 months <100% of poverty who receive recommended doses of DTaP, polio, MMR, Hib, hepatitis B, varicella, and PCV	41.9% (2009)	80%	63.9% (2011)	National Immunization Survey (NIS), CDC, NHS, NCIRP
MDMH-9.1 Increase the proportion of adults aged 18 and over <100% of poverty with serious mental illness who receive treatment	58.7% (2008)	64.6%	60.2% (2011)	National Survey on Drug Use and Health (NSDUH), SAMHSA
NWS-12 Eliminate very low food security among children <100% of poverty	4.1% (2008)	0.2%	2.8% (2011)	Current Population Survey (CPS), Census & DOL/BLS
NWS-13 Reduce household food insecurity in those with incomes <100% of poverty and in so doing reduce hunger	42.2% (2008)	6%	41.1% (2011)	Current Population Survey (CPS), Census & DOL/BLS
NWS-21.1 Reduce iron deficiency anemia among children <100% of poverty aged 1–2 years	19.9% (2005–2008)	14.3%	NDA	NHANES, CDC/NCHS
NWS-22 Reduce iron deficiency among pregnant women <100% of poverty	19.7% (2003–2006)	14.5%	NDA	NHANES, CDC/NCHS
OH-2.1 Reduce the proportion of children aged 3–5 years <100% of poverty with untreated dental decay in their primary teeth	35% (1999–2004)	21.4%	25.3% (2009–2010)	NHANES, CDC/NCHS
SA-8.2 Increase the proportion of persons <100% of poverty who need alcohol and/or illicit drug treatment and receive specialty treatment for abuse or dependence in the last year	16.8% (2008)	10.9%	17.3% (2011)	NSDUH, SAMHSA
TU-1 Reduce cigarette smoking by adults <100% of poverty	31.9% (2008)	12%	29.4% (2011)	NHIS, CDC/NCHS
TU-4.1 Increase smoking cessation attempts by adult smokers	48.5% (2008)	80%	50.8% (2011)	NHIS, CDC/NCHS
V-2 Reduce blindness and visual impairment in children and adolescents age 17 and under <100% of poverty	44.3% (2008)	25.4%	47.1% (2011)	NHIS, CDC/NCHS

CHAPTER RECAP

Poverty and homelessness are growing problems in the United States and throughout the world, and population health nurses may encounter poor and homeless individuals and families in a variety of settings. Factors related to each of the six categories of determinants of health contribute to poverty and homelessness

and to their effects on health. Population health nurses can provide direct health care services to poor and homeless individuals and families. They may also be actively involved in identifying and collaborating with others to deal with factors that contribute to poverty and homelessness at the population level.

CASE STUDY

Preventing Homelessness

An assessment of the health needs of a center city community in a large metropolitan area revealed that the number one concern of area residents was eviction and lack of affordable housing. The majority of area residents are immigrants with limited English capabilities. Housing in the area is generally more than 60 years old and is often in poor repair, not meeting city codes. Housing units, particularly for low-income renters, are scarce, and families are often doubled-up in small apartments. Most rental units are owned by absentee landlords, who give little attention to repairs or elimination of safety hazards. If tenants complain to landlords about deficiencies, they are evicted and new tenants easily found.

Because many of the area residents are refugees from repressive regimes in Southeast Asia, they mistrust government and are afraid to report code violations to the local housing authority. Others, who might report deficiencies, are discouraged by the paperwork involved. The local public health nurse has assisted some residents to file complaints and has begun to take pictures of housing code violations in the homes of many of her clients. She has shared these pictures with the local Community Collaborative, which is working to improve the health status of community members. Lack of functional smoke and carbon monoxide detectors in apartments is a big concern, particularly since large numbers of adults in the community smoke, and much ethnic cooking is done over charcoal braziers inside the apartments.

The community has the lowest mean income level in the county, and although most heads of household are employed,

their jobs usually do not include health or other benefits. Part-time employment is common, and even in dual wage-earner families incomes are often still not sufficient to meet basic needs.

Because the area is close to the city's downtown, local developers have begun to buy up deteriorated rental properties and replace them with upscale rental properties and condominiums. Although local housing codes require all new developments to include a certain proportion of low-income housing, developers can circumvent these requirements by paying a minimal fine, which is far exceeded by the potential income from high-income rental units.

Most residents cannot afford to move to other parts of the city because rents would be much higher. Even those who might be able to afford higher rents resist leaving ethnic enclaves that provide them with needed emotional and material support. In addition, residents are close to their jobs and relocation would add travel expenses. Also, a large proportion of the population is children, and parents do not want to uproot them from schools where they fit in and are doing well.

1. What biological, psychological, environmental, sociocultural, behavioral, and health system determinants are influencing the health status of this population? How might these factors contribute to homelessness in the population?
2. What health promotion, prevention, resolution, and restoration strategies might be warranted in this situation? What might be the role of the population health nurse in planning and implementing these strategies?

Care of School Populations

Learning Outcomes

After reading this chapter, you should be able to:

1. Identify the overall goal of a school health program.
2. Describe the components of a coordinated school health program.
3. Describe considerations in assessing biological, psychological, environmental, sociocultural, behavioral, and health system determinants influencing the health of the school population.
4. Identify areas of emphasis in health promotion in the school setting and analyze the role of the population health nurse in each.
5. Discuss facets of illness and injury prevention in the school population and describe population health nursing roles related to each.
6. Describe considerations in resolving existing health problems in the school setting and analyze related population health nursing roles.
7. Describe areas of emphasis in health restoration with the school population and analyze the role of the population health nurse with respect to each.
8. Identify approaches to evaluating the effectiveness of health services for the school population.

Key Terms

mainstreaming

mitigation

school-based health centers (SBHCs)

school climate

school-linked health centers

school nursing

sexual harassment

Meeting a Community Need

In 1902, thousands of children were being excluded from New York City schools by physician medical inspectors because of communicable conditions such as eye infections, head lice, and so on. A particularly severe outbreak of infectious eye disease led Lillian Wald, founder of the Henry Street Settlement, to offer nurses to treat the infected children (Robert Wood Johnson Foundation [RWJF], 2010). Wald convinced the New York City Board of Health to allow her to assign a nurse, Lina Rogers, to four schools on an experimental basis. Rogers began her work in October of 1902 and was responsible for the health of 10,000 students across the four schools (Hanink, n.d.). The experiment was so successful that Rogers was given an official appointment by the Board of Health in November 1902, and by December another 12 school nurses had been appointed with Rogers serving as the Superintendent of School Nurses.

In the month prior to Rogers's initial appointment, 10,567 children were excluded from school for health reasons. In the same month the following year, only 1,101 students were excluded (RWJF, 2010). As noted by Rogers, "a sensible nurse, with good judgment, discretion, and enthusiasm, may be a powerful factor in the general improvement of a community" (Rogers, as quoted in Hanink, n.d., p. 1). School nursing services based on the New York City model were soon initiated in multiple cities across the nation.

American Association of the Deaf-Blind: Achieving Maximum Potential

Individuals with disabilities often require specific services and support for learning. The American Association of the Deaf-Blind (AADB) is a self-advocacy group comprising deaf-blind Americans and their supporters that advocates for conditions that promote the independence and productivity of deaf-blind people and their full integration into society (AADB, 2012). The organization provides information, referral, and technical assistance related to deaf-blindness focusing on such areas as technology support and interpreter support.

In 2009, AADB sponsored advocacy training for a group of young deaf-blind adults. Group participants identified key legislative issues related to deaf-blind issues, researched the issue, and spoke with legislators and legislative assistants to acquaint them with these issues. They also met with President Barack Obama to discuss technological and educational issues for this population (AADB, 2009).

In 2011, 83 million people 3 years of age and older in the United States were enrolled in school. This figure included 5 million nursery school children, 4 million children in kindergarten, 33 million students in grades 1 through 8, 17 million high school students (grades 9 through 12), and 24 million people in college (Davis & Bauman, 2013). The 50 million children in elementary and secondary schools spend a minimum of 6 hours a day in school settings year in and year out, making the school an obvious place to educate people for healthier lives (Division of Adolescent and School Health [DASH], 2011).

The relationship between health and education is a reciprocal one. Health influences one's ability to learn, and health-related factors may result in poor school performance. By the same token, poor educational achievement contributes to poverty and increased health risks. In addition, one's education affects the ability to engage in healthful behaviors (DASH, 2013f). Approximately one third of U.S. students do not graduate from high school, and failure to graduate contributes to lifelong health risks and increased costs. In addition, students who do not graduate are less likely than others to be employed and have health insurance; they are also likely to earn lower

salaries. Adolescent pregnancy is particularly associated with failure to earn a high school diploma, with only half of teenage mothers earning their diploma by age 22 (Center for School, Health and Education, 2011).

Schools with effective health programs can capitalize on existing resources to improve the health of the community, and school curricula, policies, and environments can promote healthy behaviors and attitudes for later life. In fact, school health is now seen as a critical component of international efforts to achieve the goal of education for all (Bundy, 2011).

In a 2010, the Health Resources and Services Administration reported that 73,697 registered nurses provided care to students across the United States (NASN, 2014). Most of these school nurses are population health nurses practicing in school settings. Given their population health preparation, school nurses retain their concern for the health of the overall population and apply the principles of population health nursing to the needs of the overall community as well as to the needs of the school population. This multilevel approach reflects the original public health nursing model espoused by the nation's first school nurses. In this model, school nurses cared

for individual children during the school day, but engaged in home visits to families and provided health education and health services after school hours and during school vacations (Hawkins & Watson, 2010).

The importance of the school health program as an avenue for improving the health of the population is evident in the number of national health objectives for the year 2020 that reflect health measures in schools. A number of these objectives are directed toward improving the health of young people and target school settings for their achievement. Several of these objectives are addressed later in this chapter.

Historical Perspectives

School nursing is one of several traditional roles for population health nurses. It originated in the United States with compulsory school attendance and a concern for the number of children being excluded from school because of communicable diseases. Health activities in schools were initiated in New York City in 1897, when 150 physicians were hired to inspect students for communicable diseases for 1 hour per

Global Perspectives

Fostering Education for All

In 1990, the World Conference on Education for All adopted the “World Declaration on Education for All: Meeting Basic Learning Needs” in Jomtien, Thailand. The declaration is a commitment to achieving basic education for all people throughout the world (World Conference on Education for All, 1990). In 2000, the World Education Forum expanded on the declaration, creating an action plan laid out in the “Dakar Framework—Education for All: Meeting Our Collective Commitments.” The Dakar Framework included six fundamental goals for education throughout the world:

- Expanding and improving comprehensive early childhood care and education, especially for the most vulnerable and disadvantaged children;
- Ensuring that by 2015 all children, particularly girls, children in difficult circumstances, and those belonging to ethnic minorities, have access to complete, free, and compulsory primary education of good quality;
- Ensuring that the learning needs of all young people and adults are met through equitable access to appropriate learning and life-skills programmes;
- Achieving a 50% improvement in levels of adult literacy by 2015, especially for women, and equitable access to basic and continuing education for all adults;
- Eliminating gender disparities in primary and secondary education by 2005, and achieving gender equality in education by 2015, with a focus on ensuring girls' full and equal access to and achievement in basic education of good quality;
- Improving all aspects of the quality of education and ensuring excellence of all so that recognized and measurable learning outcomes are achieved by all, especially in literacy, numeracy, and essential life skills. (World Education Forum, 2000, p. ii)

More recently, world leaders have recognized the inextricable interrelationships between health and educational achievement. As noted in the report, *Rethinking School Health: A Key Component of Education for All*, effective education of children can only occur if they are ready and able to learn (Bundy, 2011). Children's health profoundly influences both readiness and ability to learn. The report suggests school health programs as efficient and inexpensive mechanisms to improve children's health status and educational achievement, and recommends providing health services in schools related to nutrition and treatment for common conditions that affect children's ability to learn. Treatment might include therapy for worm infestation, correction of vision problems, and resolution of other health problems affecting children's learning ability (Bundy, 2011). Both nationally and globally, educators and health care providers need to recognize and capitalize on the opportunity to improve the health of the overall population offered by educational institutions. At the same time, the reciprocal realization of the influence of health on learning needs to be addressed by adequate levels of health care for school populations.

day (Hanink, n.d.). Children who were found to have communicable diseases or parasitic infestations such as head lice were sent home. Because they received no treatment for their conditions, these children were excluded from school for extended periods of time and continued to serve as reservoirs of infection for friends and family members still in school (Hawkins & Watson, 2010). As noted above, Lillian Wald assigned nurses from the Henry Street Settlement to four New York City schools in a pilot project in school nursing. During that first year, the number of school exclusions declined 90%.

Similar events were occurring elsewhere as well. In 1901, the Chicago Board of Education asked the Visiting Nurses Association to send nurses to visit crippled children in four city schools. In 1905, Jane Adams, founder of Hull House (a settlement house similar to Henry Street, although without a specific nursing focus) provided school nurses for a 10-week trial in Chicago public schools. Again, the success of the trial led to a formalized school nurse role in Chicago in 1908, and employment of school nurses shifted to the Chicago Board of Health in 1910 (Hawkins & Watson, 2010).

Early responsibilities of school nurses included care of sick children, identification of disabilities that made learning difficult, visits to families, and health promotion and illness prevention education. School nurses also provided first-aid services and checked students for head lice and other ailments (Hanink, n.d.; Hawkins & Watson, 2010). Some nurses also provided well-child and prenatal services. In fact, one nurse even initiated sex education in the school, which was accepted by area residents because of the trust they placed in her. As noted earlier, this trust was built by the incorporation of a public health nursing model with services to the larger community as well as students in the school. Because the nurse was well known to members of the community, her intervention was accepted without protest (Hawkins & Watson, 2010).

The potential of schools as avenues for promoting health and dealing with social ills was recognized considerably earlier than the advent of specific health-related services in the school setting. For example, Benjamin Franklin advocated physical exercise as part of the school curriculum, and the report of the Massachusetts Sanitary Commission emphasized the importance of health education and the role of schools in providing it. In 1870, smallpox vaccination was required for school entry as a means of increasing immunization levels in the population, and in 1899 Connecticut made vision screening of schoolchildren mandatory.

Early school nursing focused on preventing the spread of communicable disease and treating ailments related to compulsory school attendance. By the 1930s, however, the focus had shifted to preventive and promotive activities, including case finding, integration of health concepts into school curricula, and maintenance of a healthful school environment. Treatment of any health problems by the nurse was discouraged to prevent infringement on the private medical sector.

School health nurses, dissatisfied with such a minimal role, continued to provide clandestine diagnostic services and treatment of minor ailments in addition to engaging in classroom teaching related to health. More recently, school nurses have begun to return to activities related to the diagnosis and treatment of health problems. Several factors account for current changes in the school nurse role. Among these is the number of families of school-age children in which both parents work. In these families, neither parent may have time to deal with their children's routine health problems. Other factors include increasing student diversity, higher incidence of mental health problems in school-age children, lack of access to care, and homelessness.

Mainstreaming is another major influence on the current role of school nurses in the United States. **Mainstreaming** is the practice of integrating children with serious illnesses or handicapping conditions in regular school settings and classrooms whenever possible. According to the Federal Register (Rules and Regulations, 2006), Section 300.101(c) of the Individuals with Disabilities Education Act specified that "a free appropriate public education (FAPE) must be available to any individual child with a disability who needs special education and related services" (p. 46541).

Mainstreaming has created some difficulties for school health nurses. They now spend a considerable portion of their time caring for children with special needs, which may decrease the time available to meet the needs of other children in the school setting. Population health nurses in school settings may need to advocate for a balance between caring for the special-needs population and other children. They may also need to advocate for effective funding, personnel, facilities, and equipment to provide health care for children with special needs.

The School Health Team

Health problems identified in individual children or in the community served by the school are frequently beyond the capabilities of the population health nurse acting independently. To meet the needs of the school population and the community, the school health nurse often needs to participate as a member of a team. Here we will discuss the school nurse as a member of the team as well as other typical school health team members.

The School Nurse

The National Association of School Nurses (NASN) has defined **school nursing** as specialized area of practice that fosters the health of students as well as their academic achievement (NASN, 2011b). The five main components of the school nurse's role, as defined by NASN, include facilitating normal development, promoting student health and safety and a healthy school environment, providing quality care for potential and identified health problems, providing case management

services based on sound clinical judgment, and collaborating with others to enhance student and family capabilities (NASN, 2011b).

The California Commission on Teacher Credentialing (2012), which credentials nurses for school nursing practice as required in the state, indicates that school nurses are authorized by state law to perform the following functions:

- Conduct immunization programs
- Assess the health and developmental status of students and interpret assessment findings
- Interpret health and developmental assessments to parents, teachers, administrators, and others
- Design and implement individual school health maintenance plans
- Refer students, parents, or guardians to needed community resources
- Maintain communication to promote needed treatment
- Interpret medical and nursing findings
- Consult with, conduct in-service training for, and serve as a resource person for school personnel;
- Develop and implement the school health education curriculum and participate in health instruction
- Counsel and assist students and parents in health-related adjustments, and
- Teach health-related subjects under the supervision of a classroom teacher

Additional functions of school nurses in carrying out the designated roles include providing episodic care, management of chronic illness, communicable disease surveillance, health promotion, first-aid and emergency care, screening for a variety of health conditions, administering medications, and preparing for and responding to school and community emergencies (RWJF, 2010). Nurses in specific schools may take on additional roles and functions depending on local needs. A scope and standards statement for school nursing has been developed by NASN and the American Nurses Association (2011). For further information about the standards, see the *External Resources* section of the student resources site.

Unfortunately, approximately half of U.S. schools lack a full-time school nurse (RWJF, 2010). In keeping with the *Healthy People 2020* objectives, NASN (2012a) has recommended nurse-to-student ratios of one nurse to every 750 students in the general population. Ratios decrease for school populations with students who require more intensive nursing care. Suggested ratios are depicted in Table 22-1.

Preparation for school nursing should include a minimum of a baccalaureate degree in nursing due to the need for autonomous practice and the advanced skills needed to meet the needs of school children with complex conditions. In addition to the recommendation for a baccalaureate degree, NASN supports state school nurse certification requirements and encourages national certification. As noted by NASN (2012b),

TABLE 22-1 Recommended School Nurse to Student Ratios

Recommended Ratio	School Population
1:750	General student population
1:225	Populations of students that may require daily professional service or intervention
1:125	Populations of students with complex health care needs
1:1	Individual students who require daily and continuous professional nursing services

Data from: National Association of School Nurses. (2012a). *Chronic health conditions managed by school nurses*. Retrieved from <http://www.nasn.org/Portals/0/positions/2012pschronic.pdf>

certification provides recognition of an advanced level of practice in a particular specialty.

State certification may require postbaccalaureate education for school nursing, and requirements vary from state to state. For example, California requires that a school nurse hold a state-issued School Nurse Services Credential. School nurses can obtain a preliminary credential after graduation from a bachelor's or higher degree program in nursing and becoming registered as a nurse in California. Nurses must obtain a "clear" credential within 5 years. The clear credential requires 2 years of experience as a school nurse and successful completion of a state-approved school nurse education program, often at the master's level. The preliminary credential is not renewable, but the clear credential must be renewed every 5 years after meeting practice and continuing education requirements (California Commission on Teacher Credentialing, 2012).

National certification is obtained through the National Board for Certification of School Nurses (NBCSN). Certification requirements include appropriate state RN licensure, 1,000 hours of clinical practice as a school nurse, and successful completion of the certification examination. Elements of the examination address health appraisal, health problems and nursing management, health promotion and disease prevention, special health issues in school settings, and professional issues related to school nursing (NBCSN, 2013). For further information on national certification as a school nurse, see the *External Resources* section of the student resources site.

Other Team Members

Because identified health problems may be the consequence of factors beyond the control of health care professionals, the school health team often consists of a variety of individuals, not all of whom have a health or medical background. The team acts to design a school health program that meets the health needs of students and of the larger community.

The school health team should use the group development strategies discussed in Chapter 10 to create an effective team

that can address the health needs of the school population and surrounding community. One of the critical features of group development for the school health team is negotiating member roles. Group members should clarify for themselves the roles that each will play so that infringement on anyone's professional territory is avoided.

Specific members of the team will vary with the identified needs of the population, but some of those who may be involved, in addition to the nurse, are parents, teachers, administrators, counselors, psychologists, social workers, physicians and dentists, a health coordinator, food service personnel, janitorial and secretarial staff members, public health officials and other public officials, and students. Additional team members in some school settings include nurse practitioners; unlicensed assistive personnel (UAPs); physical, occupational, and respiratory therapists; and speech pathologists. If unlicensed assistive personnel provide health services in the school setting (e.g., to assist in the care of students with special needs), the school nurse is responsible for delegating appropriate activities and supervising their performance. The school nurse may also assist in educating UAPs for activities as warranted. For example, the nurse may educate a parent volunteer about positioning a child with limited mobility to prevent pressure ulcers or suctioning a child with a tracheostomy. In educating UAPs, the school nurse would be sure to emphasize when the nurse or other provider needs to be notified of changes in a child's condition. The nurse may also educate other school personnel or volunteers in routine first-aid and other simple health-related procedures (e.g., taking a temperature, assisting with height and weight screening).

Parents, of course, have the primary responsibility for the health of their children. With respect to the school health program, parents have a responsibility to reinforce health teaching at home and to follow up on referrals for assistance with health problems identified in their children. They should also provide input into the planning and evaluation of the school health program. Parents may also provide volunteer services for first aid or "sick room duty" when there is not a nurse employed full time. Population health nurses working in school settings may need to advocate for parent involvement in the development and design of school health services as well as evaluation of their effectiveness.

Teachers have a variety of responsibilities for the health of their students, such as motivating students in the development of good health habits, encouraging student responsibility for health, and observing students for signs of health problems. Teachers also have a responsibility to model healthy behavior and provide health instruction. Other responsibilities include assisting with screening efforts and measures to control the spread of disease and helping to identify factors in the physical, psychological, and social environments that are detrimental to the health status of students and coworkers. In addition, teachers may counsel students with health problems and may make referrals for assistance as appropriate.

School administrators include principals, district superintendents, and school board members. Administrators are responsible for the implementation of the school health program and should provide both material and nonmaterial support. They also function as liaisons between the school and the larger community. In collaboration with other team members, administrators participate in planning and evaluating the school health program. Other administrative responsibilities include hiring and evaluating health service employees and fostering collegial relationships among school health team members. Finally, administrators have the ultimate responsibility for the creation of a healthy and safe environment.

Some schools employ counselors, psychologists, or social workers or contract for their services as consultants. Counselors may provide emotional counseling or assistance to students in career decisions. Psychologists may also be involved in counseling for emotional problems. In addition, they may conduct psychological testing on selected youngsters to identify emotional problems or learning disabilities, or they may be called on to administer tests of school readiness to incoming children. Social workers may likewise counsel students regarding problems and may provide referrals for students and families to assist with socioeconomic problems. When the services of these specialists are not available in a particular school setting, many of these functions may be assumed by the school nurse, if he or she is educationally prepared to carry them out, or the nurse might make a referral to an outside source of assistance.

Physicians and dentists usually are not employed by a school system, but they may provide services on a contract or referral basis. Under a contractual arrangement, physicians and dentists may spend a certain amount of time in the school assessing health and dental needs or making treatment recommendations. In other instances, students may be referred to their own physicians or dentists for follow-up treatment of identified health problems. Physical, occupational, or respiratory therapists may be employed in some school systems that provide comprehensive health services or may serve as outside consultants in the care of individual children. School systems may also have similar kinds of interactions with speech pathologists.

The school nurse may function as the school's health coordinator, or the school health team may include a health coordinator who is not a nurse. The health coordinator may be a parent, teacher, or other person with some health-related preparation. Responsibilities of the health coordinator include serving as a liaison with families and with the community, arranging in-service education for staff, facilitating team relationships, and coordinating the health instruction program. Other areas of responsibility include planning for speakers on health topics, arranging health-related learning experiences such as field trips or health fairs, and reviewing materials for use in health education.

In schools where meals are provided, food service personnel are responsible for preparing and serving nutritious meals. They may also be responsible for planning menus, depending on their background and knowledge of the nutritional needs of school-age children. School nurses may provide consultation on healthy diets appropriate to the age of children in a particular school. They may also need to advocate for the availability of foods to meet special dietary needs of children with specific health conditions (e.g., diabetes, difficulty swallowing).

The janitorial staff is usually responsible for maintenance of the physical environment. Remediation of physical health hazards usually comes under their jurisdiction as well. They also ensure the cleanliness of kitchen and sanitary facilities to prevent the transmission of disease.

Clerical personnel are responsible for maintaining student records and for processing family notification of screening test results and recommendations. They may also be responsible for notifying families in the case of student injury or illness.

Public health officials are not employed by the school, but still form part of the school health team in that they are responsible for inspection of school sanitation, cooking facilities, and immunization status. They also act to establish local health policy related to schools and other institutions and to safeguard the health of the overall community. Other public officials may also be involved in planning a school health program to meet the needs of the school's population. Fire or police personnel might be involved, for example, in designing safety education programs for children and their parents.

In older age groups, students within the school may also be part of the school health team. Student responsibilities include helping to maintain a healthful and safe environment and providing input regarding student health needs and planning to meet those needs. Older students should also be involved in evaluating the effectiveness of the school health program.

Population Health Nursing and Care of School Populations

Population health nurses working in school settings apply the nursing process to the care of individual students and their families, to the school population, and to the larger community. In the remainder of this chapter, we will explore the application of the nursing process to nursing care in school settings.

Assessing the Health of School Populations

Use of the nursing process in the school setting begins with an assessment of health needs. The school nurse may assess the health status and needs of individual students or of the school population. In this chapter, we focus on assessing the health needs of the school population and identifying the factors influencing those needs. Areas for consideration include biological, psychological, environmental, sociocultural, behavioral, and health system determinants that influence the health of the school population.

BIOLOGICAL DETERMINANTS. Areas for consideration related to the biological determinants of health include maturation and aging as they affect health and health behaviors, genetic inheritance, and physiologic function.

Maturation and aging. School nurses work with students in preschool, elementary school, junior high and high school, and college and university settings. Consequently, the age of the client population influences the types of health problems that may be present. For example, prevention of childhood communicable diseases would receive greater emphasis in the preschool population, and sexuality issues and substance abuse would be of greater concern with adolescent populations. For college students, substance abuse and sexuality issues are also pertinent, as are stress-related problems stemming from academic pressures and being away from home.

Client maturation also influences the content and process of the health education component of the school health program. Basic hygiene conveyed via cartoon films is appropriate to the preschool or early elementary-age child; a frank discussion of sexuality and sexually transmitted diseases is appropriate with older groups of schoolchildren.

Genetic inheritance. Aspects of genetic inheritance of particular interest to the school nurse are the gender and racial or ethnic composition of the population. A predominance of females in a preschool or an elementary school increases the frequency with which the nurse will encounter students with symptoms of urinary tract infection as these are more common in girls than boys in all age groups except infants. In adolescent girls, there is increased risk of unwanted pregnancy, and sexually transmitted diseases are common among both girls and boys. Boys of all ages tend to have more sports-related injuries with which the nurse must deal.

The racial and ethnic composition of the school population also influences the types of health problems encountered. For example, in schools with large African American populations, sickle cell screening might be included as a routine part of the school health program. The nurse must also be alert to the prevalence of other diseases that exhibit genetic predispositions, such as thalassemia and diabetes.

Physiologic function. An important aspect of the human biological component of the assessment is the physiologic function of the school population. School nurses may encounter students or staff with self-limiting health problems or chronic conditions that affect their abilities to function effectively in the school setting.

Examples of self-limiting conditions include communicable diseases such as the common cold, influenza, and chickenpox and injuries such as a fractured arm or leg. Diabetes, seizure disorders, and minor visual or hearing problems are examples of chronic conditions that may have health and educational implications. Many of these conditions can be controlled if properly diagnosed and treated and do not necessarily interfere

with the child's ability to function in school. Other chronic and handicapping conditions do interfere with school function. Examples are blindness, deafness, developmental delay, attention-deficit hyperactivity disorder (ADHD), and long-term effects of fetal drug exposure. Conditions related to environmental or psychological stress may or may not affect physiologic function, although they may affect the child's ability to function effectively in the school situation.

The kinds of physical health problems seen by school nurses among students and staff are many and varied. Both acute and chronic conditions are commonly encountered in the school setting. Acute conditions include a variety of communicable diseases and injuries. Population health nurses may be involved in providing care to individual students (or staff) who are ill or injured. They may also identify trends in illness or injury that require changes in environmental conditions, policies, and so on. Chronic health problems are encountered with greater frequency in today's schools than in the past. In part, this is the effect of mainstreaming children with disabilities and in part, an actual increase in chronic disease incidence in children. The number of school children and adolescents with chronic health conditions increased from 1.8% in the 1960s to 25% in 2007 and continues to climb. Chronic conditions among children in school settings include both physical and mental illnesses. The Rehabilitation Act and the Individuals with Disabilities Education Act (IDEA) protect the right of children with selected conditions to attend school and to be integrated, to the extent possible, into regular classrooms (NASN, 2012a). IDEA mandates special education and related health services for children with specifically designated mental and physical disabilities (RWJF, 2010). NASN (2012a) recommends, however, that schools use a noncategorical approach to identifying children with specific needs for service and risk for school failure rather than a disease specific approach. In 2011, 5.2 million U.S. children received special education or early intervention services. This represents nearly 7% of all children under 18 years of age (Adams, Kirzinger, & Martinez, 2012). School nurses need to be conversant not only with care of minor illness and injury but also with the complex care of children with special needs.

Asthma and overweight are two of the most common chronic problems seen by today's school nurses. Asthma in children is often poorly controlled, and results in millions of lost school days and millions of dollars in lost work time for their caretakers each year. As we saw in Chapter 16, overweight and obesity are other significant problems among school-age children.

Immunity is another important consideration related to physiologic function in the school population. The population health nurse working in the school setting monitors the immunization status of students and school employees. For example, maintenance personnel are at risk for tetanus because of the potential for dirty injuries, and their immunization status should be monitored. For female teachers and other school personnel of childbearing age, the risk of rubella during pregnancy is increased by working with children, and they should also be adequately immunized.

A final health problem frequently encountered in the school population that may have a physiologic basis is ADHD. ADHD was discussed in Chapter 16.

In addition to assessing the physiologic health status of the school population as a whole, the population health nurse working in a school setting will also assess the health status and needs of individual children. Both entry and periodic assessments may be performed by school nurses. At entry into the school system, all children should receive a comprehensive medical history and assessment of preschool experiences; language, motor, social, and adaptive development; and immunization status, as well as a complete physical examination.

Periodic assessments should be based on age-appropriate guidelines and individual needs and should address new problems, medications, changes in status, and school progress. Assessment should also include screening at appropriate ages for vision, hearing, and dental problems, as well as emotional maturity, language, and motor skills. Assessments for sports participation should also include endurance and muscle strength assessment. All assessments performed in the school setting should include anticipatory guidance for children and/or parents and problem identification and referral as needed. Biological considerations in the school health setting are included in the *Focused Assessment* below.

FOCUSED ASSESSMENT

Assessing Biological Determinants of Health in School Populations

- What is the age composition of the school population (staff and students)? Do any of the students exhibit developmental delays? Are there specific developmental issues related to the age of the student population (e.g., sexual development)?
- What is the relative proportion of males and females in the school population? What is the racial/ethnic composition of the school population?
- What chronic or communicable conditions are prevalent in the school population?
- What are the immunization levels in the school population?

PSYCHOLOGICAL DETERMINANTS. School climate and the presence of mental illness among the population are two of the psychological determinants of concern in assessing health in this setting. Each of these factors will be briefly discussed here.

School climate. Although school climate might also be considered as a sociocultural determinant of health in school settings, it is addressed here because of its psychological implications for health and well-being. **School climate** is defined as the social and educational environment in which students experience learning and social activities designed to meet designated outcomes (Thomas-Presswood & Presswood, 2008). Three elements of a healthy school climate include positive relationships among members of the population, an orientation to personal growth for all members, and elements of system maintenance and system change that support clarity in expectations and their enforcement (Thomas-Presswood & Presswood, 2008).

Positive school climates establish clear behavioral and academic expectations, encourage parental involvement, and engage in activities, programs, and staff development initiatives to prevent bullying and promote social skills and conflict mediation (Thomas-Presswood & Presswood, 2008). The elements of school climate can be seen in relationships between and among students, between teachers and students, among school personnel, and between families and school and the school and the larger community. Other elements include performance expectations and grading practices.

Characteristics of positive school climates are as follows:

- All members of the population perceive the school staff as warm, caring, and concerned.
- Teachers, staff, and administrators see students as valuable and treat them with respect.
- Policies (e.g., grading, discipline policies) are administered to promote personal and educational achievement.
- Educational programs and curricula are ethnically, culturally, linguistically, and socioeconomically inclusive.
- Educators recognize students' accomplishments and encourage them to achieve their potential.
- There is stability among teachers, who display common goals.
- There are clearly defined curricular components and expectations.
- Schoolwide celebrations recognize stakeholder accomplishments.
- Staff are recognized for their contributions to the school.
- Open communication is encouraged.
- Administrators offer tangible support for maintaining a positive school climate (Thomas-Presswood & Presswood, 2008).

Conversely, elements of school climate that have negative effects on members of the school population include poor

instruction leading to school failure, reliance on punitive behavior management or discipline strategies, provision of few opportunities for students to learn and practice interpersonal and self-management skills, and unclear and inconsistent rules and expectations or inconsistent correction of violations and failure to reinforce adherence to rules and expectations. Other characteristics of negative school climates include failure to recognize and accommodate to individual differences, failure to help at-risk students connect to the educational process, and lack of agreement among teachers, staff, and administrators regarding implementation of disciplinary strategies (Thomas-Presswood & Presswood, 2008).

Discipline is a particularly knotty problem in the school setting and school personnel should incorporate the general principles of effective discipline presented in Chapter 16. NASN (2011a) has adopted a position statement indicating that corporal punishment in schools should be legally prohibited. Similar position statements have been issued by the American Academy of Pediatrics, National Parent Teacher Association, National Association of School Psychologists, and the American Academy of Family Physicians. **Corporal punishment** is the intentional use of physical pain to motivate a change in behavior (NASN, 2011a). Research has indicated that, rather than modifying behavior, corporal punishment has negative effects on student self-image and school performance. As of 2011, corporal punishment has been prohibited in public schools in 29 states. Instead, schools need to employ a multifaceted approach to behavior management in schools that supports parents and teachers and that alters the school climate or classroom environment to minimize problem behaviors (NASN, 2011a).

Mental illness and the school setting. A significant number of school-age children in the United States suffer from mental health problems. According to surveillance data compiled by the Centers for Disease Control and Prevention (CDC), for example, more than 8% of elementary school-age children and nearly 12% of high school-age children in 2011 had ever received a diagnosis of attention deficit hyperactivity disorder. Slightly smaller percentages of students had current behavior or conduct problems in 2007 (3.8% and 4.2%, respectively). Similarly, in 2009–2010, approximately 1.4% of both age groups had received diagnoses of autism or autism spectrum disorders. A far larger percentage of high school-age students (7.8% to 8.5%) reported a major depressive episode in the past year in 2010 to 2011. For elementary-age students, the most recent data for current depression were from 2007 at 1.0% to 1.8%. Finally, between 2005 and 2010 an average of 8.3% of adolescents reported more than 14 mentally unhealthy days in the past month (Perou et al., 2013).

These data suggest the magnitude of mental health problems experienced by students in elementary and high school settings. Mental health problems severely impair students' abilities to be successful in school. For example, about half of students with mental illness fail to complete high school (National

Alliance on Mental Illness [NAMI], 2010). College students are also affected by mental health issues. According to a 2010 NAMI survey, 27% of college students responding reported experiencing depression, and 24% had bipolar disease. Severe anxiety was reported by 11% of students and schizophrenia by 6%. The prevalence of PTSD and ADHD were 6% and 5%, respectively. Among respondents who indicated they were no longer in college, 64% indicated their leaving was due to mental health issues, often as a result of loss of financial aid due to low grades or shifting to part-time study. In addition, 73% of students reported experiencing a mental health crisis while in college, but 35% indicated that their school was not aware of the crisis (NAMI, 2012).

More than half (62%) of the college students surveyed knew how to access learning accommodations, but 57% did not do so, most often because they did not realize that accommodations were available for mental as well as physical disabilities. Half of the students with mental illnesses did not disclose the illness to the institution, often out of fear of consequences of disclosure and concerns regarding confidentiality (NAMI, 2012).

Population health nurses serving in school nursing roles are ideally positioned to identify mental health problems among students at all grade levels, as are other personnel in school-based health centers (Broussard, Chrestman, & Arceneaux, 2012; Center for School, Health and Education, 2011). For example, a study of school nurses in the United Kingdom indicated the vast majority of nurses (93%) dealt with mental health issues among students and over half of them (55%) indicated that mental health problems took more than a quarter of their work time (Haddad, Butler, & Tylee, 2010). Unfortunately, few school nurses (in the United States or the United

Kingdom) have received specialized training in addressing such problems, particularly after major traumatic events such as disasters (Broussard et al., 2012; Haddad et al., 2010).

It is not only students' mental health problems that affect their performance and level of achievement in school. Children whose parents have addictive disorders have been found to have higher incidence of a variety of health problems. They are more apt to be late to school, have a higher incidence of learning disability, and receive less assistance with homework than other children. In addition, these children are more likely to experience interpersonal difficulties, social isolation, and school performance problems. Children with parents who have addictive disorders are at higher risk for psychiatric disorders than other children and may be more likely to be abused or to develop substance abuse problems themselves. School nurses should be alert to children whose parents have addictive behaviors and should endeavor to provide them with the psychological and social assistance needed to circumvent the effects of parental disability on health and school performance. The *Focused Assessment* below lists areas for consideration in assessing the psychological dimension of health in the school setting.

ENVIRONMENTAL DETERMINANTS. Factors in the physical environment of the school and the surrounding community influence student safety and other health-related considerations. For example, the distance from school influences the ability of students to engage in active transportation (Kohl & Cook, 2013). **Active transportation** is the use of active means, such as walking and bicycling, to travel to and from school. The use of active transportation declined from 41% of school

FOCUSED ASSESSMENT

Assessing Psychological Determinants of Health in School Populations

- What is the quality of the school climate? What is the quality of relationships among various members of the school population? Between families and the school? Between the school and the larger community?
- What is the extent of connectedness to the school exhibited by students?
- How do peer relationships within the school affect health? Are there students who are harassed by others? What is the effect of this harassment?
- What is the overall character of teacher–student relationships within the school? Do these relationships support connectedness? Do they promote or impede student mental health?
- What is the character of relationships among teachers and between teachers and other school staff? What effect, if any, do these relationships have on the health of students? Of staff?
- What is the character of relationships between the school and parents? Between the school and the larger community? How do these relationships affect the health of the school population?
- What are the discipline policies and procedures in the school setting? Are they implemented fairly? What health effects do discipline policies have on students?
- What are the grading policies of the school? Are they implemented fairly?
- What is the extent of mental illness in the school population? To what extent does mental illness in family members affect the health of students?

students in 1969 to 13% in 2001 (Physical Activity Guidelines for Americans Midcourse Report, 2012). Both school and neighborhood environments influence physical activity. For example, a study in New Zealand found that schools with high levels of sports team participation and communities characterized by high levels of social connection were associated with increased physical activity among students (Utter, Denny, Robinson, Amerantunga, & Milfont, 2011).

School environments may also include conditions that pose safety hazards for students and others in the setting. For example, storing supplies in stairwells may hamper building evacuation in the event of an emergency. Similarly, inappropriate storage of flammable items or inappropriate use of caustic agents for cleaning or in laboratory courses may lead to injury. In addition, architectural features of the school can influence health in multiple ways, both positive and negative. For example, architectural features such as play areas and equipment can influence physical activity. Environmental factors also affect stress, appetite, food choices, and so on (Huang et al., 2013). Similarly, solid perimeter walls (brick or concrete block) are more effective than chain link fences in preventing unauthorized entry and possible danger to students from terrorists or other potential assailants. Similarly, overlapping areas for picking up and dropping students off create the potential for pedestrian injuries (National Clearinghouse for Educational Facilities [NCEF], 2008).

Schools should engage in systematic identification of environmental hazards. A **hazard**, in this context, is any circumstance that has the potential to result in harm or damage to the school or the school population (NCEF, 2008). Risk then is the probability that such a loss will occur. School health nurses and others in the school setting should conduct an in-depth assessment of the hazards present in the setting and surrounding community. The Environmental Protection Agency (2014) has developed a *Healthy School Environments Assessment Tool (Healthy SEAT)* that can be used to assess multiple areas within the school environment. For further information about the tool, see the *External Resources* section of the student resources site.

Once safety hazards in the environment have been identified, members of the school health team can engage in mitigation efforts. The Federal Emergency Management Administration (FEMA) has defined **mitigation** as action taken to prevent or minimize the potential risk to life or property resulting from a hazardous circumstance (NCEF, 2008). Mitigation efforts may include both passive and active safety measures. Passive safety measures are those that are directed at the physical structure or layout of the school, for example, installing traffic calming features, such as speed bumps and stop signs in heavily traveled areas of campus with high risk for accidents and providing a soft surface below play equipment. Active safety measures involve changes in behavior, such as enforcing the use of sports safety equipment or increasing adult supervision during recess. Hiring security guards to prevent unauthorized persons from gaining

access to the school is another example of an active safety measure, while installing metal detectors at entrances would be a passive safety measure (NCEF, 2008). The school nurse and other members of the school health team would develop a mitigation plan to address identified hazards. There is also a need for a systematic school safety plan that details how to respond to safety issues (Safe Havens International, n.d.). For information on a tool developed by Safe Havens International to evaluate the quality and comprehensiveness of the school safety plan, see the *External Resources* section of the student resources site.

The nurse and others assess both the internal and external physical environment of the school. The external environment includes the area surrounding the school. Assessment considerations here include traffic patterns, water hazards, use of pesticides, and rodent control in the area. The proximity of hazardous waste dumps or nuclear power plants, industrial hazards, and the presence of various forms of pollution are other environmental concerns in school settings. (See Chapter 4 for a discussion of environmental health issues.)

Several aspects of the school's internal environment, such as fire hazards and sanitation, are the responsibility of official agencies such as the fire department and health department; however, other aspects of the physical environment are rarely adequately assessed. The school health nurse needs to be alert to other hazards to physical safety that may be present in the school setting. Examples of these hazards are toxic art supplies, scientific equipment in laboratories, kitchen appliances in home economics classrooms, and chemical substances used either in chemistry labs or by maintenance and janitorial staffs. Animals in classrooms may also present safety hazards in terms of the potential for scratches and bites or disease transmission. Other conditions that may jeopardize safety include asbestos used in building materials, inadequate maintenance of fire hoses and extinguishers, and inoperable communications systems in the event of an emergency.

Other areas of concern are the safety of industrial arts classrooms, the gymnasium, and play areas. As noted in Chapter 16, the safety of outdoor play equipment should be inspected on a regular basis and repairs made as needed. A similar need exists for periodic assessment of sports equipment and practices. Other hazards associated with play areas include broken glass and other refuse on the playground. Hard surfaces below play equipment increase the potential for injuries stemming from falls. Weather is another element of the physical environment that affects the health of students. For example, heat illness brought on by sports practice or competition is the leading cause of death in high school athletes. From 2005 to 2009, more than 9,000 heat-related events were estimated among high school students (Gilchrist et al., 2010). Similarly, playing outdoors on days with pollutant levels that exceed safety recommendations can result in asthma exacerbations and other respiratory conditions.

Other assessment considerations with respect to the school's internal physical environment include noise levels within and

outside of classrooms and the adequacy of lighting, ventilation, heating, and cooling. Food sanitation should also be assessed. If hot meals are provided at school, cooking facilities should be inspected regularly. Such inspections are usually the official responsibility of the local health department, but the population health nurse should also assess these facilities periodically. If students bring their lunches, the potential for food poisoning from spoiled foods should be appraised.

Assessing sanitary facilities in the school is another area for consideration. Here, the nurse would examine the adequacy of toilet facilities for the size of the school population. The nurse would also periodically inspect sanitary facilities to make sure they are in good working order and do not pose hazards for the transmission of communicable diseases. Again, this area is usually the responsibility of health department personnel, but official inspections may occur only at lengthy intervals and the nurse should be aware of hazards that might arise in the interim.

Another area of concern with respect to sanitation is the use and cleaning of shower facilities. The nurse should assess that showers are adequately cleaned to prevent transmission of communicable conditions such as tinea pedis (athlete's foot).

Physical facilities for preventing the spread of disease by infected children should also be assessed. Are there places within the school where students with infectious conditions can be isolated? All too often, these children are merely kept in the nurse's office until a parent can come for them. This presents opportunities for exposure of all those who visit the nurse while the child is there.

Special consideration should be given to the physical environment as it relates to children with disabilities. Many physical barriers may exist, particularly in older schools, which limit the ability of disabled students to benefit from the education setting. Areas of concern include the presence of ramps, easily opened doors and windows, nonslip flooring, elevators, and

curb modifications to eliminate the need to step up. Another consideration is access to toileting facilities. Are toilets accessible to wheelchairs? Are sinks placed so that a wheelchair can be maneuvered beneath them? The placement and height of mirrors, drinking fountains, and telephones are also of concern. Other considerations with respect to the environment of handicapped children are the adequacy of storage for wheelchairs and other special equipment, wheelchair space in classrooms and auditoriums, modification of laboratory and library carrels for wheelchair use, and the adequacy of evacuation plans for the disabled in case of emergency. The intent is to create a school that is barrier-free so that all students, staff, and community members who may use the premises after school hours have access to facilities and equipment. Population health nurses may need to actively advocate for modifications in the school setting that address the needs of students (or employees) with disabilities.

Finally, the school nurse should assess the level of preparation in the school setting for disaster events or terrorist activities. Elements of an effective disaster response plan include personnel organization, forms, specific considerations, and the role of the nurse.

The role of the school nurse with respect to disaster events or terrorist activities includes participation in developing the disaster plan. In the event of an actual disaster, the nurse assists in maintaining calm, triages injuries, and addresses the physical and psychological effects of the disaster. After a disaster event, the nurse helps to address the fears and grief of students and other staff members. In addition to meeting ongoing health care needs, the nurse should provide realistic and reliable information, facilitate referrals for support, and educate staff regarding the psychological effects of such events. Disaster response will be addressed in more detail in Chapter 25. Elements of a *Focused Assessment* of physical environmental considerations in the school setting are summarized below.

FOCUSED ASSESSMENT

Assessing Environmental Determinants of Health in School Populations

- Are there health hazards present in the school or the surrounding neighborhood?
- Are food sanitation practices adequate to prevent communicable diseases, vermin infestation, and so on?
- Are school facilities adequate and in good repair? Are there adequate facilities for students or staff with physical disabilities?
- What is the character of the environment surrounding the school? What health effects, if any, does the external environment have on the school population?
- What is the potential for disaster within the school setting? Is the school adequately prepared to respond to a disaster event?
- What physical barriers are in place to prevent unauthorized access to school grounds?
- What are the positive and negative health effects of building architecture and school grounds?

SOCIOCULTURAL DETERMINANTS. Sociocultural factors also play a part in influencing the health status of members of the school community. Areas to be addressed in this dimension include culture and ethnicity, economic resources, policy and legislation, abuse and violence, and the potential for terrorism.

Culture and ethnicity. Cultural factors in the school setting may affect educational priorities as well as health-related behaviors. What is the racial or ethnic composition of the school population? Are racial tensions present? Do religious beliefs influence the health of the school population? For example, if there are large numbers of children whose parents object to immunization on religious grounds, the nurse needs to be particularly alert to signs of outbreaks of childhood diseases such as measles, rubella, and diphtheria.

Another area for consideration is the cultural backgrounds of students and school personnel. Are they similar? Do cultural practices influence students' health? Do differences in cultural practices create tension among students or between students and staff? Cultural factors may also lead to inappropriate diagnoses of ADHD for behavior considered perfectly normal in the child's culture or child abuse in the face of cultural health practices such as dermabrasion or cupping. (See Chapter 5 for a discussion of various cultural health practices.) Children whose primary language is not English may also have difficulties in school, and the nurse should work to achieve culturally and linguistically appropriate education for these children. Similarly, children of migrant or homeless families of whatever cultural or ethnic background may have their education disrupted by frequent moves.

Economic resources. The level of resources available to the school is one element in assessing the sociocultural dimension of the school setting. The nurse also needs to assess the community's attitudes toward education because these attitudes determine the allocation of funds for both school and health programs. What level of priority is given to school funding in the community? Do community members support bond issues for school renovation or specific school-based programs? Population health nurses may need to advocate with school boards and other local officials for sufficient funding for school health services. Political advocacy may also be needed at state and national levels to assure adequate funding for education, particularly for school-based health services.

The economic levels of individual students and their families also influence the health status of the school population. Homelessness is an extreme socioeconomic factor that can have a profound effect on the health of school-age children. As we saw in Chapter 21, homeless children often perform poorly in school or fall behind because of frequent moves. As a result of the McKinney Homeless Assistance Act, homeless children are guaranteed access to free and public education. Under this act, homeless children may be eligible for other services that must be provided by schools receiving assistance funds. These services may include clothing, a place to bathe

and change clothes, free or reduced-cost meals, school supplies, tutorial assistance, and access to medical care.

Homelessness is often the result of divorce or violence within families. Children may be homeless because their mothers are fleeing an abusive situation. In such circumstances and in disputes over child custody, the school system needs to be alert to the potential for abduction of schoolchildren by the other parent. Similarly, abduction and mistreatment by strangers is an area of concern, and the school nurse should assess school policies designed to prevent such occurrences for their adequacy and the extent to which they are enforced.

Another factor closely related to family economic status is the prevalence of families in which both parents work. Unfortunately, children in dual wage-earner families are often sent to school when they are ill because there is no one at home to care for them. The nurse should assess the number of students who come to school ill and explore with parents their reasons for sending sick children to school. It may be a lack of awareness on the part of parents of the signs and symptoms of illness or the absence of other options.

The nurse should also assess before- and after-school care of children whose parents work. Many so-called *latchkey* children stay at home alone before and after school until parents return from work. Population health nurses can assess the availability of programs for children who are not mature enough to stay home alone and make referrals to these programs if they do not already exist within the school. In addition, nurses can assist parents to determine children's readiness to stay home alone and help to educate both parents and children on conditions that promote the safety of latchkey children.

Policy and legislation. State and federal policy that affects the health of school populations is often provided in legislation. As we saw earlier, legislation related to education for children with disabilities has profoundly influenced the role of school nurses in caring for these children, many of whom have multiple health care needs.

Other policy initiatives may also influence school health. Many policies that affect the health of school populations arise in the Office of Safe and Healthy Students (OSHS) and its three subordinate units: the Safe and Supportive Schools Group, the Healthy Students Group, and the Center for School Preparedness (OSHS, 2014). Individual states also develop laws and regulations related to school health. For further information about laws, rules, regulations, and guidelines related to school health, see the *External Resources* section of the student resources site.

Other federal and state agencies and nonprofit organizations also develop policies that influence health in school populations. For example, the Institute of Medicine (IOM) has developed nutrition standards for schools that address the fat, sugar, and sodium content of foods available in schools. The standards also address nonnutritive food items such as the availability of sweetened and caffeinated beverages, as well as food standards for the school day and for after-school activities (National Center for Chronic Disease Prevention and Health Promotion [NCCDPHP], 2012).

Finally, the standards deal with the availability of “competitive foods.” **Competitive foods** are foods sold or available in schools that are outside of federally reimbursable school meal programs and that compete with the more healthful foods offered with the nutrition programs (NCCDPHP, 2012). Similar policies exist within states. As of 2010, 39 states had policies related to the nutritive value of competitive foods (NCCDPHP, 2012). A study of state laws related to nutrition policies in schools indicated little progress from 2003 to 2008, in that the vast majority of states did not have laws related to the quality of school meals for elementary to high schools, competitive foods, or for food and beverage items used for school fund-raising (Mâsse, Perna, Agurs-Collins, & Chriqui, 2013). Federal and state standards and policies also address recommendations for health education and physical education in school settings (DASH, 2013a, 2013e). School districts and individual schools also have numerous policies that influence health in the school population. The population health nurse assesses the myriad policies and their effects on the health of the population. Some authors have suggested the employment of a school “wellness nurse” dedicated to assisting schools to develop and implement policies that promote health and to promote the incorporation of health promotion and illness prevention guidelines in the school setting (Avery, Johnson, Cousins, & Hamilton, 2013).

Bullying, harassment, and violence. A particular need in today’s society is to prevent bullying, harassment, and violence in and around the school setting. **Bullying** is “unwanted, aggressive behavior among school-aged children that involves a real or perceived power imbalance” (U.S. Department of Health and Human Services [USDHHS], n.d., para 1). School bullying includes any form of bullying that occurs on school property, on the way to or from school (e.g., on the school bus), or at school-related events. School bullying may involve peer-to-peer interactions, bullying of younger children by older children, or bullying by or of a teacher. Bullying can be differentiated by the number of bullies, the mode of bullying, or the medium used for bullying. *Pack bullying* is perpetrated by a group of individuals as opposed to one-on-one bullying by an individual. Pack bullying is more often seen in high school populations, while individual bullying is more common in elementary school. Both pack bullying and individual bullying can be physical or emotional and can be perpetrated in person or electronically. Bullying can also be differentiated by its intended target, based on homophobia, disability, racism, or religious beliefs (Bullying Statistics, 2013).

In 2011, roughly 28% of students 12 to 18 years of age reported being bullied at school. Bullying included being made fun of or called names, being the subject of rumors, threats of harm, and attempts at coercion. Other manifestations of bullying included being excluded from activities, damage to personal belongings, and being pushed, shoved, tripped, or spit on (National Center for Education Statistics [NCES], 2013).

Sexual harassment is one specific form of bullying that occurs in school populations. **Sexual harassment** is unwelcome behavior with sexual overtones perpetrated in person or electronically (Hill, 2012). In a national survey of students in grades

Violence is a significant problem in many school settings.

(Monkey Business/Fotolia)

7 to 12 conducted by the American Association of University Women (AAUW), 48% of participants reported some form of sexual harassment in the prior year, 30% via electronic media. Boys reported being less negatively affected by sexual harassment than girls, but were more likely to be harassers. In the report, sexual harassers were described as often being “misguided comedians” who have no concept of the damage caused by their behaviors (Hill, 2012). Sexual harassment often involves a verbal attack on the victim’s sexuality or appearance, for example, spreading rumors that one is gay or lesbian or sexually promiscuous, making suggestive comments, or making sexual threats.

Bullying that occurs by means of electronic media (e.g., social media postings, telephone calls, texting) is often referred to as cyberbullying or cyber-harassment. **Cyberbullying** is defined as “cruelty to others by sending or posting harmful material using the Internet or cell phone” (National Conference of State Legislatures, 2014, para. 3). In the AAUW survey, 36% of 7th to 12th grade girls and 24% of boys reported experiencing cyberbullying in the prior year (Smolinski, 2012). In another study in Massachusetts, 25.9% of students reported being bullied at school in the last year and 15.8% reported cyberbullying. Most of the students experienced bullying in both formats, which was associated with the highest levels of distress (Schneider, O’Donnell, Stueve, & Coulter, 2012). Nationally, about 9% of 12- to 18-year-old students reported being cyberbullied in 2011 (NCES, 2013). At its worst, bullying in any form may result in suicide or homicide. Suicide by victims of bullying is sometimes referred to as “bullycide,” and being a victim of bullying is one of the primary causes of homicide in school settings. Of 31 school-associated violent deaths in elementary and secondary schools during the 2010–2011 school year, just over 80% were homicides, and the remainder were suicides (NCES, 2013).

Violence of all kinds is found in school settings. In 2011, for example, nearly 33% of a nationally representative sample of American 9th to 12th graders reported being in a physical fight in the past year (12% on school premises). Nearly 17% of

students reported carrying a weapon to school, and more than 7% reported being threatened or injured with a weapon in the last year. In addition, approximately 160,000 K–12 students go home from school early due to bullying and violence and 5% report skipping school due to fear of violence (Center for School, Health and Education, 2011; National Center for Injury Prevention and Control, 2012). Finally, a full third of high school students report that violence is a big problem in their schools (Center for School, Health and Education, 2011).

Data compiled by the Bureau of Justice Statistics and the National Center for Education Statistics indicate that 31 school-associated violent deaths occurred from July 2010 through June 2011. Of the 31 deaths involving students, school personnel, and nonstudents, 25 were homicides and 6 were suicides. Eleven of these homicides involved children and youth 5 to 18 years of age, and half of the suicides were among students. This is a decrease from 19 violent student deaths the previous year (Robers, Kemp, Truman, & Snyder, 2013).

In addition, 597,500 instances of nonfatal violence ranging from simple assault to serious violence occurred among 12- to 18-year-old students in 2011. More victimizations (theft and violence) in this age group occurred at school than away from school at a rate of 49 victimizations per 1,000 children at school compared to 38 per 1,000 away from school. No differences were noted by locale among serious violent victimization. Violence is pervasive across schools with 74% of public schools experiencing at least one violent crime in the 2009–2010 school year and 16% experiencing one or more serious violent incidents (Robers et al., 2013). All of these figures suggest the magnitude of violence in school settings and population health nurses assessing the health of school populations should be alert to the presence of all forms of bullying, harassment, and violence within the population.

Violence within the school environment can be addressed by explicit codes of conduct that are clearly communicated to students and consistently and uniformly enforced. Weapons

should be strictly banned from school campuses and the ban stringently enforced. Peer counseling and off-campus counseling sites to address interpersonal problems have been effective means of reducing violence. The population health nurse in the school setting can assess the level of violence on campus as well as the effectiveness of steps taken to prevent violence. The nurse can also examine the inclusion of conflict resolution strategies and content on interpersonal relations in the school's health education curriculum.

School children may also be subjected to violence and abuse outside of the school setting. Children may suffer physical, emotional, or sexual abuse or neglect within their families. Children with disabilities are nearly twice as likely to be abused as other children, and, although boys and girls are abused with equal frequency, girls are more likely to experience sexual abuse. School nurses should be alert to signs of abuse and neglect in individual children. Child abuse is addressed in more detail in Chapter 30.

The extent of crime in the school neighborhood is another aspect of the social environment to be assessed. Is violence a problem for children going to and from school? Is drug dealing going on in the area, and will youngsters be pressured to experiment with drugs? Similarly, the nurse would assess the extent of gang activity in and around the school and its effects on the health of the school population. Questions for a *Focused Assessment* of sociocultural determinants of health in the school setting are presented below.

BEHAVIORAL DETERMINANTS. Enrollment in school is itself a lifestyle factor that influences health. School attendance increases one's risk of exposure to a variety of communicable diseases. Children generally experience an increase in the number of acute illnesses during the first few years of school, whether at the day care/preschool level or with admission to elementary school.

The rigidity of the school day may also affect the health status of students. The nurse determines whether the organization

FOCUSED ASSESSMENT

Assessing Sociocultural Determinants of Health in School Populations

- What is the ethnic and cultural composition of the school population? How do ethnicity and culture affect the health of members of the school population?
- What are the community attitudes toward education? Toward the school? To what extent does the community support the school program?
- What economic resources are available to the school?
- What is the economic status of members of the school population? How does economic status affect access to health care?
- How do legislative and policy initiatives affect the school and the health of the school population?
- What are the effects of local school and district policies on health services and health status of the school population?
- What is the extent of violence in the school population? What are the factors underlying episodes of violence? What are the school's policies with respect to violence?
- To what extent are members of the school population subjected to violence and abuse outside the school setting?
- What is the potential for Internet exploitation of students?

of the school day is conducive to health. Assessment areas to be addressed include the extent to which periods of strenuous physical activity are alternated with periods of quiet study and the extent of opportunities for developing a variety of psychomotor as well as academic skills. The nurse also assesses whether mealtimes are arranged so that students have the energy reserves to handle the tasks of the school day. For younger children, this usually means providing a snack time. Another area for assessment is the scheduling of time for toileting activities. The nurse should determine whether children are given time to go to the lavatory or permitted to go when necessary to prevent chronic constipation or urinary tract infection. There should also be opportunities for children to obtain drinks of water. Such opportunities should increase in frequency with hot weather. Other behavioral determinants to be addressed include physical activity, diet and nutrition, substance use and abuse, safety practices, and sexual behavior.

Physical activity. Physical activity affects cognitive skills, attitudes, and academic behavior. Improving physical activity in school students, particularly in time spent in physical education, may increase academic performance (DASH, 2011). With the advent of television and computer game systems, however, children are much less physically active than they were a generation or two ago. Only about 60% of youth met recommendations for physical activity, and the percentage decreased with increasing age and grade level. Boys tend to be more physically active than girls, and this disparity also increases with age. Overall, students from elementary to high school get an average of only 4 minutes of physical activity per day during school time (Kohl & Cook, 2013). Despite these low figures, however, a subcommittee of the President's Council on Fitness, Sports, and Nutrition has noted that, "School settings hold a realistic and evidence-based opportunity to increase physical activity among youth and should be a key part of a national strategy to increase physical activity" (Physical Activity Guidelines for Americans Midcourse Report Subcommittee, 2012).

According to the most recent school health policies and practices study conducted in 2006, only 80% of states required physical education (PE) classes at the elementary school level, increasing to 93% of middle schools and high schools. Even in those states that required PE, only 4% required daily sessions at the elementary level, 8% at the middle school level, and 2% at the high school level. In addition, 37% of states and 90% of school districts recommended or required a regular recess period in elementary school, although approximately 97% of schools included recess in the school day. Policies related to active transportation were even more infrequent, with 14% of states, 18% of school districts, and 44% of schools promoting active transportation (Kohl & Cook, 2013).

In addition to assessing the extent of physical education and recess time, the population health nurse can examine per capita school expenditures for education. States vary widely in the amount of money spent per pupil per year, ranging from a low of \$6,612 in Utah to a high of \$19,698 in Washington, DC. Only

Physical education is an important component of school health.

(Jim/Fotolia)

a small percentage of these funds are allocated for physical education and other health-related services (Kohl & Cook, 2013).

Recreational activities should also be assessed. Recreational and sports equipment should be examined for safety hazards, and the nurse should be aware of the types of recreational and competitive activities engaged in by students. Are activities adequately supervised? Are sports and recreational programs appropriate to children's ages and developmental levels? For example, contact sports are not appropriate for children in lower elementary grades because of the increased risk of injury. Another question is whether recreational activities are suited to children's interests. Are various opportunities available, or must all children engage in the same activity, whether they choose to or not? Is a gender bias evident in the recreational opportunities provided? For example, is soccer restricted to boys whereas girls are expected to play hopscotch or jump rope? Attention should also be given to the recreational needs of teachers. Are teachers given a break from classroom and playground duties?

The physical education curriculum of the school will also influence students' exercise behaviors. Many schools do not include the exposure to physical education activities required to meet the national health objectives. Research has indicated that features of the school environment such as physical improvements and supervision influence physical activity by students

before and after school and at lunch. For example, the presence of permanent grounds improvements such as the installation of basketball and tennis courts and football and soccer goals increases the extent of physical activity by students. Similarly, the availability of recreational equipment influences activity. The school nurse should assess the extent to which the school physical education curriculum and the physical and social environments of the school promote physical activity.

Diet and nutrition. Nutrition is another behavioral determinant that should be assessed in the school population. In one national study, 60% of teachers said that they taught students who came to school hungry. Approximately 21 million students receive free school lunches through federal meal programs, but less than half of them receive breakfast. Research has indicated that eating breakfast improves academic performance. For example, students who eat breakfast tend to score higher on standardized tests, are less likely to experience school absences, and are more likely to graduate than those who do not. Recommendations have been made to move school breakfasts out of the cafeteria and into the classroom, making them a part of the official school day and increasing the number of children who participate (Deloitte, n.d.).

Schools have been criticized for lack of nutrition in foods served and providing access to junk food. Evidence for this criticism lies in the fact that students with improved school nutrition experienced smaller increases in BMIs during the school year than during the summer. This was particularly true for students who were already overweight (von Hippel, Powell, Downey, & Rowland, 2007). In schools without a dietary consultant, the nurse should appraise the nutritional quality of school lunch and/or breakfast programs. Too often, food for such programs is purchased with an eye toward economy rather than nutritional value.

The adequacy of lunches brought from home should also be examined, as should evidence of poor nutrition of meals eaten at home. For example, the nurse would assess children for evidence of anemia, poor growth, and development or overweight

and obesity. School nurses may also encounter students who exhibit eating disorders and can assist with referrals for diagnostic and treatment services for these children. The type and prevalence of any food allergies among either students or staff are other considerations for assessment in this area. Population health nurses may need to educate food service personnel regarding food allergies and the need to avoid particularly allergenic foods (e.g., peanuts or use of peanut products in other foods) as a routine precaution.

Other lifestyle behaviors. Other health-related behaviors should also be assessed, particularly among older students. The extent of tobacco use or use of alcohol or other drugs by students or staff should be explored, as should the extent of sexual activity among preadolescent and adolescent students. Approximately half of all high school students have had sexual intercourse (Kann, Brener, McManus, & Wechsler, 2012), yet only 5% of U.S. schools make condoms available to sexually active students (Guttmacher Institute, 2012). Similarly, although a median 90% of public secondary schools across 45 states taught HIV prevention as part of a required course in 2010, only 43% of schools addressed all 11 recommended HIV prevention topics in grades 6 through 12, and the percentages of schools that did so actually declined from 2008 to 2010 (Kann et al., 2012). The nurse should assess the extent of substance use and sexual activity in the school population as well as policies that hinder preventive activities. School nurses should also be alert to signs of pregnancy and sexually transmitted diseases in individual students as well as the potential for sexual assault in the school population. The school nurse should assess the extent of substance use and abuse in the school population, ease of access to these substances in the community, and the adequacy and enforcement of school policies and community regulations regarding their sale and use. The nurse should also be alert to signs of substance use and abuse in individual students and school personnel.

Safety practices should also be assessed in the school setting. Many U.S. school children are engaged in sports activities,

Evidence-Based Practice

Building the Evidence Base for School Health

Interventions

There is considerable evidence that physical activity initiatives in school settings improve student participation in physical activity. However, the Physical Activity Guidelines for Americans Midcourse Report Subcommittee of the President's Council on Fitness, Sports, & Nutrition (2012) identified several research gaps that should be addressed to further develop this evidence base. In particular, research is needed to determine the long-term effects of such initiatives and whether or not such initiatives

vary in their effectiveness with particular subgroups within the school population (e.g., differences related to ethnicity, socio-cultural status, geographic region, and health status). There is also need to evaluate the effects of school policies related to physical activity.

1. What, if any, research is being done in schools in your area to further this evidence base?
2. How might population health nurses foster such research?

resulting in the potential for serious injury. Risk behaviors associated with injury include failure to use protective gear or seat belts, alcohol use, and access to weapons. Other behavioral risks that should be assessed include unprotected sexual intercourse, piercing, and gambling. Gambling among students often occurs on the Internet and is an increasingly common addiction among high school and college-age students. The *Focused Assessment* below provides questions for assessing behavioral considerations in the health of school populations.

HEALTH SYSTEM DETERMINANTS. Health services within schools have been described as “hidden systems” of care (RWJF, 2010) or as a “patchwork of policies and programs with differing standards, requirements, and populations to be served” (DASH, 2013f). Health system determinants influencing the health of school populations are assessed at both the individual and population levels. At the individual level, the population health nurse assesses the usual source of health care for individual children and their families. Do children have a regular source of health care? Do they make use of health-promotive and illness-preventive services as well as curative services? Or is health care for children crisis oriented, focusing only on treatment of acute conditions? Do children have unmet health needs because their families cannot afford care? The two main considerations at the population level are the presence or absence of a coordinated school health program and school-based health centers.

The coordinated school health program. A coordinated school health program has been defined by a number of organizations and agencies. One of the clearest and most useful

definitions, however, is that of the Institute of Medicine. A **coordinated school health program** is “an integrated set of planned, sequential, school-affiliated strategies, activities, and services designed to promote the optimal physical, emotional, social, and educational development of students” (IOM, as quoted in DASH, 2014, p. 1).

Coordinated school health programs serve to eliminate gaps and overlaps in services and funding streams. They also build collaborative relationships among health and education professionals in schools and enhance communication and collaboration of the school, the public health system, and health and education professionals in the community. The focus in a coordinated school health program is on aiding students to protect and promote their own health and to avoid risk behaviors (DASH, 2013f). To that end, the goals of a coordinated school health program are as follows:

- To increase health-related knowledge, attitudes, and skills among members of the school population
- To increase positive health behaviors and outcomes and decrease risk behaviors
- To improve education outcomes
- To improve social outcomes, such as self-discipline and respect for and tolerance of others (DASH, 2013c)

The components of a coordinated school health program are depicted in Figure 22-1 • and include health education; physical education; health services; nutrition services; counseling, psychological, and social services; a healthy and safe school environment; health promotion for staff; and family and community involvement (DASH, 2013b). Each component will be briefly addressed.

FOCUSED ASSESSMENT

Assessing Behavioral Determinants of Health in School Populations

- What is the extent of physical activity in the school population? Does the school setting provide opportunities for safe physical activities to meet the needs and interests of all members of the school population?
- To what extent do students walk or bike to school? What factors support or impede “active transportation”?
- What recreational opportunities are available to the school population? Do recreational activities pose health hazards? Are appropriate safety equipment and devices used (e.g., in sports)?
- What are the dietary practices of the school population? To what extent do school food choices support or deter good nutrition? What is the nutritional value of school meals?
- What percentage of students participate in school meal programs? Is school breakfast a routine part of the school day?
- What is the prevalence of food allergies among the school population? What types of food allergies are represented? Do school food services avoid particularly allergenic foods?
- What is the extent of substance use and abuse in the school population? What are the school policies with respect to substance use (e.g., tobacco and alcohol)?
- Do any members of the school population use prescription medications on a regular basis? Are medications used, stored, and dispensed as directed?
- To what extent do members of the school population engage in other health and safety-related practices (e.g., seat belt use and condom use)?
- What is the extent of gambling among the school population?
- What is the extent of piercing and tattooing among the school population? To what extent do these practices influence health?

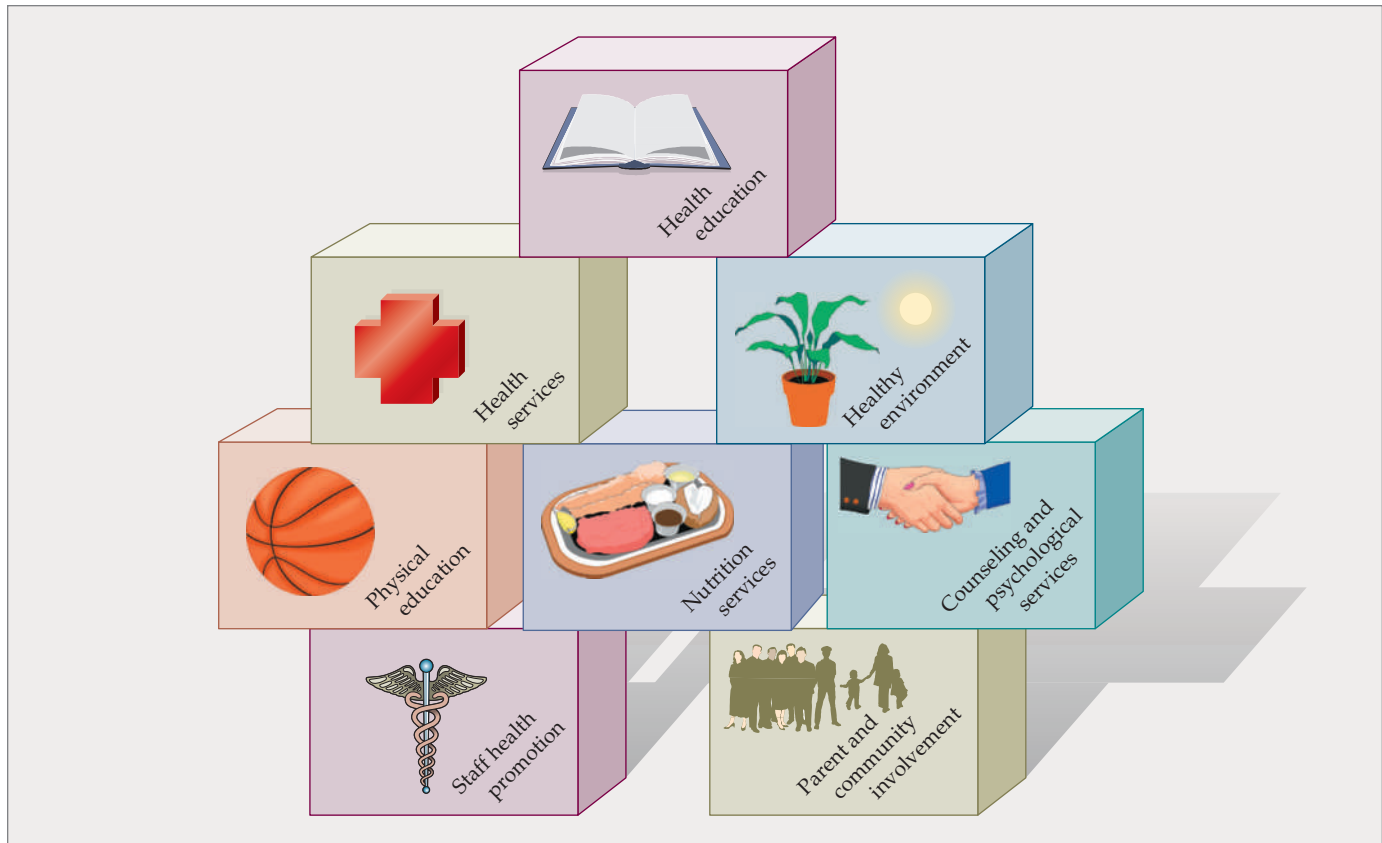

FIGURE 22-1 Components of a Coordinated School Health Program

Health education. The foci for health education in school settings include providing essential knowledge, shaping values and beliefs to support healthy behavior, shaping group norms to foster healthy behavior, and developing health-related skills. Table 22-2• presents national standards developed to guide health education programs in U.S. schools.

Effective health education curricula in schools focus on achieving clear health-related goals and behavioral outcomes;

are research based and theory driven; address individual values, attitudes, and beliefs and motivate students to critically examine related perspectives; address group norms that underlie behaviors; and focus on reinforcing protective behaviors and increasing perceptions of harm from unhealthy behaviors based on realistic personal risk assessments. In addition, effective curricula provide strategies to address social pressures and influences for unhealthy behavior and build personal and

TABLE 22-2 National Standards for Health Education Programs in Schools

Standard	Description
1	Students will comprehend concepts related to health promotion and disease prevention to enhance health
2	Students will analyze the influence of family, peers, culture, media, technology, and other factors on health
3	Students will demonstrate the ability to access valid information, products, and services to enhance health
4	Students will demonstrate the ability to use interpersonal communication skills to enhance health and avoid or reduce health risks
5	Students will demonstrate the ability to use decision-making skills to enhance health
6	Students will demonstrate the ability to use goal-setting skills to enhance health
7	Students will demonstrate the ability to practice health-enhancing behaviors and avoid or reduce health risks
8	Students will demonstrate the ability to advocate for personal, family, and community health

Source: Division of Adolescent and School Health, Centers for Disease Control and Prevention. (2013e). *National health education standards*. Retrieved from <http://www.cdc.gov/healthyyouth/sher/standards/index.htm>

social competence and self-efficacy, developing skills in communication, refusal, assessing the credibility of health-related information, decision making, planning and goal setting, and self-control and self-management. Other characteristics of effective health education curricula include provision of accurate functional health knowledge; use of strategies that personalize information and interest and engage students; incorporation of age- and developmentally appropriate information, strategies, methods, and materials; and adoption of culturally inclusive strategies, methods, and materials. Finally, effective curricula provide time for instruction and opportunities to practice and reinforce health-related skills and behaviors, as well as opportunities to connect with influential others who affirm and reinforce healthy behaviors. In addition to their focus on students, effective health education programs provide for professional development of teachers to promote their knowledge, comfort, and skill in teaching health-related content (DASH, 2013a).

The population health nurse in the school setting would assess the school health education curriculum in light of the standards and criteria for effectiveness. They would also be involved in developing and implementing effective health education programs in school settings at all levels. CDC (2013a) provides an assessment tool for analyzing health education curricula, the “Health Education Curriculum Analysis Tool” (HECAT). For further information about the tool, see the *External Resources* section of the student resources site.

Physical education. We have already addressed the need for and general lack of physical activity in school populations. The Institute of Medicine has recommended taking a whole-school approach to physical activity, so that activity is threaded throughout the school day, rather than just in the physical education curriculum. Additional recommendations include considering access to and provision of physical activity in school policy decisions at multiple levels (federal and state government, school districts, and individual schools) and creating

Population health nurses are actively involved in health education in school settings. (Lisa F. Young/Fotolia)

a mandate for physical education as part of the core curriculum in all schools across the nation. In addition, educational and public health agencies should develop systems to monitor policies and behaviors related to physical activity in schools, and training and development should be provided for teachers to promote physical activity beyond physical education and recess. Finally, all concerned should work to eliminate disparities in physical activities among students groups, particularly those related to access to facilities and opportunities for physical activity (Kohl & Cook, 2013).

As we saw earlier, elements of a whole-school approach to physical activity include an enhanced PE program, classroom physical activity, recess and other activity breaks, intramural and extramural sports, and active transportation to school. The bulk of physical activity during the school day should come from an enhanced PE program. An enhanced PE program can be achieved by increased amount of time in PE classes spent in vigorous physical activity, adding more PE classes to the curriculum, lengthening the time of existing PE classes, meeting the physical activity needs of all students, including those with disabilities, and including activities that are enjoyable and emphasize acquisition of knowledge and skills for lifetime use (Physical Activity Guidelines for Americans, 2012).

Components of a high-quality physical education program include the curriculum itself, related policies and a supportive environment, instruction, and student assessment. Requirements for achieving a high-quality PE program include adequate instructional time (150 minutes per week for elementary students and 225 minutes per week for middle and high school students), provision of instruction by qualified PE specialists, reasonable class sizes, and the availability of appropriate equipment and facilities. An effective PE program makes use of instructional strategies that are inclusive of all students, is adaptable for students with disabilities, expends most of class time in actual physical activity, incorporates well-designed lessons, includes out-of-class assignments that support learning (e.g., calculating calories burned in specific activities), and refrains from using physical activity as punishment for inappropriate behavior. Effective programs also focus on student achievement of measurable goals using appropriate assessment tools, self-assessment of performance by students, feedback to students and parents, and clarity regarding elements used to grade performance (CDC, 2006).

CDC (2013b) has created a tool that can be used by the population health nurse and other school personnel to evaluate the physical education curriculum. For further information about the “Physical Education Curriculum Analysis Tool” (PECAT), see the *External Resources* section of the student resources site.

Health services. The health services component of the coordinated school health program consists of services at all four levels of health care: health promotion, illness and injury prevention, resolution of existing health problems, and health restoration.

These services are provided to students and, on occasion, school personnel. In some school settings, health services may be provided to students' families as well. School health services may be provided on campus by health personnel employed by the school or school district, by outside providers on contract to the school, or by volunteer health professionals. In other instances, services are provided by the students' own primary care providers or by school-linked health centers upon referral by school health personnel. **School-linked health centers** are off-campus agencies that have formal agreements with schools to provide specific services to students (California School Health Centers Association, 2011).

The use of school-linked health centers allows for the provision of services that may be prohibited in the school setting itself (e.g., contraceptive services) or that require a level of expertise not held by school health personnel, such as drug abuse treatment. These centers also have the advantage of an economy of scale, providing specialty services to several schools when it would be cost-prohibitive to have specialized personnel available in each school (Advocates for Youth, n.d.).

The population health nurse assesses the availability of health care services to meet the needs of the school population. Are health-promotive and illness-preventive services easily accessible in the community? Are services available for youngsters with special health needs (e.g., handicapped children)? Are specific pediatric or adolescent services available? Is there access to contraceptive services or treatment of sexually transmitted diseases for the adolescent population?

Nutrition services. The nutrition services component of the coordinated school health program encompasses the quality of food available through and outside of school meal programs, policies and practices related to school nutrition, and the availability of feeding programs beyond the school day (Society of State Leaders of Health and Physical Education, n.d.). This component also includes education to promote good nutrition in children and their families as well as the adoption of innovative programs, such as farm-to-school programs and school gardens, to foster nutrition knowledge and healthy eating (American Dietetic Association, et al., 2010).

Best practices for school nutrition programs recommended by the Society of State Leaders of Health and Physical Education (n.d.) include:

- Creating a school health advisory council to review nutrition services in the school
- Reviewing district and school wellness policies for their effects on nutrition services
- Reviewing the school nutrition education program and integrating instruction with provision of healthy food choices
- Strengthening school nutrition services by providing breakfast in the classroom, demonstrating the relationship of nutrition and physical activity, including more fresh fruits and vegetables in school meals, providing nutrition information to families, increasing enrollment in school meal

programs, ensuring healthy options in vending machines, exploring innovative programs, and increasing the availability of affordable, healthy food at school and in the community, and

- Providing recess before lunch.

The final recommendation is based on research indicating that holding recess before lunch prevents children from rushing through meals to get out and play. More is eaten, with fewer foods wasted, and transitioning back to the classroom is easier than from recess (Society of State Leaders of Health and Physical Education, n.d.).

Population health nurses can assess the quality of school meal programs, cleanliness of preparation areas, and the extent of nutrition education in the school setting. In addition, they can help to identify students eligible for free meals and work to enroll them. Hunger among children does not stop when the school year ends, and population health nurses may also assist low-income children and their families to access existing summer food service programs supported by the U.S. Department of Agriculture (2013). If no program exists locally, nurses can assist schools or other local organizations to develop them.

Counseling, psychological, and social services. Another component of the coordinated school health program is the provision of counseling services for psychological or social problems experienced by students and their families. Population health nurses can assess the need for and availability of such services in the school population and among individual students.

Students with disabilities may need special accommodations that allow them to be successful in the educational setting. The most commonly sought accommodations are for learning disabilities, but students with other documented physical and emotional disabilities are eligible for accommodations as well. For students suspected of learning or other disabilities, school nurses can make referrals for testing and can ensure that the appropriate accommodations are made.

Students and school staff may also need counseling for a variety of other personal problems. Sometimes such services are provided within the school, but they may also be available through school-linked health centers described earlier. Suicide prevention is an area in which counseling is urgently needed, yet identification of students contemplating suicide may be difficult. SOS, the Signs of Suicide Prevention Program, is one approach to identifying these students. In the SOS program, students are taught to recognize signs of depression and possible suicide in themselves and peers and to take action using the ACT rubric of **A**cknowledging feelings, **d**emonstrating **C**aring, and **T**elling a responsible adult (Screening for Mental Health, 2010; U.S. Department of Health and Human Services [USDHHS], 2012).

Healthy and safe school environment. Elements of a safe school environment were addressed earlier. Population health nurses would assess the extent of physical safety hazards in the

environment as well as the potential for disasters affecting the school population. Another assessment consideration is school policies related to safety. In addition, the nurse would examine the school climate and any factors that threaten the psychological health of students or staff.

Health promotion for staff. Effective school health programs attend to the health needs of school personnel as well as students. The population health nurse would assess the health services (including counseling and nutrition services) available to staff beyond the basic provision of health insurance coverage. Services to school employees serve several purposes, including reduction in illness and absenteeism, enhancement of interest in health issues and willingness to address them with students, and role-modeling healthy behaviors.

Family and community involvement. The final component of the school health program is directed toward fostering partnerships among school, family, and community that enhance the health of the overall community. Family involvement in their children's education has been associated with better school performance. A current policy brief of the National Education Association (2008) notes that involvement occurs in several ways: school support and assistance with parenting, two-way communication between schools and families, volunteering, learning at home (e.g., assistance with homework, goal setting, and other activities), decision making, and community collaboration by coordinating school and community resources and initiatives. The National Parent Teacher Association (NPTA, n.d.) has developed a set of standards for family-school partnerships that include the following:

- Families are active, welcomed, and valued participants in all aspects of school life.
- Families and school staff communicate regularly and in meaningful ways about student learning.
- Families and school staff collaborate to support students' learning and development.
- Families are empowered to advocate for their own and other children to ensure access to learning opportunities that support success.
- Families and school staff are equal partners in decisions that affect children and families and collaborate in policy development.
- Families and school staff collaborate with community members to expand learning opportunities, services, and civic participation (NPTA, n.d.).

In addition, the organization has developed an assessment guide that can be used to evaluate the quality of school-family interactions. The guide includes specific indicators for each standard that are rated from "not there yet" through levels 1 (emerging), 2 (progressing), and 3 (excelling), with descriptors for each level (NPTA, 2008). For further information about the guide, see the *External Resources* section of the student resources site.

The population health nurse can use the guide to assess school-family relationships as well as the relationship between the school and the health care community. Are private physicians conversant with regulations for excluding children with communicable conditions from school? Do physicians and other health care providers work cooperatively with school personnel to meet the health care needs of individual youngsters? Do health care providers in the community provide a resource for augmenting school health services?

School-based health centers. In some schools, some of the elements of a coordinated school health program, such as school health services, counseling, and health promotion for staff, are provided through school-based health centers. Under the Affordable Care Act program of grants for school-based health center development, a **school-based health center (SBHC)** is defined as a health clinic located in or near a school facility that is organized through school, community, and health provider relationships, administered by a sponsoring facility, and provides primary health services to children in accord with state requirements for such clinics. Sponsoring facilities can include hospitals, public health departments, community health centers, nonprofit health care agencies, schools or school systems, or a program administered by the Indian Health Service, Bureau of Indian Affairs, or an Indian tribe or tribal organization (Catalogue of Federal Domestic Assistance, n.d.). Common features of SBHCs include written parental consent for student enrollment; an advisory board of community members, parents, youth, and family organizations; clinical services by a multidisciplinary team of qualified professionals; and a comprehensive range of services that meets the identified needs of young people in the community (Center for Health and Health Care in Schools, 2013).

A 2010 study by the Robert Wood Johnson Foundation (RWJF) found 1,900 SBHCs located in 45 states, Washington, DC, and Puerto Rico. These centers provide care to more than 2 million students each year, and 84% of them are led by nurse

School-based health centers may be the only source of health care for many students. (Mykola Velychko/Fotolia)

practitioners. SBHCs do not duplicate the work of the school nurse, but provide primary care and screening services for the school population. Nearly three fourths of them also provide mental health services (RWJF, 2010). Additional services may include immunizations and reproductive services (Walker, Kerns, Lyon, Bruns, & Cosgrove, 2010).

Students with access to SBHCs have been found to be 10 to 21 times more likely to seek mental health services than other students (RWJF, 2010). In addition, students who use SBHCs have been shown to have better grade point averages than nonusers, are less likely to drop out of school, and have less absenteeism. Other outcomes have included decreased hospitalizations and better attendance among students with asthma (Center for School, Health and Education, 2011). SBHCs increase access to medical care for students without a medical home. In some school systems, SBHCs also provide health care services to family members (RWJF, 2010).

Population health nurses may be involved in planning SBHCs or in evaluating their effectiveness. School nurses work collaboratively with SBHC staff to meet the needs of individual students in the school setting. In addition, as much as 20% of SBHC activity is devoted to health education activities and interactions with parents and staff, which may also involve the school nurse (Center for School, Health and Education, 2011).

Tips for assessing health system determinants in a school setting are provided in the *Focused Assessment* below. A specific guideline for conducting a population-based health assessment in the school setting is provided on the student resources site.

Diagnostic Reasoning and Care of School Populations

The second aspect of the use of the nursing process in the school setting is deriving nursing diagnoses from assessment data. Diagnoses can be derived at two levels, in relation to individual students and in relation to the school population. Examples of

diagnoses related to an individual student are “difficulty in participating in vigorous physical exercise due to exercise-induced asthma” and “need for referral to child protective services due to suspected physical abuse by father.” Diagnoses related to a population group might be “safety hazard due to placement of play equipment on asphalt surface” and “need for drug abuse education due to high prevalence of drug abuse in the surrounding community.”

Each of the sample diagnoses provided above contains a statement of the probable underlying cause of the problem. Such a statement provides direction for efforts to resolve the problem. With the individual examples, measures might be taken to provide a tailored physical activity program for the child with asthma and encourage use of a steroid inhaler or to make a referral for child protective services in the abuse situation. One approach to the playground safety hazard might be to relocate play equipment to a sandy area.

Monitoring the safety of play areas is part of the population health nurse's role in the school setting. (ksena32/Fotolia)

FOCUSED ASSESSMENT

Assessing Health System Determinants of Health in School Populations

- What health services are offered in the school setting? How are school health services funded? Is funding adequate to meet health needs?
- Are all of the components of a coordinated school health program in place? How effectively are the components implemented?
- How are school health services organized? Is there a school-based or school-linked health center associated with the school?
- What is the availability of mental health services in the school setting? Are referrals made to outside sources of care as needed?
- How accessible are needed health services in the community? To what extent does the school population use available health services?
- To what extent are school health services coordinated with primary providers and community health services?

Planning and Implementing Services to Meet the Health Needs of School Populations

Several general recommendations have been made for improving health care in school settings. The first of these is to increase the ratio of school nurses to students as identified in *Healthy People 2020* to one nurse to every 750 students. When this was done in New Jersey public schools, improvements were noted in immunization rates, identification of asthma and other life-threatening conditions, and screening rates. In addition, employment of more school nurses resulted in a return of more than 2 hours per day to other personnel who no longer had to deal with students' health problems (RWJF, 2010).

In addition, the Healthy Schools Campaign has made recommendations to both the U.S. Department of Education (USDOE) and the Department of Health and Human Services (USDHHS). Education recommendations included providing grant funding to support health-related training for teachers and principals, developing best practices related to school health, and integrating health measures into data tracking and school accountability systems. A further recommendation was the inclusion of health measures into criteria for the Blue Ribbon Schools program (Healthy Schools Campaign, 2012). The Blue Ribbon Schools program is a national award program that recognizes schools where students perform at the highest levels or that have made significant advances in student academic achievement (USDOE, 2013). Recommendations to USDHHS included reducing barriers to school health services, particularly by regularizing Medicaid payments for services provided to eligible students in school settings, and supporting schools in creating conditions that promote health and prevent illness (Healthy Schools Campaign, 2012).

Planning to meet health needs identified in the school setting takes place at two levels: the macro level, at which the general approach to providing health services in the school is planned, and the micro level, at which plans are made to meet specific health needs of the school population. The population health nurse working in the school setting participates in planning efforts at both levels.

IMPLEMENTING A COORDINATED SCHOOL HEALTH PROGRAM. At the macro level, the population health nurse will be an integral player in the development and implementation of a coordinated school health program if one does not already exist. A school health committee should plan each of the components of the school health program using the program planning process described in Chapter 15. Elements to be considered in developing the plan include the population to be served including the age range of students and the extent of services to be provided to staff. The type of services to be provided is another consideration. Typical services are summarized in Table 22-3. Other planning considerations presented in the table include personnel, resources needed and their availability, budget, record system development, planning for family and community involvement, and approaches to be taken in evaluating the program. Once the plan has been developed,

TABLE 22-3 Considerations in Planning a Coordinated School Health Program

Area for Consideration	Related Elements
Population served	Ages and grades of students involved Extent of service to be provided to staff Provision of services to families
Services provided	Assessment/screening services First aid/emergency response Acute care services Problem management services Immunizations Safety education Health education Physical activity opportunities Nutrition services/education Counseling services Reproductive services Substance abuse services
Personnel	Categories of health and other personnel needed Qualifications of health and other personnel Functions and responsibilities Staff development needs
Resources	Facilities Equipment Supplies/postage Health records Telephone
Record system	Clinical health records for individuals seen Administrative records Immunization records Absenteeism records Program evaluation records Physical activity participation records School meal participation records
Budgetary considerations	Personnel salaries Facility construction and maintenance Equipment and supply costs Record-keeping costs Staff development costs
Family/community involvement	Strategies for promoting parent involvement Roles of parent and other volunteers Strategies for promoting community involvement Availability of shared resources
Program evaluation	Focus of evaluation Data collection procedures Data analysis procedures

implementation can occur. Table 22-4• summarizes the steps in developing and implementing a coordinated school health program. For information on funding sources for coordinated school health programs, see the *External Resources* section of the student resources site.

The health services component of the coordinated school health program also includes planning for specific activities or programs at each of the four levels of health care: health promotion, illness and injury prevention, resolution of existing health problems, and health restoration. Considerations and population health nursing roles at each level are discussed below.

HEALTH PROMOTION. Health promotion in the school setting involves many of the same planning considerations as those used with children in general. Primary areas of focus include health education for lifelong health habits and promoting physical activity and good nutrition. Other concerns in health promotion include developing a strong self-image, positive coping skills, and good interpersonal skills in students.

Health education in the school setting provides a foundation for healthy behaviors in adulthood. Most states and school districts require some form of health education at the elementary and junior and senior high school level. At the elementary level, health education is most likely to be incorporated into

the total curriculum. Specific health courses are more likely at the junior and senior high level.

The principles of health education discussed in Chapter 11∞ are particularly relevant to population health nursing in the school setting. The nurse may serve as a resource for teachers on health content, provide health education classes, or both. The school nurse is also involved in the development of the health education curriculum. Activities involved in curriculum development include the assessment of needs and resources, review of health curricula from other school systems, development of goals and objectives, and design of specific learning activities. In addition, the nurse may be involved in preparing teachers to participate in the health education program. Finally, the nurse participates in the implementation and evaluation of the program. School nurses may also be involved in the provision of health education to school staff to enable them to promote their own health as well as serve as role models for healthy behavior for students.

With respect to physical activity, population health nurses working in school settings can assist school personnel in developing a multicomponent school-based activity program. School nurses can assist in the creation of a balanced plan that includes a variety of physical activity opportunities, including arrangements for activities before and after school,

TABLE 22-4 Steps in Planning and Implementing a Coordinated School Health Program

Step	Related Tasks
Secure and maintain administrative support for the program	Incorporate a coordinated school health program into the mission and vision statements of the school district/school Appoint an overseer for the program Obtain and allocate necessary resources Model healthy behavior among all personnel Develop relevant health-related policy Regularly communicate the importance of health to administrators, staff, students, and parents
Establish a school health council	Incorporate representation from all eight components of the coordinated school health program Include parents, community members, and older students
Identify a school health program coordinator	Select a coordinator with both organizational and interpersonal skills
Focus on students	Optimize health status Develop lifelong healthy behaviors Enhance educational performance
Develop a plan for a coordinated school health program using the program planning process	Develop priorities based on identified student needs Determine available resources and other needed resources Develop an action plan with realistic goals and measurable objectives Establish an implementation timeline Evaluate goal achievement
Implement multiple strategies and components	Use innovative strategies appropriate to situational constraints
Address priority health-enhancing and risk behaviors	Focus on age-appropriate health promotion and risk reduction concerns
Provide staff professional development	Educate all personnel on the overall health care program Provide discipline-specific professional education for staff who will implement specific elements of the program

Data from: Division of Adolescent and School Health, Centers for Disease Control and Prevention. (2013d). *How schools can implement coordinated school health*. Retrieved from <http://www.cdc.gov/healthyyouth/cshp/schools.htm>

incorporation of activity breaks in the classroom, promoting physical activity at recess and lunch breaks, and development of an enhanced physical education program that addresses the standards discussed earlier. In addition, population health nurses can assist schools and communities in the development of mechanisms for active transportation to and from school. For example, nurses may assist in identification of safe biking and walking routes to school or advocate for traffic calming strategies (speed bumps, traffic signals, stop signs, patrolled crossings, etc.) on routes used by students.

Nurses may also assist schools and communities in developing strategies like the “walking school bus,” which is a group of children walking to school with one or more adults. Strategies for creating a walking school bus include selecting a neighborhood within walking distance, inviting parents and children to participate, identifying a safe route (or routes) to school, walking the route without children initially to determine its safety, identifying responsible adults to supervise the walk, and developing the logistics (e.g., timing, days of operation, where to meet, etc.). Nurses may also be involved in safety training for students and adult volunteers. CDC recommendations for adult supervision are one adult to six children with more adults for younger children and fewer adults for older groups (Pedestrian and Bicycle Information Center, n.d.).

Nutrition is another important aspect of health promotion with the school population. As noted earlier, when this function is not performed by a dietitian or nutritionist, school nurses assess the nutritional status of children and monitor the nutritional value of school lunches. When nutritional offerings are inadequate, the nurse works with school administrators and food service personnel to improve the nutritional quality of meals served. The nurse may also educate children and their parents regarding nutrition and good dietary habits.

The Division of Adolescent and School Health (DASH, 2011) has developed guidelines and associated strategies for promoting physical activity and nutrition in school populations. Those guidelines and strategies are summarized in Table 22-5•.

Health promotion in the school population includes fostering mental as well as physical health. Mental health education should be provided and should address, at a minimum, self-image development, coping skills, and interpersonal skills. Sound mental health is promoted by a strong self-image developed throughout childhood. Mental health promotion in the school setting should focus on the development of a healthy self-image as well as a healthy physical self. School nurses can foster self-image development by serving as role models in their dealings with children. They can also suggest to teachers learning activities that enhance development of a positive self-image.

Another aspect of health promotion in schools is the development of coping skills. Students and personnel can be assisted to develop active problem-solving strategies that promote their abilities to cope with adverse circumstances. School health nurses can serve as role models in this respect and can also provide counseling that assists students and their families or staff to engage in positive problem solving. Nurses can also

reinforce evidence of positive coping by making others aware of their abilities to cope. In addition, the nurse can present information on stress and offer strategies for dealing with stress that enhance the development of sound coping skills.

The ability to interact effectively with others is essential to civilized society. Such abilities are not innate and must be learned. Education for effective interpersonal skills is another aspect of health promotion for the school population. Again, the nurse can serve as a role model for effective interpersonal skills and can educate students, parents, and staff regarding interpersonal interactions and the development of communication skills. The nurse can also provide information on group dynamics and communication skills that can enhance interpersonal skills within groups. For example, the nurse might promote role-play in a class to which a handicapped child will soon be admitted or help youngsters learn how to express anger at a teacher in an appropriate manner. Population health nurses working with school populations may assist individual students in developing these skills. They may also be involved in the creation and support of peer support groups for students with special needs (NAMI, 2012). Aspects of health promotion in the school setting and related population health nursing responsibilities are summarized in Table 22-6•.

ILLNESS AND INJURY PREVENTION. There are two main foci for prevention in school populations: preventing illness and other health-related conditions and preventing injury, including injury resulting from violence. Both foci will be discussed in terms of the population health nurse’s role.

Preventing illness and other health-related conditions. Major considerations in preventing illness and other conditions in school populations include immunization, preventing the spread of communicable diseases, HIV and STI prevention, preventing pregnancy, and skin cancer prevention. Students in school settings at all levels are at particular risk for a variety of communicable diseases for which immunization is possible. Immunizations against measles, mumps, rubella, diphtheria, pertussis, tetanus, and polio are required for school entry. School immunization requirements were initiated in 1885 in Massachusetts with a mandate for smallpox immunization for school entry. Immunization for school entry has been assessed by state and local health departments since 1978 (Stokley, Stanwyck, Avey, & Greby, 2011) although specific requirements may vary among jurisdictions. In many states, immunization for *Haemophilus influenzae* B, varicella, and hepatitis B are also required. Immunizations are also available for hepatitis A and influenza. These diseases are discussed in more detail in Chapter 26∞.

The school nurse may be involved in referring individuals who are not immunized for appropriate services or may provide immunizations in the school setting. In addition to providing for routine immunizations, school nurses may also suggest other immunizations in the event of exposure to certain diseases, such as hepatitis A. Population health nurses may need to keep local school boards up to date on recommended

TABLE 22-5 Guidelines and Selected Strategies to Promote Healthy Eating and Physical Activity

Guideline	Related Strategies
Use a coordinated approach to develop, implement, and evaluate healthy eating and physical activity policies and practices	<ul style="list-style-type: none"> Coordinate healthy eating and physical activity policies through a school health council and coordinator Assess healthy eating and physical activity policies and practices Use a systematic approach to develop, implement, and monitor healthy eating and physical activity policies Evaluate healthy eating and physical activity policies and practices
Establish school environments that support healthy eating and physical activity	<ul style="list-style-type: none"> Provide access to healthy foods and physical activity opportunities and to safe spaces, facilities, and equipment Establish a climate that encourages and does not stigmatize healthy eating and physical activity Create a school environment that encourages a healthy body image, shape, and size among all students and staff members, is accepting of diverse abilities, and does not tolerate weight-based teasing
Provide a quality school meal program and ensure that students have only appealing, healthy food and beverage choices offered outside of the school meal program	<ul style="list-style-type: none"> Promote access to and participation in school meals Provide nutritious and appealing school meals that comply with the <i>Dietary Intake Guidelines for Americans</i> Ensure that all foods and beverages sold or served outside of school meal programs are nutritious and appealing
Implement a comprehensive physical activity program with quality physical education as the cornerstone	<ul style="list-style-type: none"> Require K–12 students to participate in daily physical education using a planned and sequential curriculum and instructional practices consistent with national or state physical education standards Provide a substantial percentage of students' recommended daily amount of physical activity in physical education class Use instructional strategies that enhance students' behavioral skills, confidence, and desire to adopt and maintain a physically active lifestyle Provide ample opportunities for all students to engage in physical activity outside of physical education classes Ensure that physical education and other physical activity programs meet the needs and interests of all students
Implement health education that provides students with the knowledge, attitudes, skills, and experiences needed for healthy eating and physical activity	<ul style="list-style-type: none"> Require health education from prekindergarten through grade 12 Implement a planned and sequential health education curriculum that is culturally and developmentally appropriate, addresses a clear set of behavioral outcomes that promote healthy eating and physical activity, and is based on national standards Use curricula that are consistent with scientific evidence of effectiveness Use classroom instructional methods and strategies that are interactive, engage all students, and are relevant to their daily lives and experiences
Provide students with health, mental health, and social services to address healthy eating, physical activity, and related chronic disease prevention	<ul style="list-style-type: none"> Assess student needs related to physical activity, nutrition, and obesity, and provide counseling and other services to meet those needs Ensure students have access to needed health, mental health, and social services Provide leadership in advocacy and coordination of effective school physical activity and nutrition policies and practices
Partner with families and community members in development and implementation of healthy eating and physical activity policies, practices, and programs	<ul style="list-style-type: none"> Encourage communication among schools, families, and community members to promote adoption of healthy eating and physical activity behaviors among students Involve families and community members in the school health council Develop and implement strategies for motivating families to participate in school health programs and activities that promote healthy eating and physical activity Access community resources to help provide healthy eating and physical activity opportunities for students Demonstrate cultural awareness in healthy eating and physical activity practices throughout the school
Provide a school employee wellness program that includes healthy eating and physical activity services for all school staff members	<ul style="list-style-type: none"> Gather data and information to determine the nutrition and physical activity needs of school staff and assess the availability of existing school employee wellness activities and resources Encourage administrative support for and staff involvement in school employee wellness Develop, implement, and evaluate healthy eating and physical activity programs for all school employees
Employ qualified persons and provide professional development opportunities for physical education, health education, nutrition services, and health, mental health, and social services staff members, as well as staff members who supervise recess, cafeteria time, and out-of-school-time programs	<ul style="list-style-type: none"> Require the hiring of physical education teachers, health education teachers, and nutrition services staff members who are certified and appropriately prepared to deliver quality instruction, programs, and practices Provide school staff members with annual professional development opportunities to deliver quality physical education, health education, and nutrition services Provide annual professional development opportunities for school health, mental health, and social services staff members and staff who lead or supervise out-of-school-time programs, recess, and cafeteria time

Source: Division of Adolescent and School Health. (2011, September 16). School health guidelines to promote healthy eating and physical activity. *Morbidity and Mortality Weekly Report*, 60(Suppl), 1–76.

TABLE 22-6 Health Promotion Strategies for School Populations

Area of Emphasis	Population Health Nursing Responsibilities
Health education	<ul style="list-style-type: none"> Participate in designing health education curricula Provide consultation to teachers on health education topics Provide in-service for teachers related to health education Provide health education in the classroom Arrange for other health education experiences (e.g., field trips or guest speakers) Arrange for or provide health education for staff and/or families
Physical activity	<ul style="list-style-type: none"> Educate students, staff, and families regarding the need for physical activity Assist schools in developing multicomponent physical activity programs Assist schools in promoting active transportation programs Assist in the development of walking school bus programs Help in identifying safe routes to and from school Advocate for traffic calming measures on routes Provide safety training for adults and students
Nutrition	<ul style="list-style-type: none"> Assess the nutritional quality of school meals Consult on healthy school meal planning Consult on special nutrition needs for specific students Assist in developing a nutrition education program Educate students, staff, and families on good nutrition
Mental health promotion	<ul style="list-style-type: none"> Advocate for a school climate that promotes mental health Assist in the development of the mental health education curriculum Assist individual students and staff in the development of problem-solving, stress management, and coping skills Teach students and staff problem-solving, stress management, and coping skills Role model effective problem-solving, stress management, and coping skills Assist students and staff to develop effective interpersonal and communication skills Role model effective interpersonal and communication skills Assist in the development of peer support groups for students and staff

immunizations and advocate for changes in immunization requirements to accommodate new national guidelines. Political advocacy may also be needed at the state level to change immunization requirements. At the same time, nurses may need to advocate for immunization waivers for specific children on the basis of religious beliefs or medical contraindications.

School exclusion is another strategy for preventing the spread of disease in the school population. One of the earliest responsibilities of the school nurse was to determine when children should be excluded from school because they had communicable illnesses. Children were also excluded from school as part of an effort to stop the spread of scabies, lice, and other parasites among a highly susceptible population. This responsibility still requires the school nurse to be knowledgeable of the signs and symptoms of communicable disease and infestation and to be aware of state and local regulations regarding school exclusion. Several conditions that usually warrant exclusion and guidelines for readmission of individual students are listed in Table 22-7.

The responsibility of the nurse does not stop with excluding the affected child from school. The nurse should also educate parents and children regarding the need to stay home from school when they are ill and about care during illness. The nurse may also make referrals for medical care as needed. In addition, the nurse follows up on children excluded from school to make sure that they are receiving appropriate care and that they are able to return to school when there is no longer any danger of exposure to others.

Exclusion may also occur when schools are closed in the event of emergencies or communicable disease outbreaks. Population health nurses working in school settings should be actively involved in monitoring communicable disease incidence and in decisions to close schools. They should also be involved in the development and implementation of emergency response plans. Nurses may be one of several personnel responsible for notifying parents and explaining the situation, particularly in the event of disease outbreaks. They may also be involved in making sure that appropriate parties pick children up from school in an emergency situation and in helping to make sure that all children are accounted for. They may also assist working parents to plan alternative child care arrangements in the event of school closures. In one study of a school closure in response to an outbreak of H1N1 influenza, most parents were accepting of the school dismissals, although 20% reported missing work as a result of having to stay home with children, 2% of whom indicated that this was a major problem (Steelfisher et al., 2010). Assisting parents with preplanning for days when their own children are ill or in the face of school closures can help to avoid such problems.

Preventing HIV infection and AIDS and other sexually transmitted infections (STIs) involves educating students regarding these diseases and their transmission, promoting abstinence or delayed sexual activity when possible, and promoting condom use for students who are sexually active. As we saw earlier, although most school jurisdictions mandate some form of HIV education, it often occurs after sexual activity has been

TABLE 22-7 Conditions Typically Warranting Exclusion from School and Guidelines for Readmission

Condition	Readmission Guidelines
Bacterial conjunctivitis	After acute symptoms subside
Chickenpox	5 days after eruption of the first vesicles or after lesions are dried
Diphtheria	When negative cultures of nose and throat are obtained at least 24 hours after discontinuing antibiotics
Hepatitis A	One week after onset of jaundice
Impetigo (staphylococcal)	24 hours after treatment is initiated
Influenza	After acute symptoms subside
Measles	4 days after onset of the rash
Meningococcal meningitis	24 hours after chemotherapy is initiated or when the child is sufficiently recovered
Mononucleosis, infectious	After acute symptoms subside. Delay resumption of strenuous physical activity until spleen is nonpalpable.
Mumps	9 days after onset of swelling
Pediculosis	24 hours after application of an effective pediculocide
Pneumonia, pneumococcal and <i>Mycoplasma</i>	48 hours after initiation of antibiotics or when child is sufficiently recovered
Pertussis	After 5 days of antibiotic therapy or when child is sufficiently recovered
Respiratory disease (viral) and upper respiratory infection	After acute symptoms subside
Rubella	7 days after onset of the rash
Scabies	24 hours after treatment
<i>Streptococcus</i> (strep throat, scarlet fever, impetigo)	24 hours after treatment is initiated or when child is sufficiently recovered
Tinea corporis	Excluded only from gym, swimming pool, or other activities where exposure of other individuals may occur; activities resume after treatment is completed

initiated. The National HIV/AIDS Strategy, on the other hand, recommends education about HIV and STIs prior to the initiation of sexual activity (Kann et al., 2012). In essence, this means that education should occur in middle school rather than high school. Recommended topics for HIV and other STIs include the difference between HIV and AIDS, STI transmission, diagnosis and treatment information, health consequences, the benefits of abstinence, prevention strategies, and how to access reliable sources of information. Other topics to be addressed include the influence of peers, parents, and the media on sexual risk taking, communication and negotiation skills, goal-setting and decision-making skills, and compassion related to those living with AIDS.

Population health nurses may be involved in the development of HIV and STI education programs and may either teach them or support educational personnel who do so. They are also frequently involved in one-to-one counseling of sexually active students regarding risks and prevention strategies such as condom use. They may also assist students in communication and negotiation strategies to forestall unwanted sexual activity or to promote condom use. Nurses may also need to advocate for the availability of condoms to sexually active students.

Similar strategies are needed to prevent unwanted pregnancies in school populations. Such strategies occur at the individual, school, and outside-of-school levels. At the individual level, school nurses may assist students in making sound decisions for condom use. They may also provide or make referrals

for reproductive services such as contraceptives. At the school level, nurses are involved in pregnancy prevention programs and education, assisting students to develop realistic views of sexual activity and the consequences of pregnancy. Finally, population health nurses may need to advocate outside of the school setting for policies that permit provision of reproductive services as part of the coordinated school health program (Center for School, Health and Education, 2011).

Recommended topics for education programs related to pregnancy prevention include reproductive anatomy and physiology, puberty and adolescent development, identity formation, pregnancy and reproduction, and HIV and other STIs. Other areas to be discussed include healthy relationships with family, peers, and intimate partners, with particular attention to the use and impact of technology and media in relationships, and personal safety (Future of Sex Education Initiative, 2012).

Recommendations have also been made for school-based strategies to prevent skin cancer. These recommendations include adoption of policies to minimize ultraviolet exposure in school settings, provision of an environment conducive to sun-safety practices, and health education on skin cancer prevention. Other strategies include encouraging the use of sunscreen and protective clothing and minimizing sun exposure (CDC, n.d.). A final recommendation is to modify school environments to provide more shade through the use of shade structures and planting trees (Division of Cancer Prevention and Control, n.d.). The Arizona Department of Health Services (2013) has

developed a “SunWise” program to promote skin cancer prevention in schools. For further information about the program, see the *External Resources* section of the student resources site.

One final aspect of illness prevention in the school population involves prevention of heat-related illnesses. Population health nurses can educate coaches, teachers, students, and parents regarding heat illness, particularly in the context of sports participation. They can also encourage adequate hydration and advocate for implementation of acclimatization guidelines that limit the duration and intensity of summer practice sessions with gradual increases over a 2-week period. Fluid recommendations in hot weather include 200 to 300 mL every 10 to 20 minutes during vigorous physical activity. In addition, nurses can advocate for policies and systems that monitor ambient air temperatures leading to adjustment of physical activities as needed (Gilchrist et al., 2010).

Preventing injury. Elements of injury prevention for school populations include elimination of safety hazards, encouragement of safety practices, prevention of bullying and other forms of violence, and suicide prevention. Part of the school nurse’s responsibility is to identify safety hazards and report them to those responsible for eliminating them. Safety education may also be the responsibility of the school nurse. In addition, the nurse might collaborate with others within and outside the school setting to reduce safety hazards in the surrounding area. Moreover, the nurse and other school personnel might become involved in cooperative efforts with local police to reduce drug traffic in the neighborhood.

Specific strategies for preventing violence and bullying in school settings include fostering a culture of respect for all, creating connections between students and adults in the school setting, and breaking the code of silence among students with respect to plans for school violence. Tasks involved in creating a safe, connected school environment where violence is prevented include assessing the school’s emotional climate, emphasizing the need to listen to others, adopting a strong but caring stance against the code of silence, and preventing or intervening in bullying. Other tasks include involving members of the school population, parents, and the community in developing a culture of respect and safety, developing trusting relationships between students and at least one adult in the school setting, and creating mechanisms for sustaining safe schools. Population health nurses can advocate for policies related to bullying and violence, including cyberbullying, and educate parents in monitoring and enforcing proper online behavior. Legislation proposed under the Safe Schools Improvement Act would require schools receiving federal aid to have comprehensive anti-harassment and anti-bullying policies and programs to prevent such behaviors. Such legislation would also require schools to report harassment data (Long, 2012). Defeated in 2012, the proposed legislation was reintroduced in 2013, but the bill had not been passed as of June, 2014 (Human Rights Campaign, 2014).

Strategies for preventing sexual harassment in schools include sensitivity training for students and staff and changing

the culture of the school so that victims of and witnesses to harassment speak out. Population health nurses can advocate for and assist in implementing such programs. They can also teach school personnel how to recognize and respond to harassment and convey to students that harassment of any kind is not funny (Kearl, 2012).

Schools are also in a position to identify abuse of students or staff and to engage in educational programs to prevent abuse. Students can be taught personal safety, coping and resiliency skills, decision making, impulse control, and anger management. Other curricular topics include conflict resolution and stress management. Parenting education can also be provided to parents to prevent abuse.

Health services should also be provided for children who have been abused, and counseling and psychological and social services provided to address underlying factors. School personnel, including school nurses, are mandated by state law in all states to report suspected abuse to the appropriate authorities. In addition to reporting the situation, however, the nurse has a responsibility to provide counseling or referral for assistance to those involved and to serve as a support person for both victim and abuser. In such cases, referrals may also be needed to address socioeconomic problems that may be contributing to the situation. Finally, schools can participate in community-wide efforts to prevent abuse. Schools and school nurses can also be involved in collaborative efforts with other community groups and agencies to address issues of drug trafficking and gang activity that may contribute to violence on or near schools.

Suicide prevention is another area of concern in injury prevention for school populations. Strategies for prevention involve identifying students at risk for suicide and providing mental health treatment. The Substance Abuse and Mental Health Services Administration (SAMHSA) has identified Signs of Suicide (SOS) prevention programs as an evidence-based suicide prevention strategy (Screening for Mental Health, 2010). This program involves educating students and teachers to identify signs of depression and potential suicide risk in themselves or others and respond using the ACT format discussed earlier. Acknowledging feelings validates and recognizes feelings of depression. Acknowledgment is followed by expressions of caring for the person involved, and by telling a responsible adult about signs of depression and the potential for suicide. Suicide prevention and other aspects of illness and injury prevention in the school setting and related population health nursing responsibilities are summarized in Table 22-8•.

RESOLVING EXISTING HEALTH PROBLEMS. School students and staff may experience existing health problems that require resolution. There are four main approaches for dealing with existing health conditions: screening, referral, counseling, and treatment.

Screening is a major facet of most school health programs and an important responsibility of the school nurse. Screening can be used to detect health conditions that are amenable to treatment and that can be resolved with appropriate therapy.

TABLE 22-8 Illness and Injury Prevention Strategies for School Populations

Area of Emphasis	Population Health Nursing Responsibilities
General illness prevention	Teach effective hygiene, particularly hand washing Advocate for good hygiene in meal preparation
Immunization	Educate students, staff, and families regarding the need for immunization Provide or refer for routine immunization of students and staff as needed Recommend and arrange for additional immunizations as warranted by circumstances (e.g., an outbreak of hepatitis A) Advocate for modifications in immunization requirements as indicated for evidence-based practice
School exclusion	Identify students with communicable conditions and arrange for exclusion from school Notify parents and explain the need for school exclusion Refer for treatment services as needed Educate students and parents on preventing the spread of disease Follow-up on excluded students to ensure appropriate care
HIV/AIDS and other STI prevention	Assist in development and implementation of HIV/AIDS/STI education programs Provide and encourage use of condoms by sexually active students Advocate for condom availability in school settings
Pregnancy prevention	Assist in development and implementation of pregnancy prevention programs Assist students in developing negotiation skills for refusing sexual activity or insisting on safe sexual practices
Skin cancer prevention	Assist in incorporation of sun safety into school curricula Educate students, staff, and families on the importance of sun protection Advocate for sun safety policies in school Encourage use of sunscreen by students and staff for all outdoor activities Encourage wearing of protective clothing (hats, sunglasses, etc.) Encourage use of shaded areas for outdoor activities Advocate for architectural and environmental changes to increase shade on school campuses Role model sun safety practices
Heat illness prevention	Educate coaches, teachers, students, and parents regarding heat illness Encourage adequate hydration Encourage modification of physical activities based on ambient temperatures Advocate implementation of acclimatization guidelines for summer sports practices
Unintentional injury prevention	Identify and report safety hazards to appropriate school authorities Assist in developing and implementing safety education programs for students and staff Collaborate in the development of school policies that promote safety Advocate for environmental modifications that promote safety (e.g., changes in traffic patterns on school grounds, restricted access to school grounds, classroom doors that lock from the inside, safe surfaces under playground equipment) Advocate use of safety equipment in classrooms and sports activities
Bullying and violence prevention	Advocate for development and enforcement of policies against bullying, weapons carrying, and violence at school Foster effective interpersonal relationships among students Foster effective relationships between students and school personnel Teach interpersonal communication and conflict resolution strategies and assist in their incorporation in school curricula Assist in creating a culture of respect for all members of the population Educate students and staff on signs of child abuse
Suicide prevention	Educate students and staff on signs of depression and suicidal ideation Assist in development and implementation of suicide prevention programs Advocate for provision of mental health services on campus Refer depressed students for evaluation and treatment

For example, vision screening is used to identify children with visual problems, the majority of whom can benefit from corrective lenses. Screening may also help to identify children with particular needs that necessitate adjustments in the education program. For example, developmental screening may help to identify youngsters with learning disabilities who will benefit from special education programs.

A screening program also provides an opportunity to stress the importance of health promotion and illness prevention. Dental screening, for example, provides an excellent opportunity to educate students on the need for good dental hygiene. Finally, screening efforts provide one measure of the effectiveness of current preventive efforts. For example, hematocrit screening can provide evidence of one aspect of the efficacy

of a school lunch program or nutrition education program in promoting good nutrition.

Screening is a cost-effective approach to the identification of health problems. Typical costs of a screening program include those of the screening procedure itself and of retesting those with positive results, time spent by the nurse in referral, costs of diagnostic and treatment services, special education costs, and costs of corrective maintenance (e.g., for hearing aids or replacing eyeglasses). These costs tend to be far lower than the costs incurred when diagnoses are made later, after problems become more pronounced.

Screening programs typically undertaken in the school setting include screening of vision and hearing, dental screening, height and weight measurements (including BMI), and screening for mental health problems (NASN, 2011b). Other screening tests may also be employed, depending on the needs of the population served by the school. For example, tuberculosis, lead, sickle cell, and diabetes screening may be conducted in communities with high prevalence of these conditions.

The population health nurse in the school setting may perform a variety of roles with respect to screening programs. The nurse might arrange for the screening to be done, conduct the screening tests, or train volunteers to perform certain screening procedures. Moreover, the nurse is usually responsible for informing students and parents of the results of screening tests and for interpreting those results. The nurse may also need to make referrals for follow-up diagnostic or treatment services. In addition, the nurse follows up on these referrals to make sure that students are receiving appropriate health care services.

School health nurses make a number of referrals. In addition to referrals for following up on positive screening test results, the nurse may make referrals for a variety of other services. For example, the nurse might refer children who are not immunized to the local health department for immunizations, or a referral for counseling might be needed for a child with behavior problems. School personnel may also be referred for health problems that require medical attention. In making these and other referrals, the school nurse uses the principles of referral discussed in Chapter 12. If services to which children have been referred involve costs to the family, the nurse may need to assist the family to find sources of funding for these services.

Counseling is another important role for the school nurse in resolving existing health problems. As noted in Chapter 1, counseling involves assisting clients to make informed health decisions. Nurses may counsel individual students regarding personal problems, or they may assist students, families, and staff to engage in problem solving. They may also be involved in development of counseling services within the coordinated school health program.

School nurses may also be involved in the actual treatment of existing health conditions. Treatment can involve emergency care in the event of illness or injury. School nurse practitioners might even engage in medical management of minor illnesses such as antibiotic treatment of otitis media.

Nurses may also be involved in providing specific treatments designed to minimize the effects of acute and chronic conditions. For example, the nurse may need to dispense prescribed medications or engage in specific technical procedures. The need for expertise in the use of medical technology in the school setting has increased dramatically and derives from the inclusion of children with a variety of physical, mental, and emotional health problems in the school population. The school nurse may also be involved in assisting students and staff with chronic illnesses such as diabetes or asthma to effectively manage their conditions.

School nurses may assist with physical therapy or perform procedures such as tracheostomy suctioning or catheterization. They may also be involved in programs for bowel or bladder training. Population health nurses working with children with disabilities in the school setting may also find it necessary to educate other school personnel in procedures required and deal with the fears experienced by school staff regarding the child's condition.

Caring for children with special health needs in the school setting entails the development of an Individualized Healthcare Plan (IHP). Components of the IHP include a health history, identification of special care needs (e.g., required procedures), an overview of the child's basic health status, and information about medications, including who dispenses them, timing, dosages, routes of administration, and so on. Additional elements of the plan include special dietary or nutritional needs, transportation needs, requirements for specialized equipment, identification of possible problems and strategies to solve them, and a plan for emergency action and transportation. Finally, the IHP should indicate review by the nurse, physician, parent, and school administrator and be incorporated in an easily retrievable location in the student's record. According to the NASN (2012a), IHPs should be developed for students who have multiple health needs, require lengthy care or multiple health care contacts, have daily health care needs, or other identified needs for care.

In addition to planning care for students with special needs, the population health nurse monitors the therapeutic effects and side effects of medications and other treatments. Treatment may also involve monitoring self-medication by students. For conditions such as asthma, the ability to self-medicate may mean a difference between adequately controlled and uncontrolled disease. Unfortunately, some schools have policies that prohibit self-medication by students. The American Academy of Pediatrics (AAP) has recommended that responsible students be allowed to carry and self-administer medications that do not require refrigeration and do not carry the potential for abuse or sale to others. School nurses would be actively involved in determinations of a students' ability to self-administer medications (AAP, 2013).

The Council on School Health of the AAP has issued a policy statement on medication administration in school settings (AAP, 2013). The statement recommends development of medication administration policies in all schools, and

Students may need to carry and self-administer some medications. (petert2/Fotolia)

population health nurses can be actively involved in the development of such policies. The ideal situation is to have medications administered by a full-time school nurse; in the nurse's absence, however, administration may be performed by trained unlicensed assistive personnel (UAP) with appropriate supervision from a registered nurse in accord with relevant state laws, regulations, and guidelines. It is recommended that the UAP be a regular employee of the school. General principles of medication administration in the school setting include the following:

- Protecting student safety and preventing errors.
- Identifying the licensed health professional responsible for safe keeping, accessibility, and administration of medications and documentation of their use (including use by students who self-administer medications).
- Conducting regular systematic review of medication administration records.
- Providing ongoing training for UAPs who administer medications.
- Establishing and following effective communication systems related to medication administration.
- Requiring a written medication form signed by both the authorized prescriber and parent.
- Requiring written parental permission for administration of over-the-counter (OTC) medications and limiting the duration of use of OTC medications.
- Protecting student confidentiality.
- Providing training, delegation, and supervision of UAPs who administer medications.
- Permitting responsible students to carry and self-administer emergency medications authorized by school policies
- Encouraging parents to provide spare life-saving emergency medications in the health office.
- Making provision for secured and immediate access to emergency medications at all times, including before and after school and during off-campus school-sponsored activities.
- Storing medications in original, appropriately labeled containers in appropriate locations.
- Returning excess medication to parents or appropriately disposing of it at the end of the school year (AAP, 2013).

Strategies for resolving existing health problems in school settings are summarized in Table 22-9.

HEALTH RESTORATION. Health restoration services are undertaken to prevent the recurrence of a health problem or to minimize its long-term effects on health. To a large extent, health restoration measures depend on the problems experienced by the student or staff member. Generally speaking, however, there are seven aspects of restoration with which the school nurse is concerned: rehabilitation, preventing the recurrence of acute problems, preventing complications, fostering adjustment to chronic illness and disability, dealing with learning disabilities, sustaining school-based health services, and promoting recovery after a disaster or emergency event.

Students with injuries or serious illness may require rehabilitation services. For example, a student with a severe sports injury may need physical therapy, or a staff member recovering from a heart attack may need assistance with cardiac rehabilitation. School nurses may make referrals for rehabilitative services or encourage active participation in rehabilitation activities. In some cases, they may assist students or staff with physical therapy regimens, or they may monitor the progress and effects of rehabilitation.

Preventing the recurrence of acute health problems depends on adequate treatment for existing problems and elimination of conditions that might lead to recurrence. For example, the school nurse might need to educate parents and children regarding the need to complete the course of therapy for otitis media, or education might be needed related to toileting hygiene (e.g., wiping from front to back) to prevent a recurrent urinary tract infection. The nurse might also engage in efforts to help an abusive parent or unduly harsh teacher find other ways to vent frustrations, or might make a referral to help alleviate financial difficulties that are taxing coping abilities.

Health restoration interventions are also directed toward preventing complications of either acute or chronic health problems. For example, the school nurse might encourage parents of a child with strep throat to complete a course of antibiotics to prevent cardiac and urinary complications. Similarly, the nurse might suggest a cushion and frequent changes of position to prevent pressure sores in a student confined to a wheelchair.

TABLE 22-9 Strategies for Resolving Existing Health Problems in School Populations

Area of Emphasis	Population Health Nursing Responsibilities
Screening	<ul style="list-style-type: none"> Conduct screening tests or arrange for screening by others Train volunteers in screening procedures Interpret screening test results Notify parents of screening test results Make referrals for further tests or treatments as needed Follow up on referrals to determine outcomes and to ensure appropriate care for identified conditions
Referral	<ul style="list-style-type: none"> Refer children and families for health care and other services as needed Refer other school personnel for needed services
Counseling	<ul style="list-style-type: none"> Assist students, staff, or families to make informed health decisions Counsel students, staff, or families regarding personal problems Assist students, staff, or families to engage in problem solving Advocate for access to professional mental health services as needed Encourage students to disclose mental health and other stigmatized conditions to school personnel Encourage students in need of them to request teaching/learning accommodations Work to eliminate the stigma attached to mental health and other stigmatizing conditions Assure that school policies on confidentiality are known and enforced Provide or arrange for targeted mental health support services for special populations (e.g., children with disabilities, GLBT youth, veterans at the college level)
Treatment	<ul style="list-style-type: none"> Provide first aid for illness or injury Dispense medications prescribed for acute or chronic illnesses Monitor self-medication by students Develop the IHPs for care of children with special health needs Perform special treatments or procedures warranted by identified conditions Teach others to perform special treatments or procedures Monitor therapeutic effects and side effects of medications and other treatments

Health restoration measures for children with chronic or handicapping conditions involve assisting them to adjust to their condition and preventing complications. Specific measures depend on the condition involved. For example, special arrangements for physical education might be needed to prevent recurrent attacks of exercise-induced asthma, and special attention to diet might be required for the diabetic child or staff member. School-based health centers are ideally situated to monitor the effects of chronic disease management in the school population. Easy access to providers allows for drop-in visits to address questions and deal with treatment side effects or concerns (Clayton, Chin, Blackburn, & Escheverria, 2012).

Major considerations in dealing with children with chronic illness in the school setting involve money, transportation and facilities, and equipment. Additional considerations include nutrition and psychological well-being. The school nurse may need to refer students and parents to sources of financial assistance as a way to deal with the long-term care requirements of chronic and disabling conditions.

Transportation and facility considerations in the school setting include issues of physical access to facilities discussed earlier in this chapter. Another area for consideration is transportation to and from school and on field trips. The nurse identifies barriers to access in the school setting and serves as an advocate for the removal of those barriers. Likewise, the nurse attempts to arrange transportation and other circumstances so

that students with chronic or disabling conditions can participate in as many regular school activities as possible, including field trips. Advocacy in this area might also be needed with overly protective parents of children with disabilities.

There may also be a need for special equipment to be used either at home or at school. The school nurse makes referrals to obtain such equipment or sees that it is provided by the school itself.

Nutrition may be particularly problematic for schoolchildren with chronic diseases or handicapping conditions. Youngsters with diabetes, for example, may need assistance in adapting a school meal program to a diabetic diet. Severely disabled children may need assistance with eating or may need to be fed. The school nurse assesses the special nutritional needs of children with these and similar conditions and then assists the child, family, and other school personnel to meet those needs. Again, advocacy may be required to assure the availability of special diets for children with particular nutritional needs.

The final consideration for children who have chronic illnesses or disabling conditions is their psychological well-being. These children should be helped to adjust to their conditions and to participate as normally as possible in the school routine. Parents, teachers, and other students may need to be discouraged from undermining the child's independence by "doing for" them. Values clarification exercises can help other children understand the problems of disabled or chronically ill children rather than make fun of them or pity them.

Children with ineffective immune systems may also need interventions to protect them from infection. The need to use universal precautions when dealing with blood and body fluids may heighten these children's sense of isolation and alienation.

Because there does not seem to be any form of prevention available for learning disability, work with learning-disabled children focuses on minimizing the effects of their disability. Some of the interventions that may be planned to assist learning-disabled children are learning by activity, involving multiple senses in learning activities, using repetition, providing direction in small steps, and giving directions without irrelevant detail. Teaching at the appropriate level, a level that creates a challenge but does not lead to frustration, may also be helpful. Other useful strategies include avoiding drastic changes in activities, limiting distractions, and creating a climate in which success is ensured and reinforced as often as possible.

The nurse is involved in development of individualized education plans (IEPs) that allow children with learning disabilities, as well as those with other chronic or handicapping conditions, to learn as easily as possible. Again, attention must be given to the psychological effects of being labeled as *learning disabled*. The nurse may need to function as an advocate with parents, teachers, and other children to avoid the application of labels that undermine the child's self-esteem. The nurse can also function as a role model in providing positive reinforcement for the child's strengths and accomplishments.

Another intervention at this level includes sustaining school-based health services through continued funding. One suggestion for sustaining services involves converting school-based health centers to federally qualified health centers (FQHCs). FQHCs are "community-based and patient-directed organizations that serve populations with limited access to health care" (Health Resources and Services Administration [HRSA]. n.d., p. 1). FQHCs are located in medically underserved communities and have governing boards that include consumers as 51% of the board. They are funded by HRSA and provide comprehensive primary care services on a sliding fee scale as well as supportive services such as education, transportation, and translation as needed (HRSA, n.d.). Population health nurses can help schools explore the ramifications of becoming FQHCs and negotiate the application process. For further information about FQHCs, see the *External Resources* section of the student resources site.

Another aspect of health restoration at the population level is assisting members of the school population to recover from a disaster or a traumatic event, such as a school shooting. School nurses are ideally placed to recognize the psychological after effects of major psychological trauma and for assisting members of the school population to cope with and recover from such events. For example, after Hurricane Katrina, a School Nurse Disaster Response Training Program was initiated to provide school nurses with additional expertise in recognizing

and dealing with psychological problems among students and staff. Training included signs and symptoms of negative effects as well as information on local resources and how to access them. The training also addressed school nurse resiliency and dealing with their own responses to the disaster and its aftermath (Broussard et al., 2012). Students and members of the staff may also need assistance in dealing with the long-term physical effects of a disaster or emergency situation. School nurses can make referrals for needed treatment services and can also assist with rehabilitation following injury.

In addition to dealing with physical and psychological issues, population health nurses can refer students, staff, and their families to sources of financial and other assistance to promote recovery. Population health nursing roles in natural and man-made disasters are addressed in more detail in Chapter 25. Aspects of health restoration in the care of school populations and related population health nursing roles are summarized in Table 22-10.

Evaluating Health Care for School Populations

Evaluating the effectiveness of care in the school setting focuses on the outcomes of that care. Evaluation can occur at two levels: the individual child or the total school population. Evaluative criteria for the care of the individual child reflect the effects of nursing care on the student's health status. For example, if a child is no longer abused by his parent, no longer has recurrent ear infections, or is now able to interact effectively with peers, the interventions of the nurse have probably been effective.

Evaluation of population level effects will also depend on the problems for which intervention was provided. Fewer adolescent pregnancies following a pregnancy prevention program or fewer absences among students with asthma after adhering to asthma care guidelines by school-based providers would be examples of the effects of population-based elements of the school health program.

As we noted earlier, various elements of the coordinated school health program can be evaluated using tools such as HECAT and PECAT. The overall coordinated school health program can also be evaluated. The processes used in evaluating the school health program are those discussed in Chapter 15. Specific evaluation tools have been developed for assessing the adequacy of the coordinated school health program. These include the *School Health Index* (SHI) developed by CDC (2012) and a similar tool, the *Healthy School Report Card*, developed in Canada (Lohrmann, Vamos, & Yeung, 2011).

Both tools are based on the eight components of the CDC model of a coordinated school health program. The SHI is a self-assessment guide incorporating modules related to each component that schools can use to evaluate their performance. Each module includes several criteria related to a specific component

TABLE 22-10 Health Restoration Strategies for School Populations

Area of Emphasis	Population Health Nursing Responsibilities
Rehabilitation	Refer students or staff for rehabilitative services Encourage active participation in rehabilitation activities Assist with rehabilitation measures (e.g., physical therapy) as needed Monitor rehabilitation progress and effects
Preventing recurrence of acute conditions	Eliminate risk factors for the condition Teach students, staff, or parents how to prevent recurrence of problems Make referrals that can assist in eliminating risk factors
Preventing complications of and promoting adjustment to chronic conditions and disabilities	Assist parents with finding sources of financial aid to deal with chronic conditions and disabilities Advocate for educational accommodations as needed Facilitate meeting special nutritional needs Assist with meeting special needs for transportation and facilities Provide for special equipment needs Promote psychological well-being Assist students, families, and staff to deal with the eventuality of death in terminal illnesses Refer for counseling as needed Function as an advocate as needed
Preventing adverse effects of learning disabilities	Provide consultation for teachers in dealing with children's learning disabilities Participate in the design of IEPs for children with disabilities Function as an advocate for the learning-disabled child as needed Serve as a role model in positively reinforcing the child's accomplishments
Sustaining school-based health services	Assist with identification of mechanisms for continued funding of school-based health services Assist with the development of plans to apply for FQHC status if warranted Conduct research to document the outcomes of school-based health care services
Disaster/Emergency recovery	Assist in identification of students and staff with long-term physical and psychological consequences Assist students and staff in coping with the aftermath of a disaster or emergency Refer students and staff for treatment of physical consequences of an emergency or disaster event Assist students or staff with rehabilitation following injuries sustained in a disaster or emergency event Refer students and staff for counseling for psychological consequences of an emergency or disaster event Refer students, staff, and families to other sources of assistance in disaster recovery

that are rated by school evaluators from “not in place,” through “under development” and “partially in place,” to “fully in place.” The index also addresses several topics of particular interest in assessing the performance of the school health program, such as physical activity and physical education, nutrition, tobacco use prevention, asthma, safety, and sexual health. Separate versions of the tool are available for the elementary school level and middle and high school level. For further information about the tools and guidelines for their use, see the *External Resources* section of the student resources site. A source for information regarding the Healthy School Report Card is also provided.

A similar Continuous Quality Improvement Tool for School-based Health Centers is available for evaluating SBHC performance. Data address comprehensive annual risk assessments and biennial physical examinations for students seen in the SBHC, as well as “sentinel events” typical of various student age groups (Juszczak, Pastore, & Reif, 2013). Sentinel events are similar to the key indicators used for monitoring progress toward achievement of the *Healthy People 2020* objectives in the United States. Separate tools are available for elementary, middle, and

high school settings. Some sentinel events, such as annual risk assessments and biennial physical examinations, poor school performance, and treatment for ADHD, are common to all three levels. Additional sentinel events for middle school assessment include tobacco use, pregnancy risk, parent/child conflict, and depression. Sentinel events for the high school version also include alcohol use, risk for violence, STI risk, and depression risk (Juszczak et al., 2013). For more information about the tool, see the *External Resources* section of the student resources site.

The school nurse collaborates with other members of the school health team in designing and implementing an evaluation of a coordinated school health program or an SBHC. The nurse may also be involved in collecting data related to the evaluation and interpreting those data. Finally, the nurse should be actively involved in decisions made on the basis of evaluative data.

At the national level, national objectives for the year 2020 related to school health can provide additional evaluative criteria. Selected objectives related to school health are included on the next page.

Healthy People 2020

Selected Objectives Related to the Health of School Populations

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
AH-2 Increase the proportion of adolescents who participate in extracurricular and/or out-of school activities	82.4% (2007)	90.6%	82.7% (2011–2012)	National Survey of Child Health (NSCH), CDC, HRSA/MCN
AH-5.1 Increase the proportion of students who graduate with a regular diploma in 4 years	74.9% (2007–2008)	82.4%	NDA	Common Core of Data (CCD), ED/NCES
AH-5.2 Increase the proportion of students served under the Individuals with Disabilities Education Act who graduate high school with a diploma	59.3% (2007–2008)	65.2%	NDA	Common Core of Data (CCD), ED/NCES
AH-5.6 Decrease absenteeism among adolescents due to illness or injury	5% (2008)	TBD	5.3% 2011	National Health Interview Survey (NHIS), CDC/NCHS
AH-6 Increase the proportion of schools with a school breakfast program	68.6% (2006)	75.5%	NDA	School Health Policies and Practices Study (SHPPS), CDC/NCCDPHP
AH-7 Decrease the proportion of adolescents offered, sold, or given illegal drugs on school property	22.7% (2009)	20.4%	25.6% (2011)	Youth Risk Behavior Surveillance System (YRBSS), CDC/NCCDPHP
AH-8 Increase the proportion of adolescents whose parents consider them safe at school	86.4% (2007)	95%	90.9 (2011–2012)	NSCH, CDC/ HRSA/MCN
AH-10 Decrease the proportion of public schools with serious violence incidents	17.2% (2007–2008)	15.5%	NDA	School Survey on Crime and Safety (SSOCS), ED/ NCES
C-20.5 Increase the proportion of adolescents who use protective measures to prevent skin cancer	9.3% (2009)	11.2%	10.8% (2011)	YRBSS, CDC/NCCDPHP
DH-14 Increase the proportion of children with disabilities who spend at least 80% of their time in a regular education program	56.8% (2007–2008)	73.8%	59.4% (2009–2010)	Data Accountability Center (DAC), ED/ OSERS
EMC-4.3.1 Increase the proportion of elementary schools that require health education that meets U.S. national health education standards*	7.5% (2006)	11.5%	NDA	SHPPS, CDC/NCCDPHP
ECBP-2.1 Increase the proportion of elementary, middle, and senior schools that provide comprehensive school health education to prevent problems in all priority areas	25.6% (2006)	28.2%	NDA	SHPPS, CDC/NCCDPHP
ECBP-5.1 Increase the proportion of elementary, middle, and senior schools with a full-time registered nurse school nurse to student ratio of at least 1:750	40.6% (2006)	44.7%	NDA	SHPPS, CDC/NCCDPHP

Healthy People 2020 (Continued)

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
ECBP-6 Increase the proportion of the population that complete high school	89% (2007)	97.9%	89.8% (2009)	Current Population Survey (CPS), Census, DOL/BLS
FP-12.3 Increase the proportion of females who receive formal instruction on birth control before age 18#	70.5% (2006–2010)	77.6%	NDA	National Survey of Family Growth (NSFG), CDC/ NCHS
IVP-27.1 Increase the proportion of public and private schools requiring students to wear appropriate protective gear in school-sponsored physical education	76.8% (2006)	84.5%	NDA	SHPPS, CDC/ NCCDPHP
IVP-34 Decrease physical fighting among adolescents	31.5% (2009)	28.4%	32.8% (2011)	YRBSS, CDC/ NCCDPHP
IVP-35 Decrease bullying among adolescents	19.9% (2009)	17.9%	20.1% (2011)	YRBSS, CDC/ NCCDPHP
IVP-36 Decrease weapons carrying by adolescents on school property	5.6% (2009)	4.6%	5.4% (2011)	YRBSS, CDC/ NCCDPHP
NWS-2.1 Increase the proportion of schools that do not sell or offer calorically sweetened beverages	9.3% (2006)	21.3%	NDA	SHPPS, CDC/ NCCDPHP
NWS-2.2 Increase the proportion of school districts that require schools to make fruits and vegetables available when food is offered or sold	6.6% (2006)	18.6%	NDA	SHPPS, CDC/ NCCDPHP
OH-9.2 Increase the proportion of SHBCs with oral health components that offer dental care	10.1% (2007–2008)	11.1%	NDA	School-based Health Care Census (SBHCC), National Association of School-based Health Centers (NASBHC)
PA-4.1 Increase the proportion of the nation's public and private elementary schools that require daily PE for all students*	3.8% (2006)	4.2%	NDA	SHPPS, CDC/ NCCDPHP
PA-6.2 Increase the proportion of school districts that require regular recess in elementary schools	57.1% (2006)	62.8%	NDA	SHPPS, CDC/ NCCDPHP
TU-15.2 Increase tobacco-free environments in middle schools including all school facilities, properties, vehicles, and events@	58.7% (2006)	100%	NDA	SHPPS, CDC/ NCCDPHP

NDA—No data available

TBD—To be determined

*Similar objectives have also been developed for middle and high school levels with slightly different baseline data and targets.

Similar objectives have also been developed for males and for HIV/AIDS and STI education with slightly different baseline data and targets.

@ Similar objectives have also been developed for junior and senior high school levels with slightly different baseline data and targets.

CHAPTER RECAP

Population health nursing in schools provides an opportunity for promoting health and preventing illness in children and their families. Population health nurses working in school settings from preschool to college can also assist students and staff with existing health problems, as well as designing school health programs that promote the health of the general public. School nursing requires an advanced level of expertise due to the autonomy and level of responsibility involved, and certification as a school nurse is strongly recommended. School nurses work collaboratively with other members of the school health team and with professionals in the community to promote health and prevent injury and illness in the school population. They are also involved in resolving existing health problems and health restoration in individual students and staff and in the population in general.

Biological, psychological, environmental, sociocultural, behavioral, and health system determinants influence the health of the school population, and the coordinated school health program is designed to address factors in each area. Elements of a coordinated school health program include health education; physical education; health services; nutrition services; a healthy and safe environment; health promotion for school staff; family and community involvement; and

counseling, psychological, and social services. Health promotion in the school setting focuses on health education, physical activity, nutrition, and mental health promotion. Prevention of illness and other health conditions in this population addresses immunization and school exclusion, HIV/AIDS and STI prevention, pregnancy prevention, and prevention of skin cancer and heat-related illness. Injury prevention strategies focus on safety and unintentional injury prevention, prevention of bullying and violence, and suicide prevention.

Resolution of existing health problems occurs for individuals and for the population as a whole. Areas of emphasis include screening, referral, counseling, and treatment. Health restoration strategies encompass rehabilitation, preventing recurrence of health problems, preventing complications and promoting adjustment to chronic illness, and preventing adverse effects of learning disabilities. At the population level, health restoration also includes sustaining school health services and recovery from disasters or emergency events.

A variety of approaches are available for evaluating the effectiveness of school health services. These include tools to evaluate the coordinated school health program and the performance of school-based health centers as well as achievement of national health objectives related to schools.

CASE STUDY Dealing with Bullying

The mother of a fifth grade student spent some time volunteering for playground duty during lunch at her son's private religiously affiliated school. During her supervision rotations, she witnessed some cruel treatment of overweight children who could not run as fast as others. Not only were they the last ones chosen for teams during recess, denigrating comments were often made like, "You take him, we don't want him." She had attempted to tactfully remonstrate with the students involved when she witnessed this behavior, but was met with blank and hostile stares. Conversations with her son and other members of the parent organization suggested that verbal and physical aggression were common in the school, but were particularly notable in this fifth grade class. In fact, her son told her, "Mom, if you're not one of the bullies, you'll be one of the victims."

"School nurse" services were provided by non-health-professional volunteers, who did not feel that they could interfere in the situation. The mother, a population health nurse, went to the school principal with her observations and offered to conduct some sensitivity training for her son's class. The principal declined saying that this was just typical behavior of students at that age.

1. What biological, psychological, sociocultural, behavioral, and health system determinants are operating in this situation?
2. What interventions might you employ to resolve the situation? What allies might you seek in your resolution efforts?
3. How would you evaluate the effectiveness of your intervention?

23 Care of Employee Populations

Learning Outcomes

After reading this chapter, you should be able to:

1. Describe advantages of providing health care in work settings.
2. Identify types of health and safety hazards encountered in work settings.
3. Identify biological, psychological, environmental, sociocultural, behavioral, and health system determinants that influence health in work settings.
4. Describe areas of emphasis in health promotion, illness and injury prevention, resolution of existing health problems, and health restoration in work settings and analyze the role of the population health nurse with respect to each.
5. Describe approaches to evaluating health care for the working population.

Key Terms

emotional labor

employee assistance program (EAP)

ergonomics

hazard analysis

health indicators

job control

work movement index

workplace aggression

Women Workers

As should be obvious, based on prior advocacy accounts in this book, Lillian Wald was involved in much more advocacy than that represented by her work at Henry Street. In addition to campaigning for the Children's Bureau and founding both public health nursing and school nursing, Wald was actively involved in a variety of endeavors to promote the safety of workers. She lobbied for health-related inspections of workplaces and endeavored to convince employers that healthy employees were more productive, encouraging them to prevent injury and illness and to employ nursing or medical professionals in the work setting.

Wald was particularly concerned about the plight of working women, and in 1903, she helped found the Women's Trade Union League. The intent of the league was to investigate the working conditions of women and promote women's trade unions. Wald was a member of the executive committee of the New York City league and was an active advocate and fund raiser (Jewish Women's Archive, 2010). The involvement of Wald and several other WTUL supporters in the National Association of Colored People (NAACP) was instrumental in thwarting employers' plans to bring in Black workers to break the Shirtwaist Strike (Lewis, n.d.) in 1909.

In addition, Wald raised public awareness for unions through her fund-raising and picketing efforts. Wald served on the Joint Board of Sanitary Control, an agency established to monitor environmental conditions in factories. She also advocated for a minimum wage for women and served as a representative to President Woodrow Wilson's Industrial Conference (Jewish Women's Archive, n.d.). Held in October 1919, the conference brought together employer groups, labor unions, and the public. Unfortunately, management representatives refused to agree to a provision endorsing the right of collective bargaining, causing labor representatives to withdraw from the conference. A second, smaller conference was held in 1920 (U.S. Department of Labor, n.d.a).

Promoting Breast-feeding at Work

Murtagh and Moulton (2011) described a variety of benefits for mothers, children, and employers when breast-feeding and/or breast pumping are encouraged in the work setting. Breast-feeding promotes child development, better immune system function, and decreased risk of a variety of acute and chronic conditions in children. Mothers experience decreased postpartum bleeding, diminished menstrual blood loss, earlier return to prepregnancy weight levels, and decreased risk of breast and ovarian cancer. Benefits for employers include reduced absenteeism and higher productivity, retention of experienced workers, and improved employee morale and company image. Additional benefits include reduced family expenditures for formula and a projected savings of \$3.6 billion in health care costs if targeted breast-feeding rates identified in *Healthy People 2020* were achieved (Murtagh & Moulton, 2011).

Unfortunately, federal law only addresses the availability of reasonable break time to permit breast pumping, and few states have legislation that promotes breast-feeding at work. What is the policy regarding breast-feeding in your nursing education institution? Is breast-feeding of infants encouraged? Permitted? Is privacy provided for breast-feeding or breast pumping? Are there different policies related to breast-feeding by students and faculty/staff members? How might you and your classmates promote development of conditions on campus that foster breast-feeding by students and faculty/staff?

In 2010, 153.8 million people 16 years of age and older were employed in the U.S. civilian work force, and the following year, U.S. workers logged more than 258 trillion work hours (BLS, 2013c; U.S. Census Bureau, 2012a). By 2020, the number of employed people in the United States is expected to grow to more than 164.3 million (Toosi, 2012). Because of the large number of people involved, the work setting is an important place for promoting the health of the general population (Sorenson et al., 2011). Although the work environment contributes to a wide variety of health problems, it also provides opportunities to influence a major segment of the population regarding personal health behaviors and to modify the potential for exposure to hazardous circumstances.

Schulte, Pandalai, Wulsin, and Chun (2012) described four potential patterns or models of interaction between personal characteristics of employees and risk factors present in the occupational setting. In the first model, personal factors and occupational factors operate independently to result in a particular health problem. For example, a person with a substance abuse problem might be required, as part of his or her job, to operate hazardous machinery. In this case, substance abuse may combine with job requirements to lead to serious injury. In the second model, personal risk factors modify the effects of occupational risk factors to produce health-related effects. An example might be smoking on the part of an employee that makes him or her more susceptible to the carcinogenic effects of workplace exposures to coal dust and other substances. The third model posits the reverse relationship, in which workplace factors modify the effects of personal characteristics to affect health. For example, exposure to some respiratory agents in the work setting may exacerbate asthma in employees with this condition. Finally, personal and occupational factors may operate independently leading to different health problems that then interact. For example, being overweight may lead to hypertension and job strain may create stress, both of which may contribute to myocardial infarction.

The effects of work on health were noted by Bernardino Ramazzini, considered the father of occupational medicine, as early as the 1700s. In 1713, Ramazzini wrote about the occupational effects on musculoskeletal health and the effects of sedentary occupations and toxic exposures. Of particular note, Ramazzini addressed the health effects of typical women's occupations as well as those of men (Franco, 2012). Similarly, cutaneous anthrax was first associated with the handling of wool in 1837, although the disease itself was not diagnosed until 1880 (Bell, 2002). Henry Bell, a British physician who attended a man dying of anthrax, sent the death certificate to the police maintaining that the employer had caused the death due to his failure to disinfect the wool the deceased was working with. Bell's actions led to an inquiry and the institution of voluntary guidelines for the wool industry that were in effect until 1899 (Bell, 1902). In the early 20th century, Germany instituted *krankenhaussen*, sickness insurance funds for the working

class, which prompted U.S. sociologists to promote occupational disease surveys. The first such survey was conducted in 1910 and focused on "occupational poisons," specifically occupational lead exposure (Hamilton, 2001). Despite this long history of knowledge of the effects of working conditions on health, thousands of workers are injured or develop occupational illnesses every year.

Over the years, however, employers have come to better appreciate that healthy employees are more productive and that it is in the employer's interest to promote and maintain employee health. Moreover, the escalating cost of health insurance makes health promotion increasingly cost-effective. One way that some companies have chosen to decrease health-related costs is to provide on-site health care for employees.

The importance of health care in the occupational setting can be seen in the national health objectives for the year 2020. In fact, one entire section of the objectives deals with health and safety in occupational settings (U.S. Department of Health and Human Services [USDHHS], 2014). The status of selected objectives is addressed later in this chapter. The importance of achieving these objectives is underscored by the fact that the direct and indirect costs of work-related injuries and illnesses are approximately \$170 billion per year (Council of State and Territorial Epidemiologists, n.d.). Given the preventable nature of most of these events, health care focusing on the working population makes eminent sense.

Occupational Health Nursing

Not all nurses who practice in occupational settings are population health nurses. The population health nurse, however, is uniquely prepared to meet the health needs of the working population because of his or her knowledge of population health principles. Occupational health nursing is not a new role for the population health nurse. Nurses may have been employed in U.S. work settings as early as 1888, when a group of coal mining companies employed Betty Moulder to provide care for sick miners and their families (Roy, 2013). Organized industrial nursing, as it was then called, began in 1913 with the establishment of an industrial nurse registry (Committee to Assess Training Needs, 2000), and in 1914, the U.S. Public Health Service established the Office of Industrial Hygiene (Roy, 2013). By 1918, more than 800 businesses employed nurses, and colleges and universities began to offer short courses in industrial hygiene to support occupational health nursing practice (Committee to Assess Training Needs, 2000). Since that time, the role of the occupational health nurse has been expanded along with other nursing roles.

The Occupational Safety and Health Administration (OSHA) of the U.S. Department of Labor described occupational health nurses as "registered nurses who independently observe and assess the worker's health status with respect to job tasks and hazards. Using their specialized experience and education, these registered nurses recognize and prevent

health effects from hazardous exposures and treat workers' injuries/illnesses" (OSHA, n.d.b, para 1). This definition does not, however, fully describe today's population health nursing role in work settings. It concentrates on the treatment aspects of care and the nurse's dependent functions and does not acknowledge the promotional and preventive aspects that are paramount in this practice setting. In its 2012 *Standards of Occupational and Environmental Health Nursing*, the American Association of Occupational Health Nurses (AAOHN, 2012e) defined **occupational health nursing** as a specialized area of nursing practice focused on health promotion, illness and injury prevention, and restoration in the work environment.

Educational Preparation for Occupational Health Nursing

Several types of nursing personnel may be found in occupational settings, including registered nurses prepared in associate degree and diploma programs in nursing as well as in baccalaureate degree programs; licensed practical nurses; and nurses prepared at the master's level. Because of the need to apply principles of population health nursing, nurses who engage in the full scope of the occupational health nurse's role should be prepared at least at the baccalaureate level in nursing. As noted by OSHA (n.d.b), the educational preparation of occupational health nurses may vary "from entry level to PhD work." Graduate level preparation might be in occupational health nursing, in community or population health nursing, or as a nurse practitioner. According to an Institute of Medicine (IOM) report, graduate preparation for occupational health nursing typically encompasses nursing, medical, and occupational health science; epidemiology; business and economics content; social and behavioral sciences; environmental health; and legal, regulatory, and ethical issues relevant to occupational health (Committee to Assess Training Needs, 2000).

Advanced preparation in occupational health nursing may result in certification by the American Board of Occupational Health Nurses (ABOHN). Established in 1972, the organization's first certification examination was given in 1974; in 2012, ABOHN celebrated its 40th anniversary as a specialty certification body (ABOHN, 2012).

Nurses in other settings may also be involved in providing care for health conditions related to work. This fact suggests that nurse practitioners working in ambulatory care settings where occupational conditions may be seen should have a basic grounding in the principles of occupational health.

Standards and Competencies for Occupational Health Nursing

Like other nursing specialties, occupational health nursing should be practiced in accordance with established standards. The AAOHN (2012e) has established 11 standards for

competent occupational and environmental health nursing practice. These standards are focused primarily on the care of individuals in work settings and address both basic and advanced levels of practice. Areas of emphasis within the standards include assessment, diagnosis, outcome identification, planning, implementation, evaluation, resource management, professional development, collaboration, research, and ethics. For further information about the standards, see the *External Resources* section of the student resources site.

In addition, AAOHN (2012a) has developed a code of ethics for nursing practice in occupational health settings. The code addresses respect for human dignity, duty to society, privacy, collaboration, and personal competence and responsibility on the part of the occupational health nurse. (AAOHN, 2012).

Occupational Health Nursing Roles

As noted earlier, the role of the occupational health nurse has undergone significant change since the initial development of the specialty. Some of the factors contributing to those changes include an increased emphasis on evidence-based practice, greater focus on wellness initiatives in the work setting, and growing interest in alternative provider models. Additional factors include a focus on cost reduction, which may result in outsourcing of services and competition for funding, and a proliferation of other professionals who provide care for the employed population (AAOHN, 2012c).

The overall role of the occupational health nurse encompasses health and productivity management, which involves coordination of a variety of programs and services to promote, maintain, or restore the health of the employee population (AAOHN, 2012d). This role requires the occupational health nurse to collaborate with others to identify health and safety needs, prioritize interventions, plan and implement interventions and programs for the working population, and to evaluate care and service delivery systems (AAOHN, 2012c). As noted by AAOHN, occupational health nurses are in ideal positions to identify determinants affecting employee health, promote health-related behaviors, foster cost-saving interventions, and align health services with business goals. They also address legal issues in the work setting, safeguard privacy, and promote collaboration among departments of the employing organization, health care professionals, and outside vendors and organizations (AAOHN, 2012d).

The specific role functions of an occupational health nurse may vary somewhat from setting to setting, but there are some general commonalities among settings. These functions typically include direct primary care services for occupational and nonoccupational illnesses and injuries; case management, health hazard assessment and surveillance; monitoring of illness and injury trends; assuring compliance with regulatory mandates for privacy; health promotion, prevention, early recognition, and treatment of illness and injury; counseling,

coaching, and training of employees; and research (AAOHN, 2012c). Additional role functions include crisis intervention, risk reduction, assuring compliance with legal and regulatory mandates for workplace conditions (AAOHN, 2012e), interpretation of medical diagnoses to workers and their families (OSHA, n.d.b), management and administration of the occupational health unit, and the development and maintenance of partnerships with community organizations and agencies (Committee to Assess Training Needs, 2000).

Specialized occupational health nurse consultants, whether internal or external to a particular business or industry, may carry out several additional functions. These may include assessment and identification of the need for occupational health services; development and marketing of health and wellness programs to industry; development of programs to address specific problems within a given setting; provision of direct care in the absence of an occupational health nurse employed in the setting; coordination of services from outside agencies and organizations; orientation of nurses new to occupational health; assistance with research grants and publications; and certification in specialty areas (Roy, 2013).

Population Health Nursing and Care of the Working Population

Nursing care in work settings is based on the use of the nursing process and includes assessment of the health of the population; development of nursing diagnoses; and planning, implementation, and evaluation of interventions to promote, protect, and restore health.

Assessing the Health Status of the Working Population

Assessment of employee health status and health needs is undertaken from the perspective of biological, psychological, environmental, sociocultural, behavioral, and health system determinants that influence health and illness in the working population.

BIOLOGICAL DETERMINANTS. Human biological factors to be addressed in assessing employee health status include those related to maturation and aging, gender, genetic inheritance, and physiologic function.

Maturation and aging. The age composition of a company's workforce affects its health status. If employees are primarily young adults or adolescents, health conditions that may be noted with some frequency include sexually transmitted diseases, hepatitis, and pregnancy. Younger employees may also be at increased risk of injury due to limited job training and skills. In 2012, U.S. labor force statistics indicated that just under 4% of the U.S. workforce was 16 to 19 years of age (5.8 million youth) (BLS, 2013b). The number of youth in the workforce is expected to increase slightly by 2020, but they will make up a

smaller percentage of the overall workforce due to increases in the number of people who choose to remain in the workforce after typical retirement age. The percentage of youth in the workforce varies seasonally, ranging from approximately 33% in July 2013 to 24% in February 2014 when school was in session (Office of Disability Employment Policy, 2014).

Younger and older workers are more likely to be fatally injured on the job than middle-aged workers. For example, preliminary data for 2012 indicated a fatal injury rate of 2.9 per 100,000 full-time equivalent workers among 18- to 19-year-old workers. The rate decreases for workers aged 20 to 44 years and then begins to climb at age 45 to reach a peak of 9.8 per 100,000 among workers 65 years of age and older (Bureau of Labor Statistics [BLS], 2012a).

The health needs of older employees should also be considered. Because of prohibitions on forced retirement at specific ages in many occupations, many employees are continuing in the workforce beyond the time when they would have retired. Economic need and a desire for continued productivity are two factors that may influence this trend. Lack of skilled workers to replace them and the desire to embark on new careers are other factors that lead to the retention of older workers in the workforce (Wuellner et al., 2011). The number of workers over 65 years of age doubled from 1997 to 2007 (Sorenson et al., 2011). Based on Bureau of Labor Statistics data, there were more than 30 million people over age 55 in the U.S. workforce in 2010 and this group constituted 19.5% of those employed. This is the fastest growing age group in the workforce (Wuellner et al., 2011), and by 2020, an estimated 25.2% of U.S. employees or 41.4 million workers will be over 55 years of age (Toosi, 2012).

Although older workers bring valued skills and experience, declining physical ability and stamina and increasing sensory impairments place them at higher risk for occupational injury and illness. Although younger workers experience a higher rate of injury, older workers are at greater risk for occupational death as indicated earlier. For example, workers over 65 years of age are more than three times as likely as those in the age range of 18 to 54 years to experience occupational highway transportation fatalities and are twice as likely to die in traffic accidents as those 55 to 64 years of age (Pratt & Rodriguez-Acosta, 2013).

Because of diminished physical capacity, older workers consistently score lower on work ability measures than younger workers, but workplace modifications can improve the workability index for these older employees (Sorenson et al., 2011). In general, older employees tend to have fewer occupational injuries than younger workers, and illness rates are comparable (Wuellner et al., 2011), but older workers typically have more days away from work when illness or injury do occur. For example, the median number of days away from work for nonfatal injuries and illness among workers 65 years of age and older is more than four times that for workers aged 16 to 19 years (12 days and 3 days, respectively) (BLS, 2012b). Older workers are also more likely to experience falls on level surfaces and sustain fractures than younger workers, although they tend to

have lower rates for many other types of injuries (Wuellner et al., 2011).

Another effect of aging as it affects occupational health lies in the effects of shiftwork. After age 45 or 50, people have more difficulty adjusting their sleep–wake cycles to accommodate changes in working hours, leading to fatigue, decreased productivity, and increased risk for accidental injury in hazardous working conditions (Smith, Folkard, Tucker, & Evans, 2011).

In addition to the risk for illness, injury, and death, older workers planning to retire in the near future may need assistance with retirement planning and in dealing with retirement issues (see Chapter 19 for a discussion of these issues). Older workers may also face discrimination in the workplace due to inaccurate perceptions regarding disability, cognitive decline, and diminished ability to learn new skills. Older workers are a definite asset in many businesses and industries experiencing a lack of younger workers to replace those who retire. In addition, older workers often possess experience and skills lacking in younger employees. Many older workers would remain in the work setting if their needs and preferences were accommodated.

Population health nurses working in occupational settings may find themselves advocating for the special needs of both younger and older workers. For example, they may need to encourage employers to arrange schedules to accommodate school schedules for younger employees. Similarly, they may need to advocate for equipment to assist with heavy lifting or other strenuous activities for older workers.

Gender. Gender is another biological determinant that influences the health of the working population. As noted by Ramazzini in his 18th-century treatise on occupational effects on health, women are not spared from adverse effects of occupational conditions (Franco, 2012). In 2010, women made up nearly half (47.2%) of the U.S. workforce (U.S. Census Bureau, 2012b), and in 2011 women accounted for 43% of all the hours worked (BLS, 2013a).

In spite of having less physical strength than men, women tend to have fewer injuries and account for only 8% of workplace fatalities (BLS, 2013a). In part, this is a result of men being employed in generally more hazardous occupations. These figures are likely to change, however, with more women moving into occupational fields traditionally reserved for men (e.g., construction, agriculture, transportation).

Women also face unique hazards in the work setting. For example, women often experience more difficulty in reconciling work and family roles leading to greater work–family conflicts. Some toxic exposures may also have differential effects for men and women, particularly women of childbearing age, and population health nurses may need to monitor the potential for teratogenic exposures (those that can cause damage to a fetus) in the work setting. There may also be a need to assist working women with contraceptive services or to provide prenatal care and monitor pregnancies. Population health nurses may also need to advocate for work modifications to accommodate

pregnancy or to provide opportunities for breast-feeding or pumping breast milk.

Genetic inheritance. Both men and women experience the interaction of genetic inheritance factors with occupational conditions that may lead to illness. Genetic inheritance factors likely to be of greatest importance in the workforce are those related to race and family history of chronic illness. For example, in a largely African American labor force, hypertension may be prevalent. In an Asian population, particularly if large numbers are refugees, communicable diseases such as tuberculosis and parasitic diseases may be common.

Employees may also enter the workforce with a genetic predisposition to a variety of chronic conditions that can interact with occupational environmental risks to cause disease. Population health nurses can identify these genetic risks for chronic health problems and assist employees to engage in risk reduction strategies to prevent illness or to mitigate its effects. For example, workers with a family history of breast or other cancers can be referred for appropriate screening services or assistance with smoking cessation, if needed.

Physiologic function. Elements of physiologic function to be addressed in assessing the health of employees are the extent of injury and illness suffered by the population as well as immunization levels. In 2011, nearly 3 million nonfatal occupational injuries and illnesses occurred in the U.S. private employment sector for an incidence rate of 3.5 events per 100 full-time equivalent (FTE) workers. This represents a decrease in incidence from 5 events per 100 FTE workers from 2003. More than half of the events reported in 2011 required days away from work, job transfer, or restriction of job activities. Most (94.8%) of the events reported involved injuries, three fourths of which occurred in service-providing industries, such as health care, restaurants, and so on, and only one fourth in goods-producing industries. The rate of illness and injury among the additional 18.5 million public workers in federal and state agencies was 5.7 cases per 100 FTE workers, for an overall rate of 20.6 per 10,000 FTE workers (BLS, 2012d).

A total of 4,628 work-related fatalities or 3.4 deaths per 100,000 full-time equivalent workers occurred in 2012 (BLS, 2014), and another 2.9 million injuries were treated in emergency departments, 150,000 resulting in hospitalization (Centers for Disease Control and Prevention [CDC], 2013c). Transportation incidents accounted for 41% of these fatalities; falls, slips, and trips accounted for 15%; being struck by an object or equipment 10%, and other contact with an object or equipment 5%. Mortality rates are higher in some industries than others. For example, the highest rate of fatality occurred in industries related to agriculture, forestry, fishing, hunting (BLS, 2013a), followed by the construction industry (CDC, 2013b). Falls alone accounted for 4,693 fatalities overall and for 35% of deaths in the construction industry (BLS, 2013a; CDC, 2013b, 2013c), and the National Institute for Occupational Safety and Health (NIOSH) has initiated a campaign

to prevent falls and reduce fall-related injuries and fatalities (CDC, 2012a). Similarly, fatality rates for both offshore and onshore oil and gas extraction industries are extremely high at 27.1 per 100,000 workers (Gunter, Hill, O'Connor, Retzer, & Lincoln, 2013).

Mortality figures have decreased by approximately 34% from 6,217 deaths in 1992 to 4,628 in 2012 (Bureau of Labor Statistics, 2014). Estimated societal costs for fatal injuries are \$6 billion per year, with an additional cost of \$186 million for nonfatal injuries (CDC, 2012b). Musculoskeletal injuries alone, which affect more than 1 million workers each year, have an annual cost estimated at \$45 billion to \$54 billion (Sorenson et al., 2011). In 2010, for example, 3.1% of the total U.S. workforce experienced carpal tunnel syndrome, a musculoskeletal condition resulting from repetitive wrist movement or pressure, and its incidence increased with age (National Center for Health Statistics, 2011). Musculoskeletal injuries in general account for one third of time lost from work (Tarawneh et al., 2013). Cost figures, coupled with the costs in mortality, lost productivity, and diminished quality of life for those affected suggest the need for concerted efforts to prevent injuries and injury-related fatalities in the occupational setting. Nursing, for example, has a high prevalence of back injuries. Risks for occupational back pain include overexertion, vibration, and increased body mass index. An increased **work movement index**, or the extent of bending, stooping, twisting, and extended reach involved in a job, is also associated with increased risk of back injury.

Occupational illnesses include acute and chronic conditions that may affect an employee's ability to work as well as his or her quality of life. Population health nurses in occupational settings must be prepared to recognize and deal with the multitude of illnesses and injuries likely to arise from workplace conditions.

Illnesses in employees may be either work-related or non-work-related. Work-related illnesses are acquired as a result of exposure to factors in the work setting. For example, workers in

Repetitive movements can contribute to carpal tunnel syndrome.

(Goran Bogicevic/Fotolia)

the coal mines are exposed to coal dust that may cause a variety of respiratory conditions (Laney, Wolfe, Petsonk, & Halldin, 2012). Similarly, workers exposed to diacetyl, a chemical compound used to flavor popcorn, are at risk for bronchiolitis obliterans, a severe lung condition with long-term consequences (Feldman, 2011).

Between 49,000 and 50,000 U.S. workers die of occupationally acquired illnesses every year (CDC, 2012b; Murray, 2011). Cancers related to occupational exposures are the leading cause of these deaths, and the World Health Organization estimates that 8% to 16% of all cancer deaths worldwide are due to workplace exposures. Occupational risk factors have also been shown to be associated with cardiovascular disease and may account for 15% to 35% of associated mortality (Sorenson et al., 2011). Occupational illness mortality costs the United States approximately \$26 billion per year, and nonfatal conditions account for an additional \$12 billion in annual costs (CDC, 2012b). Skin diseases are the most commonly encountered occupational illness, followed by respiratory conditions, poisoning, and hearing loss (BLS, 2012b).

Obesity, another common chronic condition, also interacts with workplace factors to create problems. For example, obesity has been hypothetically linked to cardiovascular disease, vibration-induced injury, and asthma in employee populations. Similarly, obesity may modify responses to workplace stress by fostering poor eating habits such as use of high-sugar and high-fat foods. The risk of obesity may also be higher in high-demand jobs over which the employee has little control or that require long working hours. Obesity has also been associated with carpal tunnel syndrome and osteoarthritis in work settings (National Institute of Neurological Disorders and Stroke [NINDS], 2012).

The health care industry poses particular risks for occupational illness. Health care professionals are exposed to a wide variety of pathogenic organisms as well as to stress and job strain and workplace violence.

Chronic conditions, whether occupationally acquired or not, may affect employees' ability to work and their productivity while at work. These conditions may also be exacerbated by working conditions. Approximately 90 million people in the United States suffer from some type of chronic illness, and a significant number of them are included in the workforce. One of the *Healthy People 2020* • objectives (objective DH-9) focuses on reducing barriers to work participation among people who are disabled. A related objective (DH-16) focuses on increasing employment among people who are disabled, and a third (AOCBC-6) addresses reducing the effects of arthritis on the working age population. A similar objective (RD-5) addresses the occupational effects of asthma (USDHHS, 2014). Other *Healthy People 2020* objectives specifically related to occupational health and safety are addressed later in this chapter.

Work-related asthma is a growing concern in occupational settings. Millions of Americans have asthma that may be affected by their working conditions. Asthma, whether in oneself or in a family member, particularly a child, is one of the

greatest causes of missed work days. For example, in 2008, 33% of the people who experienced an asthma episode in the prior year had missed work (USDHHS, 2014). Even when workers are not absent due to these conditions, their productivity may be diminished.

Neurotoxic conditions are another concern in occupational health. Some of the conditions encountered include heavy metal poisoning, behavior changes related to chemical exposure, and difficulty concentrating and performing one's job. Specific neurodegenerative disorders, such as presenile dementia, Alzheimer's disease, Parkinson's disease, and motor neuron disease, have also been associated with occupational factors. High prevalence of each of these conditions has been found among teachers, medical personnel, machinists and machine operators, scientists, writers, entertainers, and clerical workers. Selected conditions are also noted with some frequency among workers exposed to pesticides, solvents, and electromagnetic fields.

Noise-induced hearing loss and infectious diseases are other biological considerations in occupational settings. For example, first responders (fire fighters, emergency medical technicians) and health care personnel are at increased risk of bloodborne diseases, whereas employees in manufacturing, construction, and other high-noise occupations are at greater risk for hearing loss.

With respect to dermatologic conditions arising from occupational factors, occupational health nurses are again in a position to assess the health status of employees. As with other types of health problems, the nurse should be aware of outbreaks of dermatologic conditions that indicate the presence of hazards in the environment and a need for control measures. Conditions encountered include a variety of rashes, pruritus, chemical burns, and desquamation.

Occupational injuries and illnesses do not occur only among people who work for pay. Volunteer workers are also subject to occupational risks. An estimated 64.5 million

people in the United States volunteered a median of 50 hours per person in 2012. This amounts to 26.5% of the U.S. population over 16 years of age (BLS, 2012c). Australia has developed guidelines to protect the health and safety of volunteer workers. The guidelines include a checklist that volunteer workers or nurses can use to assess the safety of their working conditions (Safe Work Australia, n.d.). For further information about the guidelines, see the *External Resources* section of the student resources site. Similarly, the Ontario Ministry of Labour (2013) has developed information for youth completing volunteer hours for high school graduation. In the United States, some states, such as California, have created programs to provide workers compensation benefits for registered disaster volunteer workers (California Governor's Office of Emergency Services, 2012). Population health nurses, armed with knowledge of injury risks and rates among both employed and volunteer workers, can advocate for safer work environments. They can also educate both employees and volunteers to minimize injury risks.

The extent and type of disability among members of the working population is another biological determinant of health and related health care needs.

Immunization is the final physiologic consideration in assessing health needs in the workplace. The nurse assesses the immunization status of employees, with special emphasis on groups of employees who may be at increased risk for certain diseases preventable by immunization. For example, employees who may be at risk for dirty injuries should be assessed for immunity to tetanus, whereas women of childbearing age should be assessed for immunity to rubella. Health care workers, on the other hand, should be particularly assessed for immunity to hepatitis B, influenza, and other infectious diseases to which they may be exposed. Elements to be considered in an assessment of biological determinants influencing health in the work setting are included in the *Focused Assessment* questions provided below.

FOCUSED ASSESSMENT

Assessing Biological Determinants Influencing Health in the Work Setting

- What are the age, gender, and ethnic composition of the employee population? What effects do these factors have on health in the work setting?
 - What is the extent of injury in the population? What types of injuries occur? What factors contribute to injuries in the employee population?
 - What occupation-related illnesses are common in the population?
 - What other illnesses are experienced by the employee population? What is the level of disability in the population?
- What types of occupational limitations are caused by disability?
- What is the effect of chronic illness or disability on the ability of employees to function effectively in the work setting? Do employees have preexisting health conditions that put them at greater risk for the toxic effects of workplace exposures?
 - What are the immunization levels in the employee population?

PSYCHOLOGICAL DETERMINANTS. Assessment of psychological considerations in the work setting involves examination of two major areas: the work climate as it affects health and the presence of mental illness in the workplace.

Workplace climate. Work climate includes the totality of factors in the psychological environment of the work setting. Some major considerations with respect to work climate include job security or insecurity, job strain, and social support. The increasing need for businesses to respond flexibly to market demands has led to greater use of part-time, temporary workers, or contract workers that allows companies to adjust the workforce to meet demands. The need for flexibility results in companies retaining only a small cadre of full-time employees. Part-time and temporary or contract workers are thus faced with increasing job insecurity in which they may be employed today, but out of work tomorrow. Reliance on a large group of part-time or temporary workers also places greater strain on full-time employees who must shoulder the tasks involved in the day-to-day running of the operation. All of this results, not only in an increased work pace, but has been shown to increase conflict and negative relationships within the workplace as employees compete for hours and even possibly for continued employment (Lundberg & Cooper, 2011).

Other elements that contribute to a poor work climate include long hours, shift work, employer surveillance, and sanctions or incentives. Perceptions of organizational injustice also foster an adverse work environment (Sorenson et al., 2011).

Organizational justice refers to perceptions of fair treatment in the organizational setting. Perceived workplace discrimination, particularly among ethnic minority or immigrant workers, is an example of workplace injustice that has negative health effects. Low perceived organizational justice may give rise to negative emotional reactions to perceptions of unfair treatment.

Job strain is a situation that occurs when one's ability to control one's job is low and job demands are high (Smith & Bielecky, 2012). **Job demands** are the elements of a job that require physical or mental effort (Demir & Rodwell, 2012). The adverse effects of high job demands can be offset by **job control**, or the extent of autonomy one has in decisions regarding how and when one's job will be performed (Demir & Rodwell, 2012). The extent of an employee's social support within the work setting (e.g., from coworkers or supervisors) or from family and friends outside of work can help offset the effects of job strain.

A second model relating psychological factors in the work setting to employee health is the effort–reward imbalance (ERI) model. In this model, the amount of effort expended in one's work is perceived to outweigh the rewards gained (Stansfeld, Shipley, Head, & Fuhrer, 2012). Rewards are not always monetary, but may include psychological rewards, such as personal satisfaction in a job well done, or social rewards, such as recognition for one's efforts or contributions.

Another area in which employees may have minimal control is what is referred to as “emotional labor.” **Emotional labor** has been defined as management of one's feelings to conform to organizational expectations (Wharton, 2009). An example of emotional labor in nursing is not allowing the anger caused by a cantankerous patient's verbal insults to show in your face or to affect the quality of care given. In the retail world, emotional labor is exemplified by the old adage, “The customer is always right.” Emotional labor occurs in the context of service occupations when the employee cannot afford to display his or her true emotions for fear of alienating a client or customer. Jobs that require emotional labor are characterized by contact with the public, the necessity for producing a favorable emotional state in the customer, and the opportunity for employers to control the emotional activities of their employees.

Some employers purposefully foster employees' control over facets of their jobs. A 2008 study by the U.S. Census Bureau (2012a) addressed the percentage of responding employers that engaged in specific practices to promote job control. The most frequently reported practice was giving leave to employees who provide care to newborn biological or adopted children and allowing them to gradually return to work (57% of employers surveyed), followed by policies allowing employees to determine when to take a break (55%), permitting career breaks for caregiving or other personal or family reasons (47%), allowing personal or family time off without pay (45%), and using paid or unpaid time for education or job training (40%). Other less frequently noted strategies to promote job control included being able to change starting and quitting times, working from home, control over the shift worked, control over paid and unpaid overtime hours, movement from full-time to part-time employment and back, job sharing, working part of the year, personal or family time off without loss of pay, compensatory time off, the ability to do volunteer service during work time, phased retirement options, and sabbatical leaves.

Poor work climate and job strain have been associated with a variety of negative health effects. For example, work stress has been associated with obesity, alcohol use, lack of exercise, anxiety, and burnout (Sorenson et al., 2011). These factors are believed to account for the frequent association between job strain and cardiovascular disease (Nyberg, et al., 2013). Among nurses, burnout due to work stress has been linked to hospital-acquired urinary tract infections in patients (Cimiotti, Aiken, Sloane, & Wu, 2012). Work stress and job strain have also been associated with depression (Sorenson et al., 2011; Stansfeld et al., 2012).

Because of the position of trust that occupational health nurses usually have with employees, they may be among the first to recognize symptoms of stress in individual employees or the work group. With this knowledge, nurses can explore the sources of stress and advocate for improvements in working conditions. Even when the stress might be the result of misperceptions among employees (e.g., rumors that massive layoffs will take place or that the company is being sold), the

effects on employee health and work ability can be significant. Population health nurses can help to identify these sources of stress and motivate employers to make changes to reduce stress levels.

Mental health and illness in the workplace. Population health nurses are also in a position to identify employees with mental health problems or to recognize a high prevalence of these problems in the workforce. The sources of workplace stress discussed above may contribute to the development of actual psychiatric diagnoses, or employees may enter the workforce with one or more psychiatric illnesses. Depression, in particular, is a growing problem in the work setting and is the chronic illness most likely to lead to work absences in the United States (Okechukwu, Ayadi, Tamers, Sabbath, & Berkman, 2012). Similarly, in Europe, the Organisation for Economic Cooperation and Development (OECD, 2011) has estimated that 20% of the working population in OECD countries has a clinical mental disorder and that the lifetime prevalence may approach 50%.

Mental illness can be differentiated between mild or moderate illness, frequently referred to as common mental disorders (CMDs), and severe mental disorders (SMDs). CMDs include mood disorders, such as depression, neurotic disorders, such as anxiety, and substance abuse disorders. Without treatment, all of these disorders can evolve into SMDs (OECD, 2011). A variety of stresses contribute to depression in the work setting. For example, lack of job control or job security, job-related conflict, high physical demands or physically uncomfortable work, and hazardous work environments have all been linked to employee depression.

CMDs are generally less debilitating than SMDs, but still have considerable consequences for quality of life and work abilities (OECD, 2011). Changes in job demands in a changing society, such as higher demands for social skills and cognitive competencies, can make it difficult for people with mental illnesses to function effectively in the work setting. In addition, people with mental health problems encounter stigma and fears among coworkers and supervisors.

Depression leads to a number of health-related consequences. For example, depression is a major risk factor for heart disease, high cholesterol, and elevated blood pressure, and depressed employees contribute to health care costs roughly twice those of nondepressed employees. A significant proportion of people with major depression commit suicide. Depression also affects the morale and productivity of coworkers, and the cost to society has been conservatively estimated at 3% to 4% of the gross domestic product of entities like the European Union (OECD, 2011).

There is a need to intervene early in the trajectory of mental illness. Unfortunately, few worksites have programs to address mental illness in employees. Because of the lack of attention to this problem, only a small fraction of people receive the care needed.

Population health nurses are strategically placed to identify employees with both common and severe mental disorders but should keep in mind several legal parameters related to psychiatric illness in the work setting. For example, employers are not permitted to ask about psychiatric illness in hiring decisions, and employees are not required to disclose such diagnoses unless they are requesting accommodations. Employers are also required by the Americans with Disabilities Act to make reasonable accommodations for employees with psychiatric disorders, particularly depression. Population health nurses working with employees with mental health problems may need to ensure access to needed treatment and advocate for accommodations in the work setting. They may also be involved in coordinating care, evaluating the functional ability of employees, and monitoring their use of psychotropic medications.

In assessing psychological determinants influencing the health of clients in work settings, population health nurses identify psychological health problems prevalent in the population and assess factors contributing to those problems. The nurse can assess individual clients or the work group for the following indicators of psychological health problems:

- Increased absenteeism (especially on Mondays, Fridays, and the day after payday)
- Mood changes or changes in relationships with others (especially with health care providers)
- Increased incidence of minor accidents on and off the job
- Complaints of fatigue, weakness, or a general decrease in energy
- Sudden weight loss or gain
- Increased blood pressure
- Frequent stress-related illnesses
- Bloodshot or bleary eyes
- Facial petechiae (especially over the nose)

The *Focused Assessment* on the next page provides guidelines for assessing psychological determinants affecting the health status of the working population.

ENVIRONMENTAL DETERMINANTS. Physical environmental factors contribute to a variety of health problems encountered in work settings. In 2011, for example, 9% of workplace fatalities resulted from environmental conditions and exposures (BLS, 2013a). Categories of health hazards in the physical environment include chemical hazards, physical hazards (radiation, noise, vibration, and exposure to heat and cold), electrical and magnetic field hazards, fire, heavy lifting and uncomfortable working positions, and potential for falls. Additional hazards that may be present in the workplace include exposure to metallic compounds and allergens and molds.

Poor lighting and high noise levels may adversely affect vision and hearing, respectively. In addition, exposure to artificial light during the hours when melatonin production is affected has been linked to incidence of a variety of health

FOCUSED ASSESSMENT

Assessing Psychological Determinants Influencing Health in the Work Setting

- To what extent does the work environment contribute to stress? What are the sources of stress in the work environment?
- How do employees cope with stress in the work environment?
- What is the extent of job security or insecurity experienced by members of the workforce?
- Does the work setting require emotional labor? How do employees in the setting approach emotional labor?
- What is the extent of job strain experienced in the work setting? What are the sources of job strain? What measures, if any, does the organization employ to increase job control and minimize job strain?
- To what extent is social support available within and outside of the work setting?
- What is the prevalence of mental illness among employees? What types of mental disorders are present in the workforce? What are the attitudes toward employees with mental health disorders in the work setting? How does the presence of mental illness affect employees' ability to work?

problems that will be addressed in more detail later in the discussion of shiftwork.

Each year, millions of workers are exposed to excessive noise levels, and noise-induced hearing loss is one of the most common occupational health problems in the United States. High noise levels are a particularly significant occupational hazard among members of the military, and military veterans are approximately 30% more likely to experience severe hearing impairment than nonveterans. Among recent veterans of Operation Enduring Freedom and Operation Iraqi Freedom, hearing loss is more than four times more common than for members of the civilian population of similar ages (Greenwald, Tak, & Masterson, 2011). Heavy objects that must be moved or repetitive motion in job tasks may result in musculoskeletal injuries (NINDS, 2012). Awkward work postures, vibration, and temperature are other environmental factors that may contribute to musculoskeletal disorders (Sorenson et al., 2011). In addition, there is a high risk for falls or exposure to excessive heat or cold in many workplaces. All of these physical environmental factors contribute to the risk of occupational injury and illness.

The use of toxic substances in work performance is another source of possible health problems related to the physical environment. Toxic substances may be encountered as solids, liquids, gases, vapors, dust, fumes, fibers, or mists. For example, workers in nail salons experience chronic exposure to a variety of toxic chemicals used in personal care products, for which there is little regulation. Approximately, 90% of more than 10,000 chemicals used in cosmetics have not been tested for safety (Quach et al., 2011). Similarly, the relationship between exposure to soot and scrotal cancer among chimney sweeps has been known since the late 1700s, but chimney soot is now being linked to ischemic heart disease, nonmalignant respiratory diseases, alcoholism, liver disease, and a variety of other cancers in this occupational group (Hogstedt, Jansson, Hugosson,

Tinnerberg, & Gustavsson, 2013). Pneumoconiosis and other advanced lung diseases can result from long-term exposure to coal dust (Laney et al., 2012).

Produce inspectors working in enclosed areas have been exposed to high concentrations of pesticides used as fumigants to protect stored produce from infestations (O'Malley et al., 2011), and lab workers, animal caretakers, and health care personnel are also at risk for toxic exposures. For example, a university researcher was infected with *Yersinia pestis*, the causative organism for plague, through contact with an attenuated strain (Ritger et al., 2011). Similarly, a phlebotomist was infected with salmonella in drawing lab samples (Smith et al., 2013). As another example, four veterinary personnel were poisoned by phosphine gas after working on dogs that had ingested a pesticide that interacts with stomach acid to produce the toxic gas (Schwartz, Walker, Sievert, Calvert, & Tsai, 2012).

Employees may need protective clothing to prevent toxic exposures. (Inzyx/Fotolia)

Health care personnel not only experience exposures to hazardous chemicals (e.g. anesthetists in surgery), but are also exposed to infectious materials from bodily substances, contaminated medical supplies and equipment, contaminated surfaces, or contaminated air (Shefer et al., 2011). In another instance of unanticipated exposure, 23 workers at a metal recycling plant became ill after exposure to chlorine gas from a ruptured salvage tank believed to be empty (Kelsey et al., 2011). Similarly, use of methylene chloride to strip paint from old bathtubs led to cases of fatal poisoning; such results have also been experienced by furniture strippers and other industries that use this chemical (Chester, Rosenman, Grimes, Fagan, & Castillo, 2012). In addition to the potential for exposure to diacetyl in the production of popcorn addressed earlier, bronchiolitis obliterans has been diagnosed on workers exposed to the chemical in coffee flavoring processes (Huff et al., 2013). Finally, workplace exposure to tobacco smoke has been linked to a variety of health problems even among nonsmokers (American Lung Association, 2014). As can be seen in the variety of examples presented here, the work environment can result in exposure to a wide array of conditions hazardous to employees' health.

Population health nurses in occupational settings engage in **hazard analysis**, or an assessment of the vulnerability of workers to workplace contaminants, the probability of exposure, and the severity of potential consequences (AAOHN, 2012e). In addition, they would monitor the frequency of exposures as well as their health effects and provide care to address the results of exposure.

Areas to be assessed relative to the potential for toxic exposures in the workplace include substances used in the setting and their level of demonstrated toxicity, portals of entry into the human body, established legal exposure limits, extent of exposure, potential for interactive exposures, and the presence of existing employee health conditions that put the individuals affected at greater risk for exposure-related illnesses. The nurse and other personnel would also assess the extent and adequacy of controls to prevent or limit exposures and the availability of and compliance with recommended screening and surveillance procedures.

For some people, seemingly innocuous substances may have toxic effects. For example, health care providers may be allergic to the latex gloves used in many settings. Similarly, the presence of food allergens in meals prepared in the work setting can have severe consequences for those with allergies. Population health nurses can be alert to the presence of people with specific allergies in the work setting and assist the company to eliminate the most common allergens. For example, the nurse might work with staff in an employee dining room to eliminate recipes that use peanuts or peanut oil. Similarly, the nurse can advocate for the use of nonlatex gloves in health care settings and other workplaces where gloves are used (e.g., by hotel cleaning staff members).

Equipment may also constitute an occupational health hazard. The use of heavy equipment or sharp tools can result in injury. There is also the potential for hand–arm vibration

syndrome in the use of tools that vibrate or visual disturbance related to the use of computer display terminals. Another relatively recent physical hazard generated by widespread computer use is the potential for tendonitis and other similar conditions. The nurse in the occupational setting identifies the presence of any hazards in the physical environment that contribute to health problems. In addition, the nurse monitors the status of known hazards and their effects on the health of employees. The presence of modifiable hazards should lead to advocacy on the part of the nurse to change the physical work environment to eliminate or reduce the potential for exposure to these hazards. Some potential questions for evaluating hazardous conditions in work settings are included in the *Focused Assessment* presented on the next page.

SOCIOCULTURAL DETERMINANTS. The social environment of the work setting can influence employee health status either positively or negatively. The quality of social interactions among employees, attitudes toward work and health, and the presence or absence of racial or other tensions can all affect health status as well as employee productivity.

Assessment of sociocultural considerations affecting health in work settings focuses on five major areas. These include the effects of policy and legislation, the interactive effects of work and family life, the type of work done, immigration, and workplace aggression.

Policy and legislation. In the United States, health-related policy and legislation have a significant impact on the workforce. The three most influential pieces of legislation are the Occupational Safety and Health Act of 1970 (OSH Act), workers' compensation, and the Americans with Disabilities Act. Other state, local, and business-specific policies and regulations also affect the health of employees. The Occupational Safety and Health Act established the **Occupational Safety and Health Administration (OSHA)**, the federal agency charged

A variety of injuries may occur as a result of heavy equipment operation. (dima266f/Fotolia)

FOCUSED ASSESSMENT**Assessing Environmental Determinants
Influencing Health in the Work Setting**

- Does the physical environment of the work setting pose any health hazards?
- What potentially hazardous substances or conditions are associated with production processes (e.g., toxic chemicals, heat)?
- What potentially hazardous substances or conditions are associated with clerical processes (e.g., repetitive movements)? With other office processes (e.g., cleaning products, pesticides)?
- What is the typical extent and duration of exposure to hazardous substances or conditions?
- What are the designated exposure limits for substances and conditions in the work setting?
- What research evidence is there for adverse human health effects (e.g., toxicity, teratogenicity, potential for injury) associated with substances used or conditions existing in the work setting?
- Do low levels of exposure have a cumulative effect?
- What is the usual portal of entry or mechanism of exposure for a specific toxic agent or condition?
- What organ systems are typically affected by specific toxic agents or hazardous conditions?
- What are the usual signs and symptoms of toxicity/health effects?
- Are there synergistic effects among substances or between substances and other conditions (e.g., heat) or health-related behaviors (e.g., smoking)?
- What are the recommended control practices to prevent or minimize potential for exposure?
- Are the recommended practices in place in a given occupational setting (e.g., ventilation, other engineering controls)?
- What are the recommended surveillance practices for monitoring environmental conditions and hazardous exposures? Are there surveillance systems in place for monitoring the presence or extent of hazardous conditions in the environment?
- Are food sanitation practices adequate to prevent communicable diseases, vermin infestation, and so on?
- Are there adequate facilities for handicapped employees?
- Are workstations designed to prevent injury and fatigue?
- Is there potential for a disaster in the work setting? Is there a disaster plan in place?

with protecting the health and welfare of the U.S. private-sector workforce. OSHA was intended to develop and enforce safety standards in work settings to protect U.S. workers from harm (OSHA, 2011). In addition, the legislation established the National Institute for Occupational Safety and Health (NIOSH) to conduct occupational research and make recommendations for safeguarding employee health (NIOSH, 2013a).

OSHA covers all private-sector employees except those who are self-employed, family members employed on farms that do not employ outside workers, and workers who are covered under other regulatory agencies (e.g., the Nuclear Regulatory Commission). Members of the military forces are also outside the jurisdiction of OSHA. State and local government employees are also not covered by the federal agency, but are protected if their state has an OSHA-approved state program. Most state occupational and safety plans cover both private- and public-sector employees. OSHA also monitors federal agencies, but these agencies are regulated under requirements that they meet the same employee protections as required by OSHA of private-sector employers (OSHA, n.d.c). Table 23-1 • presents the OSHA-mandated employee rights and employer responsibilities related to occupational safety and health.

OSHA is charged with performing periodic inspections of worksites to determine whether standards are being enforced.

Inspections may be conducted on a routine basis or may be triggered by certain specific events such as an employee death, hospitalization of three or more employees for work-related occurrences, employee complaints, or referrals from the media or other individuals. Inspections may also be conducted in the event of an imminent danger situation (e.g., possible rupture of a holding tank for hazardous materials). Unfortunately, the number and frequency of OSHA inspections and penalties for violation of standards have been steadily decreasing. In addition, OSHA has been criticized for the excessive length of time required to develop new exposure standards for hazardous substances, which may take as long as 5 to 10 years from proposal to enactment and in one case took 31 years. Finally, the Congressional Review Act of 1996 allows congress to overturn any federal agency's regulations, but to date only the ergonomics standards promulgated by OSHA in 2001 have ever received a congressional veto. In addition, executive orders have permitted the President of the United States to interfere in occupational safety regulations usually through the Office of Management and Budget, which has no related scientific or health care expertise (Feldman, 2011). Most often, such interference has come as a result of pressure from major employer organizations and lobbying groups.

TABLE 23-1 Employee Rights and Employer Responsibilities Under OSHA

Employees Have the Right to:	Employers Must:
Working conditions that do not pose a risk for harm	Follow all relevant OSHA safety and health standards
Receive information and training, in a language they can understand, about chemical and other hazards, measures to prevent harm, and OSHA standards that apply to their workplace	Find and correct safety and health hazards
Review records of work-related injuries and illnesses	Inform employees about chemical hazards through training, labels, alarms, color-coded systems, chemical information sheets, and other methods
Get copies of test results done to find and measure hazards in the workplace	Notify OSHA within 8 hours of a workplace fatality or when three or more employees are hospitalized
File a complaint with OSHA asking for an inspection of their workplace if they believe there is a serious hazard or their employer is not following OSHA rules	Provide required personal protective equipment at no cost to employees
Use their rights under the law without retaliation or discrimination and file complaints with OSHA if retaliation or discrimination occurs	Keep accurate records of work-related injuries and illnesses
	Post OSHA citations, injury, and illness summary data, and the OSHA “Job Safety and Health—It’s the Law” poster in the workplace where workers will see them
	Not discriminate or retaliate against any worker for using their rights under the law

In spite of these failings, OSHA regulations have been credited with saving the lives of more than 410,000 U.S. workers and preventing countless injuries and illnesses. Recommendations for shoring up the agency’s performance include increasing fines for violation of standards to meaningful levels, increasing the capacity of the agency to conduct inspections as mandated in its charge, enacting criminal as well as monetary penalties for failing to safeguard employee health, and basing regulation on updated scientific findings (Murray, 2011). Additional recommendations include expanding coverage to currently unprotected groups and changing the federal regulations so they also cover farm children working on family farms.

Population health nurses working in occupational settings may occasionally find themselves in the position of needing to report OSHA violations in order to protect employee health and safety. In addition, they may need to become politically active to advocate for federal and state enforcement of health and safety regulations.

Workers’ compensation legislation is designed to provide for the needs of workers injured or made ill at work and their families. At the federal level, workers’ compensation addresses wage replacement benefits, medical treatment, vocational rehabilitation, and some other benefits for federal employees. Other specific groups are also covered under federal legislation and include energy workers with occupational illnesses, longshore and harbor workers, and those who suffer from black lung disease, primarily as a result of mining (U.S. Department of Labor, n.d.b). Nonfederal employees may receive workers’ compensation benefits under state legislation, but coverage varies from

state to state. The National Conference of State Legislatures (2013) provides an annual update on worker’s compensation legislation in specific states. For further information about the report, see the *External Resources* section of the student resources site.

Prior to the establishment of the workers’ compensation system, employees were required to prove employer responsibility for an illness or injury before they could claim recompense for lost wages or the cost of medical care. Workers’ compensation provides protection for both employee and employer. Under the program, employees are guaranteed wage replacement and medical care costs if they are injured on the job. The system also protects employers from lawsuits by employees to recover lost wages or health care costs. Occupational health nurses are often responsible for tracking and administering workers’ compensation for injured employees. They may also need to assist employees to obtain workers’ compensation benefits.

The third piece of legislation that affects the workplace is the Americans with Disabilities Act (ADA). The implications of the act for the school setting were discussed in Chapter 22 and are similar for occupational settings. ADA was designed to ensure equitable occupational opportunity for those with disabilities (U.S. Department of Justice, n.d.). Under the law, employers are not required to give preferential treatment to disabled job applicants or employees, but are expected to give them the same opportunities for employment or advancement as those without disabilities. Employers are required to provide **reasonable accommodations**, or “modification or adjustment to a job or the work environment that will enable a

qualified applicant or employee with a disability to participate in the application process or to perform essential job functions” (Job Accommodation Network, n.d., para. 9). A reasonable accommodation is one that does not impose an undue burden on the employer (Rutkow, Vernick, Tung, & Cohen, 2013). The legislation does not define what constitutes a disability that is covered under the law, but consultants at the Office of Disability Employment Policy’s Job Accommodation Network can assist employers with determining whether or not a specific condition in a particular individual employee constitutes a disability that requires reasonable accommodation (JAN, n.d.).

Similar legislative efforts have been undertaken internationally. For example, the United Nations (2006) “Convention on the Rights of Persons with Disabilities” includes the right to employment for individuals with disabilities. According to the convention, adopting nations recognize the right of all individuals, including those with disabilities to gainful employment in open, inclusive, and accessible work environments (Article 27). Most nations throughout the world, including the United States, have adopted the convention (United Nations, 2013).

On occasion, ADA provisions may be in conflict with OSHA regulations designed to limit risks to which employees are exposed. Recent Supreme Court rulings have favored the right of employers to prevent people from working when a particular job would place the person him- or herself at risk due to limitations imposed by a disability. These rulings run contrary to prior decisions that only possible danger to others justified employer decisions not to employ someone in a particular capacity. Population health nurses may need to advocate for disabled workers when such decisions are made in the workplace. They may also assist applicants or employees with disabilities in requesting accommodations. Nurses, employers, and employees can find additional information and assistance with accommodations on the Job Accommodation Network website. For further information about the report, see the *External Resources* section of the student resources site.

State and local laws and policies within specific business organizations have also been found to influence health and safety. For example, by the end of 2010, 26 states and the District of Columbia had smoke-free laws that covered indoor areas of work, restaurants, and bars. An additional 19 states had laws prohibiting smoking in one or two of the three areas. Interestingly, no southern state had enacted any smoke-free legislation, but many communities in the south had local laws prohibiting smoking. Such laws have been shown to reduce nonsmokers’ exposure to second-hand smoke, promote smoking cessation among smokers, and change norms related to the acceptability of smoking in public. In addition, they have contributed to reduced incidence of heart attack and asthma hospitalizations in the general public and the workforce (Tyman, Babb, MacNeil, & Griffin, 2011).

Other legislation and policies may also affect health, either positively or negatively. For example, policies that

permit breast-feeding of infants or breast pumping are helpful for both mothers and infants. On the other hand, the absence of sick leave policies encourage employees to come to work when ill, jeopardizing their health and that of coworkers.

The work–family interface. Although employees spend considerable time in the work setting, they do have lives outside of work. Interrelationships between work and family may support or impede employee and/or family health. The work–family interface for any given employee may be one of balance or conflict. Balance may be viewed from a variety of perspectives: as the absence of conflict between roles, as full engagement in all roles, as high levels of satisfaction across roles, and as congruence with the relative value attached to multiple roles. Given these multiple perspectives, **work–family balance** can be defined as the extent to which one’s work and family roles are balanced and are congruent with one’s life values (Greenhaus & Allen, 2011).

Positive effects result from work–life balance. These may include positive spill-over, enrichment, and facilitation (Greenhaus & Allen, 2011). Spill-over involves the transfer of positive feelings, skills, behaviors, and values from one domain to the other. For example, effective interpersonal communication skills demonstrated at work may improve interpersonal interactions in the family. Enrichment relates to the extent to which experiences in one role improve the quality of life or performance in the other. For example, social support from coworkers may help an employee get through a difficult family situation. In facilitation, involvement in one domain contributes to enhanced function in another domain. Engagement in multiple roles may foster enhanced efficiency or improved delegation skills in each. For example, nursing students who are married, have children, and work, as well as going to school, are often better organized than those who are single and not working while in school.

Work–family conflict, on the other hand, is role interference that occurs when work and family roles are incompatible with each other and the resulting conflict makes effective execution of one or both roles difficult (Greenhaus & Allen, 2011). Such conflicts may be time-based, in which work and family roles compete for the limited time available, strain-based, in which strain in one role affects performance in the other, or behavior-based, in which the behaviors required in one role are incompatible with those required in the other (Slan-Jerusalem & Chen, 2009).

Work–family conflict or interference may be bidirectional. Family roles may interfere with work performance when a parent is distracted at work because he or she has a sick child at home. This situation is often referred to as FIW or family interference with work. Conversely, work responsibilities may interfere with family roles (WIF). For example, a mandatory meeting at work may conflict with a celebration of a couple’s anniversary. Because of the expanding use of technology in work realms, many employees have what are virtually 24/7

responsibilities leading to greater interference with family life (Sorenson et al., 2011).

Women are more often affected by FIW than men, but both have multiple negative effects for the individuals involved. WIF frequently leads to job dissatisfaction, intentions to leave the job, overload, work distress, and difficult relationships within the family. FIW more often results in family and marital dissatisfaction, parental overload, family distress, and poor work performance. Work–family interference has also been shown to affect employees’ overall physical and psychological well-being and health-related behaviors such as alcohol use and smoking (Nelson, Li, Sorenson, & Berkman, 2012). Work–family conflict in either direction also has implications for the employing organization in the form of reduced job and career satisfaction and turnover, reduced employee morale, lower productivity, and increased absenteeism (Slan- Jerusalem & Chen, 2009).

A final aspect of the relationship between work and family relates to paraoccupational exposure to hazardous substances. **Paraoccupational exposure** occurs when family members or others outside the work setting are exposed to hazardous substances transferred from the work setting by an employee. These exposures may involve metals, chemicals, or biological agents. For example, paraoccupational exposure to lead frequently occurs via contaminated clothing. Health care workers, on the other hand, may expose their families to infectious disease agents. Occupational health nurses can be particularly influential in teaching employees how to minimize paraoccupational exposures and in advocating employment policies that minimize the potential for exposure (e.g., through providing protective clothing and changing areas for employees working with hazardous materials). They may also assist employees in dealing with work–family conflicts or advocate working conditions and policies that minimize conflict and promote balance.

Type of work. The type of work performed and specific job demands are other sociocultural factors influencing the health of the working population. For example, agricultural work is one of the most dangerous occupations, with an overall mortality rate seven times higher than that of all other workers in the United States (Marucci-Wellman et al., 2011). Employees’ socioeconomic position may influence the type of work performed and thus their level of exposure to hazardous job conditions. Socioeconomic position has also been shown to interact with work stressors to have differential effects on health. For example, people in blue-collar positions who experience job strain have been found to have a greater risk of hypertension and heart attack than white-collar workers, possibly due to the relative lack of options for dealing with stress. In addition, employees of lower socioeconomic status tend to receive less in the way of health promotion services than those of higher status (Sorenson et al., 2011).

Increased job demands and competition for jobs in today’s society lead to a faster work pace and more stressful

Global Perspectives

Transitioning from an Agricultural Economy to an Industrial Economy

Approximately one third of the world’s workforce is employed in agriculture-related occupations, compared to only 10% of the workforce in developed nations (Marucci-Wellman et al., 2011). Many formerly third-world countries, however, are moving rapidly from an agricultural to an industrial economy. As such changes occur, many workers will move from agricultural employment to higher paying jobs in the industrial sector. Many others will combine work in both sectors. Continued agricultural work may be used to supplement income from work in industry. Both movements toward a new occupational sector and combined employment in both sectors pose unique new risks.

In one rural Vietnamese commune for example, nearly half of the workforce continues to work part-time in agriculture, while working full- or part-time in industry. A study by Marucci-Wellman and colleagues (2011) found occupational injury rates for those working fewer than 500 hours per year in the agricultural sector and as much as full-time (2,000 hours/year) in industry four times higher than rates for the overall workforce and persons working only in the industrial sector. These findings held true for both men and women working in dual sectors, but were more pronounced for men who work at more dangerous jobs in both sectors.

Fatigue from working two jobs might be one explanation of the higher injury rates. An alternative explanation might be inexperience in one sector or the other (Marucci-Wellman et al., 2011). The study’s findings suggest that workers employed in both agricultural and industrial sectors may need to be particularly targeted for injury prevention programs. The findings also highlight the need to consider the health effects of major occupational shifts in society and the effects of employment in multiple jobs.

working conditions. In manufacturing areas, higher productivity demands may increase the risk of injury if short cuts are taken. As noted earlier, the use of technology in the workplace makes possible work in different locations and at different times, possibly leading to increased expectations for responses even during one’s off time leading to a 24-hour, 7-days a week schedule that interferes with family interactions, leisure, and rest. In addition, the option of telework from home may increase the workload for those who stay in traditional worksites who have the added burden of dealing with the daily needs of the organization as well as meeting the needs of telecommuters (Lundberg & Cooper, 2011).

Some authors have noted a “global trend toward a 24-hour society” (Smith et al., 2011, p. 189). This trend has led to an increase in the proportion of the workforce that works nonstandard hours and may result in irregular schedules or in shiftwork. Shiftwork has been shown to result in a variety of health effects. For example, there is a strong association

between shiftwork and coronary heart disease. Shiftwork also interferes with normal circadian rhythms and sleep-wake cycles, with about 10% of shiftworkers experiencing shift work sleep disorder leading to poor sleep, chronic fatigue, anxiety, nervousness, and depression. Frequent association with gastrointestinal disorders and interference with female reproductive cycles have also been found. The fatigue and other effects caused by shiftwork may lead to errors and injury, particularly at night; however, data are difficult to interpret, since the intensity of work and potential for high stress events may vary from shift to shift (Smith et al., 2011). Finally, an expert group within the International Agency for Research on Cancer has concluded that the disruption of circadian rhythms involved in shift work may very well be carcinogenic (Smith et al., 2011).

Population health nurses most probably will not be able to change the operating hours of a business or industry, but they can be alert to the health effects of shiftwork on specific employees and assist them to minimize the effects (e.g., by promoting good sleep hygiene) or advocate for a change in shifts. They can also advocate for shift changes that minimize disruption of circadian rhythms, such as rotation from evening to night shift rather than the reverse (Luckhaupt, 2012). In addition, they should be familiar with the types of work performed in a given occupational setting and the potential effects on the health of employees.

Immigration and work. Immigration is one of three factors that influence the size of the U.S. workforce, the other two factors being fertility and birth rates and mortality in the working age population. Immigration may stem from efforts to escape adverse conditions in one's homeland or the desire for greater opportunity, particularly employment opportunities. Immigration contributes to both growth in the overall workforce and to diversity within the working population. Based on projections from the U.S. Census Bureau, immigration is expected to add 1.4 million people to the workforce each year through 2020, a significant increase over 2004 projections (Toosi, 2012).

Because of their typically low socioeconomic status and frequent lack of highly employable skills, many immigrants are forced into low-paying hazardous occupations. Educated immigrants may also encounter difficulties in obtaining employment in their own fields. For example, nurses educated in other countries may need to take jobs as nursing assistants until they can meet the licensing requirements for a specific state. Similar educational and licensing difficulties might be experienced by other immigrating professionals, such as physicians, lawyers, and teachers.

Among the 2.5 million farm workers in the United States, 78% are immigrants who often move around the country as agricultural labor demands wax and wane. Migrant farm workers may come to the United States alone or may be accompanied by their families. Approximately 20% of them live in employer-provided housing or camps that lack basic

amenities. In addition, they often live at a distance from health care and social services or do not have adequate time to address health care needs. Working conditions may also be substandard, and they frequently do not receive federally mandated safety training specific to the hazards of their jobs. In addition, farmworkers do not have the same right-to-know protections as other employees covered by OSHA regulations regarding communication about hazards in the work setting and their potential health effects (Farmworker Justice, 2014).

These conditions are compounded for a growing number of indigenous workers, native peoples of Mexico and other Central and South American countries who are not Latino. These workers tend to be discriminated against by both the U.S.-born farm workers and other migrant workers. Their language and cultures differ significantly from Latino workers and any safety training they may receive may be in English or Spanish, limiting their ability to understand it. Population health nurses should be alert to the presence of immigrant workers in specific work settings as well as the cultural and language barriers they experience in adapting to life and work in the United States. They may need to provide referrals for assistance for individual employees, modify safety and other health-related education to meet their needs, or advocate for equitable treatment and appropriate policies in the work setting.

Workplace aggression. Violence or aggression in the workplace is another sociocultural factor that can profoundly affect health and safety in the occupational setting. **Workplace aggression** involves actions that result in physical, psychological, or emotional harm as perceived by the recipient (Fujishiro, Gee, & de Castro, 2011). Types of workplace aggression may include verbal abuse, bullying, and intimidation; threat of physical harm; physical assault; sexual assault; and homicide. Aggression tends to involve four types of perpetrators: persons in pursuit of criminal activity (e.g., a robbery), customers or other recipients of services (e.g., patients or students), coworkers, or persons who have a personal relationship with the victim, such as spouses or intimate partners (AAOHN, 2013).

Although workplace aggression occurs in many work settings, nurses are at particular risk for victimization because they often work alone, have access to drugs that may be sought by perpetrators, care for people under stress, and have frequent close contact with patients and their families (Magnavita & Heponiemi, 2011). According to U.S. Bureau of Labor statistics, more than 25,000 physical assaults were reported in health care settings in 2007 for an incidence of 158.4 events per 100,000 workers, much higher than in any other industry. Reports of nursing risk for workplace aggression vary from 63.5% to 95% in some settings (Demir & Rodwell, 2012). In other studies, the rate is as high as 13 of every 100 employees. One third to a half of the incidents reported involved nonphysical aggression such as bullying, intimidation, or harassment (Fujishiro et al., 2011). Like bullying in the school setting addressed in Chapter 22, workplace bullying often

involves intimidation and social isolation. It has been suggested that increased job demands and low job control may lead to violations of existing social norms leading to increased risk of being bullied. For example, high job demands may result in frequent errors leading coworkers to perceive one as incompetent and engage in disparagement and bullying (Demir & Rodwell, 2012).

In a study among health care workers in the Philippines, verbal abuse and bullying were associated with poor general health and work-related injury and illness, while physical assault was associated with missed workdays. In addition, coworker conflicts were often associated with work-related injury (Fujishiro et al., 2011). Similarly, a study of Italian nurses and nursing students indicated that 43% of the nurses and 34% of the students had experienced at least one episode of verbal or physical violence in their clinical lifetimes. Nurses reported being assaulted or harassed most often by patients and their families and friends. Nursing students also reported being subjected to verbal and physical violence by colleagues, staff, and others including teachers, physicians, and supervisors (Magnavita & Heponiemi, 2011). In the United States, a recent study of more than 1,400 early career registered nurses found that nearly half reported verbal abuse from colleagues, with 49% being abused at least once in the prior 3 months, and 5% reported more than 5 episodes of abuse in the same period. Being spoken to in a condescending manner and being ignored were the most commonly reported forms of verbal abuse (Budin, Brewer, Chao, & Kovner, 2013).

Nursing home personnel in Switzerland also reported high levels of aggression (81%). Reports varied by education of the victim with nonstudents being more likely to be victimized than students and RNs more likely than ancillary staff. In part, these results may stem from the practice of reserving assignment of difficult patients to experienced nurses. The authors noted a need for caregivers to understand the factors underlying patient aggression in a more comprehensive way to enable them to deal with aggression more effectively (Zeller, Dassen, Kok, Needham, & Halfens, 2012).

In 2011, 17% of workplace fatalities were the result of violence or other injuries by persons or animals in the work setting, and 10% of those fatalities were homicides. In that same year, a total of 468 workplace homicides were reported; the majority (83%) involving male victims. Among female victims, homicide perpetrators were most often relatives or domestic partners, whereas men were more likely to be killed in robberies. Coworkers or work associates were implicated in 11% of male and 6% of female homicides. Fourteen percent of women employees and 12% of men were killed by a student, patient, client, or customer, and 6% of women and 12% of men were killed by an inmate, detainee, or unapprehended suspect (Bureau of Labor Statistics, 2013a).

Workplace violence has negative effects for both the victim and the employing organization. Consequences for victims may include increased stress and fear of victimization, anxiety, feelings of guilt and self-blame, carrying weapons for self-defense,

decreased trust of management and coworkers, decreased job satisfaction, and the intention to leave the job. For employers, workplace aggression results in increased health care and workers' compensation claims, increased legal and security costs, increased employee turnover and absenteeism, and decreased productivity (AAOHN, 2013).

Occupational health nurses may be faced with evidence of workplace violence or bullying and may be forced to advocate for clients. When the perpetrator is also the nurse's supervisor, this may place the nurse in an awkward position. When harassment is based on discrimination because of an employee's gender, ethnicity, or membership in another protected category, someone who reports harassment is protected from employer retaliation. Unfortunately, however, this is not the case when the harassment cannot be linked to discrimination. Despite this disadvantage and the potential for retribution, nurses who are aware of bullying are ethically obligated to report it to the appropriate person or group and to advocate for the safety and security of the employee or employees affected.

OSHA (2004) has recommended conducting a workplace violence risk assessment to identify risk factors for violence in the setting. The assessment would focus on an analysis of incidents of violence and the types of violence perpetrated, perpetrators and clientele characteristics that might contribute to violence (e.g., patients withdrawing from psychoactive substances, persons under significant stress), and elements of the internal and external environment that may contribute to the risk for violence. In addition, OSHA has developed specific guidelines for preventing workplace violence against health care and social services personnel. For further information about the guidelines, see the *External Resources* section of the student resources site.

Additional sociocultural factors that may affect health in the work setting include languages spoken and cultural beliefs and behaviors. For example, employers may provide the traditional Western or Christian holidays but give no consideration for important occasions in other cultural groups. Ethnic and cultural factors may also be the basis for discrimination in the work setting. For example, employees may be harassed by colleagues because of an accent, or employers may prohibit the wearing of culturally prescribed clothing, such as head scarves, in some employment settings. In other settings, such as India and Italy, businesses may close during the hottest part of the day, but stay open late into the evening.

Guidelines for assessing sociocultural determinants influencing health in occupational settings are presented in the *Focused Assessment* on the next page.

BEHAVIORAL DETERMINANTS. Health-related behaviors engaged in by employees also influence the health status of the working population. Behavioral factors to be considered here include consumption patterns related to diet, smoking, and other substance use and abuse, patterns of rest and activity, use of protective measures, immunization, and presenteeism.

FOCUSED ASSESSMENT

Assessing Sociocultural Determinants Influencing Health in the Work Setting

- Do OSHA regulations apply to the work setting? Are there other regulations that apply to the setting? If so, what are they, and how do they affect employee health or the role of the occupational health nurse?
- What is the extent of workers' compensation claims in the work group? For what types of problems is compensation provided?
- How do provisions of the Americans with Disabilities Act affect the work setting?
- What effects, if any, does work in this setting have on family relationships? Do employees work nonstandard hours?
- What assistance, if any, is provided to employees relative to child care or care of other family members?
- What is the educational, economic, and cultural background of employees? What languages are spoken by the employee population? How do cultural factors affect work, if at all?
- Does the work pose a high risk for crime victimization?
- Are there intergroup conflicts in the employee population? What is the potential for violence in the work setting?
- What is the extent of social support among employees? To what extent do coworkers support healthful behaviors?
- What is the extent of other forms of workplace aggression in the work setting? What risk factors for workplace violence are present in the setting? To what extent do the physical environment and organizational policy facilitate or impede violence in the workplace?

Consumption patterns. Consumption patterns of interest to the occupational health nurse include those related to food and nutrition, smoking, and drug and alcohol use. The influence of nutrition on health is well established, and the occupational health nurse assesses the nutritional patterns of employees with whom he or she works. In addition, the nurse assesses how the work environment affects eating habits. For example, sufficient opportunity may not be provided for employees to eat despite OSHA regulations regarding time and place for breaks and meals.

The nurse also determines whether food service is available to employees. If there is an employee cafeteria, the nurse may need to assess the nutritional quality of the food provided. If no food services are available in the workplace, the nurse would determine whether they are available nearby, or whether adequate storage facilities exist for employees who bring meals from home.

Another issue that may affect health and productivity in the work setting is the growing use of energy drinks. The amount of caffeine in such drinks is equivalent to one to three cups of coffee or caffeinated soda. Energy drink consumption has been linked to sleep problems, daytime sleepiness, decreased productivity, and risk for injury. Use of energy drinks has been found to be particularly prevalent among deployed military members, nearly 45% of whom reported consuming one such drink per day. An additional 13% of respondents reported drinking three or more drinks and getting less than 4 hours of sleep per night (Toblin, Clark-Walper, Kok, Sipos, & Thomas, 2012).

The prevalence of eating disorders in the workforce is another consideration related to dietary consumption. Occupational health nurses may identify employees (primarily, but not exclusively, young women) who have eating disorders. When employees with eating disorders are identified, the occupational health nurse would usually make a referral for diagnostic

confirmation and treatment. Eating disorders are addressed in more detail in Chapter 28∞.

Smoking is another consumption pattern of concern to the occupational health nurse. The most recent National Survey on Drug Use and Health indicated that approximately 28% of full-time employees and nearly a quarter of part-time employees were current smokers (Garrett, Dube, Trosclair, Caraballo, & Pechacek, 2011). Smoking is harmful to health in and of itself. In addition, smoking may increase the adverse effects of other environmental hazards in the work setting, particularly those that affect respiration. Many employers have recently begun to prohibit smoking except in carefully controlled areas in the workplace and have been active in promoting programs to help employees quit smoking. In addition to the health implications, such efforts cut employer expenses. For example, occupational exposure to second-hand smoke may be grounds for employee lawsuits, worker's compensation claims, or a claim of disability discrimination in failure to provide "reasonable accommodation" to protect workers with asthma and other respiratory conditions from the effects of second-hand smoke. Voluntarily creating smoke-free workplaces can save employers from potential costs in all of these situations (Zellers, Graff, & Tobacco Control Legal Consortium, 2008).

Some employers, particularly health care organizations, have gone so far as to implement nonsmoking requirements for employment and to require pre-employment nicotine testing of job applicants. Such policies have ethical implications in curtailing smokers' employment opportunities. In addition, nicotine tests do not distinguish among current smokers, persons exposed to second-hand smoke, and those using assistive devices (e.g., nicotine patches) to stop smoking. Such policies also raise concerns related to social justice since smoking is more common among lower socioeconomic groups (Voigt, 2012). In addition, it is conceivable that nicotine addiction

might, at some point, be considered a disability that would require accommodations under ADA.

The population nurse assesses the extent of smoking in the employee population as well as the specific implications of smoking in that particular environment. He or she might educate and assist employees with smoking cessation, but might also need to advocate for the rights of smokers to employment (but not for a right to smoke in the work environment).

Employees may also have problems with substance abuse. For example, an estimated 10% to 15% of nurses may be impaired or recovering from substance abuse disorders (Thomas & Siela, 2011), and other occupational groups may have similar high incidence rates for abuse. The prevalence of these problems should be monitored and the population health nurse in a work setting should be alert to signs and symptoms of substance abuse in employees and engage in interventions to address these problem consumption patterns. Worksite interventions have been shown to be successful in decreasing smoking and other drug use and in reducing fat intake and increasing consumption of fruits, vegetables, and fiber.

Rest and activity. Work places many physical and psychological demands on people. Sometimes these demands result in inadequate rest and recreation, as with the executive who works constantly or the blue-collar worker who holds two jobs in an attempt to make ends meet. Conversely, work may also lead to too much sitting and too little physical activity. Based on 2010 National Health Interview Survey results, 30% of U.S. civilian employees get less than 6 hours of sleep per night, when the

recommended amount of sleep is 7 to 9 hours. Insufficient sleep was most common among manufacturing employees (34%) and was particularly prevalent in nightshift workers in the transportation and warehousing industries (70%) and among health care and social assistance personnel (52%) (Luckhaupt, 2012). As we saw earlier, insufficient sleep is detrimental to health and may increase risk for injury or errors.

Problems encountered in the work setting may also interfere with employees' ability to rest when off the job. The nurse in the work setting assesses the amount of activity engaged in by employees and the balance between rest and exercise. He or she also obtains information on the types of recreation used by employees and any potential health hazards posed by recreational choices.

Many companies are recognizing the benefits of exercise in terms of both the physical and psychological health of employees. These companies are promoting physical exercise and may even provide facilities for exercise and recreation in the workplace. If this is the case, the nurse should be alert to potential health hazards and the possibility of too much exercise. For example, if there is a company pool, an employee with epilepsy who swims to relieve tension should be cautioned against swimming alone. Similarly, an overweight executive should engage in physical activity cautiously to lessen the risk of heart attack or injury.

Another factor related to rest and leisure time activity is the extent of multiple jobs held by employees, each of which presents its own unique risks and hazards. In addition, multiple-job holders have less time to rest and recover from the physical

Evidence-Based Practice

Advocating Smoke-free Workplaces

Smoking contributes to substantial morbidity and mortality throughout the world, not only for smokers, but also for those exposed to second-hand smoke. Internationally, an estimated 1.3 million people smoke, about 80% of whom live in low- to middle-income countries. In a given year, 600,000 deaths and 10.9 million disability-adjusted life years are attributable to the effects of second-hand smoke. Individuals with severe disabling respiratory conditions are particularly susceptible to the adverse health effects of second-hand smoke (Rutkow et al., 2013).

Some authors have suggested that legislation mandating work accommodations for persons with disabilities can be used as leverage for promoting smoke-free workplace policies. In the United States, the Americans with Disabilities Act mandates reasonable accommodations for employees with disabilities. Internationally, the United Nations Convention on the Rights of Persons with Disabilities, adopted by numerous countries around the world, has similar provisions (United Nations, 2006), and the WHO Framework Convention on Tobacco Control

calls for protection of individuals from second-hand smoke exposure in public places and in work settings (Rutkow et al., 2013).

Arguments for not instituting smoke-free workplace policies often revolve around potential loss of revenue (e.g., in restaurants) or the expense of the change in policy. Evidence has consistently demonstrated that smoking bans have not resulted in decreased revenues or have actually increased revenue slightly. Similarly, research has indicated decreases in hospital admissions for asthma and other respiratory conditions with smoking ban implementation. In addition, studies have demonstrated conclusively that less restrictive policies are not effective in protecting nonsmokers from second-hand smoke (Rutkow et al., 2013). This strong evidence base, coupled with legal mandates to protect employees with disabilities, provide significant ammunition for advocating smoke-free workplace policies in all businesses and industries.

demands of the job as well as less time for family interactions. In August 2013, 4.7% of employed workers in the United States held multiple jobs (BLS, 2013c).

Use of protective measures. Another behavioral factor that is particularly relevant to health in the occupational setting is the use or nonuse of safety and protective measures. Hazards present in the workplace frequently can be mitigated by the use of appropriate safety equipment; however, this can occur only if employees use these devices consistently and appropriately.

The population health nurse identifies the need for safety equipment and also monitors the extent to which it is used. For example, do individuals working in high-noise areas wear earplugs? Are those earplugs correctly fitted? Do people involved in heavy lifting wear weight belts, or do they ignore the potential for injury? Are heavy shoes or gloves worn in areas with dangerous equipment? Again, the attitude of management toward health promotion and illness prevention strongly influences employee behaviors. When administrators, for example, fail to use hearing protection in high-noise areas, they convey an attitude of disinterest in health, which frequently filters down to employees.

Use of sunscreen by employees chronically exposed to sunlight is another protective measure that can influence health and should be encouraged by population health nurses. Outdoor workers sustain six to eight times the sun exposure of employees working indoors, but they frequently fail to use sunscreen as a protective measure against skin cancer. For example, in one Canadian study, only 29% of people who worked more than 4 hours per day in the sun used sunscreen (Marrett, Pichora, & Costa, 2010).

Another aspect of protective measures relates to ergonomics, formerly known as human factors. **Ergonomics** is a scientific discipline that applies an understanding of human–environmental interactions to design work systems to foster human well-being and optimal performance (International Ergonomics Association [IEA], 2014). In essence, it is the practice of making a job fit the employee rather than the other way around. Properly applied, ergonomics improves employee productivity by eliminating barriers to effective work. It also results in greater physical and emotional comfort in the work setting and leads to fewer musculoskeletal injuries due to elements of work such as awkward postures, repetitive movements, and so on (American Psychological Association, 2014; OSHA, n.d.a).

Three aspects of ergonomics should be considered in assessing the health status of the working population: physical ergonomics, cognitive ergonomics, and organizational ergonomics (IEA, 2014). Physical ergonomics address human anatomical, anthropometric (e.g., height and weight), physiologic, and biomechanical characteristics as they relate to physical activity. Consideration of the placement of a computer keyboard in relation to the flexion and extension capabilities of the human wrist is an example of an anatomical characteristic, while the appropriate height of a chair addresses an individual's

anthropometric characteristics. Appropriate measures for handling toxic substances would reflect human physiologic responses to specific material, and measures to prevent back strain in lifting would be based on biomechanical characteristics of human musculature.

Cognitive ergonomics is concerned with cognitive processes such as memory, perception, and motor response as they affect the performance of work. Strategies to reduce mental workload and stress reflect cognitive ergonomics. Finally, organizational ergonomics reflects organizational structures that promote or impede work. For example, telecommuting and logical work flow may improve organizational ergonomics.

In the cognitive realm, the population health nurse in an occupational setting would assess the degree to which employees are qualified to perform their particular job function and their interest in that job. Employees who work at jobs that do not interest them, that are beyond their capabilities, or that do not provide sufficient challenge may be at greater risk for both emotional and physical health problems than those who are better suited to their jobs.

Population health nurses working in occupational health settings may be responsible for assessing the ergonomic features of a setting or a particular job. Ergonomic evaluation is frequently done when several employees develop work-related musculoskeletal disorders, but could be employed in a general assessment of the workplace to prevent musculoskeletal injuries. When possible, employees are observed performing their usual job duties. The evaluator also asks injured employees to identify tasks that are most difficult to accomplish. The difficult tasks frequently lead to the identification of specific factors that promote injury and that are amenable to change. In addition to changing features of the job or work environment, ergonomic analysis may lead to employee education in better work techniques to prevent injury.

Another aspect of ergonomic evaluation is an assessment of tools and equipment used in the job and their potential for injury. This may include both power equipment and hand tools and mechanical processes. Ease of use and appropriateness for human anatomical function are considered.

Immunization. Population health nurses in occupational settings would also assess appropriate immunizations among the employee population. For example, health care workers and teachers need a variety of immunizations to keep them from becoming ill and from transmitting infectious diseases to their charges. During the 2011–2012 influenza season, however, only 67% of U.S. health care personnel received influenza vaccine. Immunization levels were considerably higher in hospitals and health systems that mandated immunization—95% compared to only 68% in facilities where it was not mandatory (Ball et al., 2012). In 2009, New York state issued a vaccination mandate for all health care personnel. The mandate was subjected to a number of law suits on grounds of violating individual liberties. Before the suits were heard, however, the mandate was dropped due to a shortage of vaccine (Ottenberg et al., 2011).

Population health nurses can be involved in designing immunization campaigns to promote voluntary immunization. Such campaigns would include educating employees on the need for immunization and planning delivery programs that are convenient and free of cost to employees.

Presenteeism. A final behavioral factor that influences the health of employees in the work setting is working while ill, also called sickness **presenteeism** (Kumar, Grefenstette, Galloway, Albert, & Burke, 2013). CDC recommends that employees stay home for 24 hours after a fever subsides, yet many people either cannot afford to take the time from work or are concerned about being thought of as “slackers.” In these conditions and faced with the extent of job insecurity in today’s job market, many people choose to continue working when ill. An estimated 42% of the U.S. workforce would not get paid if they stayed home from work, and 33% of the labor force, particularly low-wage employees, lack paid sick days. A computer simulation indicated that nearly 12% of the attack rate for disease transmission can be attributed to workplace exposures and that providing 1 or 2 days of paid sick time would reduce infections by 25% and 39%, respectively (Kumar et al., 2013).

In addition to the lost productivity from employees whose performance is impaired by symptoms of illness, presenteeism is harmful to the ill employee as well as to others in the work setting. When an employee has a communicable disease, for example, coming to work while ill increases the risk of exposure for coworkers and clients. In addition, presenteeism may increase overall risk of premature mortality. The effects of presenteeism are seen with mental as well as physical illness. In one study, for example, mental illness presenteeism cost employers nearly twice as much as absenteeism related to mental health issues. Going to work while ill not only exposes others,

but may lengthen the eventual time lost when illness becomes worse (Lundberg & Cooper, 2011).

Population health nurses working in occupational settings assess behaviors affecting the health of individual employees in the work setting as well as the prevalence of harmful behaviors in the work group. The *Focused Assessment* below provides some guidelines for assessing this aspect of health in the work setting.

HEALTH SYSTEM DETERMINANTS. Health system factors influencing employee health relate to both external and internal health care systems. The external system reflects the availability and accessibility of health care services outside the workplace, whereas the internal system consists of those services offered within the workplace.

The external system. In assessing employee health status, the population health nurse in the occupational setting gathers information about the use of health services in the community at large. The nurse examines the type of services used and the reasons for and appropriateness of their use. The nurse also assesses the availability of services needed by company employees in the external health care system.

One of the work-related factors influencing use of outside health services is the availability of insurance coverage. Health insurance is an employment benefit for many, but large segments of the working population do not have health insurance coverage. Many of these uninsured workers do not have sufficient income to afford health insurance themselves or out-of-pocket health care expenses. For example, in 2012, 148.6 million people in the United States had health insurance coverage through their own or a family member’s employment (NCHS, 2014). During 2011, 51% of U.S. firms offered health

FOCUSED ASSESSMENT

Assessing Behavioral Determinants Influencing Health in the Work Setting

- What behavioral factors influence health in the work setting?
- Do any members of the employee population use prescription medications on a regular basis? Are medications used, stored, and dispensed as directed?
- What is the extent of substance use and abuse by members of the work group? How does substance use and abuse affect employee performance?
- Are safety policies and procedures in place in the work setting? Are they enforced? Do employees use appropriate safety equipment and procedures? Do employees use sunscreen and other protective measures against damaging effects of sunlight?
- Do employees engage in other behaviors (e.g., smoking) that increase their risk of toxic effects from workplace exposures?
- Do employees get sufficient rest and exercise to promote their health? What opportunities are provided for physical activity in the work setting?
- What is the nutritional status of the employee population? What foods are available in the work setting? Does food availability promote good nutrition in the employee population?
- To what extent do employees obtain appropriate immunizations?
- To what extent does sickness presenteeism occur in the employee population? What are the effects of presenteeism for the sick employee, for coworkers, and for the organization?

insurance coverage to their employees (Henry J. Kaiser Family Foundation, 2013). As of 2013, 72% of the overall U.S. civilian workforce had access to medical care benefits, but only 54% chose to obtain coverage, and only 23% of those with wages in the lowest 25% were covered (BLS, 2013d). A substantial proportion of employees who are eligible for health insurance through their workplaces choose not to be insured due to high premiums. In 2012, for example, employers paid an average of 80% of health insurance premiums for coverage for a single individual, but only 69% of the premiums for family coverage (BLS, 2012c). From 2002 to 2012, premiums for employment-based family coverage increased by 97%, but employee contributions to those premiums increased by 102% in the same time frame. Due to the high costs of insurance, many employees who do have coverage choose high deductible plans, particularly in small firms with few employees. In fact the number of employees choosing high deductible plans increased from 10% in 2006 to 26% in 2012. This means that more people have to pay larger amounts out of pocket (up to \$1,000 for a single individual and more for a family) before their health insurance coverage begins (Kaiser Family Foundation & Health Research & Educational Trust, 2012).

Some employers are requiring employees to complete health risk assessments. Approximately 11%, of large firms that do so, impose financial penalties on employees with health risks who do not complete wellness programs, and another 9% reward or penalize employees based on achieving biometric outcomes (e.g., weight control, smoking cessation) (Kaiser Family Foundation et al., 2012).

The occupational health nurse should become familiar with the insurance status of employees in the company and with the kinds of benefits covered under group policies, where they exist. Occupational health nurses may also need to advocate for affordable personal and family health insurance coverage for employees in the work setting.

The internal system. The internal health care system consists of those health services and programs provided to employees in the work setting itself. Internal health services may relate to each of the four levels of health care. Programs may reflect attempts to promote employee health and health-related behaviors, environmental modification to prevent illness and injury, care to resolve existing health problems, or care designed to promote rehabilitation and restoration of health. Specific work settings will vary with respect to the extent of services provided in each of these areas. For example, small businesses may not provide any on-site services other than care for emergencies such as might be provided in any setting. Large or multi-site companies, on the other hand, might provide an array of services across the spectrum of care. A few companies also provide health care services for employees' family members. Even in occupational settings that do not provide care to family members, nurses may be asked by employees for assistance in dealing with family health issues. The nurse may counsel the employee regarding resolution of family problems or may provide referrals to outside sources of assistance.

According to a group of experts involved in the Working Group on Worksite Chronic Disease Prevention, for example, health promotion and illness prevention in the worksite tends to have three foci: promoting individual behavior change, promoting change in the work environment, and promoting work–family balance (Sorenson et al., 2011). Services in these three areas might involve employee education for healthy behaviors, such as smoking cessation or weight control; modifications in the work environment or work processes that promote health and prevent illness and injury, such as minimizing employee exposure to toxic substances; or consideration of work schedules and their effects on family interactions and employee physical and mental health.

Services to resolve existing health problems, whether work-related or not, may be provided in the work setting by health care professionals. Alternatively, employees may be referred to outside sources for needed care. For example, an occupational health nurse may provide routine prenatal care for pregnant employees in the work setting or refer them to existing community services. Resolution of existing problems may address immediate stabilization of an injury, or in a large facility, involve X-rays, casting, and so on. Similarly, health care professionals may be actively involved in treating and monitoring treatment effects for chronic diseases or refer employees to their primary providers or other sources of care in the community. Generally speaking, rehabilitations services are not directly provided in the work setting, but occupational health professionals may monitor the effects of rehabilitation and determine when an employee is able to return to work. Each of these categories of services will be addressed in more detail in the discussion of planning and implementing services to meet the needs of the working population.

In assessing those needs, however, the population health nurse in an occupational setting would identify the internal and external health system resources available to employees and determine gaps in services required to address identified health needs in the population. In addition, the nurse would assess the extent of use of available resources as well as their quality and adequacy in meeting the employee population's needs.

A *Focused Assessment* addressing health system considerations in the work setting is presented on the next page. The *Population Health Assessment and Intervention Guide* provided on the student resources site can be used to assess an employee population. In addition, a specific tool for assessing health in work settings is provided.

Diagnostic Reasoning and Care of Working Populations

Population health nurses working in occupational settings derive nursing diagnoses from assessment information related to individuals or groups of employees. For example, the nurse might diagnose “inability to sleep due to work pressures” for an employee who works night shift or “poor employee morale due to increased tension and stress in the work setting.” Other nursing diagnoses related to individual employees are a “need

FOCUSED ASSESSMENT

Assessing Health System Determinants Influencing Health in the Work Setting

- What health services are offered in the work setting? How are health care services funded? Is funding adequate to meet health needs?
- How accessible are needed health services in the community? To what extent does the employee population use available health services?
- What is the extent of health insurance coverage in the employee population?
- What is the quality of interaction between internal and external health care services?
- To what extent are health promotion and illness/injury prevention emphasized in the work setting?
- What systems are in place to control and monitor toxic exposures in the work setting?
- Are surveillance procedures implemented in a systematic way to periodically assess all employees at risk for exposure?
- What health services are available to resolve existing health problems?
- What emergency response services are available in the health setting?
- What health services related to restoration of health are available?

for referral for counseling due to heavy drinking” and “moderate hearing loss due to failure to use hearing protection in high-noise areas.” Nursing diagnoses at the group level might include a “potential for exposure to hepatitis B due to frequent contact with blood” for a group of laboratory technicians in a hospital, and the “potential for falls due to work in elevated areas” for a group of construction workers.

Planning and Implementing Care for Working Populations

Interventions may be developed by the occupational health nurse alone or in conjunction with others in the work setting to address the health needs identified. In the case of individual clients, interventions would be tailored to individual needs and circumstances. When identified health problems affect groups of employees, planned interventions are likely to be more complex. Planning to meet the needs of groups in the workplace will employ the principles of health programming discussed in Chapter 15. Whether the client is an individual, a group of employees, or the total population in the work setting, interventions may be planned to address health promotion, illness and injury prevention, resolution of existing health problems, or health restoration.

HEALTH PROMOTION. AAOHN defined health promotion in the employment context as the design of health education initiatives to foster employee responsibility for their own health (Yap & James, 2010). Worksite health promotion, however, involves more than educating employees and changing their health-related behaviors. Characteristics of effective worksite health promotion programs include ongoing education and monitoring, team-based interventions versus individual delivery, a single-disease focus, goal setting, increasing employee knowledge, and self-monitoring. Effective programs also incorporate consistent reminders, initiatives to address barriers to health promotion, and rewards for employee accomplishments (Yap & James, 2010).

Federal programs in the United States can assist businesses with the development of worksite health promotion programs. For example, the National Healthy Worksite Program (NWHP) is intended to assist employers in implementing evidence-based health promotion and wellness programs to reduce chronic disease incidence. NWHP provides funding for employers to establish comprehensive worksite health programs to support physical activity, nutrition, and tobacco-use cessation (CDC, 2013a). Similarly, the Affordable Care Act has created incentives for employers to develop wellness initiatives that reward employees for participation in wellness and/or achievement of specific health-related goals (e.g., weight loss, normal cholesterol levels). Additional rewards, up to 50% of the cost of health coverage, may be provided specifically for programs that prevent or reduce tobacco use (U.S. Department of Labor, 2012).

As noted earlier, health promotion efforts go beyond motivating individual behavior to changing the work environment to promote health, and modifying work–family interactions to foster health (Sorenson et al., 2011). Health promotion initiatives may focus on both individual behavior and organizational strategies that promote health. For example, one program to address stress management encompassed both individual strategies and organizational strategies. Individual strategies included stress awareness and education, relaxation techniques, cognitive coping strategies, and approaches such as meditation and biofeedback, as well as lifestyle changes, such as increased physical activity, healthier diets, smoking cessation, and diminished alcohol intake. Additional strategies at the individual level included interpersonal skill development, promotion of adequate sleep, equalization of gender workload within the family, and focusing on life priorities (Lundberg & Cooper, 2011).

At the organizational level, strategies to promote effective stress management included task redesign and redesign of the work environment to minimize stress, use of flexible work schedules, analysis of work roles and goal establishment, and including employees in participating management and career

development activities. Additional organizational strategies focused on ensuring variation in work, providing social support and building cohesive work teams, and establishing fair work policies. Creation of “restorative environments” incorporating green spaces and recreational opportunities were also suggested as organizational strategies to promote stress management. Such environments are believed to decrease the need to constantly engage in “executive brain functions” and allow people to unwind (Lundberg & Cooper, 2011).

There is a particular need for health promotion for older workers in occupational settings. Targeted health promotion programs for older employees include the COACH program and the RealAge program, both of which include in-depth risk assessments and suggested action plans. The RealAge program is a web-based program, whereas the COACH program involves a personal coach who assists employees in developing a risk reduction plan and then provides monthly monitoring. In one study of the interventions, older employees were twice as likely to use the COACH program, and those who did were more likely to engage in more behavior changes than those who used the web-mediated program (Hughes et al., 2011).

A similar program combined weekly personally tailored e-mail messages from an occupational health nurse focused on specific risk behaviors and supplemental website information to motivate physical activity among employees. The weekly messages were found to move people further through the stages of change and resulted in greater increases in physical activity than general e-mail broadcasts (Yap, Davis, Gates, Hemmings, & Pan, 2009a, 2009b).

Population health nurses in occupational settings educate employees to lead healthier lives. They also advocate for company policies that promote health. An organizational culture that supports health conveys to employees that their health is a priority for the company. This message must be supported by company efforts to promote health within the organization. For example, some companies may promote exercise among employees, but an organizational culture that truly supports physical activity may allow time for exercise during

the workday or provide facilities (e.g., weight rooms, walking paths) that actually promote physical activity. Similarly, an organizational culture that supports health will take steps to ban all forms of tobacco use in the work setting and will provide tobacco use cessation assistance for those employees who use tobacco. Another feature of an organizational culture that supports health is positive attitudes toward health-promoting behaviors among employees. For example, in such a culture employees who engage in physical activity are the norm, and those who do not are in the minority. Employees support each other in positive health-related behaviors. Population health nurses can be instrumental in promoting an organizational culture that supports health by convincing employers of the value of health promotion in terms of increased productivity, better morale, and reduced absenteeism. They can also help to develop positive attitudes to health promotion among employees by making health-promotion activities relevant to the goals and motivations of the employee group. For example, they might approach smoking cessation from the perspective of the benefits for employees’ children if that is a strong motivator for members of the work group. Or they might plan physical activities that fit easily into the workday. Table 23-2 • summarizes health promotion strategies and related population health nursing roles in work settings.

ILLNESS AND INJURY PREVENTION. Preventing illness and injury is the second level of health care in the workplace. Population health nursing activities related to both are briefly addressed below.

Illness prevention. Preventing communicable diseases in occupational settings can involve prevention of specific illnesses through immunization or employee behaviors that prevent the spread of infection. Population health nurses would identify categories of employees at risk for specific communicable diseases and provide related immunization services. For example, personnel in health care facilities should receive a variety of immunizations, including influenza, hepatitis B, measles, mumps,

TABLE 23-2 Health Promotion Strategies for Working Populations

Emphasis	Strategies
Promoting individual health behaviors	<ul style="list-style-type: none"> • Educate employees for healthy behaviors (e.g., physical activity, nutritious diet) • Assist employees to eliminate unhealthy behaviors (e.g., smoking cessation) • Teach effective coping skills • Assist employees to balance work and family roles • Promote adequate sleep and educate employees on sleep hygiene
Fostering an organizational culture to promote health	<ul style="list-style-type: none"> • Assist in development of worksite policies that promote health (e.g., physical activity breaks and opportunities) • Advocate for development of work environments that promote health • Advocate for healthy food options in the workplace • Advocate strategies that foster job control
Promoting work–family balance	<ul style="list-style-type: none"> • Advocate for flexible work schedules • Advocate for family care leaves and support services

rubella, pertussis, and varicella (Shefer et al., 2011). Immunization is particularly important for personnel in long-term care facilities due to the vulnerability of residents (Kimura, Nguyen, Higa, Hurwitz, & Vugia, 2007). Similarly, farm workers and others who work outdoors or are at risk for dirty injuries should be adequately immunized against tetanus. Nurses in occupational settings may provide these immunizations or refer employees to outside sources of vaccine, monitoring immunization levels among the population at risk. If outside services are used, the occupational health nurse may need to advocate for cost reimbursement for employees (Ottenberg et al., 2011). When workplace exposures to certain pathogens occur, disease development can be prevented through postexposure prophylaxis. **Postexposure prophylaxis (PEP)** is treatment for a communicable disease following a potential occupational exposure to the infectious agent. For example, health care providers caring for clients with known cases of hepatitis B or C or HIV infection may receive prophylactic treatment to prevent them from developing the disease. Occupational health nurses may be involved in actually providing employees with prophylactic treatment or in referring them for needed services. Prophylaxis will be addressed in more detail in Chapter 26.

Prevention of the spread of communicable diseases in the work setting can also be accomplished through effective hygiene, adequate cleaning, and disinfection of contaminated surfaces and equipment (Smith et al., 2013), and, in the case of health care personnel, use of universal precautions (Materna et al., 2010). Strategies to minimize presenteeism can also serve to reduce the spread of many communicable diseases in the workplace. Presenteeism can be discouraged through provision of paid sick days (Kumar et al., 2013), and population health nurses may need to advocate for sick leave policies as well as educate employees regarding the need to stay home when ill. For selected occupational groups, for example, laboratory employees, use of adequate safety precautions in handling specimens would be emphasized (Ritger et al., 2011).

Another aspect of illness prevention involves modifying personal risk factors, particularly those involved in the development of noncommunicable conditions. Risk factors are personal or group characteristics that predispose one to develop a specific health problem. For example, it is well known that smoking increases one's risk of developing heart disease and lung cancer, so smoking is a risk factor for both of these problems.

Some risk factors can be modified or eliminated, thus decreasing one's chances of developing specific health problems. Again, using smoking as an example, people who quit smoking lower their risk of developing lung cancer. Occupational health nurses can be instrumental in assisting employees to modify risk factors, thereby helping them to prevent health problems. Some risk factors that receive particular attention in the occupational setting are smoking, elevated blood pressure, sedentary lifestyle, stress, and overweight.

Occupational health nurses can work on risk factor modification with individuals or groups of employees. They can also

engage in risk factor modification efforts at the company level. One example of this would be efforts to convince company policy makers that a no-smoking policy should be instituted and enforced within the workplace. Nurses can also develop weight standards for certain job categories in which being overweight is particularly hazardous.

At the individual level, the nurse can counsel employees regarding the hazards of smoking, particularly in conjunction with occupational exposure to respiratory irritants. She or he can also provide assistance to individuals who wish to quit smoking.

Environmental risk factor modification can also prevent the development of many occupational conditions. For example, work stations can be redesigned to be more ergonomic to prevent musculoskeletal injuries (OSHA, n.d.a). Similarly, exposure to toxic substances in the workplace can be minimized through engineering controls, use of safety precautions and protective gear, or replacement with safer substances and processes. For example, recommendations for preventing the fumigant poisoning of produce inspectors discussed earlier included prolonged aeration of products, conducting inspections in well-aerated areas, and improving airflow in produce storage areas (O'Malley et al., 2011). Similarly, farm workers can be educated regarding correct application of pesticides (Schwartz et al., 2012). Metal recycling plants can implement policies of only accepting containers that have been cut open to prevent release of toxic substances and exposure of workers. Such facilities and others that work with potential hazardous compounds should also develop hazardous gas release evacuation plans (Kelsey et al., 2011).

Population health nurses may be involved in developing protocols for handling of hazardous substances, but they are more likely to educate employees on their implementation as well as on emergency measures to minimize the effects of exposures. For example, they may educate employees on the correct use of ear plugs in high-noise areas or in the use of breathing equipment in high-dust areas (Laney et al., 2012). Education regarding sunscreen use and protective clothing for employees who work outdoors is another important strategy for preventing skin cancer.

Population health nurses can also advocate for measures to minimize job strain that can contribute to a variety of physical and mental health problems (Stansfeld et al., 2012). Restructuring the work environment can help in minimizing occupational stress as a risk factor for health problems. Efforts in this direction include developing flexible schedules to minimize conflicts with employees' outside responsibilities. The nurse can also facilitate employee input into work-related decisions and strive to minimize role overload and role ambiguity. The nurse can also promote opportunity for social interaction, job security, and career development.

As is obvious, many of these efforts must be undertaken by management, but the nurse can provide management with evidence of related research and can provide the impetus for change in these areas. At the individual level, the occupational

health nurse can be aware of the stressors experienced by employees in various jobs in the work setting. The nurse is also in a position to monitor the effects of stress on the individual employee and to counsel employees in stress management.

Injury prevention. Injury prevention in the work setting may entail employee education or environmental modification. Physical hazards are the most important cause of occupational morbidity and mortality (Lundberg & Cooper, 2011), and employees need to be acquainted with safety procedures to prevent accidents. For example, there is a need to prevent needlesticks in health care settings, and staff may need to be educated regarding the appropriate disposal of sharps. Similarly, periodic reminders regarding good body mechanics in lifting patients may be needed in the health care setting. There may also be a need to educate employees in the correct use of safety equipment. For example, individuals working in some areas should wear protective clothing or use breathing apparatus. As noted earlier, safety education should be provided to both paid and volunteer employees. The nurse should explain the need for safety equipment and be responsible for monitoring its use. This may entail planning periodic visits to certain areas of the workplace to determine whether employees are indeed using safety equipment as directed.

Employees may also be in need of education in other areas related to injury prevention. Handling of hazardous substances, proper use of machinery, need for fluid replacement in high-heat areas, and good body mechanics are all educational topics that may be appropriate in certain industrial settings. There is also a need for transportation safety measures, particularly for older employees. For example, vehicles may be selected or adapted to promote maximum safety. Company policies can also limit driving, particularly at night, as much as possible and encourage route and trip planning to reduce stress and fatigue. Refresher driver training may also be helpful as is education on chronic health conditions and medications that can affect driving safety. Finally, measures may be needed to compensate for perceptual or cognitive deficits in older people working in heavy traffic zones (e.g., road workers) (Pratt & Rodriguez-Acosta, 2013). There is also a need for stringent transportation safety guidelines for aircraft use. For example, aircraft operations guidelines in the oil and gas industries exceed Federal Aviation Administration guidelines, and nurses can encourage adherence to these guidelines (Gunter et al., 2013). For further information on the guidelines established by the International Association of Oil and Gas Producers, see the *External Resources* section of the student resources site.

Prevention of musculoskeletal injuries may entail redesign of work stations and processes to provide more ergonomic conditions. OSHA (n.d.a) has developed guidelines for the redesign process that include development of management support for redesign, involvement of workers, employee and management training, identification of specific problems, early reporting of symptoms, implementing ergonomic solutions,

and evaluating the outcome of redesign efforts. In addition, OSHA and NIOSH have developed ergonomic guidelines for specific industries, such as meat packing, foundries, nursing homes, shipyards, retail grocery stores, and so on. Similarly, guidelines for creating ergonomically appropriate computer work stations have been developed by the U.S. Department of Defense Computer/Electronic Adaptations Program (n.d.). For further information about these guidelines, see the *External Resources* section of the student resources site.

Another aspect of injury prevention in which the nurse may be involved is monitoring hazardous conditions in the workplace. The nurse should be aware of potential hazards and their appropriate management. In the absence of an industrial hygienist, the nurse may plan and conduct environmental testing to detect hazardous levels of chemicals, heat, or noise.

The nurse may need to acquaint management with the occurrence of injuries due to hazardous conditions and advocate changes designed to protect employees from injuries. Recommendations for dealing with the problem of noise-induced hearing loss, for example, include engineering efforts to minimize noise production, use of properly fitted hearing protection devices, education of employees and managers in the use of protective devices and their importance, and periodic audiometric screening. The occupational health nurse may be actively involved in planning and executing the majority of these recommended activities, particularly in screening for hearing loss, fitting protective devices, and educating employees and supervisors. Control of noise-related hearing loss requires commitment on the part of employees and management to the proper use of protective devices. Motivating employees to use these devices and monitoring their use are crucial functions of the occupational health nurse.

Minimizing the effects of shift work. Occupational health nurses can also help to prevent or minimize the negative effects of shiftwork. Some authors have suggested four general approaches

Use of hearing protection in high-noise areas can prevent hearing loss. (Michaeljung/Fotolia)

to addressing the effects of shift work: pharmacologic intervention, bright light exposure, education and counseling, and shift-work legislation (Smith et al., 2011). Pharmacologic intervention may involve agents to promote alertness and diminish fatigue on the job or to support adequate sleep. Many agents used for both purposes may have long-term negative effects such as dependence or sleep disruption discussed earlier in relation to the use of energy drinks. Newer sleep enhancing or wakefulness-promoting agents, such as melatonin or modafinil, have been found to have fewer negative effects than hypnotics or stimulants, respectively, but the effects of long-term use are not yet known (Smith et al., 2011).

Exposure to bright light, at approximately five times the usual indoor lighting levels, assists with adjustment of circadian rhythms, but requires a strict schedule of exposure over time (including rest days) that may be difficult for some employees or settings to achieve. Education and counseling on measures to promote adequate sleep have been used, but results are inconsistent. Finally, many European countries have adopted the European Directive related to shiftwork, mandating employee assessment prior to nightshift assignment, regular reassessment, and specific reassessment with possible change in shift in the light of health problems experienced (Smith et al., 2011). Although such assessments are not mandated in the United States, occupational health nurses can advocate for their implementation in the work setting. They can also monitor employees on non-daytime shifts for health problems, particularly sleep problems, and advocate for reassignment as needed.

Preventing workplace aggression. Prevention of workplace aggression begins with an assessment of risk. Population health nurses can help to create workplace violence surveillance systems and analyze data on incidents of violence to discover patterns and areas of risk (AAOHN, 2013). They would then be actively involved in measures to prevent violence and aggression in the workplace. NIOSH has developed a course to assist occupational health nurses to recognize and address workplace violence (NIOSH, 2013b). For more information about the course, see the *External Resources* section of the student resources site.

Initiatives to prevent workplace aggression have several foci including developing a workplace culture that does not tolerate violence, implementing engineering controls, establishing administrative controls, and educating employees to minimize violence. Development of a work culture that does not support violence involves creating management commitment to employee safety and willingness to engage in a variety of measures to promote that safety. Population health nurses in occupational settings can assist in the development of no-tolerance policies that encourage prompt reporting of aggression, prevent reprisals against reporting, and promote rapid and thorough investigation of reports (OSHA, 2004). Occupational health nurses can also educate employees to increase awareness of aggression and to promote reporting of minor events or suspicious behavior that may escalate to violence (AAOHN, 2013).

Engineering controls to prevent or minimize violence may include physical adaptations of the workplace to minimize risk. Such adaptations might include arranging furniture in rooms to prevent entrapment, installing security systems and monitoring systems, and providing sufficient lighting and visibility of employees, particularly at night. Other adaptations might include physical barriers (e.g., glass partitions) between employees and members of the public and easy telephone access.

Administrative controls might include approaches such as background checks on applicants, establishing visitor sign-in procedures, controlling access to specific work areas, and practices that discourage employees working alone, use of identification badges, and so on. Developing and implementing a security plan that includes interface with local law enforcement agencies and providing support to employees who are victims of workplace aggression are other aspects of administrative control. Occupational health nurses can advocate for these and other similar administrative controls in the workplace. They can also educate employees and management regarding workplace aggression policies and procedures and on specific safety measures (e.g., not wearing necklaces or chains that might be used for strangulation, walking to cars in groups, conducting interviews with volatile clients in pairs, etc.). Nurses may also provide education on anger management, conflict resolution, and nonviolent crisis intervention (AAOHN, 2013).

Disaster prevention and preparedness. One final aspect of injury and illness prevention in the occupational setting deals with prevention of and preparedness for disaster events. Many occupational settings pose particular risks for disasters due to the presence of volatile or toxic chemicals and other conditions. AAOHN (2012b) recommends an all-hazards approach to disaster planning in which general approaches to all types of disaster situations are identified, rather than developing different response plans for different types of disasters. Population health nurses can assist in the identification of disaster risks and in planning to mitigate those risks. They may also be involved in planning for evacuation to prevent toxic exposures or other potential for harm in the event of a disaster. Mitigation of disaster risk and the role of the population health nurse in disaster response are addressed in more detail in Chapter 25. Table 23-3 summarizes the foci and population health nursing interventions related to illness and injury prevention in occupational settings.

RESOLVING EXISTING HEALTH PROBLEMS. Resolution of existing health problems in work setting may focus on individual workers or the employee population in general. General areas of involvement for occupational health nurses include screening and surveillance, treatment for existing conditions, and emergency care.

Screening and surveillance. Screening activities can take any of three directions. Screening efforts begin with preemployment assessment of potential employees. Screening may also

TABLE 23-3 Illness and Injury Prevention Foci and Intervention Strategies for Working Populations

Focus	Strategies
Illness prevention	<ul style="list-style-type: none"> • Provide or refer for appropriate immunizations • Provide postexposure prophylaxis for communicable disease exposures • Promote use of effective hygiene (e.g., hand washing) and universal precautions as warranted • Advocate for modification or elimination of risk factors for chronic diseases in the work environment • Educate employees regarding risk factor modification (e.g., smoking cessation, weight reduction) • Provide stress reduction/management education for employees • Advocate for paid sick days and educate employees to minimize presenteeism • Encourage strict attention to laboratory safety procedures
Injury prevention	<ul style="list-style-type: none"> • Provide safety education for employees (e.g., body mechanics, universal precautions for bloodborne pathogens) • Advocate for availability of adequate safety equipment • Monitor effective use of safety equipment • Assist in development of policies and procedures that prevent injury (e.g., comprehensive driver safety policies) • Advocate for modification or elimination of injury risk factors in the work setting • Advocate for work station or work process redesign to prevent injury • Advocate for replacement of hazardous materials or processes with safer alternatives if possible • Advocate for administrative processes and environmental changes to minimize the negative effects of shift work • Advocate for development of adequate management support for injury prevention policies and procedures
Violence prevention	<ul style="list-style-type: none"> • Assist in development of workplace no-tolerance policies that create a culture of safety • Advocate for installation of engineering controls that minimize risk for violence (e.g., barriers, restricted access, security systems) • Advocate for administrative controls that minimize risk of violence (e.g., access badges, visitor sign-in processes) • Assist in development of processes and procedures for handling workplace violence or potential for violence • Assist in development of reporting and follow-up procedures for workplace aggression, including disciplinary action • Educate employees and management on personal safety, violence prevention, anger management, conflict management, recognition of potentially violent situations, and crisis management
Disaster prevention and preparedness	<ul style="list-style-type: none"> • Assist in the identification of disaster risk in the work setting • Assist in planning to eliminate or mitigate disaster risk • Assist in the development and implementation of evacuation plans to minimize injury and illness in the event of a disaster

be conducted at periodic intervals to monitor employee health status. Finally, the work environment may be screened periodically for the presence or absence of hazardous conditions. The population health nurse would be involved in planning and implementing screening efforts at all three levels. **Screening** involves testing individuals for indicators of disease or for risk factors that increase the potential for disease. Screening may occur prior to employment, when considering a job transfer, or on an employee's return from an illness or injury, or when considering retirement for health reasons. Periodic screening may also be employed to monitor employee's health status during employment (Palmer & Brown, 2013). Surveillance, on the other hand, involves the analysis of group data to identify trends and problems in the work setting rather than in individual employees.

Preemployment screening. For many employees, their first interaction with an occupational health nurse is the preemployment

screening examination. The purpose of this initial screening is to facilitate employee selection and placement. Hiring an employee for a particular job is in part dependent on his or her physical, mental, and emotional capabilities for performing that job. A similar process may be needed when considering an employee for a change of job. These capabilities can be determined in an initial screening examination. At this time, the nurse usually obtains a complete health history from the employee and conducts a battery of routine screening tests. Nurse practitioners in the occupational setting may also conduct the physical examination.

For certain categories of jobs, preemployment screening may entail criminal background checks and/or drug screening. For example, a security guard who works for a firm that designs and builds equipment for use by the armed services would probably need to have a security clearance. Similarly, a school teacher may be required to undergo a criminal background check related to child abuse or molestation. Occupational

health nurses will probably not be involved in a security check for a prospective employee, but they may be responsible for collecting specimens for drug screening tests. They may also be subject to screening themselves as health care institutions and other employers become more careful regarding the background of their employees.

Based on the information derived from the screening, the nurse may make determinations regarding the person's employability in a particular capacity. To make such determinations, the nurse must be familiar with the types of activities involved and stressors encountered in a particular job. The

preemployment screening also provides baseline data for determining the effects of working conditions on the health of employees. The questions included in the *Focused Assessment* provided below are designed to help determine an employee's fitness for a specific job. A work fitness inventory is also included on the student resources site.

Periodic screening. The nurse in the occupational setting also plans periodic screening activities to monitor employees' continuing health status. This is particularly true of employees working under hazardous conditions. For example, monitoring

FOCUSED ASSESSMENT

Evaluating Fitness for Work

General Considerations

- Does the employee have the necessary training and expertise for the job?
- How will the employee's general health affect job performance?
- What is the employee's gender? Will gender affect job performance and employee health and safety risks?
- What is the employee's body size? Will size affect work performance or risks?
- What is the employee's age? Will age affect work performance or risks?
- What is the employee's nutritional status? Will nutritional status affect work performance or health and safety risks?

Functional Considerations

- Does the employee have the physical stamina required?
- Does the employee have any mobility limitations that would interfere with performance?
- Does the employee have sufficient joint function to do the job?
- Does the employee have any postural limitations that would interfere with performance?
- Does the employee have the required strength for the job?
- Does the employee have the level of coordination required?
- Does the employee have problems with coordination or balance that would interfere with performance?
- Does the employee have any cardiorespiratory limitations?
- Is there a possibility for unconsciousness that would create a safety hazard?
- Does the employee have the required level of sensory acuity?
- Does the employee have communication and speech capabilities required by the job?
- Does the employee have the requisite level of cognitive function (e.g., memory, critical thinking)?
- Will the employee's mental or emotional state (e.g., depression) interfere with performance?

- Does the employee have the required motivational level?
- Does the employee have a substance abuse problem that would interfere with performance?
- Does the employee have effective stress management skills?
- Is there any possibility that the employee might endanger self or others?

Health Care Considerations

- Are there treatment effects that will interfere with performance (e.g., drowsiness from medications)?
- Will subsequent treatment plans interfere with performance (e.g., nausea due to future chemotherapy)?
- What is the employee's prognosis? Will existing conditions improve or deteriorate further?
- Does the employee have any special health needs to be met in the work setting (e.g., diabetic diet)?
- Are any assistive aids or appliances used or required? Will work processes or setting need to be adapted to accommodate these aids (e.g., space for a wheelchair)?

Task/Setting Considerations

- What are the physical and emotional demands of the job?
- Are there risk factors in the work setting that would adversely affect the employee?
- What is the level of stress involved in the job?
- Will the employee be working with others or alone? What health effects might this have?
- What are the temporal aspects of the job and how will they affect health (e.g., shift work, early morning or late evening work, length of shift)?
- Is there travel involved in the job? How will this affect employee health?
- Is the workstation ergonomically designed to minimize injury?

Data from: Palmer, K. T., & Brown, I. (2013). A general framework for assessing fitness for work. In K. T. Palmer, I. Brown, & J. Hobson (Eds.), *Fitness for work: The medical aspects* (5th ed., Chapter 1). Oxford, UK: Oxford University Press.

devices are used by personnel working with radiation and are periodically checked for exposure limits. Likewise, blood chemistries may be done at periodic intervals to test for exposure to toxic substances. Periodic blood pressure screenings and pulmonary function tests may also be warranted. In some occupational groups, such as the armed forces, employees are routinely screened for overweight and for physical capacity.

The types of screening done depend on the type of job performed, the risks involved, and the capabilities required. Some screenings are routinely performed on all employees in a particular setting. For example, employees may receive a routine physical examination at periodic intervals. Other screening tests are performed only on specific employees. For example, lead screening may be done routinely on individuals who work on a plant assembly line, but not on clerical personnel.

Nurses may also be actively involved in providing or promoting routine health screenings that are not related to employees' jobs. For example, the nurse may educate employees regarding the need for colon cancer screening or mammography.

Occupational health nurses are frequently responsible for conducting these and other screening tests on employees. They may also interpret test results, explain them to employees, and take action when warranted by positive test results.

Environmental screening and surveillance. Periodic screening of the environment and surveillance for negative occupational effects may also be warranted, and, in the absence of industrial hygienists or safety engineers, the nurse may be responsible for planning and conducting environmental screenings. For example, the nurse may measure noise levels in various work areas at specific intervals to determine areas in which hearing protection is required. Similarly, measurements of volatile chemicals or radiation might be done in high-risk areas.

Surveillance involves monitoring the employee population for trends in health problems. For example, AAOHN (2013) recommends surveillance for instances of workplace aggression and violence. Similarly, the nurse may note an increase in absences related to gastrointestinal problems among employees who eat in company dining rooms or increases in specific kinds of injuries.

Treatment of existing conditions. The second area of focus in resolving existing health problems in the work setting is the diagnosis and treatment of illness or injury. Population health nurses are actively involved in planning health interventions for individual employees and should also participate in planning health programs to meet the needs of groups of clients.

Many employers go beyond treating only job-related illnesses and conditions to treating a variety of major and minor conditions. The rationale for the extension of services to non-job-related conditions is that any health problem, physical or emotional, can serve to impair an employee's performance. Also, treatment of these conditions within the work setting limits time lost in pursuing outside treatment, saving the company money in the long run.

Depending on the capabilities of the occupational health unit, employees with existing health problems may be referred to the external health care system for problem resolution, or treatment may be provided within the workplace itself. Those occupational health nurses who are nurse practitioners may treat illness in the work setting. Even nurses who are not nurse practitioners may treat minor conditions on the basis of protocols established in conjunction with medical consultation.

Occupational health nurses also need to plan to monitor the effectiveness of therapy, whether or not that therapy is provided by the occupational health unit. For example, an employee with hypertension might be followed by his or her primary care provider, but the occupational health nurse will monitor medication compliance and effects on the employee's blood pressure. In addition, the nurse will educate the employee regarding the condition and its treatment.

In the case of employees with problems related to substance abuse or stress, the population health nurse usually initiates a referral to an appropriate source of assistance. The nurse may also need to function as an advocate for impaired employees, encouraging employers to provide coverage for treatment of psychological as well as physical illness. Nurses may also find it necessary to report substance abuse to supervisory personnel when either the health or the safety of other employees is threatened.

Population health nurses in occupational settings may also be involved in planning and implementing employee assistance programs for employees with psychological problems. An **employee assistance program (EAP)** is a program within the occupational setting designed to counsel employees with psychological problems and assist them in dealing with those problems. EAPs usually focus on motivating individuals to seek help and referring them for needed services. Substance abuse disorders and eating disorders are two types of problems addressed by EAPs. Generally, the occupational health nurse refers an employee to another source of services rather than providing care for these problems within the work setting. However, the nurse may be involved in the development and support of self-help groups within the employment setting to assist employees with these and other problems. For example, guided self-help and cognitive behavioral group therapy may assist employees with eating disorders. Similarly, an occupational health nurse might help to establish a bereavement group to assist employees who have experienced significant losses. Occupational settings also frequently sponsor chapters of Alcoholics Anonymous.

Emergency response. Responding to emergency situations is another aspect of resolving existing problems. Nurses may find themselves dealing with both physical and psychological emergencies and should have a basic plan for dealing with various types of emergencies that may arise. Physical emergencies may result from serious accidents or from physical conditions such as heart attack, stroke, seizure disorder, and hypoglycemia. Treatment for these emergencies is usually based on established protocols.

With respect to emergencies due to illness, it is helpful if the nurse has prior information related to the employee's condition.

For example, if the nurse has prior knowledge that the client is diabetic, the diagnosis of hypoglycemic reaction will be reached and treatment initiated more rapidly than would otherwise be the case. For this reason, occupational health nurses should be well acquainted with employees' health histories.

Psychological emergencies may result in homicide, suicide, or both. Although businesses may have generalized protocols for dealing with such emergencies as threatened homicide or suicide, the nurse faced with such situations will probably need to exercise a great deal of creativity in planning to address a psychological emergency. General considerations include remaining calm and removing others from the immediate vicinity. The nurse *should not* plan any heroic measures that may endanger him- or herself, the employee, or others. Additional interventions are dictated by the situation. Again, prior identification of employees under excessive stress may help to prevent psychiatric emergencies.

Another psychological emergency with which occupational health nurses may need to deal is sexual assault. Most victims of sexual assault in the workplace are women, and most assaults occur at night when women are working in isolation from coworkers or the public. The nurse who encounters a female employee who has been sexually assaulted should address immediate physical and psychological needs, assess the client for suicidal tendencies, and refer her for counseling. The nurse should also alert the appropriate authorities and may need to act as an advocate with the legal and criminal justice systems and provide emotional support.

One further type of emergency that requires an occupational health nursing response is the emergency that affects large numbers of people. Examples of mass emergencies are fires or explosions, radiation exposure, and hazardous substance leaks. In addition to providing treatment for those injured in such emergencies, the nurse may be responsible for assisting in

evaluating affected areas and in organizing to provide needed care. Occupational health nurses should be involved in planning the overall company response to such situations as well as in planning health care in such an eventuality. The role of the nurse in disaster preparedness is discussed in greater detail in Chapter 25. Major emphases in resolving existing health problems in work settings are summarized in Table 23-4.

HEALTH RESTORATION. Health restoration or rehabilitation was identified as an element of the occupational health nursing role by the World Health Organization as early as 1982. Rehabilitation in the context of the occupational health setting is a process designed to return the employee, as much as possible, to his or her prior level of function.

Health restoration interventions in work settings are directed toward preventing recurrence of health problems, limiting their consequences, and promoting and maintaining independence. In occupational health settings, health restoration enables the employee to return to work, and the goal is to remove obstacles to a return to productive work or to adapt the workplace to facilitate that return. In some instances, when return to an employee's former position is precluded by the long-term consequences of health problems or the nature of job demands, health restoration may involve preparing him or her for a new role.

The types of intervention strategies employed depend on the problems to be prevented. For example, engineering measures may be used to prevent subsequent leakage of a toxic chemical if a leak has already occurred.

Generally speaking, health care at this level is geared toward preventing the spread of communicable diseases, preventing recurrence of other acute conditions, and preventing complications of chronic conditions. Sick-leave policies and employee immunization are examples of measures that might be taken to stop the spread of influenza in the employee population. As noted earlier,

TABLE 23-4 Strategies for Resolving Existing Health Problems in Working Populations

Focus	Strategies
Screening	<ul style="list-style-type: none"> • Conduct preemployment screenings • Determine work capacity • Make recommendations regarding work conditions or accommodations • Conduct periodic employee screening • Conduct periodic environmental screening and surveillance • Report and interpret screening findings and make referrals for care or environmental modification as needed
Treatment of existing conditions	<ul style="list-style-type: none"> • Provide treatment for work-related illness or injury • Provide immediate first aid • Refer for outside medical assistance as needed • Develop health care delivery programs to address high prevalence problems in the occupational setting • Advocate for adequate employee health insurance coverage • Advocate for accessible internal or external health care services to meet employee health needs
Emergency response	<ul style="list-style-type: none"> • Assist in the development of individual and disaster emergency response plans for the work setting • Respond to individual physical or emotional emergencies • Refer employees for continued treatment as needed • Respond to care needs in an occupational disaster • Evaluate the health effects of occupational disasters

by encouraging employees to take advantage of sick-leave benefits when they or family members are ill, the nurse can minimize exposure of others in the occupational setting to communicable diseases and can control the spread of disease. Safety education might prevent a recurrence of accidental injuries due to hazardous equipment, and use of hearing protection might prevent further deterioration of an employee's hearing after noise exposure has already caused some damage. Similarly, treatment of an employee's hypertension can prevent further health problems.

Another aspect of health restoration in an occupational setting may be assessing an employee's fitness to return to work after an illness or injury. Assessment considerations in this case would be similar to those in preemployment assessment. The occupational health nurse would determine the job demands and assess the employee's ability to meet the requirements of the job. Sometimes this can be facilitated by modifications in job processes or responsibilities to fit an employee's reduced capabilities. Occupational health nurses may need to educate the employee, employer, supervisor, and coworkers regarding capabilities and accommodations needed. Based on the UN convention (2006), the right to work also applies to persons who acquire a disability as a result of employment and appropriate measures should be taken to protect that right.

Health restoration interventions by occupational health nurses may also involve assisting employees to adapt to chronic illness or monitoring the status of workers' compensation claims. Dealing with chronic illness or disability in the work setting may be facilitated by the development of worksite disability management programs. Such programs provide disease management services in the work setting and have been shown to result in cost savings for the organization by preventing days lost to work due to exacerbations or for follow-up appointments in the external health care system.

Occupational health nurses may assist individual employees to cope with chronic illness in a number of ways. They may educate the client to enhance personal coping abilities (e.g., through medication management, self-monitoring skills, etc.) or advocate with management or coworkers for support for self-care. For example, the nurse might arrange for flexible break or meal times to permit employees with diabetes to better manage their diets. Nurses may also advocate for working conditions that accommodate limitations or prevent further deterioration. For example, they may see that the workstation for an employee with chronic back pain is ergonomically evaluated and any needed accommodations made. Occupational health nurses may also connect employees to sources of support, such as self-help groups, outside of the work setting. Finally, they may advocate for adequate health care provider support and insurance coverage to address the costs of needed care.

Another focus in health restoration might be the provision of health care and assistance for both victims and perpetrators of workplace aggression (AAOHN, 2013). Employee assistance programs, for instance, might address anger management issues or deal with posttraumatic stress disorder resulting from an assault in the workplace. Assistance with legal claims or in processing worker's compensation claims might also be needed.

Finally health restoration interventions might be required in the aftermath of a workplace disaster. Population health nurses in occupational settings are ideally placed to identify employees suffering from physical or psychological consequences of a disaster and refer them for assistance. They can also be involved in assessing the emergency response and in improving future responses. Population health nursing roles in disaster recovery are discussed in more detail in Chapter 25. Health restoration foci and related strategies in occupational settings are summarized in Table 23-5.

TABLE 23-5 Health Restoration Strategies for Working Populations

Focus	Strategies
Preventing the spread of communicable diseases	<ul style="list-style-type: none"> • Provide employee immunization • Educate on infection control procedures • Encourage use of sick days and advocate for sick days for employees
Preventing the recurrence of other acute conditions	<ul style="list-style-type: none"> • Educate employees to prevent recurrent health problems • Advocate for environmental modifications to prevent recurrent problems
Preventing complications of chronic conditions	<ul style="list-style-type: none"> • Monitor treatment effects and disease status • Educate employees for disease self-management • Modify the work environment to accommodate limitations due to disability
Assessing fitness to return to work	<ul style="list-style-type: none"> • Follow up on workers' compensation claims • Assess recovery status • Modify work environment as needed to facilitate return to work • Educate employees, employers, supervisors, and coworkers regarding requirements for a return to work
Assisting victims and perpetrators of workplace aggression	<ul style="list-style-type: none"> • Make referrals for assistance as needed • Assist with legal or workers' compensation claims • Provide emotional support
Disaster recovery	<ul style="list-style-type: none"> • Identify employees experiencing physical or psychological consequences of disasters and provide or refer for assistance • Assist in assessing the adequacy of emergency response and in planning for future responses

Implementing nursing interventions in work settings frequently involves collaboration with others. Most often, collaboration occurs between the nurse and the employee. In other instances, the nurse may collaborate with health care providers and others within or outside of the occupational setting. For example, the nurse might collaborate with a pregnant employee’s primary health care provider to monitor her progress throughout the pregnancy. Implementing the plan of care for an employee with carpal tunnel syndrome might involve collaboration with the primary care provider and with a supervisor to facilitate movement to a job that does not necessitate repetitive wrist movements or to promote ergonomic redesign of an employee’s work station and work processes.

When health problems affect groups of employees, implementing the plan of care might involve collaboration with other health care providers and with company management and other personnel. For example, the nurse who has documented an increased incidence of respiratory conditions due to aerosol exposures will advocate plans to resolve the problem. These plans need to be approved by management and implemented by engineering personnel, if engineering controls are required, or by company purchasing agents, if special respiratory protective devices are needed. In the latter instance, the nurse may be involved in determining the types of protective devices needed and recommending their purchase to management.

Evaluating Health Care in Work Settings

As in all other settings for nursing practice, the effectiveness of health care in work settings must be evaluated. Evaluation can focus on the outcomes of care either for the individual

employee or for the total employee population. Evaluation is conducted on the basis of principles discussed in Chapter 15 and focuses on the achievement of expected outcomes and the processes used to achieve those outcomes. For example, the occupational health nurse may evaluate the effectiveness of body mechanics education in decreasing the incidence of back injuries. At the individual level, evaluation might focus on the impact of no-smoking education on an individual employee’s smoking behavior.

Selected aspects of occupational health and safety programs can also be evaluated using a set of 20 health and exposure surveillance indicators developed by the Council of State and Territorial Epidemiologists (n.d.). **Health indicators** are measures of health (injury or illness) or factors associated with health (exposures, hazards, or interventions) that allow comparisons over time and help guide priorities for prevention and intervention. The indicators are generally used at the state level to monitor occupational health statewide, but could be used in a particular occupational setting. Areas of focus include the demographic profile of the worker population; occupationally acquired illnesses, injuries, and related hospitalizations and days off work; workers’ compensation claims; employment in high-risk occupations and industries; and federal or state OSHA inspections and their outcomes (Council of State and Territorial Epidemiologists, n.d.).

Achievement of national objectives related to occupational health can also be used to evaluate efforts in the local occupational setting or at regional, state, and national levels. The status of selected national objectives is summarized below.

Healthy People 2020

Selected Objectives Related to Occupational Health

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
ECBP-8. Increase the proportion of worksites with more than 50 employees that offer an employee health promotion program	Dev	Dev	Dev	National Survey of Employer-sponsored Health Plans, Mercer
ECBP-9. Increase the proportion of employees that participate in employer-sponsored health promotion activities	Dev	Dev	Dev	National Survey of Employer-sponsored Health Plans, Mercer
IID-15.3. Increase hepatitis B vaccine coverage among health care personnel	64.3% (2008)	90%	NDA	National Health Interview Survey (NCHS) CDC/NCHS
OSH-1.1. Reduce deaths from work-related injuries in all industries (per 100,000 workers)	4.0 (2007)	3.6	3.6 (2010)	Census of Fatal Occupational Injuries (CFOI), DOL/BLS, Current Population Survey (CPS) Census & DOL/BLS

CHAPTER RECAP

Occupational settings contribute to a wide variety of health problems in individuals and in population groups, yet they also provide an ideal setting for influencing health-related behaviors and environmental conditions. Population health nurses employed in occupational settings can do much to promote the health of individual employees, work groups, and the general public.

Factors related to biological, psychological, environmental, sociocultural, behavioral, and health system determinants in-

fluence the health of working populations. Population health nurses working in occupational settings assess the positive and negative effects of these factors on the health of the employee population. They also plan, implement, and evaluate interventions to promote health, prevent illness, resolve existing health problems, and restore health and promote return to work in this population.

CASE STUDY

Nursing in the Work Setting

You are a population health nurse employed by a large manufacturing plant. On Wednesday you see several employees complaining of abdominal cramping and diarrhea. They all state that their symptoms started at home during the night. You get word from one of the plant supervisors that several of her employees called in sick this morning because of similar symptoms. In checking with other departments, you find that there are a number of absences throughout the plant. Two of the older employees and one who you know has AIDS have been hospitalized with severe dehydration. All of the people with cramps and diarrhea eat regularly in the cafeteria.

1. What biological, psychological, environmental, sociocultural, behavioral, and health system factors are operating in this situation? What additional information would you want to gather?

2. What are your nursing diagnoses?
3. What outcome objectives do you hope to achieve through intervention?
4. What measures will you employ to resolve the identified problems? Why? What illness prevention measures might have prevented the occurrence of these problems? What health restoration measures are warranted to prevent the recurrence of problems or complications?
5. How will you evaluate the effectiveness of your interventions?

24 Care of Correctional Populations

Learning Outcomes

After reading this chapter, you should be able to:

1. Discuss the impetus for providing health care in correctional settings.
2. Differentiate between basic and advanced nursing practice in correctional settings.
3. Describe biological, psychological, environmental, sociocultural, behavioral, and health system factors that influence health in correctional settings.
4. Identify major aspects of health promotion in correctional settings and analyze the role of the population health nurse in each.
5. Describe major foci in illness and injury prevention in correctional settings and related population health nursing strategies.
6. Describe approaches to resolving existing health problems in correctional settings and analyze population health nursing roles with respect to each.
7. Discuss considerations in health restoration in correctional settings and analyze related population health nursing roles.

Key Terms

assisted outpatient treatment (AOT)	jails	recidivism
compassionate release	juvenile detention facilities	reentry
correctional nursing	lockdown	search and seizure
crisis intervention teams (CITs)	lockup	self-injurious behavior
detainees	parolee	status offenses
diversion	prisons	TB prophylaxis
forensic nursing	probationer	

Misguided Reform

As we will see in Chapter 29[∞], Dorothea Dix was highly successful in initiating prison reform, but her efforts were primarily directed toward removing the mentally ill from jails and prisons and providing them with treatment facilities. In so doing, she also improved some conditions in jails and prisons throughout several states (*Prison and asylum reform, n.d.*). Unfortunately, other attempts at advocacy and reform may have done more harm than good.

In 1787, Philadelphia citizens formed the Philadelphia Society for Alleviating the Miseries of Public Prisons in response to appalling conditions in the local jail. The group investigated prison conditions and presented their findings to the Pennsylvania legislature recommending solitary confinement and hard physical labor as an alternative to previous severe physical punishments such as whipping, hanging, and pillorying (being locked in wooden stocks and subjected to public ridicule). Following passage of the legislation, Pennsylvania established “model” prisons in which inmates were confined to individual cells in a model later known as the “Pennsylvania system.” The system called for the complete separation of inmates for their entire sentence to decrease the potential for exposure to bad companions. Each cell, which inmates rarely left, included space for a work area in which the inmate worked at contract labor, a private exercise yard, central heating, a flush toilet, and shower bath. Inmates were fed and worked in their cells and received some vocational instruction. The Auburn system, instituted at the Auburn Penitentiary in New York, was similar except that inmates were fed and worked communally in strict silence during the day and returned to their individual cells as night. Both systems were widely emulated in the United States and Europe. An extensive rash of suicides in the Auburn Penitentiary, however, called attention to the deleterious psychological consequences of “solitary confinement” and these practices were abandoned except for punishment of uncontrolled and recalcitrant inmates. Society members in Philadelphia and a similar organization in Boston, the Prison Discipline Society, did, however, continue to visit prisons, providing independent oversight and perhaps ameliorating some of the more common abuses of prisoners and assuring provision of basic necessities (Johnston, n.d.; Morse, 2007).

Incorporating Health into a Public Defender’s Office

Recent arrestees often have health issues that have been neglected over significant periods of time. If incarcerated, these needs will be attended to at some point, but many arrestees are freed until their trials. At that point, matters dealing with their court date may make health care a low priority. They are often tied up with multiple appointments with public defenders planning for their trials (Venters et al., 2008).

A collaborative effort between medical residents at Montefiore Medical Center and a public defender’s office in a low-income area of New York City was initiated. Originally, social workers at the defender’s office made referrals to medical residents at a local community clinic, but few clients accepted referrals, and none of them kept their appointments. As a result, a resident was stationed at the public defender’s office on specific days. The resident saw clients at the time of their appointment at the defender’s office if he was available and ascertained health care needs. Some encounters addressed questions and others led to appointments at the community clinic. Because of their level of comfort with the defender’s office, clients often came there prior to their appointments and were walked to the clinic by staff. Kept appointment rates increased to 66%, higher than the usual rate for the clinic (Venters et al., 2008).

Challenges to the program lay in the limited time the resident was available in the defender’s office and a backlog for clinic appointments, so future plans include possible provision of health care services on site in the defender’s office (Venters et al., 2008).

The concept of prisons as a place to contain wrongdoers began as early as the 1600s with workhouses that were used to punish people who violated the law. Unfortunately, workhouses were also used to confine family members who were likely to impugn the family's honor through their activities, whether or not those activities were actually criminal in nature (Fagan, 2003). As we saw in Chapter 21, criminalization still occurs within populations that society would prefer to ignore, such as the homeless.

Correctional populations may be particularly vulnerable to a variety of health problems. In many instances, members of this population have not had access to effective health care services. In other cases, they have not seen health as a priority and frequently do not engage in practices that are conducive to good health. In addition, drug and alcohol use, which may result in incarceration, have both physical and psychological consequences for health. Incarceration, in and of itself, may have adverse health consequences.

Correctional facilities provide a relatively new practice setting for population health nursing compared to the settings discussed in previous chapters. Correctional nursing, however, is congruent with the primary focus of population health nursing—the health of groups of people and the general public. Correctional nursing frequently involves challenges not encountered in other population health nursing settings. Practice in a correctional setting requires autonomy and excellent assessment skills. Nurses are often responsible for triaging inmates during entry or sick call and identifying those who need to be seen by physicians, nurse practitioners, or other providers. Nurses may also provide routine treatments, including medication, under agency protocols. Nursing in correctional settings operates within the constraints of the security system, which may contribute to increased job stress and frustration. Another source of stress is the fear of litigation by a population that is prone to threats of litigation. Although there is some risk to the nurse's physical safety, many correctional nurses feel safer than they would in other settings such as emergency departments.

Another source of stress in the correctional setting is the potential for conflict between nursing values and those of corrections personnel. Differences in values frequently give rise to the need for population health nursing advocacy in correctional settings to ensure that health care needs are balanced with custodial and security needs. For example, the primary concerns of the nurse are health care and meeting the health needs of inmates. For custodial personnel, however, the primary concern must be security. The priority placed on security may often make it difficult for the nurse to meet inmates' needs. For instance, giving medications such as insulin in a timely fashion may be impeded by security measures like lockdowns, when nurses are not ordinarily allowed into the areas where inmates are housed. Similarly, nurses may be asked to share information obtained while taking a health history (e.g., past drug use) with custodial or law enforcement personnel, when confidentiality and privacy are primary values of the nursing profession.

Correctional nursing takes place in three general types of facilities: prisons, jails, and juvenile detention facilities. **Prisons** are state and federal facilities that house persons convicted of crimes, usually those sentenced for longer than 1 year. Municipal or county facilities are usually called **jails** and house both convicted inmates and detainees. Convicted inmates in jails are usually serving sentences under a year in length (Lee et al., 2012). **Detainees** are people who have not yet been convicted of a crime. They are being detained pending a trial either because they cannot pay the set bail or because no bail has been set. They may also have violated the terms of probation or parole. **Juvenile detention facilities** house children and adolescents convicted of crimes and those who are awaiting trial but who cannot be released in the custody of a responsible adult. Jails and juvenile detention facilities tend to be smaller and house fewer inmates than prisons.

Whatever the size of the facility or the terminology used, nurses working in correctional facilities must be committed to the belief that inmates retain their individual rights as human beings despite incarceration and that they have the same rights to health care as any other individual. Society does not categorically deprive any other group of individuals of access to adequate health care. In fact, there are carefully monitored standards of health care in such institutions as nursing homes, mental health facilities, and orphanages. It has only been as recently as 1979, however, that a program for accrediting health services in prisons was developed by the American Medical Association. Development of accreditation standards occurred at the request of the U.S. Department of Justice following a landmark court decision that depriving inmates of access to health care violated their civil rights (Rold, 2011). Only since 1985 have published standards for nursing practice in such settings been available (American Nurses Association [ANA], 1985).

The Correctional Population

Crime is a fact of life in modern-day society. In 2009, for example, 10.6 million crimes were committed in the United States for a crime rate of 3,466 for every 100,000 population. Violent crime (murder, rape, robbery, and aggravated assault) accounted for 1.3 million of these incidents and property crimes (burglary, theft, and automobile theft) for another 9.3 million (U.S. Census Bureau, 2013b). Homicide rates decreased by almost half from 10.2 per 100,000 population in 1980 to 5.4 per 100,000 in 2009 (U.S. Census Bureau, 2013d). In 2009, however, murders still claimed the lives of 13,756 people, more than 2,000 of them in the commission of a felony. More than 700 of those murders were the result of juvenile gang killings (U.S. Census Bureau, 2013c).

Globally, 9.8 million people were incarcerated in 2008 with a median incarceration rate of 145 inmates per 100,000 population (Zlodre & Fazel, 2012). The U.S. incarceration rate for 2009 was 250 per 100,000 population, the highest of any country (U.S. Census Bureau, 2013j). On any given day in 2009, more than 2.3 million people were housed in U.S. correctional institutions, but as many as 10 million people may pass through

the local, state, and federal correctional systems each year (Lee et al., 2012). More than 11 million people were arrested in the United States in 2009, and more than 2.1 million people were held in U.S. adult correctional facilities (U.S. Census Bureau, 2013a, 2013e). Federal and state prisons held 1.6 million people, 89% of whom were housed in state facilities (U.S. Census Bureau, 2013h). Another 4.2 million persons were on probation, and 819,308 on parole. Overall, 7.12 million people in the United States (3.1% of the population) were under some form of correctional supervision (U.S. Census Bureau, 2013i).

City and county jails account for an even larger number of incarcerated individuals. For example, from June 2010 to June 2011, the average daily census in U.S. jails was 735,000, and the total jail population for the year was 11.8 million people (Smith et al., 2013). The Los Angeles County jail alone houses a population of 20,000 on any given day, with 400 to 600 admissions daily and 180,000 people over the course of a year (Malek et al., 2011). Similarly, the New York City jail reports a daily census of 13,000 people, with approximately 90,000 admissions per year (Ludwig, Cohen, Parsons, & Venters, 2012).

Incarceration rates have increased dramatically in the United States. From 1980 to 2004, for example, the number of people incarcerated in the United States quadrupled. Despite increases in bed capacity, many jails and prisons are operating far over capacity. For example, California prisons had been operating at 200% of capacity for several years when the Supreme Court mandated the release of large numbers of inmates due to the system's inability to effectively meet their needs (Rold, 2011).

There are several reasons for this marked increase in correctional populations. First, there have been significant changes in sentencing guidelines, such as “truth in sentencing” and “three strikes” laws. Truth in sentencing refers to legislation mandating that persons convicted of a crime serve a minimum percentage of their sentence before being eligible for parole (Polk, 2011). Three strikes laws mandate life imprisonment for defendants with two prior convictions for serious or violent crimes. In effect, most such laws are often applied to sentencing for nonviolent crimes as well (Stanford Law School, 2013). As a result, the United States now has the dubious distinction of having the highest rate of incarceration in the developed world (Zlodre & Fazel, 2012).

The Need for Correctional Health Services

Health care in correctional facilities is an appropriate endeavor for several reasons. First, the right to adequate health care is a constitutionally recognized right. In 1976, a Supreme Court decision in *Estelle vs Gamble* ruled that neglect of serious medical needs constitutes “cruel and unusual punishment” and violates the Eighth Amendment to the U.S. Constitution (Smith et al., 2013). Similarly, failure to provide needed health services constitutes deliberate indifference under the Fifth Amendment and violates civil rights protected by the Fourteenth Amendment (Muse, 2011).

Global Perspectives

Conditions of Incarceration

Although conditions in U.S. jails and prisons are not ideal, for large portions of more than 10 million people incarcerated throughout the world, conditions may be significantly worse. A recent report by the U.S. Department of State (2012) indicated three main areas of concern in international prison conditions: unsafe conditions, mistreatment of prisoners, and inadequate legal protection. Unsafe conditions include overcrowding, unsanitary conditions, barriers to basic hygiene, malnutrition, contaminated water, and poor quality health care. In some parts of the world, correctional facilities are two to five times over capacity, to the extent that inmates in some facilities must sleep in shifts. Elsewhere, irregular facilities such as unventilated shipping containers, basements, or open-air holding facilities are used to house inmates. Much of the overcrowding and other safety issues stem from large numbers of pretrial detainees who in some places may be held for months to years before being tried.

Abuse of prisoners is another common concern. Abuse most commonly occurs among pretrial detainees in attempts to elicit confessions and among political prisoners and prisoners of conscience (persons who voice beliefs contrary to those of people in power). Abuse may also be used to control or punish inmates. Inadequate legal protection may involve incarceration for indefinite periods without conviction, prohibition of access to legal counsel or family members, or secret trials. Other areas of concern include arbitrary or discriminatory criteria for evidence and judicial corruption. Convicted inmates may also be denied their rights during incarceration.

The United Nations Office on Drugs and Crime (UNODC) has developed a set of international standards and norms for prisons that have been used by more than 100 countries in the development of their criminal justice policies (UNODC, 2013). General standards address such issues as nondiscrimination and religious tolerance, inmate registration and valid confinement orders, physical environmental conditions, sanitation and hygiene facilities, suitable clothing and bedding, adequate nutrition and exercise, adequate medical care, family communication, custody of personal property, and notification to family members of an inmate's death, illness, or transfer. The standards also address the need to separate male from female inmates, youth from adults, pretrial detainees from convicted inmates, and those accused of civil or political offenses from those accused of criminal offenses. Finally, the standards address appropriate discipline and use of restraints only to prevent escape during transfer or to protect the inmate or others from harm and never for punishment (UNODC, 2006). For further information about the standards, see the *External Resources* section of the student resources site.

In addition to the constitutional right to health care, correctional care is good common sense for a variety of other reasons. Because of poverty, lower education levels, and unhealthy lifestyles that frequently involve substance abuse, inmates may

enter a correctional facility with significant health problems (Spaulding et al., 2010). Because many of these individuals cannot afford to pay for care on the outside, the cost of care will be borne by society. Societal costs for this care will be lower if interventions occur in a timely fashion, before health problems become severe. Provision of care within the correctional facility also saves taxpayers the cost of personnel and vehicles to transport inmates to other health care facilities. Health promotion and illness and injury prevention in correctional settings are also cost-effective.

Another possible societal cost of failure to provide adequate health care to inmates lies in the potential for the spread of communicable disease from correctional facilities to the community (Malek et al., 2011). Environmental conditions and behaviors within correctional facilities lend themselves to the transmission of communicable diseases such as tuberculosis, HIV, and hepatitis. When inmates are released back into society, they may constitute a source of infection for the rest of the population.

Finally, correctional settings have been described as unhealthy environments in and of themselves and may give rise to a variety of health problems. Correctional environments limit inmate autonomy; promote social isolation and communicable diseases; limit exercise; and foster boredom, stress, hostility, and depression. Services are needed to deal with these effects of incarceration as well as the myriad health problems inmates bring with them to correctional settings.

Population Health Nursing and Correctional Health

Population health nurses working in correctional settings employ the nursing process to design interventions to meet identified health needs. Care begins with an assessment of needs that informs the planning and implementation of interventions to address those needs. Finally, population health nurses evaluate the effectiveness of care in meeting the identified needs.

Assessing the Health Status of Correctional Populations

Factors related to each of the six categories of determinants of health influence the health status of inmates and staff in correctional settings. The nurse assesses biological, psychological, environmental, sociocultural, behavioral, and health system determinants of health to identify health problems and the factors contributing to them and to direct interventions to resolve those problems.

BIOLOGICAL DETERMINANTS. Biological determinants affecting health in correctional populations include age, gender, and race; mortality; infectious and chronic conditions, injury, and other conditions. The nurse in the correctional setting assesses individual clients for existing physical health problems as well as identifying problems that have a high incidence and prevalence in the overall institutional population.

Age, gender, and race/ethnicity. Correctional populations vary greatly in their composition. There are growing numbers of youth and the elderly in U.S. correctional facilities. In 2009, for example, 1.5 million arrests were made among people under 18 years of age and more than 7,000 juveniles were housed in jails throughout the country; a threefold increase from 1990 (U.S. Census Bureau, 2013e, 2013j). In fact, there are now more youth involved in the juvenile justice system than in foster care (Smith et al., 2013). In 2009, 0.5% of the population in correctional settings was 15 to 17 years of age (U.S. Census Bureau, 2013a).

Juvenile inmates tend to have higher prevalence rates of a variety of physical and mental health conditions than their counterparts in the general population and usually have less access to care prior to incarceration. Based on data from the Northwest Juvenile Project, a long-term follow-up study of juveniles in Cook County, Illinois, 80% of the adolescents arrested were undocumented or unaddressed victims of abuse (Teplin et al., 2013). According to a National Academies report, adolescent involvement in criminal activity stems from developmental factors that make juveniles very different from adult perpetrators of crime. These factors relate to biological immaturity in the brain stem, with more rapid development in brain stem functions supporting pleasure seeking behaviors than those that foster self-control. This immaturity leads to an inability to engage in self-regulation, heightened sensitivity to external influences on behavior, and a present orientation that results in the inability to consider future consequences of one's actions. The report also notes that the majority of juvenile offenders are not engaged in serious crimes (Bonnie, Chemers, & Schuck, 2012). In addition, juveniles are often arrested for **status offenses**, conduct that would not be considered criminal if committed by an adult, such as truancy, running away, curfew violation, and alcohol or tobacco possession (Coalition for Juvenile Justice, n.d.).

Incarcerated youth also display significant levels of mental illness and substance abuse. In 2009, for example, more than 130,000 youth were arrested for drug abuse offenses, 86% of which dealt with possession of illegal drugs (U.S. Census Bureau, 2013g). Approximately two thirds of male juvenile offenders and nearly three fourths of females have at least one psychiatric disorder, and 51% of males and 47% of females have a substance abuse disorder. Post-traumatic stress disorder (PTSD) was also found in 11% of juveniles in one study (Teplin et al., 2013).

Because of the move to try more juveniles as adults, particularly for violent crimes, the number of youth incarcerated in adult correctional facilities is growing. Because of the potential for victimization by older and stronger inmates, younger inmates should be in areas segregated by sight and sound. Removing juveniles from adult facilities and sight and sound segregation are two core provisions of the Juvenile Justice and Delinquency Prevention Act (Coalition for Juvenile Justice, n.d.).

Incarcerated youth have different needs than adult inmates. For example, they have greater nutritional needs than adults (Robbins, 2009a). In addition, correctional protocols are often based on the needs of adult inmates. For example, juvenile suicide prevention plans and staff training are often modeled on

information from adult prisoners or from youth in the community and may not be effective with incarcerated youth. For instance, factors associated with youth suicide in correctional settings are considerably different than those for adults, including time and location of suicides and the role of intoxicants (Robbins, 2008). Because of these differences, the National Commission on Correctional Health Care (NCCHC) (2014b) has developed standards for juvenile detention facilities separate from those for adult facilities. For further information on the standards for juvenile detention facilities, see the *External Resources* section of the student resources site.

The American Academy of Pediatrics (Braverman & Murray, 2011) revised its policy statement on care of juvenile offenders to include the following recommendations:

- Provision of care on a par with that provided to non-incarcerated youth
- Housing of children and adolescents in facilities appropriate to their level of development
- Coordination of care between justice system providers and community providers
- Provision of evidence-based mental health and substance abuse services for youth
- Coordination of efforts to address funding for adequate health services for incarcerated youth (Braverman & Murray, 2011).

Population health nurses may need to advocate for the application of these sets of standards and recommendations in the care of the juvenile correctional population.

The fastest-growing segment of corrections populations is the elderly, primarily because of extended sentences, with a large proportion of the population growing old in the correctional setting. From 1990 to 2012, the proportion of people over 55 years of age in the general population increased by 50%, but the population in this age group in state and federal prisons increased by 550% (Smith et al., 2013). People over 50 years of age are considered “old” in correctional systems due to the accelerated aging that occurs in correctional populations. This accelerated aging process is due to life histories that often include substance abuse and withdrawal, poor health care, and high-risk behaviors as well as the stress of incarceration.

According to U.S. Census Bureau data (2013a), 1.2% of the total population in adult correctional facilities in 2009 were 65 years of age or older. Older inmates have more chronic diseases and disabilities and more cognitive impairments than younger prisoners. For example, the presence of people with dementias is increasing in correctional facilities as well as in the general population, and it is estimated that the prevalence of these conditions in correctional settings may be two to three times that in the general population (Wilson & Barboza, 2010). In addition, older inmates may have more difficulties conforming to prison life, experiencing difficulties climbing into upper bunks or dropping to the floor in an alarm situation (Smith et al., 2013).

Correctional facilities are often unprepared to address the health care needs of older inmates, nor are budgets designed

to accommodate these needs. In addition, the shift of older inmates from state and federal prisons to county jails to address overcrowding places them in facilities that are least able to address their needs. Population health nurses may need to be actively involved in assuring that facilities and services are available to meet the needs of elderly inmates as well as to protect them from victimization by younger inmates.

Correctional populations are significantly unbalanced with respect to gender and racial/ethnic composition. In 2009, men constituted 92% of the U.S. adult correctional population (U.S. Census Bureau, 2013a). Unfortunately, correctional facilities are often not well equipped to address the special needs of female inmates and their needs are often overlooked (Matheson, Doherty, & Grant, 2011).

Similar, but not as pronounced, differences in population composition are noted among incarcerated youth, with boys accounting for 75% and girls for 25% of juvenile arrests (U.S. Census Bureau, 2013e), but arrest rates are increasing faster for female juveniles than males (Coalition for Juvenile Justice, 2013). Women tend to be arrested more often for minor property crimes and drug offenses than violent crimes.

Women inmates often have high rates of physical and mental health problems such as histories of physical and sexual abuse and early initiation of sexual intercourse and drug and alcohol use. Incarcerated women also have more unplanned and frequent pregnancies than women in the community and 5% to 6% of female prisoners are pregnant during incarceration. One positive side to these pregnancies is that they often have better outcomes due to improved health care and access to antepartum services in the correctional setting. Female prisoners have higher rates of mental illness than men, and experience a 10- to 20-fold greater rate of sexually transmitted infections (STIs) (Smith et al., 2013). The prevalence of recent or current mental disorders ranges from 48% to 71% of women compared to only 31% of men (Shelton, Ehret, Wakai, Kapetanovic, & Moran, 2010).

Women inmates have special needs not experienced by men. For example, they require both routine and nonroutine gynecologic care and tend to have more difficulty with sleep disturbances due to anxiety and apprehension than men. In addition, their nutritional needs differ. Incarcerated women are more likely than men to gain weight, with an average weight gain of one pound per week, leading to obesity and a variety of adverse health consequences (Smith et al., 2013). Similarly, pain management needs may be influenced by higher levels of depression. Women’s substance abuse treatment needs also differ from men’s and treatment often must address their histories of trauma and abuse. Women are more likely to request health care and mental health services than men, so staff levels in these areas may need to be higher than in facilities for men. Unfortunately, because they are fewer in number, incarcerated women are less visible than men and services may be less available. Because of gender socialization, women inmates may also be less able to articulate and advocate for themselves, leading to a need for population health nursing advocacy to assure that their health and social service needs are met.

Because of their lower numbers, the health needs of women in correctional settings are often overlooked. (Andreykr/Fotolia)

Men and women also respond differently to the experience of being incarcerated. Men have been found to be most distressed by the loss of freedom, social rejection and loss of social status, autonomy, and self-control. Women, on the other hand, have similar concerns, but consider separation from family to be the most difficult aspect of incarceration. Other areas of concern for women include the constant stress of living in close proximity to others and lack of privacy with respect to personal property, modesty, and invasion of personal space. Women, in particular, need support in dealing with family separation and in maintaining family relationships. Unfortunately, because of fewer numbers, women's correctional facilities are less likely to be located close to their place of residence than men's facilities.

Another issue related to gender in correctional settings is the presence of transgendered individuals in the population. Concerns around transgendered individuals include housing decisions, safety, mental health issues, and maintenance of hormone therapy (NCCHC, 2009b). Decisions need to be made whether to place these inmates in male or female housing.

It is recommended that they be housed in the general correctional population if possible, with attention given to privacy for hygiene, appropriate clothing, and protection from assault by other inmates. These decisions will best be made in light of where the inmate is in the process of transition. Mental health services may also be needed to address issues of gender dysphoria or stigma. Because of the growth in this population, the NCCHC (2009b) has issued a policy statement on the care of transgendered individuals in correctional settings.

Members of racial and ethnic minority groups are disproportionately represented in correctional settings. In 2009, for example, although the actual number of White inmates was more than twice that of Black inmates, rates of incarceration are higher among Blacks. The U.S. adult correctional population was 49% White, 41% Black or African American, and 1.9% American Indian or Alaskan Native. Nearly 20% of the incarcerated population was Hispanic (U.S. Census Bureau, 2013a, 2013f). A similar disproportionate rate of incarceration exists among racial and ethnic minority youth (Coalition for Juvenile Justice, n.d.). These and other similar figures have prompted concerns for inequities and prejudice within the justice system. In addition, the ethnic and racial diversity of correctional populations may result in racial tensions and violence within facilities as well as the need for culturally sensitive health care. Population health nurses may need to actively advocate for correctional health care services that meet the needs of a culturally and linguistically diverse population as well as advocate for fair treatment for all inmates regardless of race or ethnicity.

Physiologic health status. Assessment considerations related to physical health status in correctional populations include mortality, infectious and chronic illnesses, injury, and other conditions.

Members of ethnic and racial minority groups may be overrepresented in correctional populations due to discriminatory judicial processes. (CURAphotography/Fotolia)

Mortality. Risk of mortality is higher among correctional populations than in the general population, in large part because of poor access to health care and health-risk behaviors prior to incarceration. In a study of New York City jails from 2001 to 2009, an average of 27 deaths occurred each year mostly due to chronic diseases or infections. Suicide and cardiovascular disease were the leading causes of death, and inmates experienced higher mortality than the general population for heart disease, HIV/AIDS, chronic liver disease, homicide, and suicide. On the other hand, lower rates were noted for cancer, influenza and pneumonia, and accidents. During that time period, annual mortality declined despite increases in the age of the population, primarily due to a decrease in HIV mortality with the advent of highly active antiretroviral therapy (HAART) (Brittain, Axelrod, & Venters, 2013).

Members of the correctional population are at increased risk for mortality even after release. For example, a National Academies report noted that released prisoners were 13 times more likely to die in the 2 weeks after their release than members of the general population. In addition, they were 129 times more likely to die of substance overdoses due to decreased opioid tolerance developed during incarceration (Smith et al., 2013). Another study found that this increased rate of mortality continued for the first few years after release (Zlodre & Fazel, 2012).

Infectious diseases. Environmental conditions and behavioral patterns in correctional settings foster the spread of communicable diseases. Although many communicable diseases are found in this population, four are of particular concern: tuberculosis (TB), HIV infection and AIDS, hepatitis, and other sexually transmitted infections (STIs). Overcrowding and generally poor health status are two of the factors that promote the spread of TB in inmate populations. Moreover, co-infection with both TB and HIV is occurring in large segments of some correctional populations. Additional complicating factors in the problem of TB in correctional facilities are the prevalence of multi-drug-resistant (MDR) TB and the tendency of inmates not to complete a full course of treatment.

The large portion of inmates with TB in correctional facilities makes them ideal settings for minimizing the spread of TB in the general population. Population health nurses working in correctional settings should assess inmates for signs of TB as well as provide routine screenings for TB according to agency policy. Tuberculin skin test screening in jails may be inappropriate for many inmates who stay only one or two days, so the nurse should ask about TB symptomatology and history of exposure during the intake assessment to isolate potentially infectious inmates.

HIV infection and confirmed cases of AIDS are another growing problem in correctional facilities. Many inmates are at increased risk of infection because of injection drug use, and the potential for exposure during incarceration via continued drug use and homosexual activity is high. Confirmed AIDS prevalence in U.S. correctional facilities is approximately 2.4 times that in the general population, and an estimated one in seven persons with HIV infection will

pass through correctional facilities (Division of HIV/AIDS Prevention, 2014).

Rates of HIV infection and AIDS diagnoses vary from one area of the country to another, and nurses should be aware of the overall prevalence of infection in their jurisdictions. Correctional nurses should assess all inmates for a history of HIV infection, high-risk behaviors, and a history or symptoms of possible opportunistic infections. In addition, population health nurses should advocate for effective treatment for HIV-infected inmates during incarceration and following their release into the community.

Drug use behaviors contribute to the increased incidence of TB and HIV infection in inmates. Such behaviors also place inmates at risk for other STIs and hepatitis B (HBV) and C (HCV). In addition to drug use, sexual activity and tattooing are other risk factors for HBV and HCV common in correctional populations. In assessing individual inmates for health problems, the nurse should ask about a history of STIs and hepatitis B and C and should be alert to the presence of physical signs and symptoms of these diseases.

Other communicable diseases are also prevalent in correctional populations. For example, methicillin-resistant *Staphylococcus aureus* (MRSA) is a common occurrence in institutional settings, including jails and prisons. For example, MRSA was colonized in 16% of Los Angeles County jail inmates (Malek et al., 2011). Similarly, *Chlamydia trachomatis* infection has been found in roughly 15% of girls and 7% of boys admitted to juvenile detention facilities, and gonococcal infection was found in 4% of girls and 10% of boys. Similarly, 7% of adult women and 7% of men screened positive for *Chlamydia*, while gonorrhea was found in slightly less than 2% of women and just over 1% of men (Miller, 2011).

Outbreaks of other infectious diseases, such as influenza and mumps, also occur in correctional facilities (Ringsdorf, Heerema, Ruiz, & Sanchez, 2010). During the 2009 H1N1 influenza pandemic, for example, high rates of infection occurred in correctional settings. Unfortunately, 55% of U.S. jails did not receive supplies of influenza vaccine, and only 11% of state prisons and 14% of federal facilities had vaccine available (Lee et al., 2012).

The problem of infectious diseases in correctional settings is one of international, as well as national, concern. Prevalence rates for HIV infection in the correctional populations throughout the world range from 6 to 50 times those of the non-incarcerated population. These high rates are accounted for primarily by drug use, commercial sex work, tattooing, and men who have sex with men (United Nations Office on Drugs and Crime [UNODC], n.d.).

Chronic conditions. The prevalence of chronic illness in correctional populations is approximately four times that of the general population. Chronic illnesses of particular concern in correctional settings include diabetes, hypertension, heart disease, and chronic lung conditions such as asthma. Other common physical health problems include incontinence, sensory impairments, arthritis, limited mobility, and cancer. Seizure

disorders are also common, and inmates may also exhibit seizure activity during withdrawal from drugs and alcohol. Diabetes may be particularly difficult to control given the rigid structure of the correctional routine and the need to time hypoglycemic medications, meals, and exercise periods appropriately. The availability of vending machines and the use of commissary privileges as a reward may also complicate dietary control for inmates with diabetes.

Many inmates with chronic conditions, particularly those with substance abuse problems, enter the correctional facility after prolonged periods without medications or may not know what medications they have been taking. In many instances, the nurse has to exert considerable ingenuity to obtain an accurate health history from clients, family members, and health care providers in the community. Because of poor overall health status, inmates may also be especially susceptible to exacerbations of chronic conditions. The nurse should assess individual inmates for existing chronic conditions and should also identify problems with high incidence and prevalence in the correctional population with whom he or she works.

Incontinence may also be a problem in the correctional population, and population health nurses should assess for problems with incontinence during intake assessments. In one study, for example, 43% of women prisoners reported urinary symptoms that may be difficult to address in a correctional setting (Drennan, Goodman, Norton, & Wells, 2010). Other problems that complicate life for prisoners include sensory impairments and functional incapacity. All of these are issues that population health nurses working in correctional settings can help to address.

Members of the correctional population may also experience terminal illness. A workshop sponsored by the Institute of Medicine identified the need for long-term treatment facilities and palliative care for inmates with serious illnesses, as well as policies for compassionate release for nonviolent offenders with terminal illnesses (Smith, et al., 2013). In addition, the growing prevalence of terminal illness in this population has led to a growing trend toward hospice care within correctional facilities (Hufft, 2013).

Injury. Injury is another area of physiologic function that should be assessed by the nurse. Injury may result from activities preceding arrest, from actions taken by arresting officers, or from accidents or assaults occurring during incarceration. The nurse should be aware of the potential for internal as well as visible injuries and should assess inmates for signs of trauma. In a survey of inmates of state correctional facilities, 31% reported an injury since admission. Accidental injuries were more common than those resulting from violence. The incidence rate for injuries related to violence was 50% higher than that for the general public, and the accidental injury rate was more than twice as high as in the general population (Sung, 2010). Slightly different results were noted in a study of injuries occurring in New York City jails over a 4-month period in 2010. Two thirds of those injuries were the result of violence

and only one third were unintentional. Nearly two thirds of the incidents resulted in detectable injuries that required medical attention, and 39% required outside referral for treatment (Ludwig et al., 2012).

Violence resulting in injuries in correctional settings may be associated with traumatic brain injury in the perpetrators. In a meta-analysis, for example, 60% of prisoners were found to have traumatic brain injury, decreasing impulse control and making management of their behavior more difficult (Shiroma, Ferguson, & Pickelsimer, 2010).

Self-injury may also be a problem in correctional settings and accounted for 8% of injuries reported in New York City jails (Ludwig et al., 2012). Self-injury may also be referred to as self-harm or deliberate self-harm, parasuicide, or self-mutilation. **Self-injurious behavior** may be defined as purposeful behavior resulting in mild to moderate injury to self that is not intended to result in death and does not arise from psychosis or intellectual impairment (Fagan, Cox, Helfand, & Aufderheide, 2010). Self-injury may occur in the context of other mental disorders such as depression or among transgender individuals who are prevented from engaging in desired sexual transitions (National Commission on Correctional Health Care, 2009b).

Other conditions. Dental health problems are also common among inmates. One particular problem that nurses in correction settings may encounter is a condition called “meth mouth.” Meth mouth is characterized by severe erosion and decay of teeth and usually requires emergency dental services. Meth mouth results from several factors associated with methamphetamine use, including gnashing of the teeth, poor oral hygiene, and dry mouth, which increases the acidic effects of methamphetamine. Methamphetamine use also leads to cravings for high-calorie, high-sugar soft drinks that further contribute to tooth decay (American Dental Association, 2013).

Pregnancy is the final biophysical consideration in assessing the health of correctional populations. As noted earlier, the number of female inmates increases annually. Because of prior drug use and poor health care, pregnant women in correctional settings may be at higher risk for poor pregnancy outcomes than women in the general population. Conversely, incarceration may improve pregnancy outcomes because it interrupts drug use and provides access to prenatal care that the women might not otherwise receive. Care of pregnant women in correctional settings, however, is often hampered by lack of special diets to support pregnancy, lack of exercise, and inappropriate work assignments. Fetal health may also be compromised by problems encountered in drug and alcohol withdrawal in the correctional setting. Finally, the timely transfer of women in labor to obstetrical facilities is often hampered by the security constraints of the correctional facility.

In assessing female inmates, the nurse should ask about the last menstrual period and solicit any symptoms of possible pregnancy. Because drug use can interfere with menses, menstrual history is not always reliable for indicating pregnancy or for suggesting length of gestation when pregnancy is

confirmed. The nurse should also ask about high-risk behavior that may affect the fetus, such as smoking, drug and alcohol use, and so on. The pregnant inmate's nutritional status should also be assessed. Other physical problems common in this population that may affect pregnancy outcomes include urinary tract infections and STIs, and the nurse should assess for symptoms of these conditions. Depression and anxiety are also common phenomena among these women. Advocacy may be required to assure adequate prenatal and perinatal care for pregnant inmates. For example, population health nurses may need to convince correctional personnel of the necessity of keeping outside appointments for high-risk pregnancy care, even when these require pulling security personnel away from the correctional facility.

PSYCHOLOGICAL DETERMINANTS. Psychological factors can have a profound influence on health in correctional settings. The presence of mental illness in the correctional population is one of the major psychological factors influencing the health of this population. The level of mental illness in correctional facilities has tripled in the last 30 years, with a current estimate of 16% of the population affected. In addition, an estimated 40% of mentally ill persons will be incarcerated at some time in their lives (Torrey, Kennard, Eslinger, Lamb, & Pavle, 2010). A 2010 study by the Treatment Advocacy Center found three times more severely mentally ill persons in jails and prisons than under treatment in hospitals (Stettin, Frese, & Lamb, 2013). The authors of the study concluded that U.S. correctional facilities have replaced hospitals as a place of containment for the mentally ill and described the increasing trend toward incarceration as a return to the conditions of the 1840s (Torrey et al., 2010). Mental illness is also frequently criminalized in the rest of the world.

Mentally ill inmates are often significantly disabled by their conditions and have a more difficult time adjusting to prison life than other inmates. Overcrowding and isolation units in correctional facilities may contribute to poor mental health even among those without psychiatric diagnoses (Smith et al., 2013). Incarceration itself is stressful and can lead to psychological effects, including depression and suicide. Incarceration also exacerbates existing mental illness. Correctional nurses should be alert to signs of depression and other mental or emotional distress in inmates, and assessment of suicide potential is a critical part of every intake interview. Suicide is the leading cause of death in jails and “lockups,” and is the cause of nearly 100% of deaths among incarcerated juveniles. A **lockup** is a temporary holding facility in which inmates are placed prior to transportation to a jail or other facility or to being freed on bail. Detention in a lockup is generally for less than 48 hours (Hufft, 2013).

Attempted suicide is a particularly prevalent problem among incarcerated individuals. In the United States, suicide rates in correctional populations are eight times those of the general population, and are five times higher in England and Wales (Zlodre & Fazel, 2012). Jails tend to have higher rates of

Isolation increases the risk for depression and suicide in correctional populations. (BortNG6/Fotolia)

successful suicides than prisons (43 per 100,000 inmates versus 16 per 100,000 in prisons), with smaller jails having higher rates yet.

Most adult suicides occur within the first 24 to 48 hours of incarceration, while juvenile suicides are more evenly spaced over 12 months, with a large number still occurring within the first 72 hours. Adolescent suicides shortly after incarceration are often related to intoxication. Adult inmate suicides tend to occur at night when there is less intensive supervision, but juvenile suicides occur primarily in the daytime, particularly in the early evening and are often associated with room confinement (Robbins, 2008). General risk factors for suicide include a prior attempt, mental illness (particularly depression or bipolar disorder), dual diagnosis of mental illness and substance abuse disorders, a family history of suicide, hopelessness, impulsiveness or aggressiveness, and experiencing barriers to mental health treatment. Additional risk factors include recent loss, physical illness, easy access to lethal methods, unwillingness to seek help due to stigma, the influence of significant others who have committed suicide, cultural or religious beliefs, and feelings of isolation (Fagan et al., 2010). Population health nurses should identify inmates at risk for suicide and initiate immediate interventions as well as referral for long-term treatment of underlying factors.

Another group of young offenders may be developmentally disabled, and an additional segment of this population may experience learning disabilities and other developmental disorders. Developmentally disabled individuals, particularly youth, may be persuaded to participate in group crimes in order to be accepted by their peers without fully realizing the consequences of their actions. They may display deficits in both cognitive/intellectual function and adaptive capabilities, leading to greater difficulty adjusting to life in a correctional facility. Because of their diminished mental capabilities, this group of inmates may have difficulty understanding instructions and display impulsivity and low frustration tolerance,

earning them frequent punishment for infractions in the correctional setting. This group of individuals may require particular advocacy on the part of population health nurses to assist them in their adjustment, help correctional personnel recognize their limitations, and prevent their victimization by other inmates.

Another mental health issue that correctional health nurses may encounter is acute psychotic delirium, which may result from many causes. Drug overdose, traumatic head injuries, poisoning, and a variety of medical conditions, such as acidosis, insulin reaction, or infection, may all contribute to delirium. The typical reaction to a delirious inmate is to restrain him or her, but that may result in oxygen deprivation worsening delirium or resulting in sudden death (Mathis, 2010). Correctional nurses should be alert to the signs of delirium and take appropriate actions to determine and deal with the cause. They may also need to educate correctional staff on this condition and on appropriate interventions for controlling dangerous behaviors to protect both the inmate and others.

By law, inmates are entitled to mental health services as well as medical treatment. Mental health services, however, may be lacking in some correctional systems, or the need for these services may go unrecognized. This is particularly true among women inmates, the elderly, and youth.

Another subgroup within the inmate population with significant mental health needs includes persons under a sentence of death. In the United States in 2009, more than 3,000 prisoners had been sentenced to be executed. This figure was 4.6 times higher than in 1980 (U.S. Census Bureau, 2013k). Being given a sentence of death does not always result in execution. The number of actual executions was at its highest in the United States in the 1930s, and declined precipitously due to a moratorium on executions during the 1970s. Since that time, some states have reinstated the death penalty, but from 1973 to 2009, less than 15% of death sentences issued resulted in execution (Nagin & Pepper, 2012). Despite these figures, however, persons under a sentence of death live with constant uncertainty and may develop a variety of mental health problems. Correctional nurses working in systems with “death-row” inmates should assess them for evidence of psychological problems and refer them for counseling as appropriate.

Mental health challenges in dealing with correctional populations are many and varied. Some of these challenges include determining who has mental health problems and how they should be treated, managing behavior and symptoms associated with psychiatric illness, and recognizing and dealing with the negative mental health effects of incarceration. Other challenges include understanding the difficulty in adjusting to incarceration that might be experienced by inmates with mental illness and determining the need for and providing specialized services. For example, few correctional settings deal effectively with the mental health needs of older inmates. Similarly, women and youth exposed to psychological trauma need therapy to deal with issues of abuse as well as co-occurring substance abuse. Population health nurses in correctional settings

can engage in advocacy to assure that appropriate services are provided to these vulnerable population groups.

ENVIRONMENTAL DETERMINANTS. Factors in the physical environment also influence the health of correctional populations. The physical environment of the correctional setting is constrained by the need for security. Inmates may be relegated to specific spaces at specific times of the day. Because of the tremendous growth in the incarcerated population, jails and prisons are extremely overcrowded and few jurisdictions are not in violation of space standards for inmates. Overcrowding is often due to delayed court processes and the large numbers of people awaiting trial.

Other physical environmental problems common in correctional settings include poor ventilation, lack of temperature control, and unsanitary conditions. Lack of funds for maintenance may lead to buildings in poor repair, creating safety hazards for both inmates and staff. In New York City jails, for example, 17% of inmate injuries resulted from slips and falls (Ludwig et al., 2012). Other areas that should be assessed by the nurse include the safety of recreational areas, fire protection, lighting, plumbing, solid waste disposal, and safety of the water supply. Additional environmental considerations that may affect health in correctional populations include vermin control, noise control, and lack of privacy (Smith et al., 2013).

Because correctional facilities are often situated in areas away from the general population, they may be located in sites with disaster potential such as flooding, earthquake, and so on. The nurse should assess the potential for such disasters as well as the adequacy of the facility’s disaster response plan. Disaster potential may also arise from prison industries. For example, prisoners in work programs may be employed in production industries using processes or materials that create the potential for fires or explosions. Inmate occupations may also present other physical hazards for individual clients that need to be assessed.

Overcrowding and lack of privacy contribute to the stress of incarceration. (Intoit/Shutterstock)

SOCIOCULTURAL DETERMINANTS. A wide variety of sociocultural factors influence the health status of correctional populations. An estimated 80% of law enforcement activity addresses social problems, yet police personnel are often ill-equipped to deal with them because of lack of understanding of the underlying dynamics of social problems. Like health care providers in correctional settings, law enforcement personnel may experience conflict between their law enforcement role and a role in resolving social problems. In addition, social problems that lead to criminal activity are given low priority at the societal level. Particular elements of the sociocultural dimension that influence health in correctional settings include socioeconomic and cultural influences, political and legal influences, the potential for violence in the setting, the needs of special populations, and the social consequences of incarceration. The subculture of the correctional setting itself is another sociocultural factor that may influence the health of inmates and staff.

Socioeconomic and cultural influences. To a large extent, correctional populations tend to be at the low end of economic and educational spectrums. Women offenders, in particular, often come from poverty-stricken neighborhoods with low levels of social capital. Lower socioeconomic status is also associated with worse health status among inmates.

Housing is another socioeconomic issue that may contribute to incarceration. As we saw in Chapter 21, many activities performed by homeless individuals to ensure their survival have been criminalized, with the result that they are often arrested for activities that would be tolerated in other members of society. The homeless are overrepresented in correctional populations, and recently released prisoners often become homeless due to poor reentry planning. Incarceration may also lead to homelessness due to the disruption of family and community ties and decreased employment and housing opportunities associated with the stigma of incarceration.

As we saw earlier, correctional populations include many ethnic minority group members who are frequently culturally and linguistically, as well as economically and educationally, disadvantaged. In addition, many more inmates are being incarcerated as a result of immigration offenses than in the past.

Political and legal influences. Historically, jails and prisons have served five distinct purposes and the focus of incarceration has shifted back and forth among these purposes since the inception of correctional institutions. The five purposes are (a) retribution or punishment for crimes, (b) deterrence from crime, (c) incapacitation or rendering people incapable of further crime, (d) rehabilitation or correcting deviant behavior, and (e) to render restorative justice or repair social injuries resulting from crime (Hufft, 2013). The ability of incarceration to address any of these purposes effectively is questionable. For example, a study by the National Research Council of the National Academies of Science determined that research on capital punishment does not provide a clear indication of the deterrent effects on violent crime (Nagin & Pepper, 2012).

Similarly, recidivism and re-incarceration rates argue against the effectiveness of jail and prison sentences in rehabilitating offenders.

Correctional policy is in flux and the purpose of incarceration is not always clear. For example, as we saw earlier, jails and prisons have reverted to being settings in which the mentally ill or substance abusers can be removed from society. For example, in 2012, ten times more severely mentally ill people were in U.S. jails and prisons than in state psychiatric hospitals (Treatment Advocacy Center & National Sheriff's Association, 2014). The lack of psychiatric beds in public hospitals and closure of public mental hospitals have greatly contributed to this shift of the mentally ill to correctional facilities. For example, from 2005 to 2010 there was a 14% decrease in state psychiatric beds throughout the nation, with the per capita number of beds reduced to 1850 levels. Nationwide, bed availability only met an estimated 28% of the treatment need. These figures result in a significant negative impact on correctional systems and hospital emergency departments. In addition, relationships have been shown between psychiatric bed availability and the incidence of violent crime and arrest-related deaths (Treatment Advocacy Center, 2012). A joint report by the Treatment Advocacy Center and the National Sheriff's Association (2014) recommended the following changes in public policy:

- Prevention of incarceration by eliminating barriers to treatment for mental illness
- Legislation to promote effective treatment for mentally ill inmates
- Development and implementation of jail diversion programs
- Use of court-ordered outpatient treatment programs for mentally ill offenders
- Research on the costs of incarceration to those of treatment for people with serious mental illnesses
- Careful screening of mentally ill inmates to determine medication, suicide prevention, and other needs
- Mandatory release planning and community support to facilitate recovery (Treatment Advocacy Center & National Sheriff's Association, 2014).

The U.S. response to drug abuse also involves inappropriate criminal sanctions, with drug-related incarcerations increasing from 41,000 in 1980 to half a million in 2010, 40% of which were for possession of illegal substances. This increase has resulted in an annual cost of \$22,000 per incarcerated inmate, far above the cost of treatment (Fiscella, 2010).

Recently, however, there has been more of a trend to diverting individuals with mental illness and substance abuse out of the correctional system and into treatment (Stettin et al., 2013). More and more law enforcement agencies are attempting to identify individuals whose crimes arise from mental illness and divert them to psychiatric treatment settings. **Diversion** is a group of practices, including parole and probation, designed to prevent reincarceration by linking mentally ill offenders to mandated community-based treatment services

(Stettin et al., 2013). Diversion is intended to decriminalize mental illness. Diversion relies on intersectoral collaboration between legal and mental health care systems to address factors that contribute to **recidivism** (rearrest, re-incarceration, or frequent rehospitalization) among mentally ill and substance-abusing inmates.

There are two general approaches to diversion: crisis intervention team policing (CIT) and specialized mental health courts. **Crisis intervention teams (CITs)** are specialized units of police officers trained as mental health specialists who are able to determine if diversion, rather than arrest, is an appropriate option. These officers are knowledgeable about local resources and often get to know local mentally ill offenders quite well and can take them to hospitals for evaluation or to outpatient treatment facilities or initiate court proceedings for assisted outpatient treatment. **Assisted outpatient treatment (AOT)** is the application of coercion through threats of hospitalization for noncompliance with mental illness treatment (Stettin et al., 2013).

The second approach to diversion is the establishment of specialized mental illness courts. Mental illness courts are one of several types of specialized courts including domestic violence courts, drug courts, and so on. These specialized courts seek to work with nonviolent offenders to address the underlying causes of criminal behavior, mental illness in the case of mental illness courts. Like assisted outpatient treatment, mental health courts attempt to foster compliance with mental health treatment through threats of incarceration (Stettin et al., 2013). Similar approaches are used to divert substance abusers into treatment programs. Unfortunately, less than half of the U.S. population lives in jurisdictions that have CITs or mental health courts available, and availability varies significantly from state to state from 100% in Washington, DC (which has a single criminal justice agency), to 0% in Rhode Island. In only four states are these diversion options available to more than 60% of the population (Stettin et al., 2013).

A similar approach may be taken to drug-related criminal activity. For example, California's Substance Abuse and Crime Prevention Act of 2002 marked a major shift in criminal justice policy. Under this legislation, nonviolent adult offenders can be sentenced to probation with substance abuse treatment. Similar provisions affect drug offenders on parole or probation, and offenders are allowed up to three chances to re-enter treatment without penalty. In the first 5 years of operation, this approach cost \$120 million, mostly for substance abuse treatment services, but resulted in incarceration cost savings of \$2,137 per person served (Anglin, Nosyk, Jaffe, Urada, & Evans, 2013).

For young people, zero tolerance policies in schools have led to more school dropouts and greater justice system involvement. Healthy psychological development at this age requires effective and concerned adult role models, opportunities to interact with peers who value and model academic success and prosocial behavior, and involvement in activities that promote critical thinking and autonomous decision making.

Unfortunately, the current juvenile justice system focuses on confinement and control, removing youth from positive influences on behavior and promoting further criminal activity (Bonnie et al., 2012).

Some efforts have been made to change these negative policies related to youth and criminal justice. For example, the Juvenile Justice and Delinquency Prevention Act (JJJPA) funds a variety of programs designed to prevent youth criminal justice involvement. Core requirements for program funding include a focus on deinstitutionalization of status offenders, removal of juvenile offenders from adult correctional facilities or sight and sound separation from adult inmates, and efforts to reduce the disproportionate number of minority youth in contact with the juvenile justice system (Coalition for Juvenile Justice, n.d.). The act, originally passed in 1974, was reauthorized in 2002. Unfortunately, reauthorization failed in 2008 and again in 2009, and the legislation was due to expire in 2013 (Coalition for Juvenile Justice, 2013). Reauthorization legislation was reintroduced in 2013 and contains new provisions for evidence-based assessment of at-risk youth, greater community and family support, and funding for mental and behavioral health services. Other provisions address prevention of bullying and gang activity, substance abuse and mental health screening and treatment, and reentry assistance for juvenile offenders. Congress authorized additional funds for programs under JJJPA for fiscal year 2014 (Coalition for Juvenile Justice, 2014), but the act itself had not been reauthorized as of February 2014 (Jenkins, 2014).

The Affordable Care Act (ACA) is another policy initiative that has implications for correctional populations. Incarcerated individuals are not allowed to receive government supported health insurance. According to the ACA, inmates cannot enroll in insurance exchanges if they are incarcerated at the time of enrollment, but because of a lack of clear definition of incarceration, pretrial detainees and persons on parole or probation may be eligible to enroll. In some states, insurance may be terminated during incarceration, but the Centers for Medicare and Medicaid Services (CMS) is recommending suspension of coverage rather than termination. Under the law, persons with mental illness or substance abuse disorders will be eligible for coverage regardless of incarceration status, and correctional facilities have been urged to establish linkages with Medicare, Medicaid, and other health plans to offset the cost of care for these inmates. Such linkages will necessitate the development of billing and accounting systems and electronic medical records in correctional facilities. Meeting constitutional standards of care with independent oversight of services and appropriate "through care," including continuity of care and effective discharge planning to meet health care needs on release, will also be essential (Blair & Greifinger, 2011).

Violence. Violence within correctional settings is another sociocultural factor that influences the health of the incarcerated population. For example, 40% of injuries in New York City jails

were found to be related to inmate violence (Ludwig et al., 2012). Similarly, one in ten state prison inmates have been injured in fights (Smith et al., 2013). Transgender individuals and youth, particularly GLBT youth, are at particular risk for physical and emotional victimization and violence (Coalition for Juvenile Justice, 2013; NCCHC, 2009b). Approximately 12% of youth have been sexually abused in correctional facilities by other inmates or by staff (Greifinger, 2010), and nearly 10% of state and federal prison inmates report sexual abuse (Smith et al., 2013). Cross-gender pat down searches can be particularly traumatic for women who have been sexually abused. Correctional staff may also exercise inappropriate levels of physical force in dealing with inmates (Smith et al., 2013).

Special correctional populations. The special needs of youth, the elderly, pregnant women, and transgender individuals in correctional settings have already been addressed. Another population that may have special needs is former members of the military. Approximately 140,000 veterans are in prisons. Veterans tend to be older than the rest of the correctional population (12 years on average) and are more likely to be incarcerated for violent crimes, particularly against women and children. One in four sex offenders is a military veteran. Most veterans who are incarcerated have served in wartime, but combat service has not been linked to mental illness in this segment of the correctional population. Veterans tend to be better educated than other inmates and are less likely to use drugs (National Coalition for Homeless Veterans, n.d.).

Social consequences of incarceration. Incarceration also has a variety of social consequences including its effects on families, societal costs, and effects on suffrage and future socioeconomic status.

Family effects. Incarceration disrupts families significantly. An estimated 2.7 million U.S. children have a parent who has been incarcerated (Osborne Association, n.d.). Children of incarcerated parents often have behavior problems and exhibit poor academic performance and high levels of psychological distress. Incarceration also decreases relationship commitments on the part of the incarcerated individual as well as his or her spouse or partner. Furthermore, incarceration may lead to family stress and inability to cope with the loss of the incarcerated member. Conversely, for some families, incarceration may decrease family stress related to prior illegal behavior, mental illness, or substance abuse (Dyer, Pleck, & McBride, 2012).

Family members may be the only support available to inmates on release, and weakening of family ties makes reentry that much more difficult. Maintenance of family relationships can be achieved by strategies that help families interact positively. This may include visitation by entire families, including children, eating meals with the incarcerated member, and maintaining family rituals (Dyer et al., 2012).

Concerns for children may be a source of stress for some inmates, particularly women. Because of fewer female

detention facilities, women may be incarcerated at a distance from families, making it difficult to maintain contact.

Women's facilities may be more likely than men's institutions to provide parenting education, but most such programs are provided without children present, prohibiting inmates from modeling learned skills with their own children. Problems caused by separation of children from their mothers have led some correctional facilities to allow young children, particularly newborns, to remain with their mothers in custody. Areas for concern in these types of programs that need to be addressed by correctional nurses and other correctional personnel include the security of children, liability issues, costs and mechanisms for providing health care and other services for children, and the effects of incarceration on child development.

Societal costs of incarceration. Incarceration is a costly, and largely unsuccessful, approach to containing crime. In 2008, federal, state, and local governments spent \$75 billion on correctional activities, most of it for incarceration, and correctional spending is only exceeded by Medicaid expenditures in terms of government costs (Welsh & Farrington, 2011). Incarceration also diverts state and local funds from other needed services and programs. For example, nearly half of the \$15.5 million federal budget allocation for substance abuse in 2011 went to law enforcement activities, compared to \$1.7 billion for prevention programs and \$3.9 billion for substance abuse treatment (Anglin et al., 2013).

Incarceration has other social consequences as well. For example, laws in 48 states prohibit persons convicted of felonies from voting even after serving their sentences. This inability to vote has a disproportionate effect on racial and ethnic minority populations who may already lack a voice in the body politic. Approximately 1 in 45 people (5.3 million Americans) are disenfranchised by this restriction on voting. Some jurisdictions have processes by which released felons can have their voting rights reinstated, but these vary from state to state and are often cumbersome and difficult to negotiate (Purtie, 2013).

Incarceration also damages opportunities for work, education, and housing. Some former inmates, for example those convicted of sexual crimes, are restricted from living in certain communities. Persons on probation and parole are also restricted from travel outside the area, which may put them at a disadvantage in areas with few employment opportunities.

The correctional subculture. The primary purpose of correctional institutions is custody and punishment, not health care. This custodial culture may pose considerable challenges to health care providers who must balance their health care and advocacy roles against security concerns.

Security concerns may also hamper provision of health care. In some institutions, nurses do not have immediate access to inmates unless security personnel are present. In other instances, transportation of inmates for outside services may be postponed if there are insufficient security personnel available

to accompany them. There is also the potential for violence against health care providers and their use as hostages.

The nurse should be alert to the use of excessive force or punitive conditions to which inmates may be subjected. Correctional nurses will also assess the extent of social support available to inmates. Social support may arise from interactions and programs available within the correctional system or from continued interactions with persons or agencies outside the system (e.g., family). Development of social support systems may be particularly important for clients about to be released from the facility.

Some correctional facilities have programs that promote rehabilitation and permit inmates to earn some money. In some states, there are even provisions for inmates to work to repay the victims of their crimes. Such opportunities are less readily available to women inmates than men and are rarely adequate to meet the rehabilitation needs of all inmates. The presence of occupational opportunities, however, may contribute to a variety of occupational risks to health that should be assessed by nurses in correctional facilities. Occupational hazards for correctional facility staff, as well as those for inmates, should be considered. Corrections personnel, for example, are at higher risk for infectious disease exposure. Physical and psychological safety considerations also present the need for constant vigilance among health care and other personnel in correctional settings.

There is also a subculture within the inmate population that members must adhere to. This subculture has its own rules and norms for behavior among inmates. Five common elements in such subcultures include (a) not interfering with the interests of other inmates, particularly not informing on others, (b) maintaining a low profile and not getting involved in others' issues, (c) not exploiting other inmates, stealing from them, or lying to them, (d) not whining, and (e) not trusting correctional personnel (Hufft, 2013). Some of these elements may make it difficult for correctional health care personnel to develop trusting relationships with clients or to obtain accurate health-related information.

BEHAVIORAL DETERMINANTS. Behavioral factors that influence the health of inmates and staff in correctional settings include diet, substance abuse, smoking, opportunities for exercise and recreation, and sexual activity.

Nutrition. Some subpopulations in correctional settings have unique dietary needs that have already been addressed, but all inmates need adequate nutritional intake. Unfortunately, a report of an Institute of Medicine study found that prison diets are often calorie dense and high in fats (Smith et al., 2013), and prisoners worldwide often have inadequate diets. In addition, cuts in food budgets may limit offerings. Conversely, some correctional systems have found that budget cuts have permitted them to eliminate empty calories (e.g., coffee and sugar, margarine), provide healthier alternatives (e.g., fresh fruits in place of baked goods, use of skim or powdered milk), and offer nutrient

dense foods. Such changes can also be accompanied by educating inmates on nutritious diets.

Drug, alcohol, and tobacco use. Inmates are three to four times more likely than the general public to smoke. With little to occupy their time, inmates may find themselves smoking more after incarceration than before. In addition, there are often limited options for smoking cessation. Smoking coupled with overcrowding, lack of exercise, and inadequate diet may increase inmates' risk of both communicable and chronic diseases. Access to tobacco is also a traditional reward for compliant behavior in correctional settings. Approximately 70% to 80% of all inmates and 46% of juveniles smoke and only a few correctional facilities have or enforce smoking bans or promote smoke-free environments (Cropsey et al., 2010). In addition, health care providers may see other addictive behaviors as having higher priority than smoking cessation.

Alcohol and other substance abuse are also common among correctional populations. Approximately 80% of correctional populations have a history of illicit drug use or abuse (Spaulding et al., 2010), and half of the correctional population in the United States meet the criteria for abuse or dependence disorders. Of the 1.5 million arrestees with drug abuse disorders, only 55,000 receive treatment (Fiscella, 2010).

Alcohol misuse is also common among correctional populations, even during incarceration. In fact, inmates may make an illicit alcoholic beverage known as "pruno" from fruit, water, and sugar. This concoction may also incorporate other foods, such as root vegetables, left over from meals. In one correctional setting, pruno consumption caused botulism poisoning in several inmates (Thurston et al., 2012).

The correctional nurse should assess substance use and abuse in individual clients as well as in the inmate population as a whole. The nurse should also assess nutritional status and particular dietary needs for individual inmates (e.g., those with diabetes). Nurses may need to advocate for special diets to accommodate medical or religious needs. Types of diets that may be needed include kosher diets, low-salt diets, diabetic diets, consistency-modified diets, allergy diets, bland diets, and diets to address specific renal problems or gastric reflux.

Rest and physical activity. Rigid schedules may constrain inmates' abilities to get adequate rest or exercise. Inmates may complain of difficulty sleeping due to medical conditions, stress, poor sleep hygiene, noise and other environmental factors, or shift work. Other causes of sleep disturbances may include medical conditions, medication side effects, or rebound from use of sleep aids. Nurses need to carefully assess and address root causes of sleep difficulties rather than relying on pharmacologic sleep aids.

Some inmates may engage in vigorous physical activity as a way to pass time, and the nurse needs to be alert to the potential for overuse and muscle injury. Conversely, other inmates may become physically inactive, contributing to risks for cardiovascular disease and other obesity-related conditions.

Physical activity may be particularly important for incarcerated women engaged in smoking cessation which has been linked to significant weight gain (Cropsey et al., 2010). Potential safety hazards posed by exercise and recreation activities should also be assessed.

Sexual risk behaviors. Sexual behaviors prior to and during incarceration can also influence inmate health status. Early initiation of sexual activity is common among inmate populations, and the incidence of sexually transmitted diseases is high in this population. Among incarcerated youth, 90% of juveniles in one study engaged in more than three HIV risk behaviors, and 65% engaged in more than ten risk behaviors, many of them for more than 3 years (Teplin et al., 2013).

Sexual activity also occurs within the correctional setting. Such behavior may be consensual or nonconsensual, and high-risk behaviors such as anal intercourse are common. As many as 45% of state and federal prisoners and 3.2% of local jail inmates may be sexually assaulted while incarcerated (Greifinger, 2010). Lack of access to condoms and the prevalence of STIs in correctional populations promote the spread of disease to others in the setting. The nurse should assess the extent of sexual activity among the correctional population and the availability and use of condoms within correctional systems. Nurses may also need to advocate for provision of condoms to sexually active inmates.

HEALTH SYSTEM DETERMINANTS. Factors related to the correctional health system also influence the health status of correctional populations. Correctional facilities are the only settings in which people have a constitutional right to health care (Muse, 2011). Because many inmates enter the correctional setting with multiple health problems, the adequacy of the correctional health care system has a significant influence on the health status of the population. Depending on several factors, including size and financial capabilities, correctional facilities may take one of two approaches to the provision of health care services for inmates. Services may be provided in-house by staff employed by the facility, or the agency may contract with other provider agencies for needed services. In many institutions, a combination of both approaches is used.

Specific areas to be addressed in the correctional health care system include health promotion and illness prevention services, medical and dental services, mental health services, and emergency response capabilities. Health promotion services will be discussed in more detail later in this chapter. Minimum medical services should include screening, diagnostic, treatment, and follow-up services.

The correctional health care system should also make adequate provision for diagnostic and treatment services with access to health personnel evaluation in a timely fashion. In some situations, this may mean curtailing the discretion of corrections personnel in determining whether an inmate should be brought to the attention of health care providers. If needed

diagnostic and treatment services are not available within the facility, arrangements should be in place for securing these services elsewhere. The need for diagnostic and treatment services extends to dental health and mental health needs as well as to physical health problems.

Correctional health services tend to be chronically underfunded, and some correctional systems have instituted copayments for medical and dental services provided. The intent of this practice is to decrease service utilization rates and generate funds. The courts have upheld the initiation of small fees for care. In a 2004 survey, less than 20% of correctional systems surveyed did not require some form of copayment from inmates. In one setting, institution of copayments decreased trips from emergency departments from 65 per month to fewer than 15 (Su, 2009).

Copayments may deter inmates from obtaining needed health care (Smith et al., 2013) and contribute to the spread of communicable diseases as well as increased costs for care of chronic conditions allowed to deteriorate. Correctional nurses may need to be actively involved in evaluating the effect of copayment systems on the health of inmates and the implications for the health of the general public if legitimate needs for services are not being addressed. They may also need to advocate for elimination of copayments if they are found to impede access to care.

The extent of emergency response capabilities (including suicide prevention programs) is another important aspect of the correctional health system. Emergencies may be inmate-specific or general. Examples of inmate-specific emergencies are medical emergencies (e.g., heart attack), psychiatric emergencies (e.g., suicide attempt), or traumatic injury. System-wide emergencies could include inmate-generated emergencies (e.g., riots) or natural or human-caused disasters affecting the correctional setting. Population health nurses should advocate for and be involved in disaster planning for correctional settings. Disaster planning may include plans for evacuation of inmates as well as staff. In addition to plans for safe evacuation and provision for the health and survival needs of inmates and staff, correctional disaster plans must address public safety issues and prevent escape during evacuation. Disaster planning will be dealt with in more detail in Chapter 25.

The health care system within a correctional setting should also make adequate provision for efforts to control communicable diseases. This means screening programs, isolation of infectious inmates, and follow-up on contacts both within and outside the correctional system.

For health care services to be adequate to meet clients' needs, health care personnel must be available in adequate numbers and with adequate preparation for practice in correctional settings.

Another consideration related to health system determinants is inmates' use of health care services prior to their incarceration. For example, the nurse might ask the female inmate when she had her last pap smear or mammogram. The nurse

would also want to explore prior interactions with health care providers related to existing health problems. For example, was the client being seen for hypertension or other health problems? Or has the client not been taking antihypertensive medications because he or she did not have the prescription renewed?

Correctional health nursing. Nurses are a crucial element of the correctional health care system. Correctional or “forensic” nursing is a specialized area of population health nursing with a special target population. **Correctional nursing** is defined as nursing care designed to promote health and prevent or treat illness or injury in populations involved with the criminal justice system (American Nurses Association [ANA], 2013). **Forensic nursing**, on the other hand, is nursing practice directed toward investigation of injury or death resulting from violence, criminal activity, or accident. Forensic nursing also addresses issues of liability (International Association of Forensic Nurses & ANA, 2009). Advanced practice correctional nursing involves the performance of traditional and advanced practice nursing roles within jails and prisons (Hufft, 2013). Population health nurses working in correctional settings are more often focused on correctional nursing or advanced practice correctional nursing than forensic nursing. Correctional nursing roles include screening and evaluation, specific health screening, direct care, teaching, counseling, and providing linkages to continued care on release (Muse, 2009).

Work in correctional settings requires nurses to function within specific security parameters and to understand both the legal and public health implications of care in this setting. Correctional settings place constraints on how nurses may care for clients, and nurses must often balance custodial and care functions. Correctional nurses are actively involved in advocacy and may need to take professional risks within the setting to meet inmates’ needs or initiate changes in the system. Nursing in correctional settings also requires superlative interpersonal skills and skills in collaborating with corrections personnel who often have a philosophical perspective far different from that of the nurse. Certification for correctional nurses is available from NCCHC (2014a) and the American Correctional Association (n.d.). For further information about certification requirements and processes, see the *External Resources* section of the student resources site. Certification provides recognition of the specialized expertise required for nursing practice in correctional settings (Schoenly, 2011).

Standards and guidelines for correctional health care. Standards have been established for both correctional health care systems and for nursing practice within those systems. As noted earlier, NCCHC has developed sets of standards for health care systems in jails, prisons, and juvenile facilities, as well as for mental health services and opioid treatment programs for correctional populations (NCCHC, 2014b). For further information about specific standards, see the *External Resources*

section of the student resources site. In addition, NCCHC accredits correctional health systems. Accreditation is based on adherence to the relevant sets of standards.

Standards for nursing practice in correctional settings have been developed by the American Nurses Association and were last revised in 2013. The set of 16 standards address use of the nursing process in correctional settings as well as professional performance of nurses practicing in such settings (ANA, 2013). The revised standards also address a new standard related to the nurse’s environmental health capabilities, focusing on knowledge of environmental concepts, and the use of strategies to reduce environmental health risks (Knox, 2013). For more information on correctional nursing standards, see the *External Resources* section of the student resources site.

Ethical concerns in correctional nursing. There are several ethical considerations that are particularly relevant to nursing in a correctional facility. The right to health care is an ethical as well as legal issue that has already been addressed. Other ethical issues include confidentiality and appropriate use of health care personnel, refusal of care, abuse of prisoners, and advocacy. Many of these issues are addressed in the various sets of standards discussed above, and readers should review NCCHC (2014b) documents for information with respect to these issues. Confidentiality issues may be a source of conflict in correctional settings when health care providers have access to information that may be of use in criminal proceedings against inmates. Health professionals in correctional institutions may be pressured to divulge client information or to assist with procedures designed to provide evidence for criminal proceedings (e.g., body cavity searches, blood alcohol levels) (Olsen, 2013). When these procedures need to be performed by trained personnel (e.g., venipuncture), they should be the task of personnel hired specifically for these types of responsibilities to prevent conflict of interest for health care providers and to avoid jeopardizing a relationship of trust between provider and client. Similarly, health care professionals should not be called on to engage in security measures or to participate in disciplinary decisions or in execution by lethal injection. Assuring appropriate use of personnel in the correctional setting may also mean making sure that nonprofessionals (including inmates) are not allowed to perform medical tasks or dispense medications.

Confidentiality, particularly with respect to HIV status, may be more difficult to achieve in a correctional environment. The intensive nature of treatment and the need for multiple doses of medication may serve to label inmates as infected, even when official confirmation of disease is not provided. This potential for lack of confidentiality may act as a deterrent to HIV testing and noncompliance with treatment in infected individuals. Another potential conflict related to confidentiality is the question of whether security personnel should be alerted to inmates’ HIV-infection status to ensure their use of universal precautions.

In addition to maintaining confidentiality, nurses may be called on to support an inmate's refusal of care, including forcible administration of psychotherapeutic medications. Inmates have the right to refuse care unless they are determined to be legally incompetent to make that decision. Inmates' right to refuse care, however, must be balanced against community safety (Muse, 2011; Olsen, 2013). Decisions regarding abrogation of the right to refuse treatment should be based on facts in the individual situation, including the inmate's medical condition, prognosis, benefits and burdens of treatment, and the impact of refusal on other inmates. Refusal of care should be carefully documented, including the nature of the care refused, the inmate's stated reason for refusal, the date and time of refusal, provision of education on the possible consequences of refusal, and the inmate's signature or initials.

Aggressive or potentially suicidal inmates may be subjected to physical restraint if they are deemed a danger to themselves or to others. This includes the use of medical isolation when clients suspected of infectious diseases refuse screening procedures or treatment. Medical isolation may also be legitimately employed to protect inmates with symptomatic AIDS from opportunistic infection. Although the U.S. Supreme Court has upheld segregation of HIV-infected inmates, segregation breaches confidentiality and denies segregated inmates access to programs, such as work release and other programs available to other inmates. In addition, segregation may contribute to exacerbation of psychoses or depression.

Because of the imbalance of power inherent in a correctional setting, there is always the potential for abuse of inmates in the name of punishment. Preventing this and other forms of abuse of inmates (e.g., denial of health care services) is another ethical aspect of nursing in correctional settings. Finally, nurse advocacy may be needed in the correctional setting. Advocacy may be required at the level of the individual client to ensure that rights are upheld and that appropriate health care services are received or at the aggregate level to assure adequate health care delivery systems in correctional institutions.

NCCHC (2012) has delineated three guiding ethical principles for health care in correctional settings. These principles include the following:

- **Medical autonomy:** The health professional acts first in promoting the patient's interest and judgments should be based on patient needs not legal issues.
- **Non-maleficence:** Health care providers should not engage in any actions that would lead to patient harm.
- **Medical neutrality:** Providers should provide care to all inmates regardless of background, status, reason for incarceration, and so on.

Furthermore, an NCCHC position statement on health professionals' responsibility in the event of witnessing harm to inmates indicates that they (a) should not participate in any form of interrogation or abuse, including not providing consultation on such activities; (b) should not gather forensic information

or share confidential information with authorities for use in abuse; (c) should not authorize or approve any physical punishment; (d) should promote policies that protect correctional employees who report abuse; and (e) should support training for staff to prevent abuse (NCCHC, 2012).

Features of the correctional setting that influence health are assessed by the population health nurse and then used to derive nursing diagnoses. Assessment tips for use with correctional populations are provided on the next page. In addition, a comprehensive tool for assessing the health status of correctional populations is provided on the student resources site.

Diagnostic Reasoning and Care of Correctional Populations

Based on information obtained in assessing the determinants of health, the nurse in the correctional setting formulates nursing diagnoses. Diagnoses should be validated with the client, significant others, or other health care providers when possible. Population health nurses working in correctional settings determine nursing diagnoses for individual clients as well as diagnoses related to the health needs of the total population of inmates and staff. For example, an individual diagnosis might be "uncontrolled diabetes mellitus due to substance abuse." A diagnosis related to the population group might be "increased potential for violence due to racial tensions and unrest." This second diagnosis would affect facility personnel as well as inmates since all might be involved in any violence that occurs.

Planning and Implementing Health Care for Correctional Populations

Planning to meet identified health problems in correctional settings may be accomplished independently by the nurse or in conjunction with other personnel within and outside the institution. Interventions may take place at any of the four levels of health care: health promotion, injury and illness prevention, resolution of existing health problems, and health restoration.

HEALTH PROMOTION. Health promotion in correctional settings involves provision of adequate nutrition, rest and exercise, health education, prenatal care, and contraceptive services. Health promotion in correctional settings differs from that in other settings in a number of ways. First, the general purpose of health promotion in correctional settings is to protect the health of others rather than to enhance the health of the particular inmate. Second, group health promotion efforts may be hampered by the compulsory nature of inmates' presence in the institution. For example, inmates may be resistant to health education because they perceive themselves as a "captive audience" with little option regarding participation. Third, the great majority of offenders are men who tend not to be as highly motivated with respect to health promotion as women. Health promotion in correctional settings often needs to focus less on information transmission than on attitude development or change, and behavioral change may not be as easy within the

FOCUSED ASSESSMENT**Assessing Health and Illness
in Correctional Settings****Biological Determinants**

- What is the age, gender, and ethnic composition of the correctional population (inmates and staff)?
- What communicable and chronic health problems are prevalent among inmates? Among staff?
- What is the extent of injury in the population? What factors contribute to injuries?
- What is the prevalence of pregnancy among inmates?
- What are the immunization levels in the population?

Psychological Determinants

- What procedures are in place for dealing with suicidal ideation or attempts? Are these procedures followed?
- What is the psychological effect of incarceration? Does the individual inmate exhibit signs of depression? Does the inmate express thoughts of suicide?
- What is the extent of sexual assault among inmates? What are the psychological effects of assault?
- Are there inmates in the setting under sentence of death? If so, what psychological effects does this have? Are there terminally ill inmates in the population?
- What is the prevalence of mental illness among inmates?

Environmental Determinants

- Are there health or safety hazards present in the correctional facility?
- Is there potential for disaster in the area? Is there a disaster plan?

Sociocultural Determinants

- What political/legal issues influence the health of the correctional population?
- What is the socioeconomic status of members of the correctional population? What is the general educational level?
- What ethnic/cultural groups are represented in the correctional population? How does this influence the health status or risks of the population?
- What are the attitudes of health and correctional personnel toward inmates?
- What is the attitude of the surrounding community to the correctional facility and to the inmates?
- Are there intergroup conflicts within the population? Do these conflicts result in violence?
- What is the extent of violence in the correctional population? What factors contribute to violence?
- What family concerns influence the health of inmates? What is the effect of incarceration on the families of inmates?

- What is the extent of mobility in the population?
- Are inmates employed in the correctional setting? Are they employed outside? What health hazards, if any, are posed by the type of work done?
- How do security concerns affect the ability of health care personnel to provide services?
- What are the elements of the correctional subculture? How do they affect the health of the correctional population?

Behavioral Determinants

- Are there inmates with special nutritional needs? How well are these needs being met? What is the nutritional quality of food served in the correctional setting?
- What are the health-related behaviors of the correctional population? How do they affect health?
- What is the prevalence of tobacco use in the population?
- What is the prevalence of alcohol or drug abuse in the population?
- Do inmates have access to illegal drugs or alcohol within the correctional setting?
- How are medications dispensed in the correctional setting? Are there procedures in place to prevent inmates from selling medications or accumulating them for use in a suicide attempt?
- Do conditions in the correctional setting support adequate rest?
- Do conditions in the correctional setting promote physical activity?
- What is the extent of sexual activity in the correctional setting? To what extent do inmates engage in unsafe sexual practices? What is the availability of condoms?

Health System Determinants

- What health services are offered in the correctional setting? Are they adequate to meet needs?
- Are there isolation procedures in place for inmates with communicable diseases? Are these procedures followed?
- How are health care services funded? Is funding adequate to meet health needs? Are inmates charged a fee for health care services?
- What is the quality of interaction between internal and external health care services?
- What is the extent of emergency response capability of the correctional facility (e.g., to myocardial infarction, stab wound)?
- What provisions are made for continuity of care after release from the correctional facility?

constraints of the correctional setting as in the outside world. In addition, the correctional emphasis on punishment for crimes may result in political interference with health promotion efforts. Finally, given the extensive health problems encountered in this population, there may be little time or few resources available for health promotion efforts, which may receive lower priority than curative activities.

Nutritional intake in correctional settings may be far from adequate. NCCHC recommendations include the initiation of heart-healthy diets as a routine aspect of correctional settings (Wakeen, 2008). The nurse in this setting may need to monitor the diet of inmates and may need to influence administrative decisions regarding the nutritive value of meals served. There may also be a need to suggest changes in food served to facility personnel if meals are provided for them as well. In addition, the nurse may need to make arrangements to meet the special dietary needs of specific inmates based on their health status. Examples include a diabetic diet or a liquid diet for an inmate recuperating from a broken jaw. Juveniles, in particular, have special dietary needs, including the need for increased calories, calcium, phosphorus, and iron.

Juvenile facilities may participate in the U.S. Department of Agriculture's Child Nutrition National School Lunch Programs or School Breakfast programs, and population health nurses can encourage facility participation in these programs. Such participation involves meeting specific nutritional requirements and limitations on nonnutritive foods. Juveniles in adult facilities may be given adult meals with additional milk, fruits, and snacks (Robbins, 2009a). Women also have special nutritional needs, particularly pregnant women. As noted earlier, women have a tendency to gain weight during incarceration, so attention should be given to lower calorie foods.

Attention should also be given to provisions for adequate rest and physical activity by inmates. Nurses may need to advocate for adequate space and facilities for sleeping in inmate housing units. In addition, the nurse should work to assure that time and facilities are provided for inmates to engage in physical activity. In some instances, this may mean curtailing certain activities that place inmates at risk because of existing health problems. Nurses can also educate both inmates and staff on the benefits of activity and suggest forms of physical activity congruent with health status and available opportunities. Physical activity is particularly important for women who are engaged in smoking cessation programs as they have been shown to experience significant weight gain (Cropsey et al., 2010).

Both inmates and facility staff may be in need of a variety of health education efforts. Areas of importance include the elimination of risk factors for disease. Education programs that may be planned and implemented by nurses may include smoking cessation campaigns or stress management classes. Nurses can also advocate for access to smoking cessation assistance and aids such as nicotine patches. Education regarding problem solving and positive coping strategies may also benefit both staff and inmates.

Prenatal care is a significant health promotion activity for pregnant female inmates. NCCHC recommendations include provision of pregnancy screening for all women inmates and further screening of pregnant women for HIV and other STIs. Areas to be addressed in prenatal care include adequate nutrition, the effects of smoking and other substances on the fetus, parenting skills, discomforts of pregnancy, and planning for childcare if the child is delivered while the client is still in custody. Contraceptive education may benefit both pregnant and nonpregnant inmates. Health promotion strategies for correctional populations are summarized in Table 24-1.

PREVENTION. Three aspects of prevention are pertinent to correctional health care. These include preventing incarceration as well as injury and illness prevention.

Preventing incarceration. As we saw earlier, CITs and special drug and mental illness courts are aimed at preventing incarceration of persons whose crimes are the result of substance abuse or mental illness. Similarly, programs funded by the Juvenile Justice and Delinquency Prevention Act are designed to prevent gang activity and other avenues of contact with the juvenile justice system. Other social programs may also serve to prevent youth involvement in criminal activity. For example, the Perry Preschool Project was credited with decreasing arrests, preventing school dropouts, and promoting education and employment among at-risk children. The program involved a daily preschool program with weekly home visits to address family problems over a 2-year period. Cost estimates indicate that \$17 were saved for every dollar invested in the program, primarily in reduced criminal activity and better educational attainment (Welsh & Farrington, 2011). Population health nurses can advocate for and help initiate similar programs in low-income, high-risk communities.

Preventing illness. Preventing the spread of communicable diseases in correctional settings is an important primary prevention activity.

Possible approaches to infectious disease prevention include the use of universal precautions in the handling of blood and body fluids (National Institute for Occupational Safety and Health [NIOSH], 2011), isolation of infected persons when appropriate, immunization, and education on hygiene and

TABLE 24-1 Health Promotion Strategies for Correctional Populations

- Provision of adequate nutrition
- Provision of opportunities for adequate rest and exercise
- Health education for self-care, risk factor elimination, stress reduction, etc.
- Prenatal care for pregnant inmates
- Contraceptive education
- Advocacy for available health promotion services in correctional settings

Evidence-Based Practice

Preventing Incarceration

A significant body of research suggests that prevention of delinquency and later criminal activity is much more effective than incarceration of offenders. In 2007, for example, Washington State allocated \$48 million to evidence-based crime prevention and intervention programs. Although this was a political decision, unlike many such decisions, it was based on research findings related to effective interventions. A series of research studies conducted by the Washington State Institute for Public Policy

explored the effects and cost-effectiveness of several adult and juvenile intervention programs. Based on their analysis of 571 evaluations of crime prevention and criminal justice programs, the institute was able to project the potential benefits and costs of certain intervention approaches. The evidence suggests that alternatives to prison can achieve cost savings to the public as well as some reduction in crime rates (Welsh & Farrington, 2011).

condom use during sexual encounters. Isolation is appropriate for diseases spread by airborne transmission such as measles and influenza. Isolation of HIV-infected individuals is not generally recommended. During community- or facility-based influenza outbreaks, isolation of infected inmates, removal of infected staff from duty, and prohibiting visitors with recent symptoms also help to prevent the spread of disease (NCCHC, 2009a).

Immunization is particularly recommended for HBV (Malek et al., 2011), but other immunizing agents may be needed as well, depending on the incidence of specific diseases in the general community. For example, measles immunizations may be warranted for all inmates and staff during a measles outbreak in the community, and hepatitis A vaccine is recommended for inmates at risk for hepatitis A (e.g., inmates who engage in oral–anal intercourse). Corrections staff, particularly health care personnel, should also receive HBV immunization. Condom use and substance abuse education on harm reduction strategies (e.g., use of clean needles and syringes for injection drug use) can also help to prevent the spread of hepatitis B and C in correctional populations.

Because correctional settings house a large proportion of inmates who are infected with or at risk for hepatitis, provision of HBV vaccine is a good way to minimize disease prevalence within correctional settings and in the larger community. Similarly, seasonal influenza immunization is recommended for correctional populations (Malek et al., 2011). As noted earlier, many correctional facilities do not receive adequate supplies of influenza vaccine, and states and local jurisdictions may need to re-evaluate vaccine allocation policies to address the needs of this vulnerable population (Lee et al., 2012). Population health nurses in correctional settings may be actively involved in providing immunizations and advocating vaccine availability to inmates.

Periodic outbreaks of other infectious diseases may also necessitate immunization programs to prevent the spread of disease. For example, several recent mumps outbreaks have been reported in correctional facilities. In addition to immunization, isolation of infected inmates and quarantine of

exposed inmates or staff are warranted. If infected inmates are scheduled for release, immunization of household members may also be indicated (Ringsdorf et al., 2010).

Recommended TB control measures in correctional settings include screening of all inmates for infection, isolation of suspected and confirmed cases, and treatment of persons with active or latent TB infection. Preventing the spread of TB may also employ engineering controls related to adequate ventilation systems, air filtration, and irradiation of areas where infected persons are housed. **TB prophylaxis** is the treatment of persons with reactive tuberculin skin tests but without evidence of active TB (in other words, those with latent infection), to prevent their development of disease. TB prophylaxis is also recommended for persons with HIV infection even in the absence of evidence of latent TB. Corrections personnel with positive skin tests should also receive prophylaxis. In addition, all inmates and personnel should be educated on infection control procedures and universal precautions, and health care providers should use appropriate protective barriers to prevent infection (e.g., gloves, aprons, face shields, goggles, and gowns, as needed) (NIOSH, 2011). Population health nurses are often responsible for providing directly observed TB therapy and in monitoring its effectiveness. They also monitor clients receiving therapy for potential adverse reactions to medication.

HIV prevention education is another area of importance among incarcerated women (and men) who are often at high risk for infection. Population health nurses may need to advocate for the availability of condoms for use by inmates who are sexually active. There is considerable debate on providing condoms for incarcerated inmates, but a recent study in California's state prison system indicated that condom availability in prisons would minimize the spread of HIV infection and other STIs and significantly reduce treatment costs (California HIV/AIDS Policy Research Centers, 2013).

Other more mundane avenues for preventing communicable diseases include routine skin screening for infectious lesions and effective wound infection control procedures. Promotion of inmate hygiene, use of alcohol-based hand rubs for hand washing, and effective laundry procedures can also prevent the spread

of infections, particularly methicillin-resistant *staphylococcus aureus* (MRSA) infections. Pregnancy prevention using emergency contraception may also be warranted, particularly for young girls in juvenile detention facilities (Robbins, 2009b).

Illness prevention efforts may also be required for chronic conditions. For example smoking cessation, obesity reduction, and promotion of physical activity may serve to prevent a variety of chronic illnesses. Specific prevention strategies for chronic illness are similar to those discussed in Chapter 27∞.

Preventing injury. Injury prevention is also needed in correctional settings. For example, population health nurses may identify environmental hazards or occupational hazards in the correctional setting that present injury risks and can advocate for their removal or modification. Nurses may also provide safety education for inmates and staff. Specific injury prevention strategies may also be warranted for certain at-risk populations in the setting. For instance, the nurse may need to advocate for a lower bunk for an inmate with limited mobility or ensure the availability of assistive devices such as walkers or canes. Nurses may also identify chemical hazards or rodent infestations that need to be addressed.

Other avenues for injury prevention include suicide prevention and prevention of violence. The primary mode of suicide prevention is identification of inmates at risk for suicide. Those at risk for suicide should be closely monitored and receive timely referrals for psychiatric services. Suicide assessment involves obtaining information regarding past personal or family history of suicide attempts, the extent of life stress and social support, presence of suicidal ideation, and presence of mental illness.

Components of an effective suicide prevention plan include initial screening and ongoing identification of inmates at risk, staff training, inmate assessment by qualified mental health professionals, appropriate housing, and referral to needed mental health services. Other elements of effective plans include adequate communication between corrections and health care staff, immediate intervention for a suicide attempt or suicide in progress, and availability of needed equipment and supplies (e.g., resuscitation breathing masks, gloves, defibrillators, and tools for opening jammed cell doors and cutting down a hanging inmate). Suicide prevention may also involve judicious and carefully supervised use of suicide prevention cells (Suicide Prevention Resource Center, 2014). Additional guidelines and resources for suicide prevention in correctional settings have been compiled by the Jail Suicide Task Force of the American Association of Suicidology (Kennedy & McKeon, n.d.). For more information about the guidelines, see the *External Resources* section of the student resources site.

Violence prevention activities may need to be directed to both inmates and corrections staff. The purpose of such activities is to teach alternative behavioral responses to violence (Sung, 2010). Recommended components of violence prevention programs in correctional settings include incorporation of

violence assessment (including prior exposure to violence) as part of intake screening, referral of inmates with a history of personal violence or violence exposure for counseling, education on alternative responses to potentially violent situations for both inmates and corrections staff, and referral of inmates for continued counseling on release. Prevention emphases in correctional health care are summarized in Table 24-2●.

RESOLVING EXISTING HEALTH PROBLEMS. Strategies for addressing existing health problems in correctional settings focus on screening and diagnostic and treatment activities.

Screening. Standards related to screening have been described as some of the more important standards for correctional health care. Screening has a threefold purpose: identifying and addressing the health needs of inmates, promoting early identification of key problems prior to more comprehensive assessments, and identifying and isolating potentially communicable inmates.

Screening begins with medical clearance or a determination that a specific inmate is well enough to be admitted to the facility. Medical clearance is intended to ensure that emergent health needs are met. Based on NCCHC standards, medical clearance screening is followed within 2 to 4 hours of admission by receiving screening. *Receiving screening* is the collection of health-related information to identify newly arrived inmates who pose a health threat to themselves or the general facility population. The goal of receiving screening is to identify needs for care and continued treatment of existing conditions. Receiving screening includes a comprehensive health history; observation of appearance, behavior, ease of movement, breathing, and skin integrity; and presence of suicidal ideation (Kistler & Chavez, 2011a). Receiving screening also includes an initial assessment for mental health issues that may be conducted by correctional staff, but mental health screening, required within 14 days of admission, must be conducted by qualified mental health professionals (Kistler & Chavez, 2011b). Receiving screening should also include assessment for substance abuse and signs of intoxication or withdrawal (NCCHC, 2010b).

Screening may also include specific tests for infectious diseases. For example, tuberculin skin testing is recommended for inmates who will be incarcerated long enough for the results to be read. The Centers for Disease Control and Prevention (CDC) has also recommended routine screening for sexually transmitted diseases in correctional populations, particularly among adolescent and young females (Miller, 2011). Recommendations have also been made for routine screening for sexual abuse or for risk of being abusive (Greifinger, 2010) and for evidence of dementia (Wilson & Barboza, 2010).

Routine screening for infectious diseases may be conducted on either an opt-in or opt-out basis. In opt-in screening, screening is conducted for inmates who agree to it. In opt-out screening, the screening test is performed unless the inmate specifically refuses it. CDC specifically recommends opt-out

TABLE 24-2 Prevention Foci and Related Strategies for Correctional Populations

Focus	Strategies
Preventing incarceration	<ul style="list-style-type: none"> • Community support programs for high-risk families • Delinquency prevention programs for youth • Advocacy for CITs, mental health courts, and substance abuse courts
Preventing infectious diseases	<ul style="list-style-type: none"> • Immunization • Isolation of persons with infectious diseases • Quarantine of exposed persons • Restriction of infected staff from work • Restriction of visitors with symptoms of disease • Use of universal precautions for blood and body fluids • TB prophylaxis • Education for safe sex • Advocacy for condom availability • Hygiene education
Pregnancy prevention	<ul style="list-style-type: none"> • Provision of emergency contraception
Preventing chronic conditions	<ul style="list-style-type: none"> • Risk factor modification • Smoking cessation • Obesity reduction
Preventing injury	<ul style="list-style-type: none"> • Modification of environmental safety hazards • Safety education
Preventing suicide	<ul style="list-style-type: none"> • Identification of high-risk inmates • Referral for mental health services • Staff education for recognition of risk and response to attempted suicide • Effective communication with correctional personnel regarding inmate risk status • Advocacy for emergency response equipment and supplies • Judicious use and careful supervision of isolated inmates • Immediate response and first aid for suicide attempt
Preventing violence	<ul style="list-style-type: none"> • Violence risk assessment • Referral for mental health services • Anger management counseling • Education on conflict management strategies

screening for HIV infection. Opt-out screening tends to be more effective, achieving a 90% screening rate, compared to a 72% rate for opt-in screening, and only 5% when screening is provided on the basis of inmate request (Strick, MacGowan, & Belcher, 2011). Opt-out screening has the potential for identifying inmates with hepatitis B and C, TB, syphilis, gonorrhea, and chlamydia, in addition to HIV infection, thereby promoting early treatment and preventing the spread of disease in the facility (Malek et al., 2011). Offering routine HIV screening at intake resulted in the diagnosis of 52 new cases in one correctional setting (Spaulding et al., 2013). In large volume settings in which universal screening of all inmates is impractical, screening targeted to specific arrest charges (e.g., drug charges, sex charges, parole violation) has been suggested, but evidence for the effectiveness of this approach is limited (Harawa et al., 2009).

Subsequent assessments may take one of two approaches: full population assessment or individual assessment. In the full population approach, every inmate receives a comprehensive assessment after intake screening. The individual approach provides comprehensive assessment when clinically indicated for an individual inmate. Both approaches include a review of screening information, a comprehensive health history,

further inquiry into problem areas, a physical examination, and routine diagnostic and laboratory tests. Assessments result in treatment plans tailored to the needs of particular inmates (Kistler, 2008).

Screening for mental health problems is another important element in resolving existing health problems. Mental health screening is needed to identify inmates at risk for harm to themselves or others, determine inmates' functional capabilities, identify the need to transfer inmates to a specific mental health unit, and determine the inmate's potential to benefit from treatment. There is also a need for ongoing assessment for suicide risk, particularly among inmates that may engage in self-injury (Fagan et al., 2010).

Suggested elements of mental health assessment in correctional settings include an inmate's psychiatric history, current use of psychotropic medications, presence of suicidal ideation, and a history of suicide attempt. Other relevant screening information includes drug and alcohol use, history of violence or victimization, history of special education placement, and history of traumatic brain injury. Assessment also includes evaluation of the inmate's response to incarceration and evidence of developmental disability. Population health nurses may also assess inmates' readiness and motivation for treatment.

Population health nurses may also be involved in other screening activities with inmates. For example, they may be involved in screenings for work clearance or periodic screening for work-related conditions or prior to transfer to another facility or court. In addition, they may be called upon to screen for harm following a use-of-force incident or when an inmate is restrained (Knox, 2013). In addition, they may screen for infectious diseases or chronic conditions based on risk factors or inmate health histories.

Nurses in correctional settings are also involved in triage during sick call activities. Inmates with health complaints can ask to be seen during sick call. At this time, the nurse determines the need for treatment of specific conditions under specific protocols, advice for self-care, or referral for a higher level of care (Knox, 2013). Protocols would cover, at a minimum, a problem definition and etiology, subjective and objective information to be collected, relevant nursing diagnoses with possible differential diagnoses, interventions to be considered, patient education, and disposition and follow-up care (Smith, 2009).

Diagnosis and treatment. Diagnosis and treatment may be required for medical conditions, mental illness, or substance abuse. Correctional nurses may be actively involved in the diagnosis and treatment of existing medical conditions. Many minor illnesses are handled exclusively by nurses working under medical protocols as noted earlier. In other instances, nurses are responsible for implementing medical treatment plans initiated by physicians or nurse practitioners. This may involve giving medications or carrying out treatment procedures. Treatment procedures would be handled in much the same way as in any health care facility. Dispensing medications in a correctional setting, however, requires that the nurse directly observe the client taking the medication, and often only a single dose is dispensed at a time rather than giving the client several doses of medication to be taken at prescribed times. This precaution is necessary because of the potential for inmates to sell medications to other inmates or to stockpile certain medications for use in a suicide attempt. In some instances (e.g., epidemics of communicable diseases), mass treatment of the entire correctional population or subpopulation in a given setting may be warranted.

Treatment for TB and HIV infection in correctional settings is complicated by the long-term nature of the therapies. Inmates with TB (except those also infected with HIV) should be placed in respiratory isolation in negative-pressure rooms until they are no longer contagious. If negative-pressure rooms are not available in the correctional facility, arrangements should be made to transport the inmate to a local hospital with such facilities. Respiratory isolation should also be instituted for all inmates with respiratory symptoms suspicious of TB disease. Treatment should involve a multi-drug regimen, particularly when exposure to MDR infection is suspected. Drug susceptibility testing should be carried out on all inmates with active TB, and treatment should rely on directly observed therapy (DOT).

HIV/AIDS therapy is also difficult in correctional settings because of the number of factors that promote noncompliance. As noted earlier, having to receive multiple doses of medication each day may “tag” inmates as infected and leave them open to discrimination and assault. Security practices such as lockdowns and search and seizure may interfere with dispensing of medications or attendance at support group or education programs. A **lockdown** occurs when inmates are locked in their cells at times when they would ordinarily have greater freedom to come and go throughout the facility, usually in response to a security incident or to permit a search for contraband items (drugs, alcohol, weapons) or a **search and seizure** procedure. During search and seizure, all medications are taken away, so clients in some facilities where self-medication is permitted may have their medications removed and be unable to take doses as directed.

Strategies that can increase compliance with TB treatment regimens include simplifying the regimen to include fewer doses or combining medications into a single pill, protecting confidentiality, using medications with fewer side effects, and dealing with those side effects that occur. DOT has also been found to be effective in promoting compliance with highly active antiretroviral therapy (HAART) for inmates with HIV/AIDS. Treatment is also more effective if provided by health care professionals who have expertise with HIV/AIDS. In larger systems, inmates with HIV infection may be moved to facilities with this expertise or where this expertise is available in the community.

Treatment may also be needed for a variety of chronic health problems experienced by correctional populations. Again, population health nurses working in correctional settings may provide treatment and monitor treatment effectiveness under approved protocols. They may also be responsible for making referrals for specialty services to outside health care agencies. This may require particular advocacy on the part of population health nurses to assure that outside appointments are kept when they are jeopardized by security concerns or lack of security personnel to escort inmates to community facilities.

Treatment should also be available for substance abuse and mental health problems. There are a number of sound reasons for mental health care in correctional settings. These include the need to reduce the disabling effects of mental illness and to maximize the ability of inmates to participate in rehabilitation programs. A second reason is to minimize the suffering of the inmates themselves. Finally, treatment of inmates with mental illness and substance abuse problems promotes the safety of all, both within the correctional setting and in the community when the inmate is released. Unfortunately, many inmates with mental illness or substance abuse disorders do not receive treatment, or medications being prescribed for treatment are discontinued on incarceration despite evidence that medication-assisted treatment and cognitive behavioral therapy have been shown to be effective in addressing these problems (NCCHC, 2010b). In one large longitudinal study of incarcerated youth, for example, only 15% of juvenile offenders with

major psychiatric disorders were treated when incarcerated and only 8% received treatment on release (Teplin et al., 2013). Population health nurses may need to advocate for the availability of treatment for mental illness and substance abuse disorders in correctional settings. They may also need to campaign at state legislative levels for authorization and funding of diversion programs to promote treatment options rather than incarceration (Stettin et al., 2013).

Methadone maintenance is a special area of consideration in treatment for substance abuse. For many opiate abusers, methadone may be an important step in treatment for addiction. Although a significant proportion of persons in methadone treatment programs get arrested during their enrollment, few correctional settings make provision for continuing methadone treatment except for pregnant inmates. Involuntary cessation of methadone leads to painful withdrawal symptoms and risk of death, as well as relapse to opiate use and subsequent rearrest. NCCCHC standards require mental health services for all inmates in need of them that include both individual and group counseling (Kistler & Chavez, 2010). Provision of mental health services in correctional settings is often hampered by variables related to correctional systems, personnel, and inmates. System-level variables include limited fiscal allocations for services and privatization of correctional facilities, the institutional climate, and limitations in access to care posed by inmate classification systems. Privatization of correctional settings (government contracting with private corporations for operation of correctional facilities) often leads to cost cutting to remain competitive, and cost cutting may eliminate services, such as mental health services, that are considered “nonessential.” In addition to entire correctional systems run by private for-profit companies under contract to government agencies, health care services in correctional settings may also be privatized. For example, a county sheriff’s department may contract with a private firm for health care personnel and services within the correctional setting rather than hiring health care personnel as county employees. Government service contracts are usually given to the lowest bidder, providing an incentive to decrease the quality or frequency of services in the interests of cost containment. In addition, privatization may lead to less official oversight of correctional facilities and the quality of care provided. On the other hand, privatization has the advantage of services provided by people who have a health care perspective rather than a custodial focus.

The institutional climate is frequently one of punishment rather than treatment, so inmates may not receive needed mental health services. Finally, classification of inmates as security risks may put them at risk for isolation, exacerbation of mental health problems, and lack of access to many services available to other inmates.

Personnel variables that affect mental health treatment services in correctional settings include staff attitudes to mentally ill inmates and training of correctional and health care personnel relative to mental health needs. Cultural diversity and differences between correctional personnel and inmates

may also make identification of mental health problems more difficult. Cultural factors related to mental health and illness are discussed in more detail in Chapters 5 and 28.

Inmate-related variables include mental health treatment history, a slower response to medication among inmates than in the general population due to the prevalence of substance abuse, and peer pressure within the setting to not appear weak or vulnerable. In addition, the nuisance side effects associated with psychotropic medications may lead many inmates to be noncompliant with treatment plans.

Issues that need to be addressed, in addition to mental health or substance abuse treatment needs, include continuity of public assistance, housing support, and the need for social service referrals and treatment of other medical conditions.

Research has indicated that treatment of substance abuse while an inmate is in prison reduces the likelihood of rearrest and reduces the return to previous drug use patterns. For example, treatment mandated by drug courts has successfully reduced crime rates and rearrests by 11% to 14% (Anglin et al., 2013). Promoting self-care for mental illness and using educational, behavioral, and motivational strategies have also been effective in minimizing the effects of mental illness (Shelton et al., 2010).

Treatment may also be needed for a variety of chronic conditions. Treatment would be similar to that provided to the general population, but may need to be modified to fit the correctional setting. For example, self-medication may be constrained by facility regulation, as in the case of inmates giving themselves insulin. Foci for chronic disease management in correctional settings are similar to those in community settings and include self-care when possible, development of inmate support groups, patient education, assistance in dealing with medication side effects, and reinforcing compliance to achieve treatment goals.

There may also be a need to arrange for physical and psychological treatment of sexual abuse (Greifinger, 2010) and treatment of acute psychosis as mentioned earlier (Mathis, 2010). Other areas of concern in treating existing problems are sleep disorders, dealing with violent and agitated inmates, and addressing dementia in the correctional population. Treatment for sleep disturbances usually focuses on promoting sleep hygiene (e.g., regular sleep-wake patterns, avoidance of stimulants, environmental modifications to minimize noise and light, etc.) and life changes, such as a healthier diet, stress management, and daily exercise (Anderson, 2010). Pharmacologic sleep aids, medical conditions, and medications that affect sleep may also need to be addressed.

Four basic approaches can be used to deal with aggressive and agitated inmates: de-escalation, seclusion, physical restraint, and pharmacologic restraint (Savage, 2010). De-escalation involves talking to the inmate to calm him or her, and involves listening with empathy, giving a context to the agitation, providing options, confirming non-cooperation, and more definitive action. Seclusion should be used only for immediate protection of the inmate or others, not for punishment, and the inmate should be carefully observed. Physical restraint

may be necessary, but may have serious health consequences and should be minimized, and pharmacologic restraint has the potential for drug side effects. Nurses need to keep in mind that agitation may be the result of physical illness. They may also need to advocate for judicious use of restraints and monitor the health status of inmates under physical or pharmacologic restraint (Savage, 2010). Restraint of pregnant women poses particular risks for both the women and the fetus, and should be accomplished in the least restrictive manner possible with consultation from medical staff. Wrist restraints, in particular, should be applied, if necessary, in such a way as to allow the women to protect herself in the event of a fall (NCCHC, 2010a).

Treatment for inmates with dementia involves planning ahead for a possible influx of patients as time goes by. Management includes informing inmates of their diagnosis, structuring the environment to minimize confusion, and developing and using nonpharmacologic interventions such as praise for positive behaviors, relaxation training, support of remaining skills and abilities, and promoting exercise and group interaction. Effective management also involves training staff to communicate effectively with inmates with dementia, promoting client choices, repeating introductions, using strategies for getting clients' attention, using gestures, giving simple instructions, and giving clients time to process their thoughts and responses (Wilson & Barboza, 2010).

When physical or mental health services needed by inmates are not available within the correctional health care setting, correctional health nurses are often responsible for arranging appointments with outside consultants or providers. In addition to arranging for appointments, correctional nurses usually have to arrange transportation and security supervision. This often means that scheduling of appointments can be extremely complicated. Once inmates have been seen by outside providers, correctional nurses also need to follow through on recommendations for treatment. Because many outside providers do not understand the constraints of correctional systems, nurses may need to be creative in promoting treatment compliance. For example, in some small rural jails, there are no facilities for warm soaks to injuries, and special diets may also be difficult to arrange. Other recommendations that pose security hazards may not be able to be fulfilled (e.g., metal braces that can be converted to weapons). Population health nurses may need to advocate for treatments that are not typically used in the setting, or may need to explain to outside providers why a particular treatment option is not feasible in a correctional setting.

Nurses will also be involved in emergency response to life-threatening situations. Emergency situations likely to be encountered include seizures, cardiac arrest, diabetic coma or insulin reaction, attempted suicide, and traumatic injury due to inmate violence. The nurse would respond to these situations with actions designed to relieve the threat to life and stabilize the client's condition prior to transportation to a hospital facility either within or outside the correctional system. Correctional nurses may also find themselves involved in emergency care of

large numbers of persons injured in human-caused or natural disasters involving the correctional facility (Kistler, 2009). Major foci in resolving existing health problems in correctional settings are summarized in Table 24-3•.

HEALTH RESTORATION AND END-OF-LIFE CARE.

Health restoration in correctional settings focuses on areas similar to that in any setting, preventing or dealing with complications of disease and preventing problem recurrence when possible. Intervention directed toward preventing complications of existing health problems depends on the conditions experienced by inmates. For example, health restoration for the inmate with diabetes will be directed toward preventing circulatory changes, diabetic ketoacidosis, and hypoglycemia. For the client with arthritis, restoration will focus on pain management and prevention of mobility limitations.

Population health nurses may also help inmates deal with the long-term consequences of chronic conditions. An example might be providing a walker to an inmate with mobility limitations. Health restoration activities may also be directed toward preventing the recurrence of problems once they have been resolved. For example, the nurse may educate an inmate who has been treated for gonorrhea on the use of condoms to prevent reinfection.

In addition, there are three special considerations in health restoration in correctional settings: long-term care planning, reentry planning, and end-of-life care. Each of these major foci will be addressed briefly.

Long-term care planning. With the aging of the correctional population and longer sentences without option for parole, there is a need to engage in long-term care planning for elderly inmates and those with chronic conditions. Correctional systems have taken a variety of approaches to long-term care planning for these subpopulations. Older inmates or those with disabilities related to chronic illness may be transferred to appropriate facilities or housing conditions separate from the general inmate population. Usually such facilities have an infirmary where exacerbations of chronic conditions requiring hospitalization can be addressed in-house. In other instances, inmates may be transferred to assisted living facilities that provide assistance with the activities of daily living. Terminally ill inmates may be transferred to specialized hospice units or to community hospices (Hufft, 2013). Alternatively, hospice services can be provided to inmates housed in the general population, at least until inmates become severely debilitated.

When inmates with chronic illnesses or disability are housed in the general population, correctional systems may provide "home care" services and case management to address their long-term care needs. In such systems, nurses might go to inmate housing units to provide care in the same way that they would provide home care in community settings. Another alternative is to have other inmates function as "personal care attendants" for disabled inmates, assisting them with certain activities of daily living (e.g., bathing).

TABLE 24-3 Foci and Related Strategies for Resolving Existing Health Problems in Correctional Populations

Focus	Related Strategies
Screening	<ul style="list-style-type: none"> • Screening for communicable diseases <ul style="list-style-type: none"> • Tuberculosis • HIV infection • Hepatitis B • Sexually transmitted diseases • Routine screening for chronic conditions <ul style="list-style-type: none"> • Asthma, hypertension, obesity, seizure disorder • Mammography • Papanicolaou smear • Colorectal cancer • Provision of specialized screening services for inmates at risk (e.g., diabetes) • Screening for suicide risk • Screening for pregnancy • Screening for mental illness and substance abuse • Screening for treatment motivation • Advocacy for availability of routine and specialized screening services
Diagnosis and treatment	<ul style="list-style-type: none"> • Provision of diagnostic services relevant to inmate needs • Treatment of existing acute and chronic conditions • Education for self-management of chronic conditions • Treatment of mental illness and substance abuse • Methadone maintenance for opiate users • Emergency care for accidental and intentional injuries • Treatment of sleep disorders • Treatment of violent and agitated inmates • Treatment of inmates with dementia • Care for psychiatric emergencies • Emergency care in the event of a disaster • Advocacy for effective and available diagnostic and treatment services in correctional settings

Other health restoration activities related to long-term care include providing assistive devices, monitoring the status of chronic conditions and treatment compliance, monitoring for adverse effects of treatment, and providing support in dealing with the emotional and physical consequences of long-term physical or mental illness. Population health nurses may be involved in providing these interventions or in advocating their availability in the correctional setting. They may also need to advocate for access to these kinds of services for specific inmates.

Reentry planning. Approximately 95% of the 2 million state and federal and 10–12 million jail inmates will eventually be released back into the community (Bureau of Justice Assistance, 2013). In 2009, for example, 729,295 state and federal prisoners were released back into the community, and many more were released from local jails. Many of these inmates re-enter the larger society as probationers or parolees. A **probationer** is an adult offender who has been remanded to community-based supervision, often as an alternative to incarceration. Probationers usually are held in correctional facilities for only a short time until their case has been tried in court. A **parolee** is an adult released from a correctional facility to community supervision after serving all or part of his or her sentence. Both probationers

and parolees are subject to re-incarceration if they violate the terms of probation or parole. In 2009, there were 4.2 million U.S. men and women under federal, state, or local probation and 819,308 on parole (U.S. Census Bureau, 2013i).

The dual process of incarceration and reentry has been cited as a public health opportunity. Reentry provides opportunities for addressing health care and other issues and preventing re-incarceration. Unfortunately, little planning may be initiated toward meeting inmates' reentry needs. The Second Chance Act, enacted in 2008, was designed to assist released inmates in the transition from jail or prison into the community and to prevent rearrest and incarceration. The act provides funding at federal, state, and local levels for a variety of reentry programs as well as research on reentry needs and strategies that support successful reentry (Bureau of Justice Assistance, 2013). Unfortunately, organized reentry programs are few and may not be available to the majority of inmates released from jails or prisons. A National Academies report found that less than 10% of released prisoners receive reentry planning services (Smith et al., 2013).

Reentry, in the correctional context, is the process of leaving jail or prison and being reintegrated into the larger society. Two challenges inherent in reentry are protecting the public and promoting effective reintegration into the community.

Reentry also poses risks for the spread of communicable diseases within the general population if infected inmates have not been effectively treated.

Released inmates often have limited job skills and social support networks, so many of them have difficulty reintegrating into the larger community. For example, half of released inmates lack a high school diploma, and more than half have been fired from a prior job. Prior to incarceration, many supported themselves with income from illegal activities (Urban Institute, 2014). For these reasons, released inmates may have difficulty finding employment and housing due to the stigma attached to incarceration (Bonnie et al., 2012). At the same time, the social capital or infrastructure of communities that reabsorb large numbers of released inmates are often stretched beyond their capacity (Underwood, 2011). Given the lack of support services, resources, and opportunities for legitimate employment, many released inmates return to criminal activities. An estimated two thirds of inmates released in any given year will be rearrested within 3 years of release (Bureau of Justice Assistance, 2013). Effective reentry planning and support following release can help to prevent rearrest and incarceration.

Reentry planning begins with the development of systematic discharge protocols to be used with all inmates to be released from a correctional setting. Such protocols should be developed with input from the communities to which inmates will be released. Population health nurses can be active advocates for reentry planning for all inmates. They can also advocate community involvement in the development of reentry planning protocols and in designing community infrastructures to support reentry.

Planning considerations related to individual inmates are based on an individualized needs assessment and include issues related to health care and social and financial needs. As many as 80% of persons released from correctional facilities have ongoing physical or mental health conditions that require long-term management (Wang et al., 2012). These clients need copies of their medical records, a sufficient supply of medications, referrals (and possibly actual appointments) for physical and mental health services in the community, and assistance with health insurance coverage. This may mean advocacy on the part of population health nurses to get Medicaid, Medicare, or Veteran's Administration benefits reinstated, or assisting inmates to find low-cost health care services. Advocacy may also be required to ensure that inmates have a sufficient supply of necessary medications until they can find employment and purchase medications on their own. This is particularly important for inmates who are receiving long-term therapy for HIV/AIDS or TB. Population health nurses may also need to advocate for continuing therapy for mental illness or substance abuse or for hormonal therapy for transgender individuals (NCCHC, 2009b). Released women prisoners may also need contraceptive assistance, particularly former narcotics abusers for whom cessation of use may result in increased fertility (Smith et al., 2013).

There is a particular need for effective communication between the correctional system and community health agencies. Too often, inmates are discharged with ongoing health needs (e.g., HIV/AIDS or TB treatment) without local health authorities being notified. In addition to making referrals and links to community services, population health nurses in correctional settings should also develop systems for monitoring service continuation and its effects on inmate health status.

Reentry planning should also address a variety of social and financial needs of released inmates. For example, many inmates have alienated family members and may not be able to find shelter with their families. In this case, population health nurses may need to assist in arranging housing for former inmates. Referrals may also be needed for employment assistance or job training. Unfortunately, federal spending on employment training in correctional settings has been drastically reduced in recent years, and a third of inmates in one large study would have liked to receive programs that were not available to them in correctional facilities. However, in-prison job training, holding a job while incarcerated, and earning a GED while incarcerated have been linked with successful employment on release (Urban Institute, 2014). Population health nurses may need to advocate at the societal level for job training programs for inmates and others with low levels of employability. They may also need to advocate for relaxation of restrictions on financial and other assistance benefits for people who have been incarcerated.

For some inmates, reentry planning may entail assistance with family reintegration. Population health nurses may assist families to deal with concerns about bringing a released inmate back into the family constellation, particularly if the inmate was incarcerated for a crime involving family violence. There are also some instances in which inmates should not return to families if their presence may put family members at risk of harm.

Specific programs have been found to promote effective reentry and prevent recidivism. For example, reentry housing units help ease the transition to the community for juvenile offenders. They have also been found to forestall attempts by other inmates to prevent early release by involving soon-to-be released adolescents in fights or other infractions. Such programs, which involve moving to special housing units 4 to 6 weeks prior to release, allow adolescents to develop healthy relationships with adult staff, address anxiety about release, and engage in prerelease employment activities (Maynard & Alston, 2011). Similarly, a holistic aftercare program for women drug abusers has been successful in preventing relapse, with participants being significantly less likely to return to jail within a year after release (Matheson et al., 2011).

End-of-life care. End-of-life care for inmates with terminal illnesses may be similar to that on the outside. For example, population health nurses may need to discuss advance directives with inmates and help those who wish to execute advance directives. Nurses may also need to advocate adherence to advance

directives when they have been executed by an inmate. In addition to discussing advance directives with inmates, correctional health care personnel need to develop policies regarding the timing of advance directives, communicating information about advance directives when inmates are transferred to outside hospitals or hospice settings, and addressing effective pain control for seriously ill inmates.

Just as in the general population, referral for hospice care may be appropriate for terminally ill inmates. Some correctional facilities have in-house hospice units, and others may transfer inmates to community hospices when there is no security risk to the public. Whether in a hospice setting, in an infirmary, or in the general correctional population, terminally ill inmates are likely to need assistance in setting their affairs in order. For some inmates, there may also be a need to reconcile with family members. Population health nurses can be instrumental in facilitating these end-of-life activities. For example, they may advocate with family members for reconciliation or assist inmates to obtain legal assistance in settling any assets the inmates may have on their heirs. Symptom control and palliative care are also important aspects of end-of-life care in correctional settings.

There are also two unique aspects to end-of-life care that need to be addressed in correctional settings. The first is the concept of “compassionate release” or “medical parole.”

Compassionate release is the release of a seriously ill or disabled inmate back into the community to receive needed health care services from community agencies and, often, to permit time with family members. Compassionate release is most often used for terminally ill inmates; however, the Federal Bureau of Prisons also makes provisions for compassionate release for elderly inmates, death or incapacitation of a family caregiver of an inmate’s child, or incapacitation of a spouse or registered partner of an inmate. In all instances, inmates granted compassionate release should be judged as not posing a threat to the safety of the community (U.S. Department of Justice, 2013). Similar provisions may exist in state and local jurisdictions as well. As noted in Table 24-4, population health nursing advocacy may be required to initiate or support a compassionate release decision. In addition to advocating for compassionate release when appropriate, community health nurses will assist with arranging for follow-up care after release.

The second unique aspect of end-of-life care in correctional settings relates to inmates who have been sentenced to death. These inmates have the same needs for psychological end-of-life care as those with terminal illnesses, but their care is often complicated by feelings of hopelessness and attendant security measures (e.g., the use of handcuffs and shackles and constant supervision). Aspects of health restoration and end-of-life care in correctional settings are summarized in Table 24-4.

Focus	Related Activities
Long-term care planning	<ul style="list-style-type: none"> • Transfer to appropriate facility as needed • Provision of “home care” in general population • Use of assistive devices as needed • Continued monitoring of the status of chronic conditions • Monitoring treatment compliance • Monitoring for adverse effects of treatment • Provision of support in dealing with long-term consequences of chronic illness • Advocacy for effective long-term care service availability
Reentry	<ul style="list-style-type: none"> • Development of systematic discharge protocols • Development of individual discharge plans • Provision for continuity of health care • Arrangement for a supply of necessary medications on discharge • Arrangement for health insurance coverage • Provision for housing and financial assistance needs • Assistance with job training and employment as needed • Assistance with family reintegration as needed • Coordination of community health care and correctional activities • Advocacy for effective prerelease planning for all inmates • Advocacy for development of community infrastructure to support reentry • Advocacy for civil rights of released inmates
End-of-life care	<ul style="list-style-type: none"> • Development of advance directives as desired by inmates • Symptom control and palliative care • Advocacy for compassionate release and arrangement for follow-up care • Advocacy for adherence to advance directives by personnel • Provision of emotional and spiritual support to inmates and significant others • Referral to hospice care • Assistance with setting life in order • Assistance with family reconciliation as needed

Evaluating Health Care for Correctional Populations

The principles that guide the evaluation of health care in correctional settings are the same as those applied in other settings. The nurse evaluates the outcomes of care for individual

clients in light of identified goals. Correctional nurses may also be involved in evaluating health outcomes for groups of inmates or for the entire facility population, including staff. In addition, the nurse examines processes of care and makes recommendations for improvements in terms of quality, efficiency, and cost-effectiveness.

CHAPTER RECAP

Correctional facilities present a useful setting in which population health nurses can engage in health-promotive and illness-preventive activities with clients who may have little knowledge of these activities. Clients in correctional settings may be less motivated than those in other settings, but can realize

substantial health benefits through the efforts of population health nurses during incarceration and in promoting follow-up on release. Population health nursing efforts in correctional settings also help to prevent the flow of health problems back into the larger population, thereby benefiting society as a whole.

CASE STUDY

Nursing in the Correctional Setting

You are the correctional nurse responsible for sick call. So far today you have seen eight inmates with fever and severe upper respiratory symptoms; your diagnosis is influenza infection which has been prevalent in the surrounding community for the last several weeks. Several of the inmates seen describe other inmates housed in their cell block with similar symptoms. Further checking reveals that three guards from the affected cell blocks came to work earlier in the week with symptoms of influenza, but all three went home sick when their symptoms worsened.

The affected inmates are from two cell blocks that house 30 inmates each. The inmates from these two cell blocks share a communal dining facility not used by other cell blocks. Inmates at high risk for complications of influenza received influenza

vaccine, but other inmates in the facility did not due to a lack of available vaccine. One of the infected inmates was recently transferred from another facility and is severely immunocompromised due to HIV infection. He did not receive immunization at a prior facility despite his health status. The facility infirmary is staffed round the clock, but only has a capacity of four beds.

1. What are the biological, psychological, environmental, sociocultural, behavioral, and health system factors operating in this situation?
2. What actions would you take related to illness prevention, resolution of health problems, and health restoration in this situation? Why?

25 Care of Populations Affected by Disaster

Learning Outcomes

After reading this chapter, you should be able to:

1. Describe ways in which disaster events may vary.
2. Describe the elements of a disaster.
3. Describe two aspects of disaster-related assessment.
4. Identify biological, psychological, environmental, sociocultural, behavioral, and health system considerations to be assessed in relation to a disaster.
5. Describe two aspects of health promotion related to disasters.
6. Discuss foci in prevention related to disaster events.
7. Identify the component elements of an effective disaster response plan.
8. Analyze the role of community health nurses with respect to health promotion, prevention, response, and health restoration or recovery related to disaster situations.

Responding to the San Francisco Earthquake

Early on an April morning in 1906, San Francisco experienced an 8.25-magnitude earthquake that caused massive fires. More than 3,000 people died, and 28,000 buildings burned. Half of the city's population was homeless, and more than 225,000 people were injured. Because the Central Emergency Hospital had been destroyed, nurses hastened to tent hospitals, which were being established all over the city including in Golden Gate Park, Ft. Mason, and the grounds of the Presidio. At one point, one of the makeshift hospitals was threatened by uncontrolled fires and more than 350 patients were evacuated to safer locations. Later, one of those locations was threatened by fire, but the fire was diverted before it reached the site.

Physicians who had been attending the California Medical Convention in the city also volunteered their services. Personal accounts described volunteers raiding local pharmacies for needed supplies. Some of the health care volunteers worked 7 days and nights with little rest. Although later accounts by nurses indicated a relatively well-organized response, particularly in the light of the lack of advance planning, they also described the tendency of "charity workers" to "pauperize a self-respecting community" treating displaced citizens as if they were dependent paupers. Chinese survivors were also badly treated by outside volunteers and local citizens. Despite these blots on the record, the nurses engaged in heroic work. As one of them later noted, if "continuity of life is dependent upon adaptability to the environment, we possessed that qualification in a high degree" (Lucy Fisher, as quoted in Wall & Kelly, 2011, p. 51).

Promoting Disaster Preparedness

Disaster preparedness can save lives as well as minimize physical damage. Each year, the American Public Health Association (APHA) sponsors a "Get Ready Day" when local chapters engage in advocacy activities to promote emergency preparedness in their own communities. Preparedness initiatives range from development of personal/family readiness kits including the "big six" items identified by the American Red Cross (bottled water, nonperishable food, a battery-operated or hand-cranked radio, flashlights with extra batteries, medications and first aid supplies, and important documents) (Kukaswadia, 2013) to holding preparedness fairs in schools or other community sites to working with grocers to promote stockpiling of nonperishable foods among their customers. Less labor-intensive initiatives include sharing "Get Ready Day" information with others on your Facebook or Twitter page or with people at school or work (APHA, 2014). For information on planning "Get Ready" activities for your community, see the *External Resources* section of the student resources site.

Every day, a disaster occurs somewhere in the world (Baack & Alfred, 2013). In the last two decades, worldwide disasters cost \$629 billion (Bosher & Dainty, 2011), and from 2000 to 2012, disasters affected 2.9 billion people and caused 1.2 million deaths throughout the world. In 2012 alone, disaster damage costs were more \$138 billion (United Nations Office for Disaster Risk Reduction [UNODRR], 2013). In the United States, an average of 50 federally declared disasters occurred each year from 1980 to 2011 with a peak of 99 disasters in 1999 alone (Veenema & Woolsey, 2013).

Defining and Categorizing Disasters

A **disaster** is a destructive event that interferes with normal everyday function, the consequences of which cannot be effectively managed by the population experiencing it (Veenema & Woolsey, 2013). This definition highlights the difference between an emergency and a disaster. An **emergency** is a sudden event with serious adverse consequences that requires an immediate response but lies within the capabilities of those

affected. A house fire, for example, is an emergency. A disaster, on the other hand, cannot be addressed with usual procedures and requires assistance beyond the ordinary. The wildfire that destroyed more than 300 homes and caused 16 deaths in San Diego in 2003 is an example of a fire-related disaster.

The Center for Research on the Epidemiology of Disasters (CRED) maintains a database of disasters that occur throughout the world. Four criteria are used to define disasters for inclusion in the database. These criteria include: (a) more than 10 deaths, (b) more than 100 people affected, (c) declaration of a state of emergency, and (d) a call for international assistance (CRED, 2009b). Based on the final criteria, the majority of U.S. disasters would not meet the definition since the bulk of them are handled without assistance from abroad.

Disasters are classified into two broad categories: natural and man-made or human-generated. **Natural disasters** are destructive events arising from natural forces, such as severe weather patterns; epidemics of human, plant, or animal diseases; or insect infestations (Baack & Alfred, 2013). **Human-generated disasters**, on the other hand, are catastrophic events arising from human actions, either intentional or unintentional, that cause significant damage to people, the environment, or property (Baack & Alfred, 2013). Both categories can result in a **health care disaster**, which is an event that overwhelms health care resources (Veenema & Woolsey, 2013).

These general categories can be further classified into several subcategories. For example, human-generated disasters may be complex emergencies, technological disasters, or synergistic disasters. **Complex emergencies** are situations that cause numerous casualties and numerous other adverse events (e.g., starvation, displacement) and populations exposed to war, political conflict or civil unrest (Veenema & Woolsey, 2013). **Technological disasters** are events caused by major transportation accidents, industrial accidents, unplanned nuclear energy release, fires, explosions, or releases of hazardous substances that have direct or indirect adverse effects on large numbers of people (Veenema & Woolsey, 2013). **Synergistic disasters**, also called NA-TECH disasters, are a combination of natural and technological disasters.

The Centers for Disease Control and Prevention (CDC, 2014c) categorizes disasters as (a) natural disasters and severe weather, (b) bioterrorism, (c) chemical emergencies, (d) mass casualties, and (e) radiation emergencies. Natural disasters and severe weather are definitely not human-generated, whereas bioterrorism results from intentional human actions. Chemical and radiation emergencies and mass casualty events (e.g., the collapse of a building or an explosion) may be either intentionally caused or unintentional.

Natural disasters can be further broken down into geophysical, meteorological, hydrological, climatological, and biological disasters (CRED, 2009a). Geophysical disasters are those resulting from movements within the earth and include earthquakes and resultant tsunamis, volcanic eruptions, rock falls, avalanches, landslides, and subsidence. Meteorological disasters include severe winter weather, severe thunderstorms,

hurricanes, tornadoes, cyclones, severe sandstorms, and tropical storms. Hydrological disasters include floods and wet land mass movements, such as mud slides. Climatologic disasters include extreme temperatures due to heat or cold waves, drought, and wildfires. Finally, biological disasters result from epidemics of disease in people, plants, or animals (CDC, 2014d, CRED, 2009a). Epidemics that affect major segments of the world are called **pandemics**.

CDC distinguishes among a number of different types of chemical emergencies including biotoxins, blister agents, blood agents, caustics, choking/lung/pulmonary agents, incapacitating agents, long-acting anticoagulants, and metals. Additional chemical agents include nerve agents, organic solvents, riot control agents, toxic alcohols, and vomiting agents (CDC, 2014b). Table 25-1 • summarizes the various types of natural and chemical disasters.

War and civil conflict and terrorism are specific forms of human-generated disasters that occur with increasing frequency throughout the world. War and civil conflict are usually long-term events that have a singular capacity to destroy societal infrastructures leading to significant suffering among those affected (Burkle, 2013). War is defined as widespread conflict between groups of people, often motivated by religious or political differences or socioeconomic factors.

War and civil conflict result in a number of adverse effects for populations in addition to the numbers of people killed and injured. Some of these effects include destruction of a population's economic structure, food and water systems, electrical power sources, and transportation and communication systems. Other effects include famine, poor health, and violation of human rights. In large part, these effects are due to the diversion of resources from meeting population needs to supporting a war effort (Klare, Levy, & Sidel, 2011). A further significant effect lies in the displacement of large numbers of people. Displaced persons may include those who move from one area of

Some parts of the world experience frequent earthquakes that result in widespread devastation. (lapas77/Fotolia)

TABLE 25-1 Types and Examples of Natural Disasters and Chemical Emergencies

Types of Natural Disasters	Examples
Biological: Disasters caused by exposure of living organisms to pathogenic microorganisms	Epidemics of human, animal, or plant diseases
Climatological: Disasters resulting from extreme changes in climate	Heat wave, cold wave, drought, wildfire
Geophysical: Disaster events originating from solid earth movements	Earthquake, tsunami, volcanic eruption, rock fall, avalanche, landslide, subsidence
Hydrological: Disasters related to deviations in the normal water cycle or overflow of bodies of water	Floods, mudslides
Meteorological: Disasters due to severe weather conditions	Severe winter storms, blizzards, severe thunderstorms, sandstorms, hurricanes, tornados, cyclones, tropical storms

Types of Chemical Emergencies	Examples
Biotoxins	Digitalis, nicotine, ricin
Bliester agents/vesicants	Mustards, chlorasine
Blood agents	Arsine, carbon monoxide, cyanide
Caustics (acids)	Hydrofluoric acid, hydrogen chloride
Choking/lung/pulmonary agents	Ammonia, bromine, chlorine, phosphine
Incapacitating agents	Fentanyl and other opioids
Long-acting anticoagulants	Super warfarin
Metals	Arsenic, mercury, thallium
Nerve agents	Sarin
Organic solvents	Benzene
Riot control agents	Tear gas
Toxic alcohols	Ethylene glycol
Vomiting agents	Adamsite

Retrieved from <http://emergency.cdc.gov/disasters/>

a country to another to avoid the effects of civil unrest. These people are known as **internally displaced persons (IDPs)**. Refugees are another category of displaced persons. A **refugee** was defined by the 1951 United Nations Convention Relating to the Status of Refugees as a person who “owing to a well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group, or political opinion, is outside the country of his nationality and is unable to, or owing to such fear, is unwilling to avail himself of the protection of that country” (quoted in United Nations High Commissioner for Refugees [UNHCR], 2012, p. 4).

Other categories of displaced persons include asylum seekers and stateless people. Asylum seekers consider themselves refugees fleeing persecution, but their claim has not yet been accepted by the country in which they are seeking asylum. Stateless people are those who are not considered to be nationals of any country or who may be outside the protection of their country of residence (UNHCR, 2012). In 2012, 14 million refugees, 15.4 million IDPs, more than 850,000 asylum seekers, and 3.4 million stateless people were of concern to the UNHCR with respect to protection of human safety and rights. An additional 3.7 million people who had returned to their

homelands were also of concern. The plight of these displaced populations is more challenging than ever because of restricted access to countries of relocation following the September 11, 2001, bombing of the World Trade Center and the U.S. Pentagon (UNHCR, 2012).

War and civil conflict can have devastating consequences for those affected. For example, Iraq, which has experienced almost continuous periods of war from 1980 to the present has suffered worker shortages and skill-set imbalances, unreliable supply distribution, unstable leadership, and land degradation. Other effects have included destruction of much of the water supply system and industrial contamination of the Tigris and Euphrates rivers with consequent increases in waterborne diseases and toxic chemical exposures. Sanctions resulting from the Gulf war have led to decreased food importation and availability (Zolnikov, 2013). A March 2013 news report estimated that the war in Iraq resulted in an estimated 116,900 civilian fatalities as well the deaths of 4,487 U.S. and 197 British troops (Blair, 2013). Similarly, Somali refugees fleeing to Kenya experienced high mortality rates prior to departure (primarily due to malnutrition), during their journey to safety, and after arrival in Kenyan refugee camps (Spiegel et al.,

2011). In addition, repeated civil wars in Sudan have resulted in hundreds of deaths. Even after South Sudan declared its independence from Sudan, hundreds of thousands have fled the country or become internally displaced due to continued fighting (*South Sudan Profile*, 2014). Among Sudanese refugees in one camp, crowded living conditions and lack of sanitation resulted in more than 5,000 cases of hepatitis E with high case fatality rates, particularly among pregnant women (Thomson et al., 2012).

Terrorism is a growing concern and source of disasters throughout the world. Although there is no commonly accepted definition of terrorism, most definitions include the targeting of civilian populations and the intention of creating fear and social disruption. Some definitions also include a purpose of achieving change in policies or practices. The People's Health Movement, Medact, and Global Equity Gauge Alliance (2008) indicated a need for a comprehensive definition of terrorism that encompasses four elements:

- Actual or threatened violence, particularly targeted at civilians, to create fear
- Perpetration by state or non-state individuals or organizations
- Occurrence within or across national boundaries
- Perpetration during war, peace, and periods of internal or civil conflict

The following definition has been recommended: “politically motivated violence or the threat of violence particularly against civilians, with the intent to instil (sic) fear, whether conducted by nation-states, individuals, or sub-national groups” (People's Health Movement et al., 2008, p. 114).

Terrorism is defined in the U.S. Code of Federal Regulations as “the unlawful use of force and violence against persons or property to intimidate or coerce a government, the civilian population, or any segment thereof, in the furtherance of political or social objectives” (Federal Bureau of Investigation, 2005). **Bioterrorism** is “the intentional release of viruses, bacteria, or other germs that can sicken or kill people, livestock, or crops” (CDC, 2014a). Potential agents for bioterrorism are classified as category A, B, or C on the basis of the ease of spread of disease and the anticipated severity of effects. Category A includes organisms or toxins that pose the greatest risk to public health and national security based on their ease of transmission, high death rates and potential for major public health impact, ability to cause panic and social disruption, and requirements for specific public health preparedness activity. Examples of category A agents include anthrax, botulism, plague, smallpox, tularemia, viral hemorrhagic fevers (e.g., Ebola and Marburg viruses), and arenaviruses (CDC, n.d.).

Category B agents are moderately easily spread, result in moderate illness and low death rates, and may require specific enhancement of laboratory and disease surveillance and monitoring systems. Examples include brucellosis; food safety threats, such as *salmonella*, *E. coli*, and *shigella* species; psittacosis; Q fever; ricin toxin; staphylococcal enterotoxin B; typhus fever; viral encephalitis; and water safety threats, such

as cholera and cryptosporidium. Category C agents include emerging pathogens that could be engineered for mass dissemination in the future due to their easy availability, ease of production and transmission, and the potential for high morbidity and mortality and severe health impact. Examples might include nipah virus and hantavirus (CDC, n.d.).

Disaster Trends

Disasters seem to be occurring with greater frequency than ever before. In part, this may be due to more extensive news coverage of catastrophic events around the world. It is clear, however, that disasters are having more horrendous effects than in the past. For example, between 2000 and 2012, disasters affected 2.9 billion people, caused 1.2 million deaths, and resulted in \$1.7 trillion in damage (UNODRR, 2013). In 2012 alone, natural disasters resulted in \$1 trillion in damage in Asia, \$800 billion in the Americas, more than \$200 billion in Europe, and significantly less in Africa. Most damage in the Americas was due to storms, with earthquakes causing the most damage in Asia. The 2011 earthquake in Honshu, Japan, for example, was the most expensive disaster in terms of damages since 1975 followed by hurricane Katrina in 2005, the Wenchuan earthquake in China in 2008, and the 1995 Kobe earthquake in Japan (CRED, 2014a). Africa suffered minimal physical damage because the built environment is considerably less well developed than in other parts of the world.

Mortality due to disasters decreased significantly for biological disasters from 1900 to 2012, primarily due to the advent of antimicrobial therapies. Deaths from other types of natural disasters have generally declined in the same period, with periodic peaks. The exception is geophysical disasters for which mortality has increased due to increased population density in areas subject to such events. Conversely, the numbers of people affected by disasters from 1900 to 2012 has increased

Hydrological disasters may result in severe flooding and population displacement. (Fotonazario/Fotolia)

for all types of natural disasters except for biological disasters, with the greatest number affected by hydrological disasters, again because of increased population density in areas prone to flooding (CRED, 2014a).

With respect to technological disasters from 1900 to 2012, the number of disasters peaked at more than 350 events in 2000 and then again in 2006, with approximately 160 technological disasters occurring in 2012. The greatest extent of damages occurred in the Americas (\$25 billion), primarily due to fires, with the second-highest damages seen in Europe (\$13.5 billion), mostly related to flooding. Two major oil spills caused significant damage in 2010 and 2012. Transportation incidents comprised a significant portion of technological disasters and their frequency has been increasing over the last two decades. Overall deaths due to technological disasters, on the other hand, have declined from more than 12,000 in 2002 to about 6,000 in 2012. Unlike other parts of the world, however, deaths related to technological disasters show increasing trends in Africa and Asia, possibly due to lack of effective building

Wildfires can spread rapidly resulting in extensive property damage and loss of life. (Gemenacom/Fotolia)

codes and other regulatory measures. Similarly, the number of people affected by disasters has declined from a peak of more than 1 million in 1981 to somewhat over 3,000 in 2012 (CRED, 2014b).

In the United States, from 2003 to 2013, CDC's Emergency Operations Center (EOC) implemented a full Emergency Management Plan 55 times in response to disease outbreaks, natural disasters, national security events, and man-made disasters. Another 109 events required CDC support but did not necessitate full EOC activation (Leidel, Groseclose, Burney, Navin, & Wooster, 2013).

Worldwide, terrorist activities have declined somewhat in the last few years. U.S. Department of State statistics include 10,283 incidents of terrorism in 2011, down slightly from 14,415 in 2007. Declines in attacks resulting in at least one death, injury, or kidnapping have decreased even further dropping from 11,085 incidents in 2007 to 7,453 in 2011, and the number of attacks resulting in the death of 10 or more people declined from 353 to 193 in the same time period. Overall, the number of people killed as a result of terrorist activity has decreased by almost half from 22,720 to 12,533 (National Counterterrorism Center, 2012).

Although terrorist attacks occurred in more than 70 countries, approximately three fourths of them took place in the Near East and South Asia. Approximately two thirds (64%) of all attacks occurred in three countries, Afghanistan, Iraq, and Pakistan. Terrorist attacks increased by nearly 40% from 2010 to 2011, mostly related to the activities of the Revolutionary Armed Forces of Columbia. The majority of attacks (80%) in 2011 involved armed attacks and bombings, with suicide bombings accounting for 21% of terrorism-related deaths. Half of those deaths occurred among civilians (National Counterterrorism Center, 2012). Table 25-2 • provides information on some recent disaster events.

The increasing severity of disaster effects is due to a number of societal changes. Human populations are more densely concentrated and increasingly found in areas with high disaster potential (Landesman, 2011). Global climate changes are also altering weather patterns, creating more severe storms with resulting damage. In addition, technological advances increase the potential for human-generated disasters such as toxic leaks, transportation disasters, and massive electrical power outages. Finally, recent events have demonstrated the willingness of some radical groups to engineer massive disasters to achieve their political goals through terrorism.

Characteristics of Disasters

Disasters vary with respect to a number of characteristics, including their frequency, predictability, preventability, imminence, and duration. Disasters also vary in terms of the extent of their effects. Some disasters occur relatively frequently in certain parts of the world. Consequently, people in those areas have some knowledge of what to expect and what can be done to minimize the effects of the event. For example, earthquakes

TABLE 25-2 Recent Disaster Events

Date	Event/Locale	Category	Effects
January, 2010	Earthquake in Haiti	Natural: Geophysical	222,570 deaths 300,000 injuries
July–August, 2010	Flooding in Pakistan	Natural: Hydrological	18 million people affected, 1,700 deaths, 1.9 million homes damaged or destroyed, 10 million people without shelter
October, 2010	Cholera epidemic in Haiti and the Dominican Republic	Natural: Biological	121,518 cases, 63,711 hospitalizations, 2,491 deaths
April, 2011	351 tornadoes in Alabama, Arkansas, Georgia, Mississippi, and Tennessee	Natural: Meteorological	338 deaths
May, 2011	Tornado in Joplin, Missouri	Natural: Meteorological	159 deaths, 1,000 injuries, fatal fungal infections due to soft tissue injuries
October, 2012	Hurricane Sandy, eastern United States	Natural: Meteorological	117 deaths, 7 to 8 million people without power, 20,000 people in shelters
April, 2013	Boston marathon bombing	Terrorism	3 deaths, 260 injured

occur periodically in California, and residents in earthquake-prone areas are encouraged to be prepared in the event of a large quake. Similarly, hurricanes and other severe storms are frequently experienced during certain seasons in other parts of the country.

Some disaster events are predictable. In general, the probability of destructive tornadoes increases from April through June in the United States. Similarly, many rivers are known to flood periodically with heavy spring rains. Severe blizzards can also be predicted, allowing people to stockpile food supplies, medications, or fuel for heating in case they are isolated by the storm. Other events, such as a plane crash, a fire in a chemical plant, or a terrorist attack are not predictable.

Some types of disasters are more easily prevented than others. For example, periodic flooding can be prevented by rerouting waterways or by building dams. Others, such as earthquakes and severe winter storms, cannot be controlled or prevented. Increased security measures are one attempt to prevent disasters resulting from terrorist activities, but their effectiveness remains to be seen.

Disasters also vary with respect to their imminence in terms of their speed of onset and may have a period of forewarning before striking. Some disasters provide evidence of their imminent occurrence and allow time for preparation prior to impact. For example, blizzards, hurricanes, and other severe storms can be tracked and their probable path determined.

People along that path usually have sufficient warning to take preventive actions that minimize the potential for death and destruction. Other disasters such as fires and explosions occur instantaneously, with no prior warning. Catastrophic disasters tend to have a rapid onset, whereas pervasive disasters, such as drought or famine have a more gradual onset (Institute of Medicine, 2013). In some cases, the disaster event itself is of

Tornadoes are somewhat more predictable than other types of disasters allowing more time for preparation or evacuation.

(Michael Ballard/Fotolia)

short duration (Veenema & Woolsey, 2013), as in the case of an earthquake or a transportation disaster. At other times, the disaster event lasts some time. Examples of prolonged disasters are epidemics, famine, and war. Disasters such as hurricanes and blizzards have an intermediate duration.

Finally, disasters vary in terms of their impact and their destructive potential. Some disasters are fairly limited in scope, affecting a small geographic area or a relatively small number of people. For example, the effects of a mine cave-in are generally restricted to the area where the mine is located. The effects of war or famine, on the other hand, may be more far-reaching. For a particular organization, the extent of a disaster may be conceptualized as internal or external. External disasters do not affect the organization directly but tax its resources. For example, an explosion at an industrial plant probably does not affect a local hospital directly, but caring for the injured will tax the hospital's resources. Internal disasters, on the other hand, result in disruption of organizational function due to loss of personnel or damage to the facility (Veenema & Woolsey, 2013). The extent of disaster effects will be discussed in more detail later in this chapter.

The Disaster Role of the Public Health System

Disasters are events that have significant effects on the health of the public. It is not surprising, then, that the public health system should play a major role in planning for and responding to a wide variety of disaster occurrences. Disaster-related public health responsibilities include the following:

- Preventing and responding to epidemics and the spread of disease
- Protecting the public from environmental hazards
- Preventing injury
- Promoting healthy behavior and mental health
- Responding to actual disaster events and assisting in community recovery
- Ensuring access to quality health services in the event of a disaster (Reed, Veenema, & Rains, 2013)

These responsibilities might be executed in activities before, during, and after a disaster event. Before a disaster, members of the public health care system should be involved in identifying disaster risks and particularly vulnerable populations. They should then educate those populations regarding disaster prevention and preparedness. In addition, they should cooperate with other agencies to develop plans to prevent disasters when possible and to limit effects of disasters that cannot be prevented. They can also assist in the identification of resources available for disaster response. This may include the recruitment and training of volunteer health professionals to deal with the potential health effects of a disaster. Finally, public health professionals, including population health nurses, can advocate for and help develop public policies that reduce

the potential for and effects of disasters (Landesman, 2011). For example, they might advocate for building codes that create structures that will withstand major earthquakes, or brush removal ordinances in fire-prone areas.

During a disaster event, public health professionals will assess and communicate information regarding health-related effects to relevant government agencies. They will also coordinate the provision of needed emergency and routine health care immediately after the disaster. Other activities include advising and assisting in the prevention of injury and promotion of food and water safety, vector control, and control of communicable diseases. They may also be involved in inspecting shelter sites for health risks (Landesman, 2011).

Following a disaster, public health professionals would be involved in assuring that follow-up care is available to disaster victims with continuing needs. They would also participate in a collaborative evaluation of the disaster response and subsequent redrafting of response plans for future disasters (Landesman, 2011).

The public health system also has a similar role in responding to the health consequences of terrorist activities. Public health activities to prevent terrorism may include reducing access to biological agents. In addition, public health professionals should assure that a balance is maintained between terrorism preparedness and addressing other public health issues and between preventing terrorism and protecting individual civil rights. Both of these latter responsibilities may require concerted advocacy initiatives on the part of public health professionals, particularly population health nurses. Preparedness and prevention should not lead to inappropriate responses that infringe on civil rights or that draw resources from other important public health initiatives.

Elements of a Disaster Event

Disaster literature typically addresses three main elements of a disaster occurrence: the temporal element, the spatial element, and the role element. In this chapter, we will also address a fourth element, the effects element.

The Temporal Element: Stages of Disaster Response

Disaster experts characterize disasters as cyclic phenomena unfolding in five stages: (a) the nondisaster or interdisaster stage, (b) the predisaster stage, (c) the impact stage, (d) the emergency stage, and (e) the recovery stage. Other classifications of the stages of a disaster focus on the preimpact, impact, and postimpact stages (Veenema & Woolsey, 2013).

THE NONDISASTER STAGE. The nondisaster stage, also referred to as the interdisaster phase, is the period of time before the threat of a disaster materializes. This period should be a time of planning and preparation. During this stage, communities should engage in such activities as identifying potential disaster risks and mapping their locations in the community.

Vulnerability assessment and capability inventory are other features of this stage in which the community assesses the potential consequences of disasters likely to occur within the community and its ability to cope with these consequences. **Vulnerability analysis** involves predisaster determination of groups most likely to be adversely affected, property most likely to be damaged, and community capacity to deal with the effects of a disaster (CRED, 2009c; Veenema & Woolsey, 2013). Loss may be conceptualized in terms of death or injury, damage to or destruction of homes, or economic losses. Elderly persons, those with disabilities, and members of ethnic minority groups are examples of highly vulnerable populations. The extent and location of vulnerable populations should be determined and plans made for meeting their unique needs in the event of a disaster. Capability inventory involves determination of the adaptive capacity of the community through inventory of resources that are likely to be needed in the event of specific types of disasters and their availability in the community.

During the nondisaster stage, the community should also engage in prevention, preparedness, and mitigation activities. As we saw in Chapter 22, mitigation is action taken to prevent or reduce the harmful effects of a disaster on human health or property (Federal Emergency Management Agency [FEMA], 2013c). Mitigation may be either structural or nonstructural. Structural mitigation involves construction or alteration of the built environment to withstand the effects of disasters. Nonstructural mitigation is reflected in measures to protect critical supplies, systems, and functions (Davis, Hansen, Kushma, Peek, & Phillips, 2013). Retrofitting or reinforcing major highway overpasses is an example of hard mitigation being used in California to prevent the collapse of highways and bridges in the event of an earthquake. Examples of nonstructural mitigation include stockpiling vaccines in the event of an epidemic, and creating backup communication systems and early warning systems. Other examples related to mitigation include enforcing strict building codes for new construction and repair of existing structures; adapting zoning ordinances to minimize building in disaster-prone areas; relocating structures in danger areas; and building community shelters and safe rooms in schools, homes, and other locations (FEMA, 2013a).

Some of the major foci in mitigation activities include developing cost-effective strategies agreed upon by major stakeholders and the public for reducing risks, focusing resources on the greatest risks and vulnerabilities, and building partnerships and collaborations. Additional mitigation foci include increasing public risk awareness, communicating priorities to state and federal officials, and aligning risk reduction with other community goals (FEMA, 2013b).

The final area of activity in the nondisaster planning period is the education of both professionals and the public regarding disaster prevention and preparation. Unfortunately, many communities deny the need for disaster planning when they are not faced with the direct threat of a disaster. Even when disaster planning occurs, if the plan is not widely disseminated, disaster response can be impeded.

THE PREDISASTER STAGE. The predisaster stage occurs when a disaster event is imminent but has not yet occurred. This stage may also be referred to as the warning or threat stage. Major activities during this stage are warning, preimpact mobilization, and, in some cases, evacuation. Warning involves apprising members of the community of the imminence of a disaster event and of the actions that should be taken to minimize its consequences. For example, storm warnings are broadcast in many areas when there is potential for a severe storm, but people do not immediately go to a storm cellar or leave the area because the possibility remains that the storm will bypass the area.

The U.S. federal government has developed the Integrated Public Alert and Warning System (IPAWS) to “enable rapid dissemination of authenticated alert information over as many communication pathways as possible” (FEMA, 2012b, para 1). The system allows authenticated local, state, tribal, territorial, or federal authorities to create location-specific messages regarding emergency situations for specific populations at risk. The resulting messages are broadcast by existing communication systems including the Emergency Alert System through radio and television stations, National Oceanic and Atmospheric Administration Weather Radio, and other national weather service systems. In addition, the Commercial Mobile Alert System sends alerts to cell phones and other mobile devices in specified locales. Alerts may also be sent to giant voice sirens or digital road signs increasing the warning capacity of the system (FEMA, 2012b).

Just as communities may accept or deny the need for disaster planning, members of the community may respond positively or negatively to warnings of possible disasters. Several factors can influence a person’s response, including the source, content, and mechanism for warning, and individual perceptions and beliefs. Warning messages that are clear, practical, and relevant or that originate from credible sources are more likely to be acted on than vague or impractical warnings. Warnings need to specify the exact nature of the threat and provide specific recommendations for action. For example, vague warnings of the potential for additional terrorist activities following the September 11, 2001, attacks provided little direction for action. Specific guidelines on how to handle mail potentially contaminated with anthrax spores, on the other hand, were more effective in promoting action. Warnings should also contain sufficient information to allow people to decide on an appropriate course of action. It is sometimes erroneously believed that detailed information about a disaster will cause panic. In effect, failure to provide information usually leads to failure to act on warnings; providing information does not seem to contribute to panic among individual citizens.

Response to a warning is also affected by each individual’s perceptions about the possibility of disaster. These perceptions arise from past experiences with disaster, psychological traits, and sociocultural factors. For example, if people have previously been only on the fringes of a hurricane path, they may not perceive a hurricane as a very frightening event, and they

Because of the lack of imminence, tsunami warnings following distant earthquakes may be ignored. (Zacarias da Mata/Fotolia)

may ignore storm warnings. Similarly, if the individual has a fatalistic attitude that one's own actions will not make much difference in the outcome of an event, he or she might not act in response to warnings. Such an attitude may be the result of an individual personality trait or a sociocultural norm in the group.

Warning confirmation also influences the way people respond. Warnings tend to be believed if the source of the warning is official, if the probability of the event is increasing, and if one is in close geographic proximity to the area where the disaster is likely to occur. For example, people who live on a recognized geological fault line are more likely to take warnings about potential earthquakes seriously than those who do not live on a fault line.

Belief also influences action with respect to warnings. Again, belief in the potential for disaster is enhanced if the source of

the warning is an official agency and if that agency has credibility. For example, if there have been numerous false alarms in the past, people are less likely to pay attention to warnings. Belief is also enhanced if the medium of the warning is personal rather than impersonal. People are more likely to evacuate their homes if they receive a targeted telephone message than if they hear a warning on the radio. Previous experience also influences the likelihood of belief. If one has experienced the full force of a hurricane before, one is more likely to believe and act on a hurricane warning than would otherwise be the case.

The frequency with which the warning is received also influences belief, as do observable changes in the situation. For example, if people see evidence of flames on a nearby hill, they are more likely to believe in the imminence of danger posed by a wildfire. Perceived behavior of others can influence belief either positively or negatively. When others act in response to the warning, belief is enhanced. If others appear to be ignoring the warning, however, belief is less likely. Factors influencing responses to disaster warnings are summarized in Table 25-3.

Preimpact mobilization involves initiation of activities designed to avert an imminent disaster or minimize its effects. Activities involved in this stage might include efforts to prevent the disaster or its effects, seeking shelter from the effects of the disaster, evacuating people from areas threatened by the disaster, and implementing plans to deal with the effects of a disaster. For example, in the threat of a flood, people may sandbag riverbanks to divert floodwaters from a town, or board up windows and tie down equipment when a hurricane is forecast. People may seek shelter from tornadoes or other storms by moving to a basement, a storm cellar, or an interior room of a house. Preimpact mobilization might also involve evacuating people from an area threatened by fire, radiation, or chemical leakage. Finally, the initial phases of a disaster response plan may be implemented. For example, off-duty health care

TABLE 25-3 Factors Influencing Response to Disaster Warnings

Warning Feature	Influencing Factors
Warning message	<ul style="list-style-type: none"> • Clarity • Practicality • Relevance • Informativeness
Individual perceptions	<ul style="list-style-type: none"> • Past experience with disasters • Psychological traits • Sociocultural attitudes
Warning confirmation	<ul style="list-style-type: none"> • Official source • Increasing evidence and probability of disaster • Geographic proximity to the expected disaster location
Beliefs	<ul style="list-style-type: none"> • Credibility of warning sources • Personal rather than impersonal contact • Previous experience of disaster • Observable changes in the situation • Frequency of warning • Belief and action by others

personnel may be recalled to health facilities in preparation for treating anticipated casualties.

THE IMPACT STAGE. In the impact stage of a disaster, the disaster event has occurred and its immediate effects are experienced by the community. One major activity in this stage is the assessment of the impact of the disaster with an inventory of the immediate needs of the community. Inventory is a rapid assessment of the damage to buildings and the type and extent of injuries suffered. This information is used to determine actions needed in carrying out the efforts of the emergency stage.

THE EMERGENCY STAGE. The focus of the emergency stage of a disaster is on saving lives through rescue efforts, first aid, and emergency treatment (Landesman, 2011). The emergency response to a disaster usually begins with community members because there has not been time for assistance to arrive from outside sources. If the community is geographically isolated or access to the community is impeded by the disaster, this isolation period will be prolonged. Later, relief assistance is provided from sources outside of the area affected by the disaster. The activities performed are essentially the same, although performed by different agents in the two phases, and include search and rescue operations, first aid, emergency medical assistance, establishment or restoration of modes of communication and transportation, surveillance for public health effects of the disaster (e.g., infectious diseases, mental health problems), and, in some cases, evacuation of community members from affected areas.

THE RECOVERY STAGE. In the recovery stage, the focus is on returning the community to equilibrium. This stage can be divided into substages of restoration and actual reconstruction and ends in reconstitution. Mitigation may also occur in the recovery stage with efforts to prevent a recurrence of a disaster or to enhance preparedness and response capabilities.

Restoration is the reestablishment of a basic way of life following a disaster, usually occurring within the first 6 months. Activities of this stage include returning to homes or seeking alternative shelter, removing debris, and replacing lost or damaged property. At the community level, restoration involves reestablishing community services that may have been disrupted by the disaster (Landesman, 2011). After a flood, for example, people may return to their homes, clean up the mud, and replace water-damaged furniture. Schools reopen and residents return to work. If a prominent community official was killed in the flood, someone is appointed to fill that post until an election can be held.

Reconstruction involves the rebuilding and reordering of the physical and social environments following a disaster (Landesman, 2011). Homes, schools, businesses, and other structures may need to be rebuilt. Dams or levees may be constructed to prevent future flooding. Reconstruction may also entail alterations in the social environment. For example, terrorist activity has led to enhanced security provisions in airports, at international borders, and even in educational

institutions, which are now required to more closely account for the activities of foreign students.

Reunification is a special instance of reconstruction for refugee families who may have been separated during their travels in search of safety. Immigration restrictions in permanent host countries may result in lengthy separations of family members as portions of families migrate in sequence. Refugee literature has identified three stages of separation and reunification for families—before the separation, during separation, and afterwards—each of which creates an imbalance in family function and challenges families' abilities to function effectively.

Reconstitution is a state of affairs that occurs when the life of the community has returned, as far as possible, to normal after a disaster. This return to normal may take several months to several years, depending on the degree of damage sustained in the disaster. It may take several years after a flood, for example, to restore the landscape of the community to its former state or to replenish the city treasury after disaster costs have depleted it. It may also take some time for individuals to adjust to the loss of loved ones or for the community government to be reconstituted. In extreme disasters, full reconstitution may never occur. For example, many people believe that life in the United States was completely changed by the terrorist attacks on September 11, 2001, and the full effects of that disaster are not yet known.

The final stage of recovery after a disaster is mitigation, which involves future-oriented activities to prevent subsequent disasters or to minimize their effects. For example, a community that has experienced a flood may take engineering action to prevent the likelihood of subsequent floods, or a community that was unprepared for disaster may develop a disaster response plan. Increased security measures are another example of efforts aimed at preventing subsequent terrorist activities and their effects. These activities cycle the community back into the nondisaster stage. Stages and related activities in the development of and response to a disaster are summarized in Table 25-4.

The Spatial Element

The spatial elements of a disaster refer to the extent of its effects on specific geographic regions. These regions include the area of total impact, the area of partial impact, and outside areas (Figure 25-1).

The area of total impact is the zone where the most severe effects of the disaster are found. In an earthquake, for example, this would include the area where the greatest damage to buildings has occurred and where the greatest number of injuries was sustained.

In the area of partial impact, evidence of the disaster can be seen but the effects are not of the magnitude of those in the total impact area. Using the earthquake example, windows may be broken or objects shaken from shelves in the partial impact area, but buildings are intact. Injuries, if any, are infrequent and relatively minor, or only telephone and electrical services might be disrupted in the partial impact area.

**FIGURE 25-1** Areas of Disaster Impact

The outside area is not directly affected but may be a source of assistance in response to the disaster. Areas immediately adjacent to the disaster area are called on first to provide assistance, with further outlying areas being involved later as needed. In a major disaster, the federal government may be called on to provide assistance. This occurs once the area affected has been declared an official disaster area. Figure 25-2 depicts the process by which a presidential declaration of a major disaster or emergency is initiated and federal assistance is provided. As indicated in the figure, when a disaster occurs, local emergency personnel respond and assess the magnitude of the disaster. They inform local government officials of the extent of the problem and the need for outside assistance. Local officials request assistance from the state governor. The governor executes the state emergency plan. If it is determined that dealing with the disaster and its effects is beyond available state

and local resources, the governor may initiate a request for federal assistance through the regional FEMA office. In initiating such a request, the governor certifies that the magnitude of the disaster falls outside the ability of state resources and that federal assistance is needed. The governor must also certify adherence to cost sharing requirements for assistance. A preliminary damage assessment (PDA) is conducted by FEMA and state officials. Regional and national FEMA offices review the PDA and the governor's request and make a recommendation for a presidential emergency disaster declaration. Once the President of the United States has made the official declaration, elements of the federal response plan are implemented and federal disaster assistance is provided to the local jurisdiction (FEMA, 2012a, 2012c).

Spatial elements of a disaster vary greatly from event to event. For example, the total and partial impact areas affected

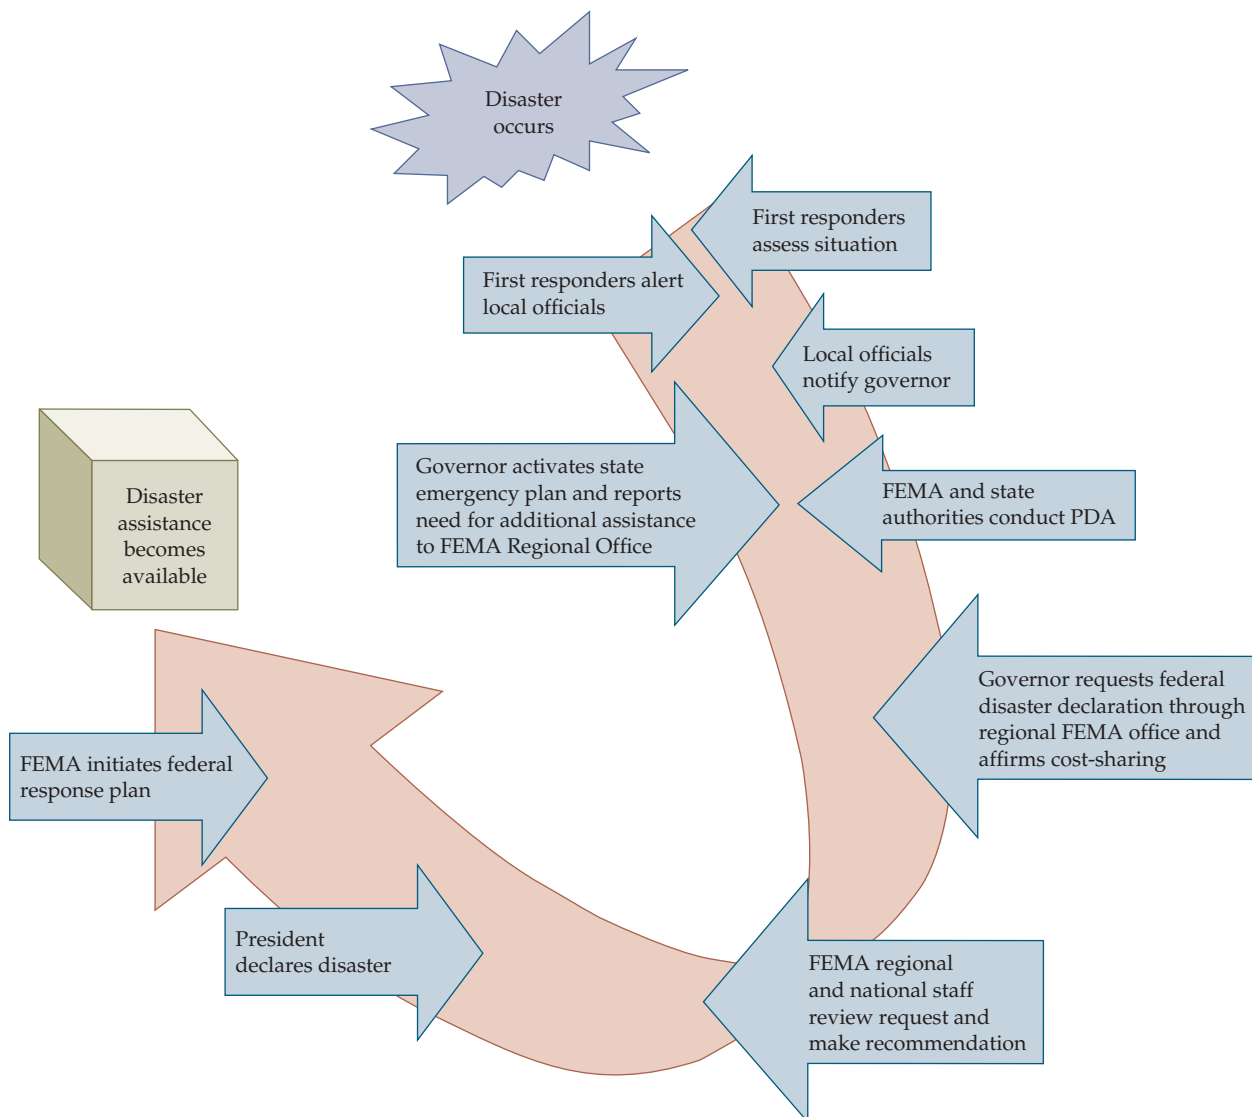

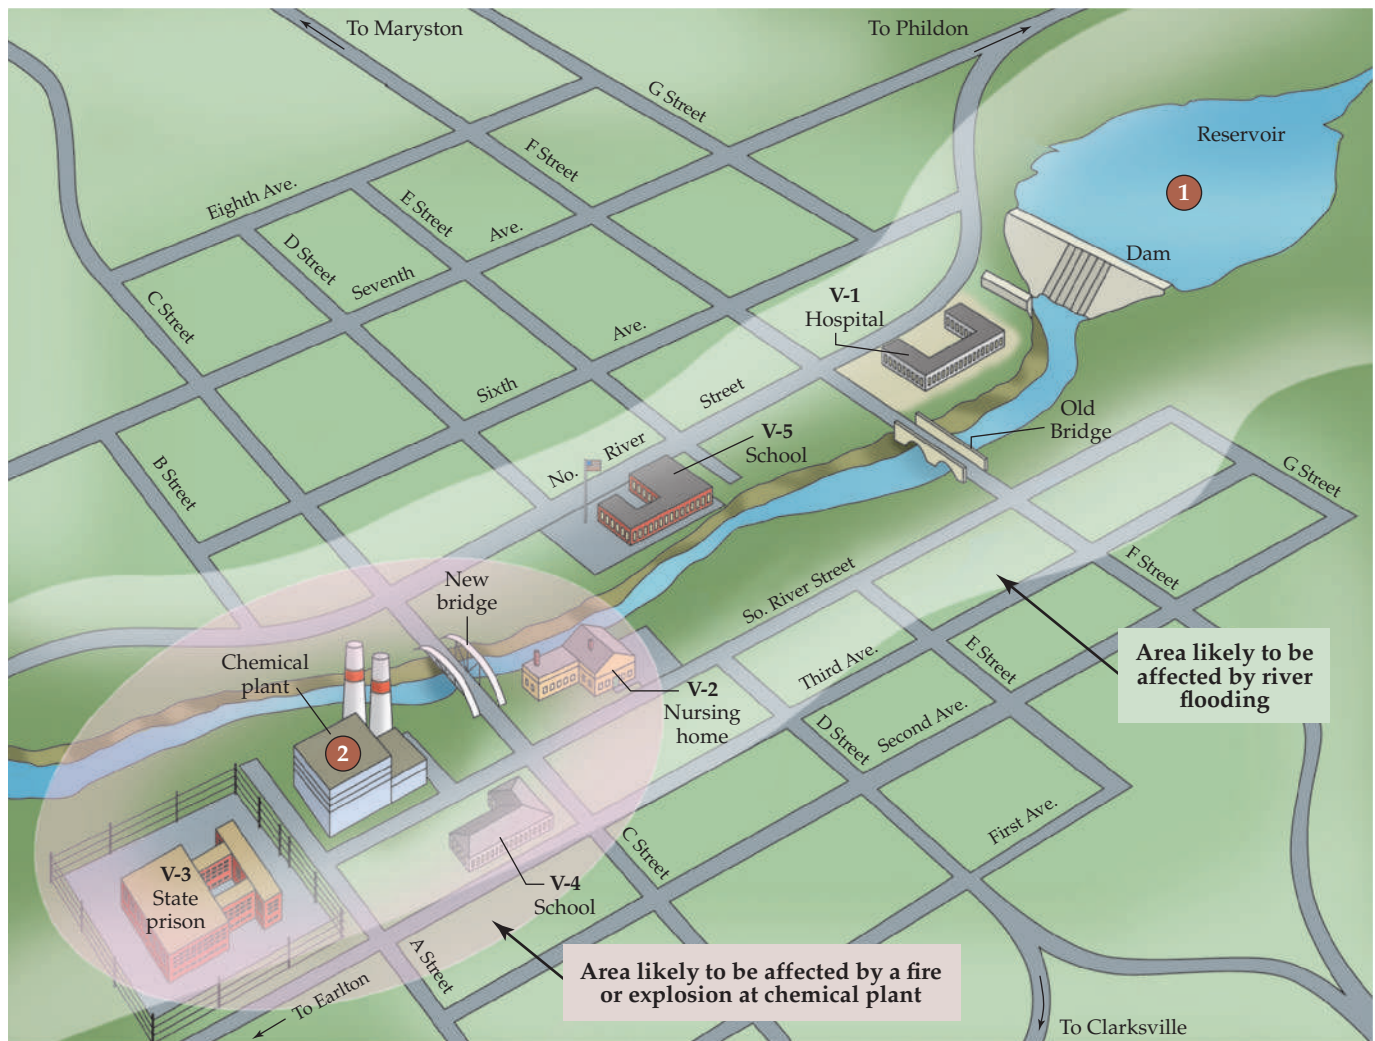

FIGURE 25-2 The Federal Process of Disaster Declaration

by a nuclear accident would be far larger than those affected by a fire at an industrial chemicals plant. The area from which assistance might be requested would also be larger given the greater magnitude of the problem, the number of victims involved, and the damage sustained.

Spatial elements of a potential disaster can also be explored prior to a disaster event. Creation of hazard maps to identify and locate potential disaster hazards in a country, state, or local area has been suggested. At the community level, community risk maps and community resource maps are used to help delineate spatial dimensions in disaster planning. **Community risk**

maps are geographic representations pinpointing the locations of disaster risks within a community. Risk maps also delineate probable areas of effect for different types of disasters. Figure 25-3 is an example of a community risk map. Two primary disaster risks are identified in the community risk map in the figure: a dam and reservoir that could result in flooding and a chemical manufacturing plant on the south side of the river. In addition, this community is in an area that experiences periodic tornadoes. The community risk map delineates the areas of the community likely to be affected by a flood (along the river) and a fire or explosion at the chemical plant. The area affected

Legend:

by a tornado would depend on where the tornado touched down. The map also indicates several pockets of particularly vulnerable populations in areas likely to be affected by disasters. These include residents of a nursing home, prison inmates, and schoolchildren in the vicinity of the chemical plant. These same groups, along with patients at the hospital at F and North River Streets and children in the school just north of the river, would be at risk in the event of a flood on the river.

Community resource maps are maps indicating the locations of resources likely to be needed in the event of each of the types of disasters for which a particular community is at risk. Notations on a community resource map include, for example, potential shelter locations, designated command

headquarters (and alternates if advisable), storage places for supplies, areas where heavy equipment is available, health care facilities, and proposed emergency morgue areas for the dead. Resource maps also indicate primary and alternate evacuation and transportation routes. Figure 25-4 is a sample resource map related to the community risks identified in Figure 25-3. Looking at Figure 25-4, we see that city hall is adjacent to the river and likely to be affected by a flood. Therefore, the command headquarters has been situated at the television station in the northern part of town. It was believed that placement at the station would facilitate communication because of the equipment available there. A southern command post has also been established in the event that both bridges are impassable and

 - Evacuation route

FIGURE 25-4 Sample Community Resource Map

response operations on the two sides of the river cannot be coordinated. Because of the potential for splitting the community and lack of access across the river, potential shelter sites have been established and supplies have been stored on both sides of the river. Health services are also available on both sides even if the hospital at F and North River Streets has to be evacuated due to flooding. Rescue operations for people stranded along the river would have to be handled from the north side of the river because that is where the boat docks are located. Personnel and supplies can be brought in from other towns in several different directions and could be brought directly to tent shelter sites if necessary. Only the road from Phildon is likely to be impassable if flooding reaches that far from the reservoir. Both the community risk and resource maps allow disaster planners to visualize what is likely to occur in a disaster event and to plan the most effective response to a disaster.

The Role Element

The third element of a disaster is its role element. Two basic roles for people involved in a disaster are *victim* and *helper roles*.

One of the ways in which the role aspect of a disaster influences disaster response lies in the actions taken by those affected. As we will see later, disaster planning needs to take into consideration the likely response of people to the occurrence of a disaster. Disaster planning can be completely ineffective if it fails to account for public response. People affected by a disaster are likely to take whatever actions seem best to them at the moment. When people are not educated regarding appropriate disaster response, those actions may not actually be in their own best interests or those of the community at large.

The second aspect of the role element of a disaster involves persons that play helper roles. Helpers include designated rescue and recovery personnel as well as community members who help provide care or who assist in the provision of necessities such as food, shelter, and clothing. Victim and helper roles may overlap, and rescue and recovery personnel or other community helpers may themselves have suffered injury or loss as a result of the disaster.

Both victims and helpers are under stress as a result of the disaster. Stressors for victims may be quite obvious and include injury and the loss of loved ones or property. Additional stressors for helpers during the rescue and recovery periods include encounters with multiple deaths that are frequently of a shocking nature, experiencing the suffering of others, and role stress. Frequently, the overwhelming nature of role demands or needs for assistance by victims leads to feelings of helplessness and depression. Other sources of role stress include communication difficulties, inadequacies in terms of resources or staff, lack of access to people needing assistance or resources to help them, bureaucratic difficulties, exhaustion, uncertainties regarding role or authority, and intragroup or intergroup conflicts. Stress may also arise from conflicts between the demands of the helper's family members and the needs of victims, and between the demands of one's regular job and one's disaster role.

The Effects Element

The final element of a disaster is the effects element. We have already discussed the geographic distribution of disaster effects in the spatial element of a disaster, but there are also various categories of effects that may result from disasters.

Many experts distinguish between direct or primary and indirect or secondary and tertiary effects of disasters (Nelson, 2013). Primary disaster effects are the immediate effects of the disaster event itself, such as the extent of death, injury, and destruction of property. Rapid-onset natural disasters, such as earthquakes, often have severe primary effects. Secondary disaster effects are those that occur indirectly as a result of the disaster. Examples include homelessness resulting from damage to residences or flooding due to the collapse of a dam as a result of an earthquake. Tertiary effects are long-term effects of the disaster, such as increased rates of post-traumatic stress disorder (PTSD), malnutrition due to disruption of food supplies, or the disruption of the local economy. Disaster effects may also be tangible or intangible. Tangible effects are usually those that can be measured in economic costs. Intangible effects are those that cannot be measured in terms of monetary losses, such as death and suffering.

Disasters also vary in terms of the severity of their effects. Some disasters cause moderate loss of life or property and result in only temporary inability to function, whereas others are devastating. The destructive potential of a nuclear explosion, for example, is far greater than that of a single plane crash.

Another way of categorizing the effects of disasters is into physical and mental health effects, economic effects, structural effects, and social effects. Physical health effects may arise as a direct result of the disaster itself (e.g., deaths or injuries) or as secondary effects (e.g., an epidemic of diarrheal disease among shelter residents). Mental health effects may be seen immediately after a disaster or surface days, weeks, or months later. Structural effects include homes, roads, and other structures destroyed by the disaster, and economic effects include the cost of rebuilding these structures as well as the economic costs of lost productivity, lost income, and care for disaster victims. Finally, social effects may occur that are either positive or negative. An example of a positive social effect might be an increased sense of community cohesion, whereas distrust and scapegoating of persons believed responsible for a disaster would be a negative effect. Change in the health care delivery system is another example of a social effect of a disaster. Each of these categories of disaster effects will be addressed in more detail in the discussion of disaster assessment later in this chapter.

Population Health Nursing and Disaster Care

As public health professionals, population health nurses have a significant role to play in both disaster preparedness and response. Effective disaster response by population health nurses

and other health professionals rests on development of certain competencies. The Columbia University School of Nursing has developed a set of competencies for health care professionals involved in disaster response. These competencies include an understanding of their role in a disaster; abilities to recognize possible disaster-related health effects, use effective infection control and decontamination practices, and accurately report cases of disease; expertise in referral; use of reliable information sources, abilities to communicate effectively with others and to educate the public on risks and appropriate actions; and abilities to assist others with stress management and dealing with psychological effects of a disaster (American Nurses Association, 2008).

In addition, the Association of Community Health Nurse Educators has identified competencies in disaster assessment, planning, intervention, and process and outcome evaluation as core components of population health nursing education (Kuntz, Frable, Qureshi, & Strong, 2008). For more information about the competencies, see the *External Resources* section of the student resources site.

Further responsibilities of population health nurses in disaster preparedness and response include assessing community needs and disaster risk, surveillance for adverse effects, communication to promote accurate dissemination of information, management of points of supply distribution or mass countermeasure centers (e.g., mass immunization campaigns for disease outbreaks), on-site triage, and education of families and community groups to foster disaster preparedness (Spencer & Spellman, 2013). Finally, the International Council of Nursing has identified several disaster-related roles for nurses in two categories: (a) prevention, mitigation, and preparedness and (b) relief response. Responsibilities related to prevention, mitigation, and preparedness include developing awareness of disaster potential and human behavior, lobbying for disaster preparedness at multiple levels, participating in disaster planning and implementation, development of chain of command policies, training nurses for disaster response, and networking with other health care professionals. Response-related responsibilities include mobilizing resources, helping with emergency care, advocating for and addressing the needs of vulnerable groups, assisting with recovery, and caring for responders (Speraw & Persell, 2013). Execution of these responsibilities occurs in the context of the nursing process.

Disaster-related Assessment

The assessment activities of population health nurses with respect to disaster care have two major aspects: the types of assessment conducted and specific assessment considerations.

TYPES OF ASSESSMENT. Assessment with respect to disaster preparation and response occurs in two stages: before and after a disaster occurs. Population health nursing involvement in predisaster assessment involves assessing the potential

for disaster and response capabilities within a specific community. Assessment during a disaster focuses on identification of disaster effects and related health needs.

Assessing disaster risk and capacity. Earlier we discussed the need to create community risk and resource maps. Because of familiarity with communities and their physical and social features, population health nurses are often in a prime position to identify potential disaster risks in a community. Not only are they aware of the types of industries in a community that may pose disaster hazards, but they may also recognize early signs of pending civil unrest among segments of the population that they serve. Identifying the potential for disaster in a particular community involves forecasting the types of disasters possible and the likelihood of their occurrence (Gebbie & Qureshi, 2013). The possible types of disasters, of course, vary from community to community. Disaster potential and the probable effects can be systematically assessed by examining factors related to each of the six categories of determinants of health. The determinants-of-health perspective can also be used to assess the effects of an actual disaster. Both of these aspects of disaster assessment are discussed in the section on assessment considerations.

Assessment of response capability is another aspect of predisaster assessment. This is closely tied to an assessment of the degree of disaster preparedness in the community and community attitudes to disaster planning. The population health nurse should assess the attitudes of community members toward disaster preparedness. Some of the questions to be addressed might include the following:

- To what extent are individuals and families in the area prepared for potential disasters?
- Have families in an earthquake-prone region, for example, gathered supplies that will be needed in the event of an earthquake and placed them in an accessible location?
- Have emergency escape routes from homes, schools, and other buildings been identified?
- Have families discussed an emergency contact person who can relay messages for and about family members separated in a disaster?
- Or are these types of preparation largely ignored?

Population health nurses also have knowledge of resources that might be brought to bear in a disaster situation. For example, they may be aware of community residents who should be involved in disaster response planning, or they may have a better grasp of potential public response to proposed disaster response initiatives than others involved in disaster planning. Again, specific categories of response capability are addressed in the discussion of the determinants of health later in this chapter.

Postdisaster assessment. Postdisaster assessment includes both rapid assessment and surveillance. Following the occurrence of an actual disaster event, population health nurses

will be actively involved in rapid assessment of disaster effects. Rapid assessment involves determination of the extent of damage caused by the disaster as well as the number of deaths, injuries, and/or illnesses resulting from the disaster. Population health nurses may be involved in identifying and reporting the extent of health-related disaster effects.

Surveillance is intended to provide early warning of severe consequences of a disaster. Most disaster plans make provision for early warning systems based on surveillance data. Disease early warning systems (DEWS), for instance, are intended to foster early identification of and response to epidemic-prone diseases. As an example, DEWS in Afghanistan were intended to provide early warning of disease outbreaks. Due to reporting problems, however, only 130 outbreaks were reported after flooding in 2010. Following improvements in the system, more than 5,000 outbreaks were captured by the system after similar flooding in 2011 (Sabatinelli et al., 2012).

The World Health Organization (WHO) has developed guidelines for what it terms Early Warning and Response Network or EWARN systems (early warning systems for epidemic diseases). These include focusing data collection on information that would trigger a major response rather than normal surveillance data, monitoring suspicious symptom syndromes (e.g., fever and diarrhea) rather than confirmed disease diagnoses, which may take time, providing for immediate alerts as well as weekly reporting, and focusing on clusters of deaths rather than overall mortality. Additional recommendations include collecting data from all available sources using standardized reporting forms, aggregation and analysis of data at local levels to promote immediate action, inclusion of threshold indicators for action, and inclusion of information on outbreak preparedness and response (WHO, 2011). Population health nurses will be actively involved in recognition of symptom clusters and may have major responsibility for the collection and reporting of surveillance data.

ASSESSMENT CONSIDERATIONS. Both risk and capacity assessment and assessment of the health-related effects of an actual disaster can be framed in terms of the determinants of health as they influence a disaster situation.

Biological determinants. One determinant in forecasting potential disasters is that of human biology. Certain groups of people are more likely than others to be affected by a disaster. For example, if the anticipated disaster is an epidemic of influenza, those most likely to be severely affected are the very young and the elderly; however, there also will be illness among the health care workforce that may impede efforts to halt the spread of disease. On the other hand, if there is potential for an explosion in a local chemical plant, those affected are likely to be company employees and persons in surrounding buildings. Again, this might include children if there is a school nearby. In disasters requiring evacuation, the elderly and disabled are at particular risk because of potential mobility limitations (Davis

et al., 2013). The elderly and disabled are also the most likely groups to have necessary health care services disrupted and quality of life diminished by a disaster.

Human biology is also a factor in predicting the types of effects expected as a result of the disaster. In the case of an influenza epidemic, illness potentially accompanied by dehydration and electrolyte imbalance may be expected. In an earthquake, many deaths result from injuries due to falling debris. After the earthquake in Haiti, for example, 42% of hospitalizations were due to injuries including fractures, dislocations, wound infections, and head, face, and neck injuries, and 28% were earthquake-related (Hotz et al., 2011). In the classic 1906 San Francisco earthquake, on the other hand, the majority of damage was caused by the ensuing fires and rupture of city water mains. Similarly, soft tissue injuries incurred during tornados in Joplin, Missouri resulted in 13 cases of a rare fungal infection causing five deaths (Benedict et al., 2011). Floods result primarily in drownings, but the floodwaters in New Orleans after hurricane Katrina also led to clusters of diarrheal disease, wound infections, and skin infestations from working in contaminated water. Terrorist dissemination of anthrax spores, on the other hand, may result in cutaneous, inhalation, or intestinal forms of disease with related symptoms and complications (CDC, 2014a). War and other civil unrest can contribute to a variety of biological effects. For example, large numbers of Bhutanese refugees admitted to the United States suffer from hematologic and neurological disorders stemming from vitamin B12 deficiencies after two decades of poor nutrition (Walker et al., 2011).

The overall health status of the community also influences disaster planning requirements. For example, if hypertension is prevalent in the community, provisions need to be made in a disaster plan for ongoing treatment of hypertension or other prevalent diseases, particularly communicable diseases such as tuberculosis (TB) and HIV infection. For example, nearly 1,900 people in the areas most affected by hurricane Sandy were being treated for TB at the time of the disaster and special initiatives were needed to maintain treatment continuity (Burzynski et al., 2013).

It has been suggested that people with disabilities and other complex chronic conditions establish “go packs” that can be ready in case of the need for evacuation. Go packs should contain essential medication for at least 7 days, easily accessible assistive devices (e.g., canes), food and water for guide animals, and emergency health information. People with chronic conditions should also know where to evacuate so their own particular needs can be met (Landesman, 2011).

In the event of a disaster, the population health nurse assesses the physiologic effects of the event on human biology. The most catastrophic effect of disasters is, of course, death. Disaster-related deaths may be of three types: direct deaths, indirect deaths, and disaster-related natural deaths. Direct deaths are those caused by the disaster itself. For example, fires directly cause death through burns and smoke inhalation. Indirect deaths are due to circumstances caused by the disaster.

For example, starvation is indirectly attributable to drought and famine. Disaster-related natural deaths are the result of existing conditions that are exacerbated by the disaster. For example, a death due to myocardial infarction during a hurricane would most likely be a disaster-related naturally caused death. The terrorist attacks of September 11, 2001, actually led to development of a new category of mortality and morbidity in both the WHO *International Classification of Diseases, Tenth Revision* (ICD-10) and clinical modification to classify deaths and injuries related to terrorist activities in the U.S. ICD-10 (Centers for Medicare and Medicaid Services [CMS], 2010).

The nurse appraises the extent of injuries incurred by victims and relief workers and may also assess other needs for health care. For example, the nurse might need to assess the health status of a disaster relief worker with diabetes or of a child with a fever. The nurse assists in assessing the health status of groups of people including both victims and rescue workers. Other people not immediately affected by the disaster may also develop disaster-related illnesses. For example, worsening asthma is frequently noted by many people following wildfires and volcanic eruptions. Possible biological effects of several types of disasters are presented in Table 25-5.

Psychological determinants. Psychological determinants can profoundly influence the effects of a disaster on health.

Many people who experience disasters, either as victims or helpers or both, will experience some level of psychological distress as a result. An estimated 54% to 60% of those affected will develop immediate psychiatric symptoms. The proportion of those affected drops to about 41% within 10 weeks or so, but approximately 22% will have continuing psychological problems after a year. Depression is the most common long-term result, affecting about 41% of people, PTSD may be experienced by 22% to 59% of people, generalized anxiety disorder by 10%, and substance abuse disorder by 14% to 22% (Plum & Meeker, 2013).

Suicide is another relative common psychological effect. For example, the suicide rate among Bhutanese refugees settled in the United States (21.5 per 100,000 people) is far higher than the rate for the general U.S. population (12.4/100,000) or the international rate of 16 per 100,000. In addition, nearly one third of the refugees knew someone who had committed suicide. Other psychological problems noted in this group were anxiety, depression, and PTSD. Contributing factors included lack of nationality, sudden flight, lack of freedom of movement, language difficulties, and concerns about family members left

TABLE 25-5 Potential Biological Effects of Selected Disasters

Type of Disaster	Potential Biological Effects
All disasters	Greater loss of life and injury among the elderly, young children, and chronically ill and disabled persons
Avalanches	Asphyxiation; frostbite and other exposures to cold; fractures or other forms of trauma
Bioterrorism	Widespread communicable disease, death, and disability
Chemical spills or chemical terrorism	Chemical burns of the skin, respiratory irritation and illness; poisoning with a variety of symptoms depending on the chemical involved; eye irritation
Earthquakes	Crushing injuries and fractures from falling bricks, masonry, and other objects; may also cause crushing syndrome Burns suffered in fires and explosions due to ruptured natural gas mains Waterborne diseases because of ruptured water mains and lack of safe drinking water Electrocutions from fallen power lines
Epidemics	Communicable diseases with a variety of symptoms depending on the diseases involved
Explosions	Burns due to associated fires; fractures or crushing injuries due to explosion impact or falling bricks, masonry, and other debris
Famine	Developmental delay in young children; failure to thrive in nursing infants due to inadequate lactation by mothers; protein-energy malnutrition and other nutritional deficiencies
Fire	Minor to severe burns; secondary infections; respiratory problems due to inhalation of smoke and hazardous fumes from burning objects
Floods	Waterborne and insect-borne diseases from contaminated water supplies and insect breeding grounds; drownings
Nuclear attacks or radiation leakage	Radiation burns or radiation sickness; later cancer; later infertility, spontaneous abortion, or fetal defects
Storms	Crushing injuries due to windblown objects and debris; minor to severe lacerations due to flying glass from broken windows
Transportation disasters	Crushing injuries and other trauma; burns from associated vehicle fires; drowning or asphyxiation if disaster occurs over water or in a tunnel; exposure to the elements if disaster occurs in a remote area
Volcanic eruptions	Toxic gas or radiation exposure; respiratory or eye irritations

in Bhutan. In addition, 36% reported experiencing four to seven presettlement trauma events (Cochran et al., 2013).

A number of factors have been identified that influence the psychological response of individuals to disaster. These include traumatic bereavement or loss of loved ones, being injured or hospitalized as a result of the disaster, loss of one's home or employment, and disruption of one's life. People with existing mental illness and disaster workers who handle severely injured victims or the dead are also at greater risk for long-term psychological effects of disasters. Psychological effects may manifest as emotional, behavioral, cognitive, or somatic symptoms of psychological distress (Plum & Meeker, 2013).

Similar factors influence the prevalence of psychological distress in communities recovering from a disaster. These factors include a high incidence of deaths and traumatic injuries, severe widespread property damage in the area affected, and ongoing economic problems in the community. Generally speaking, communities and individuals with good coping skills usually respond more effectively in a disaster situation than those who have poor coping skills.

As noted earlier, both victims and relief workers may experience stress related to a disaster, and the nurse should be alert to signs of emotional distress in both groups.

Types of immediate psychological responses to disasters range along a continuum from calm, collected action to confusion and hysteria. Plans should be made for services to address each level of response. Health care providers should also keep in mind that psychological responses may change with time and with the progression of the disaster event. Psychological recovery occurs for most people within 6 to 12 months of the disaster, but a small segment of the population may exhibit ongoing problems and require therapy.

Population health nurses working in disaster situations can assess the extent and severity of psychological reaction in individual clients (victims, rescue personnel, and others) and population groups. They can use this information to make appropriate referrals for individual assistance and to help in the development of services to address identified mental health needs in the population.

Environmental determinants. Many disasters arise out of features of the physical environment. For example, the presence of a river near the community and the likelihood of heavy rainfall both contribute to the potential for flooding, as does the construction of homes and businesses on floodplains. In fact, the number of people in the United States at risk for flooding is expected to double from 1 to 2 million before 2050 (Bosher & Dainty, 2011). A geological fault, a nuclear reactor, and a chemical plant are other examples of factors in the physical environment that may increase the potential for a disaster. Similarly, the potential effects of climate change may give rise to increased frequency, duration, and intensity of tropical storms as well as emergence and reemergence of tropical diseases (Yumul, Cruz, Servando, & Dimalanta, 2011).

Elements of the physical environment can either help or hinder efforts to control the effects of a disaster. For example, limited traffic access to the part of town where an explosives plant is located could hinder movement of emergency vehicles in the event of a fire or explosion. Similarly, the physical isolation of a mountain community may impede rescue efforts in the event of a forest fire or flood. On the other hand, such isolation might spare the community from the effects of an epidemic in the surrounding area.

In conducting a community assessment, the population health nurse identifies physical environmental factors that might contribute to the occurrence of a disaster. The nurse also determines whether the community is prepared for potential disasters. When the community is not prepared, the nurse would advocate the planning activities described later in this chapter.

The nurse also identifies factors that might impede the community's response in the event of a disaster. The nurse can then share these observations with others involved in disaster planning, and interventions to modify or circumvent these factors can be incorporated into the community's disaster response plan.

Disasters may also contribute to a wide variety of environmental health hazards. For example, hurricane Katrina gave rise to many wound infections with methicillin-resistant *Staphylococcus aureus* and other pathogens due to exposure to floodwaters. Flooding may also contaminate drinking water supplies, whereas fires and explosions result in exposure to smoke and other air pollutants. Mosquito infestations are another potential result of extensive flooding. Population health nurses can be actively involved in educating the public to prevent health effects of environmental hazards arising from disasters.

Crowding and congregate living in shelters, as well as lack of access to adequate sanitary facilities and facilities for bathing, washing clothes and bedding, and washing dishes, may also contribute to health problems for disaster survivors. Population health nurses can identify poor shelter conditions and assist in planning to improve environmental conditions in shelters and refugee camps.

Finally, community responses to disaster conditions may give rise to environmental conditions that imperil health. For example, hurricane Sandy, for instance, resulted in 263 reports of carbon monoxide poisoning mostly due to improper placement of generators and indoor use of charcoal grills after power failures (Clower et al., 2012). Population health nurses can advocate for safe use of such equipment and help educate residents on the hazards of portable generators and their safe use based on the client education tips provided on the next page.

Environmental factors may also promote effective response and disaster recovery. For example, public parks may serve as settings for congregate shelters. In addition, they may foster physical activity and stress reduction among affected populations as well as serving as a social outlet (Rung, Broyles, Mowen, Gustat, & Sothorn, 2011).

CLIENT EDUCATION

Preventing Carbon Monoxide (CO) Poisoning

- Do not use portable generators or other gasoline-powered tools indoors.
- Place gasoline-powered equipment away from doors, windows, and air intakes.
- Do not use gasoline-powered equipment in enclosed spaces (e.g., garage, basement, carport).
- Do not heat homes with gas oven or charcoal.
- Properly vent space heaters and use in well-ventilated spaces.
- Install carbon monoxide detectors in home.
- Open windows and fans are not enough to prevent CO buildup.
- Leave the area and seek medical help if CO alarm sounds or if symptoms of CO poisoning are noted (headache, fatigue, dizziness, nausea, vomiting, loss of consciousness).

Data from: Clower, J., Henretig, R., Trella, J., Hoffman, R., Wheeler, K., Maxted, A., . . . Schier, J. G. (2012). Carbon monoxide exposures reported to poison control centers and related to hurricane Sandy—Northeastern United States, 2012. *Morbidity and Mortality Weekly Report*, 61, 905.

Sociocultural determinants. In assessing disaster potential, the population health nurse identifies social factors that might influence the way people respond to a disaster or even give rise to one. For example, the presence of racial tensions could trigger outbreaks of violence in some communities. War is another disaster arising out of social environmental conditions.

Terrorism, like war, arises out of sociocultural factors. Terrorist activity is fueled by perceptions of the United States as being arrogant, decadent, and indifferent to the plight of others. Similarly, terrorism is often a strategy used by those who lack political or military power to address what they perceive as social wrongs. Poverty is another sociocultural factor that motivates terrorist activity, particularly in the face of affluence in other segments of society. Environmental justice issues, such as loss of biodiversity or perceived highjacking of natural resources without consideration for others who depend on them for their livelihood, also fuel terrorist initiatives. Many politically motivated terrorists are generally motivated by a single issue, which if effectively addressed may defuse terrorist activity.

Terrorism also has roots in religious beliefs and may surface in conflicts between religious groups at the national or international level. Concepts of national honor and shame may also motivate terrorist activity—for example, in response to perceptions that adoption of Western values is corrupting women or youth. Ethnic/nationalist conflicts may have a religious

component to them, but there is often a long history of intolerance of social and cultural differences outside of religious beliefs.

Sociocultural factors may also contribute to the ability of terrorists to achieve their goals. Media attention to terrorist attacks, for example, provides perpetrators with the public attention to their position that they need. Some authors have described terrorism as a Western phenomenon dependent on a free press. Media coverage can be controlled in countries without a free press, thereby denying terrorists the showcase for their political ideology that is one of the major intents of terrorism. The same may be true of media coverage of other disasters designed to promote giving or to highlight specific political perspectives. For example, media coverage of hurricane Katrina tended to portray minority victims as passive individuals with little expertise, overreported crime, and underreported acts of kindness and heroism. It has also been suggested that media treatment of the disaster may have delayed outside responses due to fear for personal safety of volunteers (People's Health Movement et al., 2008). Treating disaster victims as individuals with dignity rather than as hopeless objects is one of the tenets of the *Code of Conduct* for the International Federation of Red Cross and Red Crescent Societies (n.d.).

Other aspects of society may lend themselves to terrorism. For example, dependence on mass-produced foods makes the United States more vulnerable to agroterrorism. Widespread destruction of food crops or animals would have significant effects on the health of the population as well as on national economics. Similarly, disruptions in electrical power or telecommunications could bring much of everyday life to a halt. Access to the Internet and other technological advances also make information on weapons that can be used for terrorist activity readily available to the general public. For example, from 2003 to 2011, 134 reports of homemade chemical bombs were received in the United States, more than four times the number reported between 1996 and 2003 (Strain et al., 2013).

Elements of the sociocultural dimension also may increase or limit the effects of a disaster on a community. For example, the economic status of community members and of the community at large may limit the ability of people to prepare for potential disasters or to recover after a disaster event. Language barriers may hamper evacuation or rescue efforts. Strong social networks in the community that can be tied into disaster planning aid in effective disaster response; intragroup friction hampers response effectiveness. The nurse identifies social and cultural factors present within the community that may decrease the effectiveness of the community's response to a disaster and participates in planning efforts to modify these factors.

Community resilience is an important factor that assists communities to recover from disasters. **Community resilience** is the ability of a community to recover from an adverse event or situation (Chandra et al., 2011). Components of community resilience include social and economic well-being;

the physical and psychological health of the population; effective risk communication; integration and involvement of government and nongovernmental organizations in planning, response and recovery; social connectedness; community engagement; and development of community self-sufficiency (Chandra et al., 2013). Community resilience includes preparedness at the individual-citizen level as well as a supportive social context (Plough et al., 2013). Population health nurses can assist communities to develop the components of resilience.

Community engagement is a related sociocultural determinant that influences community disaster preparation. There is a need for community engagement in disaster planning and preparedness. Unfortunately, although most people recognize the need for preparation, few actually are prepared for a disaster. In one study, for example, less than 31% of people responded that they were prepared for disasters, 26% indicated that they did not have time to engage in preparation, and 22% reported that they did not know what to do to be prepared (Miller, Adame, & Moore, 2013). Behavioral Risk Factor Surveillance System (BRFSS) data for 14 states from 2006 to 2010 also indicated differing levels of household preparedness. For example, although 94% of households had working battery-operated flashlights and 90% of people had at least a 3-day supply of necessary medications, only 83% had stored a 3-day food supply, 78% had a working-battery-operated radio, and 54% had a 3-day supply of water for family members. In addition, only 21% had developed a written evacuation plan (DeBastiani & Strine, 2012).

This lack of engagement in disaster preparedness extends beyond the individual or family household level. In a study by the Trust for America's Health (2012), most states were not adequately prepared for disaster events, epidemics, or bioterrorism. For example, only two states had met the target for 90% immunization rates of children. Similarly, 35 states and the District of Columbia did not have plans to address extreme weather events, and 20 states did not mandate all-hazard response evacuation plans for child care facilities. In addition, 29 states had cut public health funding that supports disaster preparedness, 16 of them for the second year in a row, and 13 state public health laboratories did not have the capacity to address infectious disease outbreaks. The study scored states for their level of preparedness on a scale of 1 to 10; no state received a score greater than 8, and only 6 states received a score that high. Two states received scores of 2 (Trust for America's Health, 2012).

Based on study findings, the organization recommended reauthorization of the Pandemic and All-hazards Preparedness Act and assurance of sufficient funds for public health preparedness. Other recommendations included providing ongoing support for community-level preparedness; modernization of biosurveillance systems; efforts to address continually developing antimicrobial resistance; increased readiness for extreme weather conditions; updating the nation's food safety system; and facilitating research, development, and manufacture of

medical countermeasures for disease (Trust for America's Health, 2012).

The Institute of Medicine (2013) has recommended actively involving community members in disaster planning. Five tenets for community engagement were put forth in the Institute's report, "Engaging the Public in Critical Disaster Planning and Decision Making." These included (a) acknowledging that engagement may be sought for a variety of reasons (e.g., fostering public awareness of the need for preparedness, incorporation of community values and priorities, and promoting adherence to plan elements), (b) recognizing that engagement requires resources that promote community input, (c) the need for inclusion of widespread participation in planning, (d) the need for meaningful support of opportunities for input, and (e) the need for transparency regarding how community input will be used in disaster planning. An earlier IOM publication, "Crisis Standards of Care" (Hanfling, Altevogt, Viswanathan, & Gastin, 2012), identified essential principles of public engagement. These principles include the following:

- Policy makers are committed to considering public input.
- Participants represent community diversity.
- Participants receive information and meaningful opportunities to engage in discussion.
- Deliberation is a goal in and of itself.
- Public input is considered in decision making processes.
- Top-down support and sufficient resources are available to promote meaningful input. (Hanfling et al., 2012)

Economic capacity is another sociocultural factor that influences community response to a disaster. Economic capacity includes local resources as well as the availability of outside assistance. Obviously, a more affluent community would be able to better withstand the effects of a major disaster than a poverty-stricken one. However, the nurse would need to assess the extent to which the economic foundation of the community is affected by the disaster. For example, if a disaster event damages a large portion of local industry, jobs are lost, tax revenues decrease, and even affluent communities may have diminished recovery capabilities. Even more simple economic effects may be felt by a community following a disaster. For example, access to supermarkets declined by 42% in New Orleans following hurricane Katrina and still had not returned to predisaster levels by 2009, making access to healthy foods difficult in the areas most affected (Rose, Bodor, Rice, Swalm, & Hutchinson, 2011).

External economic assistance is also a factor in community recovery from disasters. Humanitarian aid may be available from a variety of sources, but it is usually short-term funding and may not assist in rebuilding of community infrastructures damaged by a disaster. In addition, aid resources may not effectively prioritize recovery needs, misallocating resources. Provision of aid may be restricted by perceptions of responsibility for a disaster or other political considerations. For example, foreign policy considerations may weigh more heavily in aid decisions than humanitarian needs. In addition, with

the exception of assistance by the International Red Cross, foreign aid requires a request for assistance from the host country that, again, may not be forthcoming for political reasons (People's Health Movement et al., 2008). Funding streams for global disaster response identified by the People's Health Movement include government funding; private foundations (e.g., the Gates, Ford, and Rockefeller foundations, Wellcome Trust); other private organizations (e.g., individuals and corporate social responsibility programs); multilateral funding agencies, such as the World Bank; bilateral programs, such as PEPFAR and USAID; global health funding agencies, such as the Global Fund and GAVI; and United Nations agencies like WHO, UNICEF, and UNAIDS. In the United States, disaster relief and recovery assistance is often provided by a variety of governmental and humanitarian organizations, making coordination of efforts difficult and resulting in gaps and overlaps in services.

Economic endeavors may also contribute to disaster occurrence. For example, there is some concern that human-induced seismic activity may contribute to earthquakes. Such activities usually involve either extraction of substances from the earth or injection of wastewater into the earth. A recent IOM report by the Committee on Induced Seismicity Potential in Energy Technologies and others (2013) found that fracturing or fracking, a process of injecting water and sand into the earth under high pressure to create fractures allowing release of oil and gas, is not a major contributor to seismic activity, and that injection of wastewater from oil and gas production poses minimal risk. Carbon capture and storage, another process that involves injection of large volumes of fluid into the earth, may have considerable potential for seismic activity although the risk is less if a balance is maintained between extraction and injection of substances. The report concluded that further research is needed to determine the risk posed by these newer energy technologies.

The population health nurse assists in identifying social factors that enhance or impede the community's ability to respond effectively in the event of a disaster. Planning groups could then capitalize on positive factors in designing an effective disaster plan. For example, well-established cooperative relationships between groups and agencies in the community are an asset in designing and implementing a disaster plan, whereas the presence of relatively isolated cultural groups may impede planning and response efforts.

Occupational factors are another element of the sociocultural dimension that contribute to the potential for disaster in a community and should be assessed by the nurse. Occupational disasters are events related to a particular business or industry in which more than five deaths occur. The population health nurse should be aware of industries in the area that pose hazards related to fire or explosion. The potential for radiation exposure or leakage of toxic chemicals in the community should also be determined. The nurse may also want to appraise the extent to which local industries adhere to safety regulations related to hazardous conditions. Population health nurses

working in industrial settings would be particularly likely to have access to this type of information. Other population health nurses may need to advocate for regular inspection of industrial conditions by the appropriate authorities.

The population health nurse also identifies occupational factors that may enhance a community's abilities to respond effectively in the event of a disaster. The nurse and others involved in disaster planning would explore the adequacy of rescue services and personnel for dealing with potential disasters. Is the number of firefighters in the community, for example, adequate to deal with an explosion and fire in a local chemical plant? Do firefighting units possess the equipment needed to deal with such an event? Planners also assess the existence of other occupational groups that may assist with disaster response. For example, are there construction companies in the community that could supply heavy equipment that might be needed for rescue operations?

In the event of an actual disaster, the nurse might also assess sociocultural factors influencing the community's disaster response. For example, the nurse might identify growing intergroup tensions in shelters for disaster victims or disorganization in efforts to reunite families separated by the disaster. Other areas for consideration include the degree of cooperation among groups providing disaster relief and, following the disaster, the availability of recovery assistance to individuals and families. Failure of government agencies and other organizations to interact effectively may be a sociocultural factor that hampers adequate disaster response. For example, lack of coordination between local, state, and federal agencies delayed control of the San Diego wildfires in 2003, resulting in increased loss of life and extensive property damage. Steps have been taken since to improve coordination and collaboration.

Another social response to disasters, particularly those caused by terrorist activities, may include anger and hostility toward groups deemed responsible for the disaster. These emotions may be demonstrated in prejudice, discrimination, and attacks on innocent parties believed to be related to the perpetrators. Population health nurses may need to be involved in advocacy to prevent discrimination and violence against such groups. Anger may also be directed at public officials. Other related social responses may include loss of faith in social institutions, demoralization, and social isolation (Plum & Meeker, 2013). Even well-intentioned social responses to disaster may have adverse effects. For example, food aid provided to countries experiencing famine may do as much harm as good. Potential negative effects of food aid include undermining the local economy and promoting black market sales of food goods. Other effects may include promoting rural to urban migration of people seeking relief assistance. Foreign aid may also create national dependency rather than promoting self-sufficiency. Misuse of supplies is also a problem. In addition, the costs and problems of shipping, storage, and dissemination of food supplies exhaust funds that could be used more effectively to promote local economies and infrastructures that prevent disaster. A balance of food and economic aid is recommended

to promote the ability of developing countries to address their own needs while meeting the current survival needs.

One particular social group that needs to be considered in disaster response planning is jail and prison inmates. Evacuation of these populations poses special considerations related to public safety and security. Correctional officials may need to be able to safely relocate major inmate populations to multiple locations.

Finally, assessment of sociocultural determinants in a disaster setting includes exploration of the availability and adequacy of basic social services. Areas to be addressed include the availability of shelter, transportation, financial assistance, communication networks, and other goods and services. Population health nurses can help in the rapid assessment of postdisaster conditions, making referrals for assistance, and planning to assure that assistance is available to those in need.

Behavioral determinants. Behavioral factors related to consumption patterns and even leisure pursuits can influence the occurrence of disasters and their effects on the health of community members. Consumption patterns such as smoking, drinking, and drug use can contribute to disasters. Smoking, for example, is often the cause of residential fires and wildfires that result in loss of life as well as extensive property damage. Drinking and drug abuse have both been known to contribute to transportation disasters, and they may also contribute to industrial disasters when the abuser is working in a setting with disaster potential. For example, if a person responsible for monitoring the safety of a nuclear reactor is intoxicated, he or she is unlikely to recognize or respond appropriately to signs of danger. The population health nurse assesses the extent of smoking and substance abuse in the community in relation to the potential for disaster. The nurse may also want to assess (or encourage others to assess) the effectiveness of substance abuse policies in transportation services and industries where there is potential for disaster. Another area for assessment is the extent of safety education with regard to smoking (e.g., not smoking in bed) that occurs in the community. Population health nursing advocacy may be needed to assure attention to these concerns.

Consumption patterns may also intensify the effects of a disaster on the health of a population. A community whose members are poorly nourished, for example, is at greater risk for consequences of disaster such as communicable diseases. Substance abuse may limit one's potential for appropriate behavior in an emergency and lead to injury and even death due to failure to respond appropriately. For example, intoxication may prevent someone from fleeing a burning building.

Consumption patterns and their effects are particularly relevant in disasters involving famine and large displaced or refugee populations. Famine is a population-wide condition involving substantial mortality from malnutrition. Common nutritional effects of famine among refugee populations include *protein-energy malnutrition (PEM)*, a severe state of undernutrition that may be either acute or chronic, and deficiencies of specific micronutrients such as vitamin A, iron,

vitamin C, niacin, and thiamine. In some cases, famine is less a function of lack of food than of the inability of some segments of the population to afford what food is available.

Lack of exercise in the population can limit the ability to engage in strenuous labor that might be demanded in a disaster situation. Unaccustomed activity may result in exhaustion or heart attack. The nurse assesses the levels of exercise engaged in by the general population. Population health nurses in occupational settings may also be responsible for determining the physical fitness of personnel who would be involved in rescue operations in the event of a disaster (e.g., firefighters).

The leisure pursuits of community members may, on occasion, contribute to the occurrence of a disaster event. Careless campers, for example, could ignite a forest fire, or skiers might trigger an avalanche. Fires can be started by sparks from recreational vehicles. The population health nurse and others involved in disaster planning assess the extent of such leisure pursuits in the community, the existence of safety regulations related to these pursuits, and the degree of adherence to safety regulations. Advocacy may also be required for the development or enforcement of such regulations.

Leisure pursuits can also enhance the community's response to a disaster event, and the nurse assesses the presence of leisure pursuits that may have this effect. For example, the existence of a group with an interest in wilderness survival may be an advantage in the event of an avalanche or a plane crash in a remote area. Social groups within the community may also serve as a vehicle for preparedness education.

Finally, disasters may affect consumption patterns other than dietary intake. For example, smoking, alcohol consumption, and drug use may increase as means of coping with the negative psychological effects of a disaster.

Health system determinants. The adequacy of the health care system's response capability in the event of a disaster influences the extent to which a disaster affects a community and the health of its members. Assessing the ability of the health care system to respond to a disaster includes examining facilities and personnel as well as the organizational framework in which they operate. A community that has a variety of health care facilities joined in a cooperative network can respond more effectively to the health care demands of a disaster situation than can a community with limited facilities or no existing system for coordinating efforts.

The nurse and other disaster response planners identify the types of health care facilities available in the community and the number and type of health care personnel that could be called on in the event of a disaster. Planners might also determine the existence and adequacy of disaster plans developed by health care facilities. For example, has a local hospital developed a plan for evacuating patients if the hospital is affected by the disaster? Is there a plan for handling mass casualties of various types in the event of a disaster?

Large populations affected by a disaster increase the demand for services by health systems and hospitals. These

effects can be mitigated by widespread preparedness in the population. Health care systems need to assess the likelihood of specific disasters in the area and prepare accordingly. The IOM has recommended that health care and other organizations identify indicators and triggers for initiating specific actions in response to disaster events. Indicators are measures, events, or other data that predict a change in demand for services or the availability of resources. Indicators may be either actionable or predictive. Actionable indicators are those that can be influenced by action taken within the organization or as an element of the emergency response system. An example of an actionable indicator might be an increasing number of cases of a particular communicable disease in the dormitories of your school. A predictive indicator is one that cannot be influenced by action, such as notification of isolation of H1N1 cases in the local community (Hanfling, Hick, & Stroud, 2013).

Triggers are decision points that require a change in activity based on information about available resources. For example, a specific number of disaster-related traumatic injuries needing surgical intervention might trigger a hospital decision to cancel all elective surgeries, reserving surgical resources for disaster victims. Crisis care triggers mark the point at which the scarcity of resources requires movement from routine care to crisis care. Cancellation of elective surgeries is an action taken in response to a crisis care trigger; a decision to call in additional personnel to address increased needs would be an example of a noncrisis care trigger. Triggers may be either scripted or non-scripted (Hanfling et al., 2013). Scripted triggers are predetermined points at which action is to be taken. For example, when the number of cases of disease in the dormitories reaches a certain predetermined level, classes may be canceled. Nonscripted triggers are not predetermined. For example, a countywide power outage in San Diego resulted in cancellation of all university classes for several days.

Indicators and triggers lead to tactics or actions to be taken to address the issue of concern. Tactics may also be scripted or unscripted. Scripted tactics are predetermined actions to be taken in the event of the occurrence of certain specified indicators or triggers (e.g., establishing mass immunization sites when the incidence of a particular disease reaches a predetermined level). Nonscripted tactics vary based on the situation and what seems to be the most effective approach to solving an identified problem (Hanfling et al., 2013). The IOM has developed a toolkit to assist organizations, agencies, and jurisdictions in identifying indicators, triggers, and tactics for disaster response. For further information about the toolkit, see the *External Resources* section of the student resources site.

Specific public health preparation for disasters should also be assessed. Preparation includes:

- Establishing close working relationships and mutual-aid agreements with other health and emergency agencies
- Participating in vulnerability and risk assessment
- Conducting system capacity assessments

- Acquiring resources and surge capacity needed to continue basic services
- Developing plans, procedures, and guidelines congruent with those of other response agencies
- Developing operational objectives for public health emergency response
- Developing basic surveillance systems for morbidity, mortality, syndromic, and mental health issues
- Developing guidelines and procedures for risk communication
- Engaging in resource typing and credentialing of personnel, resources, and assets
- Ensuring training and certification of agency personnel regarding safety and health practices and use of personal protective equipment
- Providing orientation and training to response personnel, including volunteers
- Participating in planning and implementing preparedness exercises
- Participating in after-action performance reviews (CDC, 2011)

Population health nurses and others assessing disaster preparedness should determine the extent to which state and large local public health agencies (e.g., those in large metropolitan areas) are capable of carrying out these responsibilities.

In the event of an actual disaster, there is also a need to assess the effects of the disaster on the health care system and its ability to respond effectively. For example, are facilities badly damaged or unusable for other reasons? In some instances, health care facilities have collapsed in earthquakes or become inaccessible due to floodwaters or highway damage. Damage to the health system, as well as other elements of the community infrastructure that permit access to health care services (e.g., roads, electricity, communication networks), can have negative consequences for the population's health.

Questions for assessing disaster potential and the health-related effects of a disaster are included in the *Focused Assessment* on pages 723–724. Two assessment tools are included on the student resources site. One is the “Community Disaster Preparedness Checklist” a tool for rapid assessment of the level of community disaster preparedness. The other tool is the more detailed “Disaster Assessment and Planning Guide” designed to assist with assessment of disaster potential and planning to deal with disaster occurrences.

Diagnostic Reasoning and Care of Populations in Disaster Settings

Based on the assessment of biological, psychological, environmental, sociocultural, behavioral, and health system determinants of health, the nurse derives nursing diagnoses related to disaster care. These diagnoses may reflect the potential for disaster occurrence, the adequacy of disaster preparation, or the extent of effects in an actual disaster. A diagnosis related to disaster forecasting is “potential for major earthquake

FOCUSED ASSESSMENT**Disaster-related Assessment Considerations*****Biological Determinants***

- What is the age, gender, and ethnic composition of the population involved in the disaster? Are the effects of the disaster likely to be worse for some subgroups than others (e.g., the disabled, elderly)?
- What is the extent of injury or disease resulting from the disaster?
- What existing health problems are prevalent among those involved in the disaster?
- Are there pregnant women involved in the disaster?

Psychological Determinants

- How does the population respond to disaster warnings? What is the public's attitude to disaster preparedness?
- What is the extent of community/individual ability to cope with the disaster?
- What is the extent of existing mental illness among those involved in the disaster?
- What is the extent of damage or loss of life involved in the disaster?
- Does the disaster present the potential for continuing damage or loss of life?
- What is the effect of the disaster on rescue workers? On victims? What are the long-term psychological effects of the disaster on the community?

Environmental Determinants

- What physical features of the community create the potential for disaster? What types of disasters are likely to occur?
- What structures are likely to be threatened by a disaster? To what extent are vital structures likely to withstand a disaster?
- What structures could be used as emergency shelters?
- Will weather conditions influence the effects of the disaster?
- Are there elements of the physical environment that will hinder response to the disaster (e.g., blockage of roads)?
- Have buildings been structurally damaged? Is there potential for additional structural damage? Does structural damage pose further risk to victims? To rescuers?
- Is there a need for sources of shelter for persons displaced by the disaster?
- Is there a safe water source available to victims of the disaster?
- To what extent are animals involved in the disaster? What health effects might this have?

Sociocultural Determinants

- Do relationships in the community have the potential to create a disaster (e.g., civil strife, war)?

- What is the level of community resilience? What factors contribute to or impede resilience?
- How cohesive is the community? Are community members able to work together for disaster planning? What level of priority is given to disaster planning by official agencies? By private organizations and individuals?
- What provisions have been made for reuniting families separated by disaster?
- What is the extent of social support available to disaster victims?
- What is the extent of collaborative interaction among relief agencies involved in the disaster?
- Has the community disaster plan been communicated to residents? How are disaster warnings communicated to residents? Are there language barriers that impede communication in the disaster setting? What is the effect of disaster on normal channels of communication?
- What community groups are responsible for disaster planning? Who is available to provide leadership in responding to the disaster? What is the level of credibility of leaders among those affected by the disaster?
- What community industries pose disaster hazards? What types of hazards are present? To what extent do local industries adhere to safety procedures that would prevent a disaster? Is adherence monitored by regulatory bodies?
- What occupational groups in the community are available to respond to the disaster?
- What is the extent of property damage and loss resulting from the disaster?
- What is the economic status of those affected by disaster? Do they have economic resources available to them? What is the effect of the disaster on the local economy?
- What external sources of economic assistance are available?
- What is the effect of the disaster on transportation?
- What is the effect of the disaster on community services? What community services are available to assist with recovery?
- Is equipment needed to deal with the disaster available and in good repair?

Behavioral Determinants

- To what extent do consumption patterns (e.g., drugs or alcohol) create the potential for disaster in the community?
- Do community members engage in leisure pursuits that pose a disaster hazard? To what extent do community members engage in recreational safety practices that can prevent disasters? What leisure pursuits by community members could enhance the community's disaster response?

(Continued)

FOCUSED ASSESSMENT

(Continued)

- What is the availability of food and water to disaster victims? To rescuers? Are there special dietary needs among those affected by the disaster? What provisions have been made to meet these needs?
- To what extent have psychological effects of the disaster increased the incidence or prevalence of substance abuse?

Health System Determinants

- How well prepared are health service agencies to respond to a disaster?
- What health care facilities are available to care for disaster victims? What are their capabilities? What health care personnel are available to meet health needs in a disaster? How can they best be mobilized?
- What is the extent of basic first aid and other health-related knowledge in the community?
- What is the effect of a disaster on health care facilities? On health care services?
- What physical and mental health care services are needed as a result of disaster? Are available services adequate to meet the need?

damage and injury due to community location on a geological fault.” A diagnosis of “inadequate disaster planning due to fragmentation of planning efforts among community agencies” is a possible nursing diagnosis related to disaster preparedness. A diagnosis derived from information about the effects of an actual disaster is “need for additional shelter sites due to destruction of planned shelters by fire.”

In the event of an actual disaster, nursing diagnoses might relate to individual clients as well as to the status of the overall community. Examples of individual level diagnoses include “grief due to loss of husband” and “pain due to leg fracture suffered in building collapse.” Nurses may derive diagnoses related to disaster helpers as well as victims, such as “role overload due to need to rescue disaster victims and care for own family” and “stress related to constant exposure to death.”

Planning: Disaster Preparedness

Activities related to disaster preparedness and response occur at all four levels of health care, but the terminology used is somewhat different.

HEALTH PROMOTION. General health promotion activities such as good nutrition, physical activity, and development of effective coping skills assist individuals and communities in withstanding the effects of disasters. In addition, specific activities designed to enhance community resilience are an element of health promotion related to disaster care. The Committee on Increasing National Resilience to Hazards and Disasters, Committee on Science, Engineering, and Public Policy, and The National Academies (2012) have identified several universal steps in fostering community resilience. These include engaging the whole community in policy making and planning, linking public and private performance and interests to resilience goals, improving public and private infrastructure and essential services, and promoting a culture of resilience by communicating

risks and connecting community networks. Other steps include organizing communities, neighborhoods, and communities to prepare for disasters.

In the event of a disaster, actions that promote overall physical and mental health within the population will assist in disaster recovery. Goals of health promotion in a disaster include meeting basic survival needs for food, water, shelter, and security, ensuring access to goods and services, empowering survivors to advocate for themselves and promoting the highest achievable level of health in the population affected (Reed et al., 2013). Table 25-6• presents health promotion foci and population health nursing strategies related to disasters.

PREVENTION. Prevention, in the context of disaster, has two main foci: preventing disasters from occurring and minimizing their effects. Disaster prevention relies on risk analysis and hazard identification with subsequent activities to reduce risks.

Preventing disasters. Population health nurses may be involved in identifying and eliminating factors that may contribute to disasters to the extent that they identify these factors and report their existence to the appropriate authorities. For example, the population health nurse working in an occupational setting may note that an employee who is responsible for monitoring pressure levels in a boiler may be drinking heavily. This employee’s drinking problem may lead to lack of attention to rising pressures and an explosion and fire in the plant. In such a case, the nurse would call the employee’s drinking behavior to the attention of a supervisor.

Population health nurses may also become politically active to ensure that risk factors for potential disasters present in the community are eliminated or modified. For example, the nurse might campaign for stricter building codes or serve as a mediator in an attempt to defuse social unrest in the community.

CLIENT EDUCATION Family Disaster Planning

Important Information

- Provide each family member with emergency contact information (name, phone number, location) for someone out of the immediate area
- Develop and inform family members of the family disaster plan, including:
 - Where and how to safely shut off utilities (electrical circuit breaker, main water valve, gas valve, location of a wrench, manual garage door override, other utilities)
 - Floor plan with marked window and door exits, utility shutoffs, first aid and emergency supplies (also inform babysitters and guests of this information)
 - Avenues of escape from the home or other buildings
 - Two possible reunion locations: immediately outside the home and away from home if family members cannot get home.
 - Alternative evacuation routes out of the neighborhood
- Obtain information on school and employment disaster policies (keeping children to be picked up, etc.)
- Record medication information for each family member
- Obtain and post utility phone numbers, police, medical, contact information
- Obtain information on local emergency plans, shelter locations, and evacuation plans
- Obtain information on community disaster warning signals and their meaning
- Assign activities related to evacuation (e.g., designate the person responsible for taking the baby or family pets)
- Know the general plan and designated routes for evacuating the community
- Know what actions should be taken when warning is given
- Know where to seek additional information

Important Papers

- Medical consents for children
- Insurance papers, bank account numbers
- Identification papers
- Emergency release permissions provided to children's schools
- Pet immunization records
- Significant medical information
- Cash

Important Skills

- Utility shut off
- First aid/CPR as age appropriate
- Personal protection in case of storms, fire, earthquake, toxic fumes

Home Inspection and Risk Reduction

- Install and maintain smoke detectors in homes
- Identify potential risks and evacuation routes

- Secure water heater and heavy furniture to wall studs
- Move heavy items to lower shelves
- Remove or isolate and secure flammable materials
- Install locking devices on cabinet doors
- Install and support flexible connections on gas appliances
- Install fire escape ladders as needed at upper windows
- Keep stairways and doors free of obstacles to permit an easy way out

Disaster Supplies

- Medications, glasses, and first aid supplies
- Flashlights, radio, and extra batteries and bulbs
- Food and water sufficient for 72 hours
 - Water (one gallon per person per day)
 - Nonelectric can opener
 - Canned, dehydrated, or precooked food requiring minimum heat or water
 - Special dietary needs (baby formula, pets)
- Blankets and extra clothing (at least one complete change of clothes per person), outer wear
- Other: fire extinguisher, first aid kit and book, watch or nonelectric clock
- Sanitation supplies: powdered chlorinated lime (to add to sewage), large plastic bags, pre-moistened towelettes, sealable bags, newspapers, hand soap/liquid detergent, shampoo, toothpaste and toothbrushes, dentures, feminine supplies, infant supplies, toilet paper, paper towels, deodorant
- Safety items: heavy shoes, gloves, candles and waterproof matches, garden hose, knife or razor blades, tools, household bleach
- Cooking items: sealable plastic bags, paper plates, utensils, paper towels, cooking pots, barbecue or gas grill, charcoal and lighter or propane
- Tent or other type of shelter

Immediate Response

- Get to a safe location
- Seek shelter from hurricanes or tornadoes in basements or inner rooms without windows
- Seek high ground in the event of a flood
- Assist family members with mobility limitations and functional needs
- Check for injuries and provide first aid as needed
- Check for fires and hazards
- Turn off utilities (only turn off gas in the event of a suspected leak)
- Check on neighbors

CLIENT EDUCATION (Continued)

- Stay apprised of events with a battery-powered radio
- Do not touch downed power lines
- Clean up or avoid potentially harmful materials
- Check for damage if safe to do so
- Do not use the telephone except in emergency
- For updated information and shelter information call the Red Cross
- Open doors carefully
- Cooperate with safety officials
- Be prepared to evacuate if necessary
- Purify water if needed by boiling, adding ¼ tsp household bleach/gallon of clear water (2½ tsp/gallon for cloudy water) or water purification tablets
- Engage in safe use of electric generators
- Do not use charcoal grills or other carbon monoxide-producing fuels indoors

Other

- Practice implementing the plan
- Replace stored food, water, and medications periodically

as seeking shelter from severe storms, moving to safer parts of the house in the event of an earthquake, or turning off utilities and safe use of portable generators, and can encourage the placement of CO monitors in all homes. Public education with respect to response to nuclear or radiological attacks would include staying indoors, limiting consumption of milk and locally produced food, and use of potassium iodide prophylaxis following exposure. Population health nurses may need to advocate for the availability of prophylactic antidotes for a variety of potentially hazardous substances depending on the disaster potential in the community.

Postdisaster prevention may also involve use of personal protective equipment (PPE) for those working in disaster-affected areas. For example, those working in floodwaters should wear heavy boots and other protective gear to avoid wound exposure to contaminated water. PPE (e.g., respirators) should also be used in disasters such as fires and the collapse of buildings in which smoke and lingering particulate matter pose health hazards for rescue and clean-up workers. PPE should be standardized across agencies when possible, and all responders, including volunteers, should be adequately trained in its use. Similarly, work to identify the dead poses risks for morgue personnel, who should use PPE during examinations and arrange for appropriate disposal of bodies and autopsy fluids and samples.

Postdisaster immunization campaigns (e.g., for hepatitis A, influenza, varicella) may be warranted in shelter settings depending on conditions such as crowding, poor sanitation, or contamination of food and water. Vaccination may also be needed for autopsy workers and mortuary personnel and their families in the event of disease outbreaks with multiple deaths. Population health nurses may be involved in the design and implementation of immunization campaigns and in educating the public about the need for immunization.

Prevention of mental health problems resulting from disaster may involve preventing group panic by providing reliable risk communication focusing on specific actions that can

be taken to promote safety. Health officials should also avoid “knee-jerk” responses to circumstances (e.g., imposing mass quarantine regulations for disease outbreaks). Prevention of mental health effects can also be fostered by assisting people to manage fear and anger and restoring them to a useful social role. Provision of respite may also be warranted for rescue and other personnel and other people with significant care burdens (e.g., single women with children, caretakers of persons with disabling conditions) (Plum & Meeker, 2013). Table 25-7• presents some of the specific activities of population health nurses related to prevention in disaster settings.

RESOLVING PROBLEMS: RESPONSE PLANNING. Resolving problems arising from a disaster involves implementing the disaster response plan. Prior to implementation, however, the plan needs to be developed. Disaster response is based on disaster planning that occurs in the nondisaster stage. In discussing disaster response, we will address purposes and principles and challenges in disaster planning, general considerations in planning, and specific elements of a disaster response plan.

Disaster response planning should be a collaborative effort that incorporates members of the community in plan development, dissemination, and implementation. Planning activities should encourage personal and community responsibility for preparedness rather than relying on the actions of governmental bodies (Chandra et al., 2011).

Purposes of disaster planning. Emergency or **disaster preparedness** involves the development of knowledge, skills, and plans for action needed to prepare for or respond to a disaster (Baack & Alfred, 2013). The general intent of disaster preparedness is to limit the morbidity and mortality resulting from a disaster and to decrease the population’s vulnerability to the effects of a disaster. A second general purpose of disaster planning is to ensure that resources are available for effective response in the event of a disaster. This aspect of planning involves determining procedures that will be employed in response to a disaster event

TABLE 25-7 Prevention Foci and Strategies Related to Disasters

Focus	Strategies
Disaster prevention	<ul style="list-style-type: none"> • Assist in the identification of disaster risks • Advocate for the elimination or modification of disaster risks • Advocate for appropriate controls on the production, transport, storage, and use of hazardous materials • Advocate for measures to promote human dignity and prevent civil unrest • Advocate for effective building codes, maintenance, and security • Advocate for adoption of sound land use planning practices • Provide immunization services and educate the public on the needs for immunization • Educate the public regarding disaster preparedness
Minimizing disaster effects	<ul style="list-style-type: none"> • Assist in communicating community disaster response plans to the public • Educate the public about major disaster risks, how to prevent disasters, and how to minimize their consequences • Advocate for the availability and use of PPE by disaster responders • Educate responders on the use of PPE • Initiate postdisaster immunization campaigns and educate the public regarding the need for immunization
Preventing psychological effects	<ul style="list-style-type: none"> • Prevent group panic through timely and honest risk information and direction for action to foster safety • Provide reassurance and assistance in dealing with anxiety • Advocate avoidance of knee-jerk responses • Assist with the management of fear and anger • Provide people with useful social roles • Provide respite as needed

and obtaining material and personnel that will be required to implement the disaster plan.

Principles and challenges of disaster planning. Effective disaster planning is based on several principles that include the following:

- Planning must be based on a scientific understanding of human behavior.
- Planning should incorporate findings from current research.
- Preparedness must go beyond routine response to everyday emergencies.
- Planning should be based on regularly updated community assessment information.
- Planning needs to incorporate establishment of a chain of command prior to a disaster event.
- Disaster response plans should incorporate measures to mobilize local resources during the first 24 to 48 hours after a disaster.
- Planning needs to be based on identification of the needs of vulnerable populations and address those needs.
- Planning should incorporate development of mutual aid agreements with state and federal organizations and include knowledge of what assistance can be expected.
- Plans also need to be flexible.
- Plans need to consider the training and resource needs of response personnel.
- Plans need to incorporate mechanisms for early damage assessment of the overall magnitude of the disaster, health

effects, integrity of health system function, specific health care needs of survivors, disruption of public services needed for survival, and the extent of local response (Veenema & Woolsey, 2013).

Disaster preparedness, particularly as it relates to responses to bioterrorist threats, poses several challenges. These include preventing disaster (e.g., the spread of disease) without unduly infringing on individual freedom, supporting economic stability in the face of security controls that may disrupt commerce, supporting and restoring social bonds in the face of suspicion and uncertainty, and alerting the public to the occurrence of a crisis without creating fear and panic. Additional challenges include earning public confidence and support regarding the use of resources in responding to the disaster, maintaining credibility in situations in which information on which to base sound decisions is lacking, and promoting collaboration among multiple social sectors to promote effective response.

Population health nurses should be actively involved in disaster response planning and can help to assure that principles of effective planning are incorporated and that the challenges are met. For example, population health nurses might advocate for collection of community perspectives prior to developing a response plan or might help to assure that civil liberties are protected as much as possible. Similarly, population health nurses might advocate for a response plan that meets the needs of diverse segments of the community (e.g., non-English-speaking residents or those who cannot afford recommended disaster preparation activities).

General considerations in disaster response planning. General considerations in planning the response to a disaster event include designating authority, developing communication mechanisms, providing transportation, and developing a record-keeping system.

Authority. An effective disaster response plan designates a central authority and delineates the responsibilities that are delegated to specific persons and organizations. For example, if it is clear that evacuation decisions are made by the mayor and implemented by members of a local military installation, while police have the responsibility for keeping roads open, there will be less confusion, and evacuation efforts will be carried out more smoothly. Central authority may be assigned to several people in a hierarchical order so that in the absence of the first person designated, the second person has authority to implement the plan. In this individual's absence, a third person would assume that authority, and so on.

Authority for on-the-spot decisions should be delegated, whenever possible, to persons at the scene of a disaster to avoid time-consuming delays in response to an emergency situation. At the same time, there needs to be a balance between immediate response and overall coordination of activities. Areas in which authority will be needed should be identified and responsibility designated. Gaps in authority should be prevented since this results in inability to engage in timely response. For example, one of the policies that prevented effective response to the San Diego wildfires in 2003 was the routine grounding of U.S. Forest Service helicopters half an hour before sundown. There was no one with local authority to invalidate this policy and allow at least one flight with fire retardant chemicals that could have helped contain the fires. Pilots of one helicopter that was already en route had to return to base even though they believed they could safely drop their load of chemicals before flight conditions became too dangerous.

Communication. Communication is critical to the effective implementation of a disaster response plan. Effective communication serves a number of purposes. First, it increases the likelihood of appropriate action by responders and the general public. Second, it reduces anxiety and unnecessary action by segments of the population that are not threatened by the disaster. Third, and most important, effective communication facilitates relief efforts.

Modes of communication should be established and disaster personnel and the general public should be familiarized with them. Specific considerations in this area include how warnings of an imminent disaster will be communicated, how communication between various emergency teams and facilities will be handled, and how communication with the outside world will be facilitated. It is important to remember that normal means of communication may be disrupted during an emergency, and that there is a need for "redundant communication systems" using multiple modes of communication from and to multiple locations (Davis et al., 2013).

Some consideration should also be given to facilitating communication among members of the community. For example, there may be a central bulletin board where messages can be left or a specific agency that is responsible for handling personal communications that permit family members separated by a disaster to locate each other. There should also be two-way communication between authorities and the public so disaster response best meets community needs. This may be facilitated by emergency information systems that collect data about disaster effects during impact, response, and recovery phases (Landesman, 2011).

Disaster-related communication should be factual, positive, and reassuring whenever possible. CDC has adopted the acronym STARCC to reflect the characteristics of effective disaster communication: **S**imple, **T**imely, **A**ccurate, **R**elevant, **C**redible, and **C**onsistent. Trust and credibility may be fostered by expressing empathy and caring, competence and expertise, honesty and openness, and commitment and dedication. Additional communication tips include avoiding over reassurance, acknowledging uncertainty, explaining the processes to be used to find answers, acknowledging people's fears, providing direction for specific action, and asking people to share risk. In addition, risk communication messages and information "hot lines" should be updated regularly and coordinated with other responding organizations (CDC, 2011).

Communication mechanisms and messages may need to be targeted to specific audiences, which may necessitate developing ongoing relationships with public media prior to a disaster. Media representatives may need to be educated regarding their potential role in disaster communications (Chandra et al., 2011). Ethnic radio and television stations can broadcast warnings and instructions in a variety of languages, but specific contacts should be established before a disaster event occurs. Development of media dissemination plans will support disaster-related communication with the public. Specific messages should be developed based on communication and behavioral theory to promote positive responses, and messages should be accurate, clear, consistent, and timely in their delivery. Another consideration is the need for interoperable communication systems between response agencies that interface well. In addition, plans should be made to accommodate communication between and among fixed and mobile locations. There is also a need for emergency alert systems that will be easily understood by the general public (e.g., the air raid sirens designed to warn of enemy attack in the 1940s and 1950s). Other aspects of communication include designating reporting sites for rescue and health care personnel and mechanisms for identifying who these people are. For example, color-coded vests might be used to distinguish health care providers from rescue workers. Several prepared public service announcements (PSAs) and podcasts are available from CDC to inform residents of emergency preparedness and appropriate actions. For further information about these media messages, see the *External Resources* section of the student resources site.

Communication-related components of a disaster response plan should consider three possible scenarios and develop contingency plans for each. In the first scenario, normal communication channels remain intact and can be used for disaster response purposes. In the second scenario, some normal channels are intact, but others have been incapacitated. In the third scenario, there is little intact communications technology and other means of communication need to be employed.

Communication considerations in disaster response planning must also include dissemination of the plan to the general public, the scientific and professional community, and other stakeholders to permit them to take appropriate action regarding their own preparation for and response to a disaster. Again, these communications should be targeted to specific audiences and be delivered by trusted spokespersons. Population health nurses can help identify appropriate mechanisms for communicating with particular segments of the community and draft meaningful messages.

A final, highly specialized consideration with respect to disaster communication is how notification regarding the death of a family member will be handled. Protocols should be developed regarding how significant others will be notified of deaths and may necessitate coordination with mental health personnel (Landesman, 2011).

Transportation. General plans for the provision of necessary transportation must also be considered in disaster response planning. There will be a need to transport personnel and equipment to the disaster site as well as to transport victims away from the site. There will also be a need to move personnel to areas where they are most needed. Another consideration with respect to transportation is keeping access roads open so that emergency vehicles can pass. There is also a need to provide alternate transportation routes, especially for evacuating people from a high-risk area, in case first-choice routes are blocked.

Records. Records are needed prior to a disaster regarding the availability of supplies and equipment and areas where they are stored. This information should be updated on a regular basis, and a systematic process for its updating should be established. Local institutions such as schools and businesses should be encouraged to keep records of all those present at any given time so that everyone can be accounted for and those missing can be identified as early as possible. Institutional records may also include emergency contact and health-related information that will facilitate reunification of families or meeting ongoing health needs. One of the disaster plan elements that facilitated continued TB treatment for infected individuals following hurricane Sandy was the maintenance of duplicate records and emergency contact information for patients. All of the 1,899 people under treatment for TB in the most affected areas were located and their care continued without interruption (Burzynski et al., 2013).

During the disaster itself, a variety of other types of records are needed. Victims must be identified and their condition

and treatment documented. Deaths should also be recorded. Records are also needed of the use of supplies and equipment so that additional materials can be obtained if required. Records of the deployment of rescue personnel are needed to ensure the most effective use of personnel. It would be difficult to develop systematic record-keeping systems during an actual disaster, so it is important that such systems be in place before a disaster occurs.

Elements of a disaster response plan. A comprehensive disaster plan should address notification, warning, control, coordination, evacuation, and rescue. Additional elements of the plan should specify protocols for immediate care, supportive care, recovery, and evaluation. These last two elements will be discussed under health restoration or recovery, and the others will be briefly examined here.

Notification. An effective disaster response plan specifies in a systematic fashion the means of notifying the person or persons who can set the plan in motion. Persons who might be in a position to have advance warning of a disaster (e.g., local weather service personnel) should have a clear understanding of who should be apprised of the potential for disaster. There must also be specific plans for notifying personnel and organizations involved in the disaster response. Notification should always include the fact of occurrence of a disaster, the type of disaster involved, and the extent of damage as far as it is known at the time. Notification should also convey any other relevant information that is known about the situation.

Warning. The disaster plan should also spell out the procedures for disseminating disaster warnings to the general public. Procedures should specify the content of warnings, who will issue the warnings, and the manner in which warnings will be communicated. For example, the plan might specify that warnings include the type of disaster involved, the area affected, and specific directions on actions to be taken by community members. Warnings may be issued by local radio and TV stations and by police vehicles with loudspeakers. Sirens may be used to alert people if they have been informed beforehand of the meaning of the siren and where to turn for more information. If warnings are to be communicated by media personnel, the plan should specify contact persons at radio and TV stations. Recent technological developments have allowed information to be disseminated in a variety of other ways, for example, through social media or by means of mobile telephones (FEMA, 2012b).

There is also a need to consider mechanisms to provide warning for certain particularly vulnerable segments of the population. For example, sign language or closed caption messages may accompany audio messages on television stations or vibrating alarms may be used. Use of other high-tech mechanisms for warning messages may miss low-income households, and the tendency to provide media messages in English does not meet the needs of non-English-speaking segments of the population (DeBastiani & Strine, 2012).

Control. A disaster plan also specifies how the effects of a disaster are to be controlled. Different control efforts are required for different types of disasters, and a community should be prepared to implement a variety of control activities. In the case of an earthquake, for example, control measures are directed at preventing and extinguishing fires before further damage is caused. Again, the procedures, materials, and personnel needed to carry out control measures must be specified in the plan. Disaster response plans frequently include measures to prevent looting of evacuated homes; however, research has indicated that looting is not generally a widespread problem and such measures may siphon off protective services personnel who could be better used in other capacities.

Logistical coordination. Another element of a community disaster plan deals with logistical coordination. **Logistical coordination** is the coordination of attempts to procure, maintain, transport, and disburse needed materials in a disaster. The disaster plan specifies where and how supplies and equipment will be obtained, where these will be stored, and how they will be transported to the disaster site.

Traffic control is another aspect of logistical coordination. The disaster plan should specify personnel and procedures for controlling access to the disaster site. Traffic control procedures should also specify means by which access to the disaster site is ensured for rescue vehicles and vehicles carrying personnel, supplies, and equipment.

Evacuation. An effective disaster plan also specifies evacuation procedures. The plan should indicate how those to be evacuated will be notified, what they can take with them, and how the evacuation will be accomplished. The plan may need to specify several contingency evacuation procedures, depending on the type of disaster.

The disaster response plan also provides for the logistics of evacuation, including the personnel needed to carry out the evacuation, how they are to be recruited and assigned, and how they will be notified. The plan also specifies the forms of transportation to be used during evacuation, where appropriate vehicles can be obtained, and how they will be refueled.

Rescue. The response plan should specify the process to be used to assess rescue needs and who is responsible for carrying out the assessment. Once the assessment is made, procedures should be in place for obtaining the appropriate personnel and equipment. For example, in the event of an earthquake, heavy construction equipment and operators are needed, whereas fire department personnel are needed in a fire-related disaster.

The rescue operation should focus on removing victims from hazardous conditions and providing first aid as needed. **Rescue chains** are the logistical component of emergency health services including plans for moving injured persons to appropriate health care facilities. Rescue personnel should refrain from providing other forms of care as much as possible.

This care can be provided by others, thus freeing rescue personnel to carry out the rescue operation.

Immediate care. Provision of immediate care is another consideration detailed in a disaster response plan. **Immediate care** is health care required on the spot to ensure a disaster victim's survival or a disaster worker's continued ability to function. Plans for providing immediate care in four areas in the vicinity of the disaster site should be detailed in the disaster response plan (Figure 25-5●). Immediate care begins at the actual site of the disaster, with a rapid initial assessment of all victims by the first health care provider on the scene. This phase of immediate care is geared to correcting any life-threatening problems.

The second area of immediate care is the triage area. **Triage** is the process of sorting disaster casualties on the basis of urgency and their potential for survival to determine priorities for treatment, evacuation, and transportation. Triage decisions are intended to maximize the number of survivors of a disaster event without consuming excessive resources (Romig, 2013). When victims are easily accessible, triage can take place at the site of the disaster. Victims are then removed to treatment areas based on their triage priority. In a disaster occurring in an enclosed environment (e.g., in a mine or in a building), victims may not be easily accessible and will probably need to be removed to a more distant triage area as they are found. Triage in the event of exposure to hazardous materials may occur in hot, warm, and cold zones. Hot zones are those immediately adjacent to the exposure area and triage and treatment in this area are minimal. Warm zones are located at least 300 feet from the exposure area; triage here addresses essential stabilization prior to transportation to other area. In the cold zone, victims who have undergone decontamination are retriaged and directed to appropriate treatment areas based on their conditions and prognosis (Romig, 2013).

The triage process usually involves placing color-coded tags on victims. Typically, black tags are attached to victims who are already dead and those for whom death is imminent without heroic measures or extensive resource utilization. Red tags indicate top priority and are attached to victims who have life-threatening injuries but who can be stabilized without undue resource utilization and who have a high probability of survival (Romig, 2013). Priority is automatically given to injured rescue workers, their family members, hysterical persons, and children. Yellow tags, indicating second priority, are assigned to victims who have injuries with systemic complications that are not yet life threatening and who are able to withstand a wait of 45 to 60 minutes for medical attention, but whose condition could deteriorate with significant delay. Green tags indicate victims with local injuries without immediate systemic complications who can wait several hours for treatment without risk of deterioration in their conditions (Romig, 2013).

Triage in an epidemic setting is designed to prevent secondary spread of disease. Those at least risk are persons who have been immunized or are receiving prophylactic medication. Persons who are "removed" are those who are no

FIGURE 25-5 Areas of Operation in Immediate Care

longer considered infectious or who have died. The next level is persons who are infectious, followed by those who have been exposed, but do not yet exhibit symptoms, and finally by persons who are susceptible, but unexposed (Romig, 2013).

The third area of immediate care at the disaster site is the treatment area to which victims are removed after triage. In this area, medical stabilization, temporary care, and emergency surgical stabilization are provided as needed. There may also be a need for psychological first aid at this point. The final area at the site of the disaster is the staging area. It is here that immediate care operations are coordinated and vehicles and personnel are directed to areas of greatest need. The disaster plan should specify the procedures for setting up and operating each of the four areas of immediate care. The plan should also address the supplies, equipment, and personnel needed in each area, how they will be obtained, and how they will be transported to the area.

Another aspect of immediate care that should be addressed in the disaster plan is care of the dead. Plans should be included for procedures to identify bodies and transport them to a morgue of some sort. Records of deaths should be kept, and procedures for rapid disposal of bodies should be specified should contagion be a problem. Plans should also include where and how body bags and identification tags will be obtained.

Plans should be made for casualty distribution and transport of persons with specific types of health problems to specific facilities (Veenema & Woolsey, 2013). Casualty distribution

plans prevent overloading health care facilities closest to the disaster, and may be based on the specific capabilities of certain health care facilities. For example, victims with severe burns may be sent directly to a facility with a burn unit, whereas physical trauma patients may be taken to other facilities.

Supportive care. Supportive care is another component of an effective disaster response plan. Supportive care includes providing food, water, and shelter for victims and disaster relief workers. Other considerations in this area are sanitation and waste disposal, providing medications and routine health care, and reuniting families separated by the disaster.

Shelter is required for those who are evacuated from their homes or whose homes are damaged in the disaster. The disaster response plan should specify which community buildings can be used to shelter victims and how victims are to be transported to shelters. There may also be a need to use the homes of private citizens to shelter victims if public shelters are insufficient. When such is the case, the plan should specify how to notify concerned citizens of the need to place victims in their homes and how placement is to be handled. It is helpful to have a list of people willing to provide shelter to others should a disaster occur. In the case of large groups of displaced persons, refugee camps may be set up. Potential camp sites should be carefully selected in relation to possible physical hazards or water runoff.

Within the shelter, there is a need for supplies to sustain daily living (Chandra et al., 2011). Shelters should have adequate sanitation and sleeping facilities. There should be plans

for heating shelters and cooking food if area gas and electrical power systems are disrupted. Shelters should also meet accessibility standards for disabled individuals and provide separate space, if possible, for families with children or persons with dementia. Additional considerations include privacy for breastfeeding women, durable medical equipment (e.g., wheelchairs, walkers) for those in need, auxiliary power supplies for persons on oxygen or respirators, and private examination and counseling areas (Davis et al., 2013). Mechanisms should also be specified for governance and security within the shelter, particularly if the shelter will be in use for some time. Shelter leaders can be appointed or elected, and persons within the shelter should have a means of providing input into governance in long-term shelter situations.

Food supplies should be planned and obtained prior to a disaster. There should also be a mechanism for obtaining more food and other supplies from outside the community in the event of damage to stores and stockpiled supplies. A source of clean water is needed, and the disaster plan should identify how and where water will be supplied. Equipment and supplies for water purification should be stored in case of need. Considerations that need to be addressed in planning to feed large groups, in addition to the availability of food supplies, include toilet and hand- and dishwashing facilities, waste storage and removal (both liquid and solid), cooking and refrigeration facilities, serving dishes and utensils, and food preparation personnel and equipment. Rodent control and food safety information for preparers are other elements of this part of the disaster response plan (Landesman, 2011).

Victims may have other health care needs unrelated to the disaster that need to be met, so plans for providing basic health care in shelters should also be specified. These plans should include stores of medications most likely to be needed by the general public and critical to survival. For example, diabetics will continue to need insulin or oral hypoglycemics, whereas individuals with heart conditions may need a variety of medications. Priority should be given to medications required for serious illnesses rather than for minor conditions. Because communicable diseases spread more rapidly in a debilitated population following a disaster, antibiotics and vaccines should be stored in case of need.

Actions to meet population health needs after a disaster are dependent on identification of those needs. Such identification can occur through early warning systems or syndromic surveillance. **Early warning systems** are planned surveillance systems designed to alert health care personnel of potential large-scale health problems resulting from a disaster. For example, an effective early warning system would identify early cases of communicable disease in a refugee camp, permitting immunization or other control measures to prevent an epidemic. Local surveillance for cases of anthrax or smallpox is another example of an early warning system. The success of early warning systems is dependent on timely reporting and investigation of case reports of specific conditions, pattern recognition, and monitoring of new types of data that can suggest disease outbreaks

(Sabatinelli et al., 2012). As we saw earlier, WHO (2011) has developed guidelines for effective early warning systems.

Syndromic surveillance is a special form of early warning system in which data are collected regarding specific clusters of symptoms or syndromes from a variety of sources (WHO, 2011). Surveillance activities in the case of chemical releases or nuclear attacks may include environmental sampling as well as evidence of disease.

Specific screening activities may also be needed in a postdisaster situation. For example, TB screening may be warranted in extended shelter situations such as refugee camps. Similarly, screening for scabies or other infestations might be needed when outbreaks occur in sheltered populations. Screening may also be undertaken to identify people with mental health problems arising from the disaster.

Health care providers may need to be educated to recognize covert releases of biological or chemical agents. Covert releases are often difficult to recognize because initial symptoms of exposure might be mild or nonexistent or might be similar to those of other conditions. In addition, health care providers may not be familiar with symptoms of diseases or chemical exposures that are not often seen in their practice. Finally, cases of diseases may occur over a long period of time in various locations, making it difficult to identify any particular patterns. Epidemiologic cues that suggest covert chemical releases include an increase in the number of people presenting specific symptoms, unexplained deaths in healthy young people, clients emitting unusual odors, and clusters of illness in people that display common characteristics. Other potential signs of covert release include rapid onset of symptoms following exposure to potentially contaminated media (e.g., food or water supplies), unexplained wildlife deaths, and symptoms suggestive of syndromes associated with chemical exposures.

Resolving existing health problems in a disaster situation will also include treatment for conditions identified. As noted earlier, antidotes for potential chemical and radiological agents should be readily available and providers should know how to administer them. Treatments for chemical exposures should be based on syndrome categories (e.g., respiratory effects) rather than on specific agents to minimize time spent in identifying specific agents. Appropriate treatment should also be provided for diseases caused by biological agents as well as for existing illness in the population affected by the disaster (e.g., hypertension, diabetes, HIV/AIDS, TB).

Supportive care also includes psychological counseling for those who are not coping adequately with the situation. Counseling may be required by both victims and disaster workers, and plans should be made to provide crisis intervention services during the response stage of the disaster. General principles of psychological disaster response include the following:

- Interventions generally need to be taken to survivors who will often not seek help on their own.
- Survivors and bereaved members of the affected population are sensitive to perceived voyeurism so assessment for mental health problems should not be intrusive.

- Children should not be separated from family members unless unavoidable.
- Exposure of survivors and helpers to dead and mutilated bodies should be minimized as much as possible.
- Those affected should be given accurate and truthful information.
- Victims' privacy should be protected and exposure to the media limited.
- Use naturally occurring support systems whenever possible.
- Avoid medicalizing reactions and assure victims of the normalcy of their responses.
- Minimize retraumatization of victims (e.g., through interviews with police) and do not force them to recount details of their experiences.
- Do not mandate psychological debriefing of rescue workers, but provide assistance as needed. (Meeker, Plum, & Veenema, 2013)

Interventions for psychological effects include reducing distress and providing for immediate needs, promoting adaptive functioning, crisis intervention as needed, social support, psychological triage, referral for mental health services if needed, and attention to the needs of disaster workers as well as victims and survivors (Meeker et al., 2013).

Elements of psychological intervention that should be incorporated into disaster response planning include mental health triage, emergency psychological first aid and crisis intervention, provisions for meeting physical health needs, and establishment of a calm, stable environment that provides a sense of safety and protection. Disaster victims may require goal orientation and guidance, and they can be directed to perform specific tasks that help them achieve a sense of control. Support is needed for those who must identify loved ones among the dead. Expression of feelings should be fostered, and victims should be encouraged to make use of available support networks. Immediate referral to mental health personnel may be required in some instances. Structuring the environment and regularizing schedules, particularly in shelters, can also help to reestablish a sense of security.

Some relief from psychological stress can frequently be obtained if victims can be assured that family members are safe. Disaster plans should therefore include mechanisms for locating people and reuniting families. Names of persons admitted to shelters or health care facilities should be recorded and communicated to a central location where others can check for word of loved ones. Deaths should also be reported if the dead can be identified, and information should be kept on the assignment of disaster workers to specific areas. It is helpful if institutions, such as schools and businesses, compile the names of those who were present prior to a disaster so that they can be accounted for afterward.

Aside from advocacy for and participation in the development of disaster response plans, population health nursing involvement in resolution of existing problems in disaster response lies primarily in the areas of immediate care

and supportive care. Population health nurses may be involved in triage activities and immediate first aid for disaster victims or rescue workers. Population health nurses may also be responsible for shelter supervision and action to meet the supportive care needs of the population after a disaster. They will most likely be involved in assessing health care needs in shelters and addressing those needs directly or making referrals to needed physical and psychological health services. Population health nurses can also advocate for participation in shelter governance by those housed there and help to address areas of conflict among shelter residents.

Population health nurses will also be involved in surveillance activities, and, because of their interactions with disaster victims, may be among the first to recognize signs of disease outbreaks. They may also identify symptoms in the general population suggestive of covert biological or chemical terrorism. If specific screening activities are warranted in shelter situations, population health nurses will probably be involved in developing and implementing screening programs. Finally, population health nurses may be involved in educating the public and other health care providers regarding recognition and treatment of health conditions related to the disaster. Areas of emphasis and related population health nursing strategies to resolve health problems in disaster situations are presented in Table 25-8•.

HEALTH RESTORATION: RECOVERY. Health restoration is referred to as recovery in a disaster context. Recovery has two major goals. The first is recovery of the community and its members from the effects of the disaster and return to normal. The second aspect of recovery is preventing a recurrence of the disaster. Recovery issues include physical rebuilding, restoration of livelihoods, provision of permanent shelter, and coordination of humanitarian aid. One other issue has been referred to as “disaster diplomacy” or sensitivity to the needs of victims and efforts to empower them and reduce dependence on external sources of assistance (Veenema, 2013). During the recovery period, there may be a need to reestablish medical care and other services in the community.

Population health nurses have responsibilities in both community recovery and prevention of subsequent disasters. Nurses may be called on to provide sustained care to both victims and disaster workers following the disaster. They may also be involved in identifying health and psychosocial problems that require further assistance. Population health nurses should plan to provide counseling or referral for persons with psychological problems stemming from their experiences during the disaster. There may also be a need to refer disaster victims to continuing sources of medical care. Population health nurses may also need to plan referrals for clients in need of social and financial assistance. For example, disaster victims may require help in finding housing or in getting financial aid to rebuild homes or businesses.

Population health nurses may also provide input into interventions designed to prevent future disasters or to minimize

TABLE 25-8 Foci and Strategies for Resolving Health Problems in Disaster Settings

Focus	Strategies
Immediate care	<p>Triage</p> <ul style="list-style-type: none"> • Assess disaster victims for extent of injuries/illness • Determine priority for treatment, evacuation, and transportation • Place appropriate colored tag on victim depending on priority <p>Treatment of injuries</p> <ul style="list-style-type: none"> • Render first aid for injuries • Provide additional treatment
Supportive care	<p>Shelter supervision</p> <ul style="list-style-type: none"> • Coordinate activities of shelter workers • Oversee records of those admitted and discharged from shelters • Promote effective interpersonal and group interactions among shelter residents • Promote independence and involvement of those housed in the shelter <p>Surveillance and screening</p> <ul style="list-style-type: none"> • Participate in specific surveillance activities • Recognize evidence of disaster-related health effects • Recognize other health needs in the disaster population • Implement screening activities as needed • Educate health care providers and others regarding recognition and treatment of disaster-related health effects <p>Treatment</p> <ul style="list-style-type: none"> • Provide treatment as needed for disease and injury under medically approved protocols • Refer for additional medical or psychological treatment as needed

their effects. For example, if the disaster involved rioting by members of oppressed groups, the population health nurse might advocate measures to meet the needs of minority group members to prevent further rioting; or the nurse might campaign for stronger building codes to prevent the collapse of buildings in subsequent earthquakes. Population health nurses can also help to educate the public on disaster preparedness to minimize the effects of subsequent disasters. A particular challenge following disasters resulting from terrorist activities involves protection of civil liberties while promoting national

security. Health restoration/recovery foci in disaster settings and related population health nursing strategies are summarized in Table 25-9.

Implementing Disaster Care

Prior to the occurrence of a disaster, the population health nurse may be involved in activities preliminary to implementing a disaster plan, particularly in disseminating the plan to others. Dissemination needs to occur among persons and agencies that will have designated responsibilities

TABLE 25-9 Restoration/Recovery Foci and Related Strategies in Disaster Care

Focus	Strategies
Follow-up care for injuries and illnesses	<ul style="list-style-type: none"> • Monitor response to treatment • Provide continued care for people injured as a result of the disaster or during rescue operations • Provide rehabilitative care for injury or illness or make referrals for care as needed • Monitor disaster effects on existing chronic health problems and refer for assistance as needed
Follow-up care for psychological problems resulting from the disaster	<ul style="list-style-type: none"> • Provide counseling for those with psychological problems resulting from the disaster • Refer clients for counseling as needed • Monitor progress in resolving psychological problems
Recovery assistance	<ul style="list-style-type: none"> • Refer clients for financial assistance • Provide assistance in finding housing, employment, etc.
Prevention of future disasters and their consequences	<ul style="list-style-type: none"> • Advocate measures to prevent future disasters • Educate the public about disaster preparation to minimize the effects of subsequent disasters • Advocate for protection of civil liberties while promoting national security

during a disaster. Population health nurses participating in disaster planning are responsible for communicating elements of the plan to members of their employing agency. They may also ensure that the plan is disseminated to nursing organizations in the area (e.g., to members of a district nurses' association). The nurse who assumes this responsibility should be sure that the general plan, as well as the specific part to be played by members of the agency or organization, is understood.

The essential features of the community's disaster response plan should also be communicated to the general public so residents will be prepared to follow the plan in the event of a disaster. The population health nurse may be involved in helping to communicate the plan to the public by apprising clients with whom he or she works of relevant aspects of the plan. Population health nurses may also involve community advocacy groups in disseminating information to particularly vulnerable populations, such as members of ethnic minority groups, or recipients of home health care (Chandra et al., 2011). The public should be alerted to mechanisms that will be used to inform them of a disaster and where to go for additional information. Community members should also know the general procedures to be followed in terms of caring for disaster victims and setting up shelters. They should also be informed of the locations of proposed shelters. Finally, community members should be told of specific disaster preparations that should be undertaken by individuals and families.

When a disaster occurs, population health nurses will be actively involved in implementing the disaster plan. Some of the activities involved in implementation were discussed earlier in the section on resolving health problems in a disaster setting or in promoting recovery.

Evaluating Disaster Preparedness and Response

The final responsibility of population health nurses with respect to disaster care is evaluating that care. Nurses and others

involved in the disaster participate in evaluative activities outlined in the disaster plan. Evaluation focuses on the adequacy of the plan for curtailing the disaster and meeting the needs of those affected by it.

In this effort, it may be helpful to examine the disaster response in light of the six determinants of health. Did the plan adequately provide for the needs of the people affected and the kinds of health problems that resulted? Did environmental, psychological, or sociocultural determinants impede implementation of the plan or limit its effectiveness? What influence did behavioral factors have on plan implementation, if any? Were health care services adequate to meet the health needs posed by the disaster itself as well as those encountered in the period after the disaster? Data obtained in the evaluative process are used to assess the adequacy of the community disaster plan and to guide revisions of the plan to better deal with future disasters.

The effectiveness of care provided to individual disaster victims should also be assessed. Evaluation in this area focuses on the degree to which individual needs were met and the extent to which problems resulting from the disaster were resolved.

The Sphere Project's (2011) *Humanitarian Charter and Minimum Standards in Disaster Response* provides a set of guidelines that may be used to evaluate the effectiveness of disaster response planning. The Sphere Project (2011), a group of humanitarian non-governmental agencies and Red Cross and Red Crescent Societies, has developed a handbook to address international disaster response. The handbook incorporates basic principles of protection, six core standards, and related actions and key indicators that can be used to evaluate the effectiveness of disaster response. Guidance notes and points to consider in applying the standards are also included. A description of the Sphere Project standards and related considerations are included in the *Global Perspectives* feature on the next page. For further information about the standards, see the *External Resources* section of the student resources site. Population health nurses would participate in using the standards to evaluate the response to a particular disaster. In addition,

Evidence-Based Practice

Community Involvement in Generating Evidence

Svensden et al. (2010) have noted that epidemiologic research following disasters has often been imposed from outside researchers and government agencies. This often leads to resentment among community members who are trying to rebuild lives shattered by disaster and its short- and long-term effects. The authors proposed that a community-based participatory research (CBPR) strategy be used to address questions of particular interest to those affected by the disaster to enable them to better prepare for future disaster events. They noted that some of the

earliest CBPR research, although not given that label, occurred many years after the bombings of Hiroshima and Nagasaki, after health and reconstruction needs of the population had been addressed and trust in U.S. officials, including researchers, had been established. They emphasized the vulnerable status of those affected by disasters and stressed the need for special care to "address the immediate health needs of the community first, rather than the pressing needs to answer important scientific questions" (p. 77).

Global Perspectives

The Sphere Project

The Sphere Project was established in 1997 by several non-governmental disaster relief organizations as a way to monitor and improve their performance in disaster response throughout the world. The result was the development of a handbook incorporating a set of minimum standards for humanitarian response to disaster based on three core beliefs: (a) that people affected by disasters have a right to lives with dignity, (b) that they have a right to humanitarian assistance, and (c) that they have a right to protection and security. In keeping with these principles, actions taken by humanitarian organizations should incorporate consultation with and accountability to those affected.

These beliefs are reflected in four protection principles that include:

- Avoid causing further harm in the course of providing assistance
- Ensure access to impartial assistance
- Protect people from physical or psychological harm due to violence or coercion
- Assist people with rights claims, access to remedies, and recovery from abuse

The handbook includes core standards in six key areas, as well as key actions to achieve the standard, indicators of accomplishment, and guidance notes on addressing practical difficulties. The key areas addressed include the following:

- *People-centered humanitarian response*: Focuses on widespread inclusion of those affected in decision making and evaluation related to assistance activities, support for local capacity, use of local labor and self-help initiatives when possible, cultural sensitivity, and provision of avenues for airing grievances.
- *Coordination and collaboration*: Addresses collaboration and coordination with governmental and other non-governmental organizations in the provision of assistance, intersectoral collaboration of activities (e.g., health-related and development

activities), sharing of knowledge and progress information, strengthening overall advocacy among organizations to deal with shared concerns, and development of policies for interaction with non-humanitarian organizations (e.g., business or industrial concerns).

- *Assessment*: Addresses participation in interorganizational assessment, use of predisaster capacity data, rapid assessment of needs, consideration of a wide variety of perspectives in assessment (particularly vulnerable populations), systematic collection of data, assessment of capacity of in-country systems and those affected, assessment of psychosocial as well as other aspects of well-being, and sharing of assessment information.
- *Design and response*: Focuses on development of programs based on needs and capacity of those affected, filling gaps between local capacity and need; prioritization of urgent needs; addressing the needs of vulnerable populations; providing equitable access to assistance; minimizing negative effects of assistance (e.g., undermining local economies); promoting risk reduction and resilience to future disasters; modifying programs to maintain relevance and appropriateness; and planning exit strategies.
- *Performance, transparency, and learning*: Focuses on continual monitoring of agency performance and effectiveness, adapting programs based on monitoring data, conducting final effectiveness evaluation and sharing results, and participating in collaborative learning to inform future disaster responses.
- *Aid worker performance*: Addresses the adequacy of leadership and management training of supervisors, appropriate worker recruitment and orientation, providing for the physical and psychological needs of workers, promoting respectful interactions between workers and recipients of services, monitoring worker performance, developing worker safety, health, security, and evacuation guidelines, investigating and addressing complaints about worker performance.

population health nurses would advocate for the evaluation of disaster services from the perspective of service recipients. One further consideration in disaster evaluation is the cost of the disaster response and mechanisms to decrease the cost of future responses while maintaining quality of services to those affected (Landesman, 2011).

Healthy People 2020 also addresses four national objectives that can be used to evaluate some aspects of disaster preparation. Some of these objectives are developmental in nature, so

there are as yet no data related to the achievement of most of them. Data are available for objectives PREP-3.2 dealing with the ability of Laboratory Response Network (LRN) chemical laboratories to meet professional competencies. Unfortunately, the objective is moving away from the 95% target, declining from 92% of laboratories in 2008 to 91% in 2011 (U.S. Department of Health and Human Services [USDHHS], 2014). The preparedness objectives may be viewed on the *Healthy People 2020* website.

CHAPTER RECAP

Although disasters occur infrequently in population health practice, population health nurses should be prepared to respond effectively when they do occur. They should also be instrumental in assuring that individual clients and families, as well as communities, are prepared to respond effectively in the event of a disaster. Preparation for a disaster event includes assessment of disaster potential as well as the effects of a disaster from the perspective of the six categories of determinants of health. Activities at each level of health care are relevant

to disaster nursing. For example, basic health promotion and promotion of community resilience can help to mitigate the effects of disasters and promote recovery after a disaster. Prevention focuses on prevention of disaster events and prevention or mitigation of their effects. Resolution of health problems resulting from a disaster are based on the type of disaster involved, but should be addressed by the basic elements of a community disaster plan. Finally, population health nurses also have a role in health restoration or recovery after a disaster.

CASE STUDY Nursing in a Disaster Setting

Two commuter trains have collided in a tunnel at rush hour. Both trains derailed and one of them struck the side of the tunnel, causing it to collapse on two of the derailed cars. There were approximately 300 passengers on the two trains, and 50 or more people are trapped in the two buried cars. The accident occurred approximately one quarter mile from the west end of the tunnel and two miles from the east end. The largest portions of both trains lie on the west side of the collapsed portion of the tunnel.

One of the passengers is a population health nurse. The nurse was not injured in the accident and was able to get out of

the wreckage to the west end of the tunnel, where most of the survivors are gathered.

1. What are the biological, psychological, environmental, sociocultural, behavioral, and health system determinants that may influence this disaster situation?
2. What role functions might the population health nurse carry out in this situation?
3. What health promotion, prevention, resolution, and restoration activities might be appropriate in this situation? Why?

Population Health Issues

Chapters

- 26** — Communicable Diseases
- 27** — Chronic Physical Health Problems
- 28** — Mental Health and Mental Illness
- 29** — Substance Abuse
- 30** — Societal Violence

26 Communicable Diseases

Learning Outcomes

After reading this chapter, you should be able to:

1. Analyze major trends in the incidence of communicable diseases.
2. Identify the modes of transmission for common communicable diseases.
3. Describe the influence of biological, psychological, environmental, sociocultural, behavioral, and health system determinants on communicable disease incidence and prevalence.
4. Analyze the role of population health nurses in controlling communicable diseases as it interfaces with those of other health professionals.
5. Provide examples of health promotion strategies that minimize communicable disease incidence.
6. Describe major considerations in prevention of communicable diseases.
7. Discuss population health nursing strategies for resolving health problems related to communicable diseases.
8. Identify health restoration strategies related to communicable diseases and possible population health nursing roles in each.

Key Terms

anergy	expedited partner therapy (EPT)	outbreak
chain of infection	extinction	preexposure prophylaxis (PrEP)
co-infection	immunity	prodromal period
communicable diseases	incubation period	quarantine
contact investigation and notification	induration	reservoir
control	infectious diseases	selective screening
cross-immunity	isolation	social distancing
directly observed therapy (DOT)	mass screening	superinfection
endemic disease	nosocomial infection	vector
epidemic	opportunistic infections (OIs)	vehicle

Sled Dogs and Communicable Disease

In the winter of 1925, Nome, Alaska, experienced a diphtheria epidemic that threatened the entire population of the region. Lacking a supply of diphtheria antitoxin, the local physician sent dozens of telegrams requesting help. The closest large supply of antitoxin was more than 600 miles away in Anchorage. Sea ice around Nome prevented sea delivery of the antitoxin; there were no roads or rail lines and air service was unavailable. Mail delivery was by sled dogs and “mushers” (sled dog drivers). Traveling day and night over rugged terrain, through blizzards and in temperatures of 50 degrees below zero, 20 teams of mushers and 150 dogs made the trip over the Iditarod Trail in 5 days and 7 hours to deliver the needed supplies in a third to a quarter of the usual time (Centers for Disease Control and Prevention [CDC], 2013b).

This heroic feat required the cooperation of hundreds of people from across the nation. It captured the attention of the media and the general public and became a significant motivator for the use of diphtheria vaccine. The event is commemorated each year by the Iditarod Trail Sled Dog Race (CDC, 2013b).

One Little Candle

In 1952, Perry Como sang “One Little Candle” extolling the virtues of bearing light rather than stumbling in the dark. Sometimes when we reflect on the chapters of our lives, a song heard from the distant past makes more sense than when it was a pop tune on the radio.

In 1997, my son Jeremy worked at an internationally staffed YMCA Camp in the mountains of southern California, with counselors from all over the world—Holland, Germany, even Tanzania, East Africa. Those from far flung regions weren’t able to go home for weekends, so Jeremy invited Frank Manase, a counselor from Tanzania, to our house for the weekend.

Frankie nearly fell over when I called out a Swahili greeting: “Jambo, habari!” I only know a few Swahili words, learned when I spent part of a summer in a Seventh-Day Adventist mission compound in Kenya, Kendu Bay, at age 15. Frank’s musical laughter, gratitude, and loving heart made him an easy addition to our family. His skills in tracking animals, illustrating the mysteries of nature to the children at the camp, made him such a valued counselor that the YMCA extended his visa for a year. In that role, he continued to inspire children, not only with the beauties of nature, but with the goodness of getting along, working as a team, and enjoying the outdoors. At the end of the year, he had made so many friends and learned to love America so much that he wondered about the possibilities of staying and studying in the United States.

However, he had a place in medical school back in Tanzania, a rare privilege and a secure opportunity. After thinking it through I said, “Frankie, some people are tempted by drugs, some are tempted by alcohol, and some are tempted to stay in America. Your people need you.” So Frank went back to Tanzania. On a 2001 visit to meet our Tanzanian family and lecture at the university there, he laughingly introduced me as “my American mom, who made me come back to Africa!”

Five years later, as a new physician, Dr. Frank Manase was given the opportunity to study hospice and palliative care through the international scholars program at San Diego Hospice. He then received a scholarship from the International Hospice & Palliative Care Association to study for his Master’s degree in Hospice and Palliative Care in South Africa. His work at Pastoral Activities and Services for people with AIDS Dar es Salaam Archdiocese (PASADA) enabled him, as medical director, to implement radical models of care that were family-centered and included the use of volunteers to facilitate care of patients. PASADA serves approximately 40,000 patients, 11,000 of

whom are children. Some of the highest risk children who have lost everything—family, property, their health—are also given the opportunity to participate in a year-long art or music/drama therapy program where they are able to express their grief as well as their resilience and joy through art and song. In a country where the typical antiretroviral (ARV) drug adherence rate is 30–40%, PASADA's personal approach to caring for patients and families has dramatically increased adherence to ARVs to 89%, thereby promoting both length and quality of life for their patients.

Recently, 14 years after our relationship began, 10 years after my last visit to Tanzania, I was able to visit and witness Frank's accomplishments. I asked him if, in 1998, I had given the right advice to go home, become a doctor, and help his people. His answer: "so much, Mom, so much." As we stood with a gathering of HIV-infected children served through PASADA, the family-centered care staff lighting candles and remembering those affected by HIV/AIDS around the world, the power of light through God working in his people who are everywhere in this world burned brightly in my heart.

The following is a song written by the PASADA children's choir that symbolizes their need for care and understanding.

WE ARE FULL ORPHANED, WE ARE LEFT ALONE

Due to loss of both of our parents as a result of HIV and AIDS, we are left depressed with many of life's uncertainties.

We do feel lonely. Some of us are living with relatives, good Samaritans, or family friends. As orphans, we have encountered a lot of practical life difficulties. These include: stigma and discrimination, lack of education, inadequate availability of food and shelter, lack of involvement in issues that touch our lives and legal limitations. It was not our choice to be orphaned, please listen to our cry.

Our message to the Tanzanians and the whole world is as follows:

There are so many orphaned children who live in the most risky environment here in Tanzania and over the world. Being a Tanzanian community member, you have valuable contribution to offer to this vulnerable group of people.

Many children wish to get a reasonable education and medical care but it has not been possible for them. Dear uncle, father, mother, brother and sisters, government and non-government sector and all citizens, it is your turn to participate and provide support to these children so that they get education and quality medical care. By doing so, you will enable children to celebrate their childhood just like many other children.

Many children have experienced relatives taking their family belongings by force encountering many legal barriers when they try to recover. Many children are considered young and therefore less responsible. Our message to the community is, despite our young age, we strongly believe we have legal rights of owning our late parents' belongings. Will you please listen and attend to our expressed needs.

It was not our choice to be orphaned.

(Written by the PASADA children's choir—Simba wa Afrika Group—used with permission). Gail Reiner, DNP, RN

Human beings have been subject to illnesses caused by pathogenic microorganisms throughout history. For example, testing of mummies has provided evidence of tuberculosis (TB) in a mother and child who lived 9,000 years ago, and the earliest evidence of disease caused by the malaria parasite dates from 3,500 years ago. Similarly, smallpox DNA has been recovered from a 300-year-old frozen mummy from Siberia, and similar findings indicate that up to 80% of the population of medieval Britain may have suffered from sinusitis exacerbated by air pollution from local industries such as brewing, tanning, and lime burning (Williams, 2013).

Although these and other illnesses can be considered infectious illnesses, not all of them are communicable diseases. **Infectious diseases** are those illnesses that result

from the growth of pathogenic microorganisms in the body.

Communicable diseases, on the other hand, are diseases caused by pathogens that are transmitted directly or indirectly from one person to another. Bacterial otitis media and wound infections are infectious diseases. Measles, hepatitis A, and HIV infection are examples of diseases that can be transmitted from one person to another and are communicable diseases.

Historical events and human migrations have led to the spread of communicable diseases. For example, smallpox is thought to have originated in Africa and was possibly brought to Europe by Arab invaders. Similarly, there is no evidence that diseases such as measles and smallpox existed in the Western Hemisphere until after the advent of Europeans. Both Aztec and Incan rulers died of smallpox in the 1500s after the arrival of

Spanish conquistadors (Smallpox History, 2011). Conversely, travel from the new world may have been responsible for the introduction of syphilis in Europe (Syphilis, 1494–1923, n.d.). Changes characteristic of syphilis have been identified in bones found in the area of the Dominican Republic where Columbus first landed. No similar changes have been identified in pre-Columbian Europe, supporting the theory of transfer from the New World to the Old (Rothschild, 2005). Similarly, it is believed that tuberculosis originated in East Africa and spread to Europe and Asia, and from Asia to the Americas prior to the arrival of the first European explorers (McDaniel, 2006).

In the last century-and-a-half, immunization has enabled control of a number of communicable diseases. Incidence of vaccine-preventable diseases has decreased significantly from peak incidence rates prior to vaccine availability. However, periodic outbreaks continue to occur, and new diseases continue to emerge to challenge human ingenuity. In spite of the remarkable decline in mortality due to communicable diseases in the United States and other developed nations, these conditions continue to exact a toll in worldwide suffering, death, and economic costs.

General Concepts Related to Communicable Diseases

Several communicable disease concepts must be understood before control efforts can be undertaken. These include concepts related to the “chain of infection,” such as modes of transmission and portals of entry and exit, and the concepts of incubation and prodromal periods.

Chain of Infection

In communicable diseases, epidemiologic factors related to biological, psychological, environmental, sociocultural, behavioral, and health system determinants create what is often called a chain of infection. A **chain of infection** is a series of events or conditions that lead to the development of a particular communicable disease. The “links” in the chain are the infected person or source of the infectious agent, the reservoir, the agent itself, the mode of transmission of the disease, the agent’s portals of entry and exit, and a susceptible new host. The concepts of agent and host were introduced in Chapter 3. This discussion focuses on the remaining links in the chain: reservoirs, modes of transmission, and portals of entry and exit.

Modes of Transmission

The mode of transmission of a particular disease is the means by which the infectious agent that causes the disease is transferred from an infected person or animal to an uninfected one. Infected people or animals are one type of reservoir, but there are other reservoirs that do not have the infection or disease. A **reservoir** is an animal, person, plant, soil, or substance where an infectious microorganism lives and from which it is transmitted to a susceptible host (CDC, 2012b). People are the reservoir for illnesses like measles or varicella (chickenpox) that can be spread directly from one

person to another. Animals may also serve as reservoirs or sources of infection for human beings. For example, infected animals, like dogs, bats, raccoons, and so on, are reservoirs for rabies. In some instances, inanimate objects serve as reservoirs. For instance, soil is a reservoir for tetanus bacilli.

Communicable diseases may be spread to a susceptible new host by any of several modes of transmission: airborne transmission, fecal–oral (gastrointestinal) transmission, direct contact, sexual contact, direct inoculation, insect or animal bite, or via inanimate objects or soil. Two general mechanisms for transmission of infectious agents are direct and indirect transmission. In direct transmission, the microorganism passes directly from one person to another. In indirect transmission, the microorganism is transmitted by a living or nonliving entity. Contaminated food would be a nonliving means of indirect transmission of a disease-causing microorganism, also called a **vehicle**. A living means of indirect transmission of diseases, or **vector**, might be a mosquito that transmits West Nile virus (CDC, 2012b). The mosquito does not have the disease, but merely transmits it from one person that it bites to another.

AIRBORNE TRANSMISSION. Airborne transmission occurs when the infectious organism is present in the air and is inspired (inhaled) by a susceptible host during respiration. Diseases transmitted by the airborne route include the exanthems (diseases characterized by a rash, such as measles and chickenpox), infections of the mouth and throat (such as streptococcal infections), and infections of the upper and lower respiratory system (such as tuberculosis, pneumonia, influenza, and the common cold). Certain systemic infections are also products of airborne transmission. Examples of these are meningococcal meningitis and pneumococcal pneumonias, hantavirus pulmonary infections, coccidioidomycosis, anthrax, and smallpox. In the case of anthrax and smallpox, disease may also be transmitted by aerosolized dissemination of microorganisms.

FECAL–ORAL TRANSMISSION. Fecal–oral transmission of an infectious agent may be either direct or indirect. Direct transmission occurs when the hands or other objects (fomites) are contaminated with organisms from human feces and then put into the mouth. Indirect transmission occurs via contaminated food or water. For example, a person with hepatitis A may defecate, fail to wash his or her hands properly, and then prepare a sandwich for someone else. The second person would ingest the virus with the sandwich and, if susceptible, might develop hepatitis A. Additional examples include *Salmonella*- or *Shigella*-caused diarrheas. Botulism is another disease in which the causative organism is ingested with contaminated food or water. Contamination usually occurs by accident through inadequate canning and preserving processes, but could potentially occur as a result of bioterrorist activity. Ingestion of anthrax may also result from the intentional introduction of spores into food supplies.

DIRECT CONTACT. Direct contact transmission involves skin-to-skin contact or direct contact with mucous membrane discharges between the infected person and another person.

Diseases typically spread by this route include infectious mononucleosis, impetigo, scabies, and lice. Smallpox may also be transmitted by contact with the lesions of infected persons. Scabies, lice, and other parasitic diseases also may be transmitted through contact with clothing and other items containing the eggs of the parasites. Similarly, the cutaneous form of anthrax is transmitted by handling contaminated objects (CDC, 2013a).

SEXUAL TRANSMISSION. Transmission of diseases via sexual contact is a special instance of direct contact transmission. Diseases spread by this mode of transmission are usually referred to as sexually transmitted infections (STIs) or sexually transmitted diseases (STDs). Diseases spread during sexual intercourse include (but are not limited to) HIV/AIDS, gonorrhea, syphilis, genital herpes, and hepatitis B, C, and D. These diseases may also be spread by other modes of transmission. For example, hepatitis B, C, and D and AIDS may be spread by direct inoculation.

TRANSMISSION BY DIRECT INOCULATION. Direct inoculation occurs when the infectious agent (a bloodborne pathogen) is introduced directly into the bloodstream of the new host. Direct inoculation can occur transplacentally from an infected mother to a fetus, via transfusion with infected blood or blood products, through the use of contaminated hypodermic equipment, or through a splash of contaminated body fluid to mucous membrane or nonintact skin. With the advent of several screening tests for blood donors, transmission via transfusion has been significantly decreased. Health care workers are particularly at risk for several communicable diseases caused by bloodborne pathogens. Diseases commonly spread by direct inoculation include HIV/AIDS and hepatitis B, C, and D.

TRANSMISSION BY INSECT OR ANIMAL BITE. Insect and animal bites can also transmit infectious agents. For example, the bite of the *Anopheles* mosquito is the mode of transmission for malaria, a disease that is widespread in much of the world. West Nile virus infection is another disease that

is primarily transmitted by mosquitoes (Kelly et al., 2013). Rabies frequently is transmitted via a bite from infected, warm-blooded animals such as dogs, skunks, and raccoons. Incidence of diseases such as rabies is low in the United States, due to widespread immunization of pets. Approximately 90% of rabies cases occur as a result of the bite of a wild animal (Kellogg et al., 2013). Rabies can also be transmitted from one person to another, however, placing family contacts and health care personnel caring for someone with rabies at risk for infection. Lyme disease and Rocky Mountain spotted fever are transmitted by the bite of infected ticks, and plague can be transmitted by fleas on infected rodents. Human encroachment into wildlife areas is increasing the potential for exposure to diseases caused by insect and animal bites.

TRANSMISSION BY OTHER MEANS. Some communicable diseases are transmitted through contact with spores present in the soil or with inanimate objects. For example, exposure to the bacillus that causes tetanus frequently occurs through a dirty puncture wound. Modes of transmission and typical diseases most often transmitted by each mode are summarized in Table 26-1 •.

Portals of Entry and Exit

Communicable diseases also differ in terms of the portals through which the infectious agent that causes the disease enters and leaves an infected host. Portals of entry include the respiratory system, the gastrointestinal tract, and the skin and mucous membranes.

Portals of exit also differ among communicable diseases. Infectious agents may leave an infected host through the respiratory system or through feces passed from the gastrointestinal tract. Blood and other body fluids such as semen, vaginal secretions, and saliva are the portals of exit for infectious agents causing diseases such as HIV/AIDS, gonorrhea, and hepatitis B. The skin acts as a portal of exit as well as a portal of entry for conditions such as impetigo, cutaneous anthrax, and syphilis. Portals of entry and exit and related modes of disease transmission are summarized in Table 26-2 •.

TABLE 26-1 Modes of Disease Transmission and Typical Diseases

Mode of Transmission	Diseases Transmitted
Airborne	Measles, mumps, rubella, poliomyelitis, <i>Haemophilus influenzae</i> type B (HiB) infection, tuberculosis, influenza, scarlet fever, diphtheria, pertussis, hantavirus, respiratory anthrax, coccidioidomycosis, smallpox, plague (pneumonic form)
Fecal–oral/ingestion	Hepatitis A and E, salmonellosis, shigellosis, typhoid, polio (in poor sanitary conditions), botulism, ingestion anthrax
Direct contact	Impetigo, scabies, lice, smallpox, cutaneous anthrax
Sexual contact	Chlamydia, gonorrhea, hepatitis B, C, and D, HIV infection, herpes simplex virus (HSV) infection, human papilloma virus (HPV), syphilis
Direct inoculation	Syphilis, hepatitis A, B, C, and D, HIV infection
Insect or animal bite	Malaria, rabies, Lyme disease, plague (bubonic form)
Other means of transmission	Tetanus, hookworm

TABLE 26-2 Portals of Entry and Exit for Each Mode of Disease Transmission

Mode of Transmission	Portal of Entry	Portal of Exit
Airborne	Respiratory system	Respiratory system
Fecal–oral/ingestion	Mouth	Feces
Direct contact	Skin, mucous membrane	Skin, mucous membrane
Sexual contact	Skin, mouth, urethra, rectum, vagina	Skin lesions, vaginal or urethral secretions
Direct inoculation	Across placenta, bloodstream	Blood
Animal or insect bite	Wound in skin	Blood, saliva
Other means of transmission	Wound in skin, intact skin	Animal feces, soil

Incubation and Prodromal Periods

The **incubation period** of a communicable disease is the interval from exposure to an infectious organism to development of the symptoms of the disease (Gerstman, 2013). The length of the incubation period for a particular disease may influence the success of efforts to halt the spread of the disease. Some diseases, such as influenza and scarlet fever, have incubation periods of less than a week. Others typically require incubation periods of one to two weeks (gonorrhea, measles, pertussis, and polio), two to three weeks (rubella, chickenpox, and mumps), or months (viral hepatitis, syphilis). In some diseases, such as AIDS, the incubation period can be years.

The **prodromal period** of a communicable disease is the period between the first symptoms and the appearance of the symptoms that typify the disease. For example, prior to the appearance of the jaundice that is characteristic of viral hepatitis, the client may experience prodromal symptoms of nausea, fatigue, and malaise. Similarly, a cough, runny nose, and watery eyes are prodromal symptoms for measles. In many diseases, the prodromal period is the time of greatest ability to infect others.

Immunity

Immunity is another concept of great importance in the control of communicable diseases. **Immunity** is a state of nonsusceptibility to a disease or condition. Physiologic immunity is based on the presence of specific antibodies to disease and is described as passive or active depending on the role of the host in developing those antibodies. In *active immunity*, the host is exposed to antigens, substances related to the disease-causing microorganism, which prompt the host's immune system to create antibodies that render the antigen harmless. Exposure to the antigen may occur as a result of having the disease or through immunization with active antigens (e.g., bacterial toxins such as tetanus or diphtheria toxoid or portions of live viruses that cause diseases such as measles and mumps). Active immunity is relatively long lasting, waning over several years if at all. In *passive immunity*, externally produced antibodies are provided to the host by way of immunization (e.g., immune serum globulin from someone who has had a specific disease and developed active immunity) or transfer (e.g., from a mother with active immunity to her fetus across the placenta).

Cross-immunity occurs when immunity to one microorganism or disease also confers immunity to a related disease-causing agent. Cross-immunity was the basis for the smallpox vaccine developed by Edward Jenner. Jenner inoculated people with material from cowpox lesions to prevent smallpox after noticing that milkmaids who developed cowpox from exposure to infected cows did not develop smallpox.

Herd immunity is another concept related to physiologic immunity that has particular relevance for population groups. Herd immunity is generalized resistance to a particular disease within the population that arises because the majority of people have developed specific immunity to the condition. Herd immunity decreases the potential for exposure to the disease among those few people who do not have immunity.

Other Communicable Disease Concepts

Additional concepts related to communicable diseases reflect the extent of a particular disease within a specific population. An **endemic disease** is one that is constantly present in a particular geographic area (Gerstman, 2013). Prior to the advent of adequate sanitation, a wide variety of diarrheal diseases were endemic in the United States and remain endemic in many developing nations. Endemic diseases contrast with those that occur with epidemic frequency. An **epidemic** involves the occurrence of a great number of cases of a disease, beyond what would ordinarily be expected in a given population (Gerstman, 2013). Earlier in U.S. history, for example, periodic epidemics of cholera swept the country. At that time, cholera was generally an endemic disease, with low incidence rates most of the time. Influenza epidemics continue to occur with some frequency in the United States, and there have also been periodic epidemics of pertussis when incidence rates far exceed those normally seen in a given year. A disease **outbreak** is an increased number of cases in the population that does not approach epidemic proportions. Disease outbreaks may be defined differently for different diseases depending on the usual number of cases of a disease typically encountered in the population. For example, a particular city might experience an outbreak of diarrheal disease when drinking water has been accidentally contaminated by sewage. As we saw in Chapter 25, a pandemic is the simultaneous experience of extensive disease outbreaks or epidemics in several parts of the world.

Four other related concepts are important in the consideration of communicable diseases: control, elimination, eradication, and extinction. **Control** refers to a reduction in disease incidence or prevalence or a decrease in its associated morbidity and mortality to an acceptable level in a given locale as a result of deliberate intervention. Elimination, as noted in Chapter 800, is the reduction of the incidence of a specific disease to zero in a defined geographic area, again as a result of deliberate efforts, while eradication involves worldwide reduction in disease incidence to zero. In **extinction**, on the other hand, the infectious agent that causes a specific disease no longer exists, either in nature or in the laboratory (CDC, 2014). To date, only one disease has been eradicated worldwide (smallpox); measles and some other diseases have been eliminated in some areas; and no currently known microorganism is extinct.

Trends in Communicable Diseases

As noted above, overall mortality from communicable diseases has declined significantly in some parts of the world, but these trends are not universal. Because of the potential for rapid spread of disease throughout the world, population health nurses need to be aware of trends in communicable disease incidence, prevalence, and mortality in their local areas as well as nationally and internationally. Communicable disease incidence also varies among geographic areas within the United States and among ethnic groups. Generally speaking, most communicable diseases have higher incidence rates among ethnic minority groups than among Caucasians, due to a number of social conditions such as poverty and lack of access to care.

As noted above, one communicable disease, smallpox, has been completely eradicated from the world, although there is potential for its reintroduction through bioterrorism. The goal of the World Health Organization (WHO) is the elimination of several diseases, with their eventual eradication throughout the world. Information about elimination and eradication efforts for several communicable diseases is presented in the *Global Perspectives* feature on the next page. Trends related to common vaccine-preventable diseases, STIs, foodborne and waterborne diseases, bloodborne diseases, tuberculosis, hepatitis, arthropod-borne diseases, and selected emerging diseases will be discussed.

Vaccine-preventable Diseases

A number of communicable diseases are preventable using vaccines. Such diseases include measles, mumps, rubella, pertussis, tetanus, diphtheria, varicella (chickenpox), influenza and pneumonia, poliomyelitis, *Haemophilus influenzae* type b, meningococcal disease, and rotavirus infection. Human papilloma virus (HPV) infection is also vaccine preventable, but will be discussed with other STIs. Hepatitis A and B are also discussed separately with other forms of hepatitis. Vaccines are also available for other diseases, such as cholera, typhoid, and tuberculosis, but are not routinely used in the United States,

except for certain populations (e.g., persons traveling to endemic areas).

Measles has been eliminated in the United States since 2000 (defined as interruption of continuous transmission for at least 12 months). Unfortunately, cases of measles continue to be imported from other parts of the world. Approximately 20 million cases of measles still occur worldwide each year, and from 2001 to 2012 a median of 60 imported cases occurred each year in the United States (Wallace et al. 2013).

Decline in immunization rates and failure to be vaccinated led to a resurgence of measles as well as other diseases (McLean, Fiebelkorn, Temte, & Wallace, 2013). For example, the number of measles cases reported in 2011 was the highest since 1996. The vast majority of cases (87%) occurred in persons who were not vaccinated or whose vaccination status was unknown, and 36% of cases were known to have claimed a vaccine exemption (a waiver of the requirement for immunization for school enrollment) based on personal, religious, or philosophical beliefs. The WHO European region, which experienced more than 30,000 cases of measles in 2011, was the source of 41% of imported U.S. cases (Adams et al., 2013). During that year, measles outbreaks occurred in 36 of the 53 nations in the European region, accounting for 26,074 cases, mostly in unvaccinated older children and adults (Martin et al., 2011).

From January 1 to August 24, 2013, a total of eight outbreaks and 159 cases of measles were reported in the United States, 82% in unvaccinated individuals. Details of one outbreak highlight the potential for spread of the disease when cases are imported from endemic regions. In 2013, a measles outbreak occurred in a religious community in New York. The source of the outbreak was an intentionally unvaccinated adolescent exposed during a trip to London. The outbreak consisted of six generations of cases in 58 individuals in two neighborhoods. More than three fourths (79%) of the cases occurred in three extended families who declined immunization. The outbreak necessitated 3,500 contact investigations in health care, home, and school settings, school immunization audits, a mass immunization campaign using measles, mumps, and rubella (MMR) vaccine or immune globulin, and testing and vaccinating of several pregnant women (Arciuolo et al., 2013), which heavily burdened the local health jurisdiction.

U.S. mumps incidence in 2011 was 0.13 cases per 100,000 population (National Center for Health Statistics [NCHS], 2014). MMR vaccine effectiveness in preventing mumps is 78% for one dose and 88% for two doses of vaccine. Although required as part of the routine immunization program in the United States, only 62% of countries worldwide include mumps in their national immunization programs, and vaccination rates in Europe have declined in response to vaccine safety concerns. These conditions have led to periodic outbreaks and importation of cases into the United States. For example, one mumps outbreak on a university campus resulted in 29 cases, mostly in unvaccinated students. Again, the source case was an unvaccinated student who had traveled to Europe prior to the start of the school year. Public colleges and universities

Global Perspectives

Eliminating Communicable Diseases Worldwide

Complete eradication of a communicable disease has only, thus far, been achieved for smallpox. However, the World Health Assembly has established targets for the elimination of several communicable diseases moving eventually to complete eradication. For example, measles has been eliminated in the WHO Region of the Americas since 2002. In 2010, the World Health Assembly established three milestones for measles eradication to be achieved by 2015: (a) increasing to at least 90% the number of children who have had at least one dose of measles vaccine in all countries, (b) reducing annual measles incidence to less than five cases per million population, and (c) reducing measles mortality by 95% from 2000 figures. Elimination of measles from four WHO regions is targeted for 2015 and five regions by 2020. By 2011, global vaccine coverage had increased to 84% of the world's children; measles incidence had decreased to 52 cases per million population, and mortality decreased by 71%. During 2010–2011, however, measles activity increased with several outbreaks reported (Perry et al., 2013). Work remains to be done to increase vaccine coverage and eradicate measles.

Malaria is another communicable disease that is being addressed worldwide as a significant source of morbidity and mortality. In 2000, leaders of 44 African nations committed their countries to decreasing malaria deaths. The estimated costs of global malaria control are \$5.1 billion per year. A combination of domestic and international funding provided less than half of the required amount in 2012 (WHO, 2013c).

Recommendations for malaria control include insecticide-treated bed nets (ITNs), and by 2012, a total of 110 countries had adopted this recommendation, 88 of which provide the nets free of charge. Overall requirements to meet the need for protection in sub-Saharan Africa amounts to 150 million nets per year; an estimated 136 million nets were expected to be delivered in 2013. The proportion of individuals with access to nets varies across countries from 7% to 84%, but 89% of persons with nets use them (WHO, 2013c).

Another recommendation is the use of indoor residual spraying for mosquitoes in 88 high-malaria-risk countries. In 2012, only 4% of the population at risk lived in homes that were protected. In addition, a number of countries reported mosquito resistance to at least one commonly used insecticide (WHO, 2012).

Intermittent preventive therapy (IPT) for malaria is also recommended for pregnant women and infants. In 2012, 37 countries had national policies related to IPT for pregnant women, and a mean of 44% of pregnant women in high-burden countries received two doses of IPT. Only one country had adopted IPT for infants and two had adopted a 2012 recommendation for seasonal IPT for children aged 3 to 59 months (WHO, 2013c).

Overall, these interventions have prevented 274 million cases of malaria and more than 1.1 million deaths. Despite these achievements, malaria resulted in 219 million cases and an estimated 660,000 deaths in 2010 indicating the need for additional concerted prevention and treatment initiatives (WHO, 2013c).

Polio is a third disease with catastrophic global impact that has been slated for eradication. In 2012, the World Health Assembly designated completion of polio eradication activities to be a public health emergency. To date, polio has been eliminated from much of the world, but wild polio virus transmission remains endemic in three countries: Afghanistan, Nigeria, and Pakistan. Efforts to eliminate transmission have focused on increasing immunization levels among children. During 2012 and 2013, for example, Nigeria engaged in an N-STOP program (National Stop Transmission of Polio), one focus of which was locating and vaccinating susceptible children. As part of this initiative, public health workers engaged in outreach activities to enumerate children in more than 40,000 remote settlements. Enumeration resulted in identification of 53,738 children who had never been immunized as well as detection of 211 cases of unreported polio. N-STOP is operated entirely by Nigerian citizens, expanding public health capacity to deal with polio as well as other public health problems (Gidado et al., 2013). Outbreaks of imported wild poliovirus transmission have occurred in 21 previously polio-free countries due to importation from endemic countries. Until WPV transmission is eliminated from all parts of the world there is a continued risk for importation in other countries (WHO, Regional Office for Africa, 2013).

Overall, significant strides have been made, however, in the effort to eradicate polio. For example, annual global polio incidence decreased 99% from the launch of the Global Polio Eradication Initiative (GPEI) in 1988 to 2012, and the number of new cases decreased by 66% from 2011 to 2012. Similarly, the number of imported cases in polio-free countries decreased from 309 in 12 countries to 6 in 2 countries. From January to March 2013, only 22 wild poliovirus cases had been reported worldwide, less than half of the number in the same time period in 2012 (Polio Eradication Department, WHO, 2013b).

Vaccination rates have also increased. By the end of 2011, approximately 84% of the world's children had received the routine three doses of vaccine. In 2012, 2.05 billion doses of OPV were administered to 448 million people, most children under 5 years of age. Supplemental immunization activities (SIAs), including national and subnational immunization days, child health days, and mop-up rounds, were conducted in 46 countries, and no new wild poliovirus outbreaks had been reported in polio-free countries as of April 2013 (Polio Eradication Department, WHO, 2013b).

in 22 states and the District of Columbia require two doses of mumps vaccine prior to enrollment to prevent such outbreaks, but many more campuses have no such requirement (Zipprich et al., 2012).

U.S. 2011 rubella incidence was zero cases per 100,000 population (NCHS, 2014), with similar rates for 2009 and 2010, exceeding the *Healthy People 2020* target of 10 or fewer cases per year (U.S. Department of Health and Human Services [USDHHS], 2014). Rubella has been targeted for elimination in the WHO region of the Americas by 2010 and in the European region by 2015. In addition, accelerated control targets have been identified for the Western Pacific region, in part in response to a 2013 epidemic in Japan that resulted in 5,442 cases and 10 infants with congenital rubella syndrome. More than three fourths (77%) of the Japanese cases occurred in adult men who typically not targeted by vaccination programs, which focus on children and childbearing women (Tanaka-Taya et al., 2013).

Like many other vaccine-preventable diseases, the incidence of pertussis declined sharply with the advent of an effective vaccine, dropping from 265,269 cases in 1934 to 1,010 cases in 1976. Unfortunately, the number of cases increased to 25,827 in 2004 and averaged slightly more than 18,000 cases per year from 2004 to 2008 (Pour et al., 2011). The 2009 incidence in the United States was 5.54 cases per 100,000 population, but climbed again to 8.9 per 100,000 in 2010 and dropped to 6.1 in 2011 (Adams et al., 2013).

Periodic outbreaks of pertussis continue to occur. For example, there was a 1,300% increase in the number of pertussis cases in Washington State between 2011 and 2012, primarily in infants and 10-year-old to adolescent children, suggesting early waning of immunity (Tondella et al., 2012). In 2012, 41,880 cases and 14 deaths in infants under a year of age were reported in the United States (Sawyer, Liang, Messonnier, & Clark, 2013).

The availability of vaccine has resulted in a 95% decrease in tetanus cases and a 99% reduction in mortality since 1947. From 2001 to 2008, only 233 cases occurred in the United States. Unfortunately, when cases do occur, fatality rates are relatively high at 13.2% of those affected. The average incidence across all age groups is 0.1 per million persons, but increases to 0.23 per million for people over 65 years of age, primarily due to lack of immunization among older persons. Approximately 40% of older people in the United States have not been immunized. In addition, persons seen for wounds for whom treatment status was known did not receive adequate tetanus prophylaxis, putting them at risk for developing tetanus (Tiwari, Clark, Messonnier, & Thomas, 2011).

No cases of diphtheria were reported in the United States in 2011. Globally, however, an estimated 25,000 deaths occurred in the same year. During 2012, 4,489 cases were reported worldwide. Varicella or chickenpox, on the other hand, continues to occur in the United States, with an incidence of 8.3 per 100,000 population in 2011. This figure represents a decrease of roughly 74% from 2006 and is the result of increasing vaccine coverage (Adams et al., 2013).

Poliomyelitis due to wild poliovirus (WPV) has been eliminated in the United States, and the incidence in 2011 was zero cases per 100,000 population (NCHS, 2014). In 1988, the Global Polio Eradication Initiative (GPEI) established a partnership between WHO, Rotary International, CDC, and the United Nations Children's Fund (UNICEF) to promote polio immunization throughout the world. By 2012, the annual incidence of polio had decreased by 99% worldwide (Polio Eradication Department, 2013a). The number of new cases decreased by 66% from 2011 to 2012 and only three countries (Afghanistan, Nigeria, and Pakistan) continued to experience endemic WPV transmission in 2013. From January to March, 2013, only 22 cases of WPV were reported compared to 48 cases in the same time period in 2012 (Polio Eradication Department, 2013b). Imported cases of polio continue to occur in countries that have eliminated WPV, but only 223 cases were reported globally in 2012. In 2013, WPV was reintroduced in Somalia and Kenya and 50 cases had been reported by June of that year (WHO, Division of Global Migration and Quarantine, 2013a).

Two other diseases of young children that can be prevented by vaccines are *Haemophilus influenzae* type b (Hib) and rotavirus. Since the advent of Hib vaccine in 1987, incidence of invasive disease in children under 5 years of age decreased by 99% to less than one case per 100,000 children (Adams et al., 2013). Rotavirus is the leading cause of diarrheal death in children under 5 years of age resulting in an estimated 8,000 deaths per year in this age group. In 2007, WHO recommended the inclusion of rotavirus vaccine as part of routine national immunization programs in the Americas and Europe. This recommendation was expanded to all children under 32 months of age in 2009 (de Oliveira et al., 2011).

Meningococcal disease also affects young infants, but is also found among adolescents and young adults. Although cases are at a historic low since vaccine availability, cases continue to occur. In 2011, for example, a total of 257 vaccine preventable invasive meningococcal infections occurred in the United States, with the highest rate among children under 1 year of age (0.34/100,000 population) and a second peak in the 15 to 24 age group (0.10/100,000). Overall vaccine-preventable invasive meningococcal disease incidence decreased from 0.10 per 100,000 people in 2001 to 0.08 per 100,000 in 2011 (Adams et al., 2013).

Influenza and pneumococcal pneumonia are two other vaccine-preventable diseases. Influenza virus infection exhibits different seasonal patterns in different areas of the world. For example, the disease tends to appear in early August in Australia and New Zealand. In 2013, peak disease incidence in South Africa occurred in June and then again in August, while incidence in temperate areas of South America peaked in June and declined through September (WHO Collaborating Center for Surveillance, Epidemiology and Control of Influenza, 2013). The typical influenza season in the United States is from late fall to early spring (Grohskopf et al., 2013).

Both influenza and pneumonia contribute to considerable morbidity and mortality. For example, influenza and pneumonia are the eighth leading cause of death in the United States (American Lung Association, 2014). Similarly, influenza accounted for anywhere from 55,000 to 431,000 hospitalizations each year from the 1976–1977 season to the 2002–2006 seasons. The highest influenza complication rates occur among young children and those over 65 years of age (Grohskopf et al., 2013). In 2001, 115 influenza deaths occurred among U.S. children, 46% of them under 5 years of age (WHO Collaborating Center, 2011).

U.S. pneumonia hospitalizations decreased by 20% overall from 2000 to 2010 with slightly larger decreases in older age groups (NCHS, 2012). Among children, introduction of the seven-valent pneumococcal conjugate vaccine resulted in a 77% decrease in invasive pneumococcal disease from 1998 to 2005, and 2008 rates had exceeded the *Healthy People 2010* target (National Center for Immunization and Respiratory Diseases, 2008). Unfortunately, pneumonia continues to account for 20% of child deaths throughout the world (CDC, 2012d).

Sexually Transmitted Infections

A variety of diseases are transmitted by means of sexual contact and result in more than 20 million cases per year at a cost of \$16 billion per year in direct medical costs alone (CDC, 2013g). Sexually transmitted diseases to be addressed here include *Chlamydia trachomatis* infection, gonorrhea, HIV infection and AIDS, syphilis, and HPV infection. Some forms of viral hepatitis can be transmitted sexually as well, but they will be discussed in the section on viral hepatitis.

Chlamydia and gonorrhea are the two most frequently reported infectious diseases in the United States (Rotblatt, Montoya, Plant, Guerry, & Kerndt, 2013). Because many cases of both diseases are asymptomatic, their actual frequency is probably far underreported. Both diseases can result in significant reproductive problems, including pelvic inflammatory disease, infertility, and chronic pelvic pain in women. An estimated 4 to 5 million cases of *Chlamydia trachomatis* occur each year in the United States (Singh, Fine, & Marrasso, 2011). In 2011, 1.4 million cases were reported for an incidence rate of 457.6 cases per 100,000 population. This figure represents an 8% increase over the 2010 incidence rate (Adams et al., 2013).

Reported incidence of gonorrhea declined by 79% from 1975 to 2009, but increased by 6% from 2009 to 2011 for an incidence rate of 104 cases per 100,000 population (Adams et al., 2013). This translates to more than 300,000 cases reported with many more that are undetected because of the frequently asymptomatic nature of the disease. In addition to the female reproductive consequences noted above, gonorrhea may result in disseminated disease and neonatal conjunctivitis and blindness. Gonorrhea also facilitates HIV transmission (Hook, Shafer, Deal, Kirkcaldy, & Iskander, 2013).

Approximately 1.1 million people were living with HIV infection/AIDS in 2013 and 50,000 new infections occur each year (McCree et al., 2013). Worldwide more than 3.3

million people are affected and 2 million deaths occur each year (Talman, Bolton, & Walson, 2013). With the advent of antiretroviral therapy (ART), mortality rates due to AIDS have declined significantly in areas where ART is available. For example, age-adjusted AIDS mortality among men in the United States declined from 16.2 per 100,000 population in 1995 to 2.6 per 100,000 in 2010 (NCHS, 2014).

The incidence of primary and secondary syphilis, the two most infectious and treatable stages of the disease, decreased by 90% from 1990 to 2000, but has recently begun to increase. In 2011, the incidence of primary and secondary syphilis was 4.52 per 100,000 population. Congenital syphilis, acquired through transplacental transmission from mother to fetus, declined from a high of 368.3 per 100,000 live births in 1950 to a low of 7.7 in 1980, but rose again to 92.95 cases per 100,000 live births in 1990. In 2011, congenital syphilis incidence had decreased to 8.48 (NCHS, 2014), but remained above the *Healthy People 2010* target of one case per 100,000 births (U.S. Department of Health and Human Services [USDHHS], 2013).

Unlike many STIs, HPV not only contributes to immediate conditions, such as genital warts, but is also a significant risk factor for several types of cancer. Several HPV serotypes have different effects. For example, types 16 and 18 cause approximately 70% of cervical cancers and most other HPV-related cancers (e.g., vulvar, vaginal, penile, or oropharyngeal cancers). Types 6 and 11, on the other hand, contribute to 90% of cases of genital warts. An estimated 26,200 new HPV-related cancers occur each year in the United States, with women accounting for nearly twice as many cases as men (Stokley et al., 2013). In 2008, more than 529,000 cases of cervical cancer and 275,000 deaths occurred worldwide. In the United States, more than 12,000 new cervical cancer diagnoses and 4,000 deaths were anticipated in 2013 (Henry J. Kaiser Family Foundation, 2014).

Globally, 44% of the world's population is infected by one or more types of HPV, most commonly young men and women under 25 years of age (Mah, Deber, Guttman, McGeer, & Krahn, 2011). An estimated 79 million people in the United States are HPV infected, and approximately 14 million new cases occur each year (Stokley et al., 2013).

Viral Hepatitis

Viral hepatitis occurs in several different forms based on the causative organism: hepatitis A virus (HAV), hepatitis B virus (HBV), hepatitis C virus (HCV), hepatitis D virus (HDV), and hepatitis E virus (HEV). Hepatitis A and E are transmitted primarily by the fecal oral route and usually produce acute infection, although sexual transmission of hepatitis A has occurred among men who have sex with men (MSM). Hepatitis B, C, and D are transmitted via infected blood (e.g., transfusions, injecting drug use, paraoccupational exposure, or perinatal transmission) and can cause both acute and chronic disease. Chronic hepatitis B and C are the leading causes of cirrhosis and liver cancer (Kirkey et al., 2013).

In 2011, U.S. HAV incidence was 0.45 cases per 100,000 people, while HBV incidence was more than twice as high at

0.94 per 100,000 (NCHS, 2014). Hepatitis B occurs frequently throughout the world and has an estimated prevalence of more than 8% in the Western Pacific region of WHO, resulting in approximately 325,000 deaths per year due to cirrhosis and liver cancer (Xeuvatvongsa et al., 2013).

HCV infection is the most common bloodborne infection in the United States. Approximately 70% of cases are mild or asymptomatic leading to under diagnosis and reporting. An estimated 75% to 85% of those affected develop chronic HCV infection, and of those 60% to 70% will develop active liver disease (Division of Viral Hepatitis, 2014). In the United States, an estimated 4.1 million people have ever been infected with HCV (Getchell et al., 2013), and approximately 3.2 million people are living with chronic HCV infection, 45% to 85% of whom are unaware of the infection (Mahajan, Liu, Kleven, & Holmberg, 2013). In 2008, for example, 144,015 cases were reported in the United States, but it is believed that figure represents only approximately half of the actual cases that occurred due to the largely asymptomatic nature of the disease, reporting failures, and insufficient follow-up to establish infection status (Hart-Malloy et al., 2013). HCV appears to be more common in persons born from 1945 to 1965, and this population has been specifically targeted for routine screening for the disease (Bornschelegel, Holtzman, Kleven, & Ward, 2013). WHO estimates that 130 to 170 million people are infected with HCV worldwide, with 10% of the population of countries like Egypt affected (El-Sayed et al., 2012).

HCV creates a significant societal burden. For example, HCV mortality now exceeds that of HIV infection in the United States (Iverson, Wand, Topp, Kaldor, & Maher, 2013). In addition, the estimated direct medical costs of HCV infection in the United States are expected to be \$10.7 billion from 2010 to 2019, with additional costs of \$54.2 billion related to premature mortality and lost productivity, and \$21.3 billion in disability costs (Kleven & Tohme, 2010).

HDV and HEV virus infections occur far less frequently in the United States than hepatitis A, B, or C. Hepatitis D occurs only in conjunction with hepatitis B as a co-infection or as a superinfection (CDC, 2013d). **Co-infection** means that the two diseases occur simultaneously, in the case of hepatitis B and D, usually as a result of injection drug use (IDU). **Superinfection** occurs when one disease is superimposed on an existing disease; hepatitis D is superimposed on an existing HBV infection. HDV infection is uncommon in the United States and occurs primarily through percutaneous (e.g., IDU or needlestick) or mucous membrane exposure (CDC, 2013d).

Hepatitis E occurs primarily in areas of poor sanitation and, in the United States, is usually diagnosed in travelers returning from endemic areas such as South Asia and North Africa. HEV infection is unusual in the United States, but approximately 20 million people become infected annually worldwide, resulting in 3.4 million cases of disease and 70,000 deaths. Case fatality rates are relatively high at 0.2% to 4% in the general population and as high as 25% among pregnant women (Thomson et al., 2012).

Given the disease burden caused by viral hepatitis, particularly hepatitis B and C, the USDHHS has developed a comprehensive viral hepatitis action plan for control of these diseases. Major foci of the plan include preventing health-care-associated viral hepatitis, reducing hepatitis incidence and prevalence among injecting drug users, and strengthening disease surveillance systems (CDC, 2012c). Strategies related to these foci will be addressed later in this chapter.

Tuberculosis

TB is another communicable disease of interest to population health nurses. TB occurs in two forms: active infection or TB disease, and a quiescent form, latent TB infection (LTBI). Persons with active TB disease and positive sputum are capable of transmitting the disease by coughing, singing, or talking. Cases tend to be clustered based on their molecular characteristics, suggesting a common source of infection (Feske, Teeter, Musser, & Graviss, 2013).

TB is spread by the airborne route, particularly in congregate settings, such as long-term care facilities, homeless shelters, or correctional institutions (Bargman et al., 2013). Roughly one third of the earth's population or 2 billion people are infected with tuberculosis, and 1.8 million deaths occur each year worldwide (Otrompke, 2009). In the United States, age-adjusted TB mortality declined 57% from 1999 to 2010, with a 2010 mortality rate of 0.3 per 100,000 population. CDC's goal is to reduce TB incidence to less than one case per million people. In 2012, 9,951 new cases of TB were reported for an incidence rate of 3.2 per 100,000, a decrease of 6.1% from 2011. The TB incidence rate for foreign-born persons in the United States remains high, however, approximately 11.5 times the rate for U.S.-born persons (Miramontes, Pratt, Price, Navin, & Lo, 2013).

Food and Waterborne Diseases

A number of infectious diseases are transmitted through contaminated food and water. For example, approximately 170 million cases of acute gastroenteritis (AGE) per year are transmitted by food or water. These diseases can also occur via person-to-person contact, and from 2009 to 2010, 2,259 person-to-person outbreaks of AGE occurred resulting in 81,491 cases of illness, 1,339 hospitalizations, and 136 deaths (Wiksw & Hall, 2012).

The most common microorganisms implicated in food and waterborne disease outbreaks are norovirus, *Salmonella*, *Shigella*, *Escherichia coli*, and rotavirus. Different organisms tend to occur more commonly in some seasons than others. For example, norovirus infections tend to occur primarily in winter in the United States, and *Shigella* and other AGE infections are more common in spring and summer months (Wiksw & Hall, 2012). Many of these microorganisms include multiple disease-causing strains. For example, there are five genotypes of norovirus, more than 34 genotypes, and new strains emerging every 2 to 3 years, often resulting in disease outbreaks (Barclay et al., 2013).

The Foodborne Diseases Active Surveillance Network (FoodNet) identified 19,351 laboratory confirmed cases of foodborne infection in 2012 (Gilliss et al., 2013), and foodborne outbreaks in 2009 and 2010 resulted in 29,444 cases of disease, 1,184 hospitalizations, and 23 deaths. Forty percent of the reported outbreaks were associated with norovirus and 30% with *Salmonella*. Foods most often implicated included beef, dairy, fish, and poultry sources (Gould, Mundai, et al., 2013). A number of other foods, however, can cause disease outbreaks, including crustaceans, mollusks, pork, grains and beans, oils and sugars, fruits and nuts, leafy vegetables, sprouts, and vine or stalk vegetables (Gould, Walsh, et al., 2013). For example, an outbreak of norovirus infection was associated with frozen raw oysters that were distributed internationally (Brucker et al., 2012). Similarly, raw milk produced from one dairy resulted in recurrent outbreaks of *Campylobacter jejuni* (Weltman et al., 2013). In another outbreak, 91 cases of *Salmonella* infection were attributed to mobile lunch trucks selling products from one catering company that was using illegally sourced eggs (Honish et al., 2013). *Salmonella* outbreaks have also been associated with peanut butter and almond butter, as well as raw and roasted shelled and in-shell peanuts, produced by one company (MacDonald et al., 2013) and poultry from another producer (Grinnell et al., 2013).

Waterborne disease outbreaks may be associated with drinking water or water used for recreational or nondrinking purposes. From 2009 to 2010, 33 drinking water outbreaks were reported in the United States resulting in 1,040 cases of illness, 85 hospitalizations, and 9 deaths. Most of these outbreaks were attributed to *Legionella* in plumbing systems, untreated ground water, and distribution system deficiencies (Hillborn et al., 2013). Similarly, from 2007 to 2008, 134 disease outbreaks in the United States were attributed to recreational water (Hlavsa et al., 2011). A significant portion of recreational water-related outbreaks is related to *Cryptosporidium*, which is chlorine tolerant and may not be destroyed by common water treatment approaches (Adams et al., 2013).

Dracunculiasis, or guinea worm disease, is another waterborne infection present in the developing world. The disease is spread by ingestion of the eggs of a parasitic worm in contaminated water. The worms hatch in the new host and burrow to the skin where they cause secondary infection, pain, and disability. The World Health Assembly has called for worldwide dracunculiasis elimination. As of 2013, the disease remained endemic in four countries (south Sudan, Chad, Mali, and Ethiopia), with a total of 542 cases reported in 2012, 83% of which occurred in south Sudan (Hopkins, Ruiz-Tiben, Eberhard, & Roy, 2013).

Bloodborne Diseases

Bloodborne diseases are transmitted through infected blood. Transmission may occur via transfusion, injecting drug use, or cross-placental transmission from mother to fetus. Bloodborne infections may also occur in health care personnel as a result of needlesticks or other exposure to contaminated blood. In the

United States, transmission of bloodborne diseases through transfusion is rare, due to screening of donors for major risk factors and testing of donated blood. For example, the risk of HIV transmission via transfusion is approximately one case in 1.5 million transfusions (Laffoon et al., 2010). Transfusion remains a major source of HIV infection in sub-Saharan Africa, however. One of the major foci of the President's Emergency Plan for AIDS Relief (PEPFAR) is the provision of support for improved blood transfusion services in 14 countries in the African region (Holmberg, Basavaraju, Reed, Drammeh, & Qualls, 2011). Another example of bloodborne transmission is transfusion-acquired West Nile Virus (WNV) infection. However, only 12 cases of transfusion-related WNV have been identified in the United States since the implementation of screening of blood supplies for WNV.

Arthropodborne (Arboviral) Diseases

Another group of infectious diseases are spread by the bite of arthropods, primarily mosquitoes and ticks. Common U.S. arboviral diseases include WNV infection, La Crosse virus infection (LACV), Powassan virus infection (POWV), St. Louis encephalitis virus infection (SLEV), Eastern equine encephalitis virus infection (EEEV), and Jamestown Canyon virus (JCV). These diseases are commonly spread from infected vertebrate hosts, such as birds or small mammals, to people via mosquito or tick bites. In 2012, these viruses caused 5,780 cases of illness, 51% of which were neuroinvasive conditions (Lindsey, Lehman, Staples, & Fischer, 2013). Rocky Mountain spotted fever is also spread by ticks.

Two other arthropodborne diseases seen in other parts of the world include lymphatic filariasis (elephantiasis) and malaria, both transmitted by mosquito bites (Mace et al., 2011; Streit et al., 2013). Filariasis affects more than 120 million people worldwide, and WHO has called for the elimination of this disease by 2010 (Streit et al., 2013). Malaria has been targeted by WHO for eradication, and by 2010, 11 countries and the WHO African region had achieved a greater than 50%

Ticks transmit a number of diseases from animals to humans.

(Bildagentur Zoonar GmbH/Shutterstock)

reduction in malaria cases and deaths (CDC, 2011). Malaria in the United States occurs primarily due to travel to endemic areas of the world, with occasional cases related to infected blood products, congenital transmission, laboratory exposure, and, rarely, local mosquitoes. In 2011, 1,925 cases were reported in the United States, all but four of which were imported. This figure represented an increase of 14% from 2010 and the highest number of cases since 1971 (Cullen & Arguin, 2013).

Globally, half of the world's population lives in malaria transmission areas, and 219 million cases and 660,000 deaths occurred in 2011. Pregnant women and young children are at risk for more severe disease than other groups. More than 40% of children under 10 years of age in central and western Africa are infected. One strain of the causative organism, *Plasmodium falciparum*, has a 15% to 20% fatality rate due to severe anemia, seizures, acute respiratory distress syndrome, and other organ failure (Mace et al., 2011). Two strains of plasmodium have a dormant stage in the human liver that can reactivate months or years later (Cullen & Arguin, 2013).

Emerging Diseases

The diseases discussed here are not the only communicable diseases to affect the health of populations. Each year, new emerging and reemerging diseases occur due to a variety of circumstances. One example of an emerging disease is Middle East Respiratory Syndrome Coronavirus (MERS-CoV) infection. This disease was first reported in humans in September of 2012 and has been designated as a “condition of serious concern.” Cases identified thus far have been linked to travel in or near the Arabian peninsula (WHO, Division of Global Migration and Quarantine, 2013c). Reports of MERS-CoV cases in France, Italy, Tunisia, and the United Kingdom and instances of nosocomial transmission to health care personnel in some countries have raised concern about the potential for importation of the disease to other regions of the world (WHO, Division of Global Migration and Quarantine, 2013b).

New pathogens are being identified each year, many of which contribute to significant disease burden. In addition, diseases once thought controlled are becoming more frequent and harder to treat due to development of antimicrobial-resistant

strains of microorganisms. Resistance is discussed in more detail in the section of this chapter devoted to treatment of communicable diseases.

Population Health Nursing and Communicable Disease Control

Control of communicable diseases in individuals and population groups entails use of the nursing process. The population health nurse involved in communicable disease control assesses determinants of health contributing to communicable disease, develops related population nursing diagnoses, and plans, implements, and evaluates strategies to prevent or control disease occurrence.

Assessing Determinants of Health in Communicable Disease

The development and effects of any communicable disease are influenced by factors related to each of the categories of determinants of health in the population health nursing model. Population health nurses concerned with control of communicable diseases should be familiar with factors in each category that influence disease development and control. Such knowledge provides guidance for interventions to prevent the disease, deal with it when it occurs, and prevent further spread in the population.

BIOLOGICAL DETERMINANTS. Biological considerations such as age, gender, race/ethnicity, and physiologic health status influence the development of many communicable diseases. In the case of some diseases, age may influence susceptibility to a disease or its effects. For example, the U.S. incidence of cryptosporidiosis for 1- to 4-year-old children in 2011 was more than twice that of any other age group. Similarly, measles incidence was twice as high for infants under a year of age as any other group. On the other hand, adolescents and young adults are at greater risk than other age groups for STIs due to sexual risk behaviors. For instance, the 2011 incidence rate for Chlamydia in 15- to 24-year-olds was four times higher than for any other age group at 2,313.29 cases per 100,000

Evidence-Based Practice

Preexposure Prophylaxis (PrEP) for HIV Infection

In PrEP, persons who are uninfected take medication to prevent infection. This is not a new concept and has actually been used for years to prevent malaria in travelers to malaria-endemic regions. It is a relatively new approach to HIV prevention, however, designed to add another preventive strategy to existing behavioral strategies such as safe sexual behaviors and harm-reduction strategies in drug use. Several clinical trials have indicated the efficacy of PrEP for HIV prevention in men who have sex with men

as well as heterosexual men and women and injecting drug users (AIDS.gov, 2014). In 2013, CDC updated guidelines on the use of PrEP for these groups at high risk for HIV infection (Smith et al., 2013). Some authors, however, caution that use of PrEP should be considered in light of its costs, the related costs of compliance counseling, potential for development of resistant viral strains, and lost opportunity costs in draining funding from other initiatives (Leibowitz et al., 2011).

population compared to 559.93 per 100,000 for those aged 25 to 39 years, the next highest group. Similarly, invasive disease due to *Haemophilus influenzae* occurred at a higher rate in adolescents and young adults due to lack of immunity. Invasive vaccine preventable meningococcal disease incidence, on the other hand, was highest in infants (0.34/100,000) followed by those over 65 years of age (0.19/100,000), and pertussis incidence was more than three times higher in infants than in any other age group (Adams et al., 2013).

In 2011, TB incidence was higher in persons over 65 years of age than in other age groups. The elderly are also at the greatest risk for tetanus in the United States because they are the least likely to have been immunized. For example, the 2011 incidence rate for tetanus in persons over 65 years of age was three times higher than that of any other age group (Adams et al., 2013). In developing countries with unsafe delivery conditions, neonates are at high risk for tetanus fatality. Neonates are also at risk for diseases that can be passed from mother to child perinatally. Such diseases include congenital rubella syndrome (CRS), HIV infection, syphilis, and hepatitis B and C. As we will see later, treatment of infected women during pregnancy can generally prevent transmission of these diseases to their infants.

Age may also affect the symptoms with which some communicable diseases present. For example, children with hepatitis A are often asymptomatic. Similarly, elderly persons with pneumococcal pneumonia may not present with classic symptoms of cough and fever, but may instead exhibit gastrointestinal symptoms.

Age also influences one's chances of exposure to some communicable diseases. For example, STIs and hepatitis B, C, and D occur more frequently in younger than older people because of their propensity to engage in high-risk sexual behaviors and injecting drug use. As we saw earlier, pertussis and mumps incidence have increased in adolescents and young adults, largely because of waning immunity from initial immunizations.

Communicable disease incidence and prevalence also vary by gender and by race/ethnicity. In 2011, incidence rates for most communicable diseases were higher for males than for females. Exceptions included *Chlamydia trachomatis* infection with a rate of 651.51 cases per 100,000 women compared to 255.36 cases per 100,000 men, some diarrheal diseases, and invasive *Haemophilus influenzae* infection. The incidence of HIV infections was more than four times higher in men than women, and primary and secondary syphilis incidence was more than eight times higher for men than for women (Adams et al., 2013). In addition, transgender females who engage in sex work to pay for hormone therapy or gender recognition surgery are at high risk for HIV-infection, contributing to a 26% infection rate in this population in San Francisco (Rapues, Wilson, Packer, Colfax, & Raymond, 2013).

Racial and ethnic differences in communicable disease incidence are more likely to be the result of differential levels of exposure and other behavioral and sociocultural factors than of differences in inherent susceptibility. For example,

disparities in TB incidence, which is more than three times higher among Asians and Pacific Islanders (APIs) than among other racial groups, may reflect crowded living conditions. Similarly, increased incidence of other diseases in some ethnic minority populations (e.g., pertussis, which is highest among American Indians and Alaska Natives [AIAN]) may be a result of lack of access to health-promotive and illness-preventive knowledge and resources. Although disparities do not arise because of gender or ethnic minority group membership per se, population health nurses should be aware of gender and racial/ethnic differences in communicable disease incidence in order to be able to target intervention strategies to those most in need of them.

Racial disparities in STIs are particularly pronounced. In 2011, for example, Blacks had gonorrhea incidence rates 14 times higher than Whites and nearly 5 times higher than AIANs. Similarly, incidence rates for HIV infection were six times higher among Blacks than for any other group, and rates for both primary and secondary and congenital syphilis were approximately five times higher. Conversely, *Chlamydia trachomatis* infection rates were highest in Whites; invasive *Haemophilus influenzae* infection rates were highest among AIANs; and TB incidence rates were more than three times higher in APIs than in other groups. Persons of Hispanic origin tended to have higher incidence rates for some diseases (e.g., *Chlamydia trachomatis*, hepatitis A, HIV infection, mumps, pertussis, salmonellosis and shigellosis, primary and secondary syphilis, and TB) and lower rates for other diseases (e.g., congenital syphilis, hepatitis B and C, measles, and invasive *Haemophilus influenzae* infection) than non-Hispanics (Adams et al., 2013).

The presence of other physical health conditions may also influence one's propensity to develop certain communicable diseases. For example, pregnant women are at higher risk for complications and death due to influenza (Newsome et al., 2011) as well as mortality related to HEV infection (Thomson et al., 2012). Similarly, HIV infection increases one's risk of a variety of opportunistic infections. **Opportunistic infections (OIs)** are diseases caused by organisms that either do not usually cause illness in humans or that usually cause only mild disease. For example, HIV infection increases the incidence of TB as well as the rate of progression to active disease. HIV infection and TB form a syndemic in which both diseases act "synergistically" to cause morbidity and mortality beyond what would be expected of either disease alone. For example, the lifetime risk of developing TB disease is 5% to 10% in the general population, but is much higher in those with HIV infection. HIV infection also makes it more difficult to diagnose TB because sputum smears and chest X-rays are less reliable indicators of disease. In addition, individuals with HIV infection are more likely than the general population to have extrapulmonary TB (Getahun et al., 2012).

Conversely, the presence of other STIs increases the potential for HIV infection. This is particularly true for STIs that cause lesions, such as secondary syphilis and herpes simplex

virus (HSV) infection, but also occurs with inflammatory STIs such as gonorrhea and *Chlamydia* infections. Syphilis infection may also speed progression from HIV infection to AIDS. The presence of several of these diseases also increases the infectiousness of HIV due to the increased virus present in genital fluids, more so than in peripheral blood (Kalichman et al., 2011). Diseases, such as hemophilia, or other conditions that require transfusions or organ transplantation (e.g., chronic kidney disease) may contribute to exposure to a variety of bloodborne infections, including HIV, hepatitis B, C, and D, WNV, and other communicable diseases.

Another biological consideration with respect to communicable diseases relates to the effects of the diseases themselves. Most childhood diseases are relatively mild and self-limiting. On occasion, diseases such as measles, varicella, and mumps result in death. The overall case fatality rate for untreated tetanus in unimmunized individuals, however, is high as is mortality for HEV infection, particularly in pregnant women (Thomson et al., 2012). As noted in Chapter 3∞, the case fatality rate is the number of persons who have a disease who will die as a result of it. Hepatitis B, C, and D often result in chronic liver disease with increased risk of death. As noted earlier, persons with hepatitis B and C are also at high risk of cirrhosis and liver cancer, and those with HDV superinfection have a greater risk of developing chronic liver disease than those with HBV alone.

Immunization levels within the population constitute a final biological consideration influencing communicable diseases and their control. Routine immunization recommendations for children and adults were addressed in Chapters 16∞ through 19. Population health nurses would determine the extent of vaccine coverage for specific diseases for individuals as well as within the overall population.

Worldwide, vaccination coverage for children under 12 months of age in 2012 ranged from a low of 11% for rotavirus infection to highs of 84% for polio and meningococcal vaccines, and 83% for diphtheria, pertussis, and tetanus immunization. Approximately 79% of the world's infants had received three doses of HBV vaccine, and 45% received three doses of Hib vaccine, but immunization rates for pneumococcal conjugate vaccine (PCV) were only 19% (Department of Immunization, Vaccines, and Biologicals, 2013). As of 2012, 68% of WHO member nations had achieved greater than or equal to 90% coverage for three doses of DTP vaccine, and only six countries had DTP immunization levels below 50% (WHO, 2013b). In Latin America and the Caribbean, rotavirus vaccination, the most recently recommended vaccine, had been added to 44% of national immunization programs, and a median of 89% of children under 1 year of age had been immunized across the region as of June 2011 (de Oliveira et al., 2011). Similarly, in Laos, where hepatitis B is endemic, 74% of babies born in health care facilities and 41% of those born at home had received the birth dose of HBV vaccine. Overall, HBV vaccine coverage increased from 3% in 2006 to 34% in 2011 (Xeuatvongsa et al., 2013). As these figures indicate, however, much remains to be done to increase international immunization levels.

Immunization levels also vary among populations and across vaccines in the United States. For example, in 2012, based on National Immunization Survey data, 68% of U.S. children 19 to 36 months of age had received all of the recommended immunizations, and only 1% had received no immunizations. Immunization levels were highest for the completed polio series (92.8%) and lowest for rotavirus (68.6%) (Black, Yankey, & Kolasa, 2013). Similarly, during the 2012–2013 school year, most federally funded immunization programs were at or near the national goal of 95% coverage for all recommended vaccines.

The mean exemption rate (children who have been exempted from immunization requirements for health, religious, or philosophical reasons) across jurisdictions was 1.8% (Seither, Shaw, Knighton, Greby, & Stokley, 2013). Unfortunately, exemptions can cluster within communities, decreasing overall herd immunity and increasing the risk for the spread of disease outbreaks as we saw earlier.

Among adolescents 13 to 17 years of age, nearly 85% had received at least one dose of Tdap, 74% had received at least one dose of meningococcal conjugate vaccine, and nearly 95% had received at least one dose of varicella vaccine. In addition, nearly 21% of males and 54% of females had received at least one dose of HPV vaccine (Curtis et al., 2013). Although the percentage of girls receiving HPV vaccine increased from 25% to 54% from 2007 to 2012, only a third of adolescent girls had received all three recommended doses, and one fourth of parents surveyed did not intend to have their daughters vaccinated against HPV (Stokley et al., 2013).

Annual influenza immunization rates also vary among groups. For example, the immunization rate among children 6 months to 17 years of age during the 2011–2012 influenza season was roughly 57%; among adults over 18 years of age only 38% were immunized (Lu et al., 2013). As we saw in Chapter 19∞, the influenza immunization rate among people over 65 years of age in the 2009–2010 season was 72% (Serse et al., 2011). Influenza immunization also varies by economic status. For example, only 37.5% of the poor received influenza vaccine in 2010, compared to nearly 48% of the near poor, 51% of middle-income individuals, and 54% of high-income individuals. Despite universal recommendations for annual influenza vaccination for health care personnel (HCPs), only 72% of HCPs were immunized during the 2012–2013 season, with only 58% of those working in long-term care facilities covered (Ball et al., 2013). Immunization levels among HCPs increase in organizations where it is required. For example, during the 2011–2012 influenza season, immunization rates were above 95% in hospitals where it was required, but only 68% if immunization was not required (Ball et al., 2012).

The overall pneumococcal vaccination level in 2012 was 19.8%, but ranged from 8.7% for people aged 18 to 64 years to nearly 60% for those over age 65. Less than 20% of people 18 to 64 years of age at high risk for serious pneumococcal disease, however, had received the vaccine (NCHS, 2014). Slight increases in coverage rates had been achieved by 2011 when 62%

of those over 65 years of age and 20% of younger adults at high risk were immunized (Williams et al., 2013).

Immunization levels for other diseases among adults also vary considerably. For example, in 2008, less than 6% of adults 18 to 64 years of age had received Tdap (Miller, Ahmed, Lu, Euler, & Kretsinger, 2010). Similarly in 2011, the tetanus immunization rate was 64.5% for persons 19 to 49 years of age, and 63.9% for those over 65. Hepatitis B coverage was 12.5% among those 19 to 49 years of age, HPV coverage was 29.5% for those 19 to 26 years of age, and herpes zoster vaccine (HZV) coverage was roughly 16% in people over 60 years of age (Williams et al., 2013). Possible questions for assessing biological determinants contributing to communicable disease incidence in the population are included in the *Focused Assessment* provided below.

PSYCHOLOGICAL DETERMINANTS. Psychological considerations may play a part in the development of some communicable diseases. For example, stress has been shown to contribute to the development of active TB disease in persons with latent infection. Psychological factors may lead to risk-taking behaviors such as unprotected sexual activity or injecting drug use that increase the risk of STIs, HIV infection, and hepatitis B, C, and D. For example, the presence of post-traumatic stress disorder (PTSD) has been associated with high-risk sexual behaviors in low-income inner-city women. Women with PTSD in one study had more sexual partners, were more likely to have sex with a partner at high-risk for STI, and were more likely to experience partner violence related to condom use than women without PTSD (El-Bassel, Gilbert, Vinocur, Chang, & Wu, 2011).

Communicable diseases may also have psychological consequences for those infected. This is particularly true for conditions that have long-term consequences (e.g., HSV infection, HIV infection, or chronic hepatitis C) or require changes in lifestyle and behavior. In addition, clients with HIV/AIDS may develop dementia, which alters behavior and makes them difficult to care for. Depression may also be a significant

consequence of stigmatizing diseases such as HIV infection or TB in some cultural groups. Failure to disclose one's HIV-positive status, for example, has been linked to a three-fold increased risk for depression (Li et al., 2010). The *Focused Assessment* questions provided on the next page can assist the population health nurse to identify psychological factors related to communicable disease incidence in the population as well as in an individual client.

ENVIRONMENTAL DETERMINANTS. Environmental factors play a part in the development of diseases spread by airborne transmission and those transmitted by fecal–oral means. Overcrowding contributes to the incidence of such diseases as measles, mumps, rubella, polio, diphtheria, pertussis, and varicella. Crowded living conditions also enhance the spread of TB and influenza. For example, an outbreak of 28 cases of TB was associated with a homeless shelter and two neighboring bars frequented by shelter residents (Dobbins et al., 2012). Wind factors are an element of the physical environment that would influence the spread of aerosolized pathogens in the event of a terrorist attack.

Sanitation and disposal of both human and animal feces are other factors in the physical environmental dimension that affect the development of communicable diseases, particularly hepatitis A, tetanus, and polio. The organism causing tetanus is found on a variety of surfaces and is more common in areas where there is animal excrement. In addition, home delivery and poor hygiene on the part of untrained midwives in developing countries contribute to the development of tetanus in neonates and, occasionally, in postpartum women.

In developing countries, poor environmental sanitation contributes to the incidence of diseases such as hepatitis A and E and poliomyelitis. Sanitation is a less likely factor in the development of these diseases in the United States; however, as we saw earlier, contaminated food and water supplies have been implicated in several disease outbreaks related to *Escherichia coli*, hepatitis A, botulism, and other enteric pathogens.

FOCUSED ASSESSMENT

Assessing Biological Determinants Influencing Communicable Diseases

- What age groups are most likely to develop the disease? Are there differences in disease effects among age groups?
- Are there racial/ethnic or gender differences in disease incidence?
- What physiologic conditions, if any, increase the risk of disease?
- Does treatment for existing physiologic conditions increase the risk of disease?
- What are the signs and symptoms of the disease?
- What are the physiologic effects of the disease? What is the effect of the disease in pregnancy?
- What is the mode of disease transmission? What are the physiologic portals of entry and exit?
- Is there a vaccine available for the disease? If so, what are the immunization levels within the population?

FOCUSED ASSESSMENT

Assessing Psychological Determinants Influencing Communicable Diseases

- Does exposure to stress increase the risk of disease?
- Do psychological factors increase the risk of exposure to disease?
- What effect, if any, do psychological factors have on high-risk behaviors that contribute to disease?
- Is past trauma or PTSD associated with the risk of disease?
- Does the presence of mental illness (e.g., depression) increase the risk of disease?
- Does the disease have potential psychological consequences (e.g., suicide risk)?

Exposure to tick-bearing animals such as white-tailed deer, elk, and wild rodents in recreational areas or during outdoor work increases the risk of tickborne diseases such as Rocky Mountain spotted fever. Household pets may also be infested by ticks and pose a risk of exposure to humans. Lyme disease is another neurological disease transmitted by ticks. Approximately 30,000 cases of Lyme disease occur each year in the United States in areas where the black-legged tick are common including the northeastern and mid-Atlantic states and in the west (CDC, 2013e). In 2012, the U.S. incidence rate for Lyme disease was 7 cases per 100,000 population (CDC, 2013f). Other species of ticks may also transmit a variety of diseases to humans.

Animals serve as a source of human infection for many diseases. As we saw in Chapter 4, zoonoses are diseases that can be transmitted from animals to human beings. Rabies and bubonic plague are two examples of zoonoses. Human rabies is relatively rare in the United States, but can be transmitted by the bite of an infected wild or domestic animal. In one case, for example, a woman was infected with rabies from bats roosting in her home. Prior to becoming ill, the woman had sought help for bat removal, but was not referred to the local health department or warned of the potential for rabies (Rupprecht et al., 2013). In other instances, *E. coli* and *Cryptosporidium* outbreaks have occurred as a result of contact with infected animals in petting zoos, state fairs, and at summer camps that include care of livestock (Collier et al., 2011; Griffin et al., 2012). Similarly, MERS antibodies have been found in camels and bats in the Arabian peninsula suggesting possible transmission to human beings (MERS Antibodies Detected in Camels, 2013). Schistosomiasis or snail fever is another disease with environmental links. Humans are infected after skin contact with water contaminated by parasitic worms that emerge from snails. The worms lay eggs throughout the body that cause extensive damage, particularly to the liver. Global climate changes and construction of dams have led to increases in infected snail populations in some areas resulting in increased disease incidence (Fan, 2012).

Recreational pursuits may increase the risk for exposure to pathogens. For example, walking in brushy or heavily wooded areas may result in exposure to disease-bearing ticks.

Many animals transmit diseases to humans.

(Hitdelight/Fotolia)

In California, an outbreak of hantavirus pulmonary syndrome occurred as a result of exposure to mouse droppings in cabins at Yosemite National Park (California Department of Public Health, 2012).

Prevention of infection in human beings often depends on disease control in animals. Population health nurses can help educate the public regarding zoonoses and actions that will prevent their spread to people. For example, routine vaccination of pets against rabies has led to marked decreases in the incidence of human rabies. Population health nurses can educate people on the need to immunize their pets and to avoid wild animals that may have rabies. Similarly, nurses can educate the public about the danger of eating raw eggs, which are often contaminated by pathogens such as *Salmonella*.

Because of differences in physical environmental conditions by region and by season, there are geographic and seasonal differences in the incidence of some communicable diseases. As we saw earlier, there are seasonal differences in influenza

incidence in different areas of the world. Similarly, urban and rural differences are noted in disease incidence. For example, the incidence of HCV is increasing in some rural communities that are less likely than urban areas to mount prevention initiatives (Stanley et al., 2012). Conversely, TB incidence is higher in urban than rural areas, with 48 large U.S. cities accounting for 36% of all cases from 2000 to 2007. Contributing factors include the extent of homelessness, population density, and declining public health infrastructures for TB control. Another factor is the fact that most immigrants from highly TB-endemic countries tend to settle in urban, rather than rural areas (Oren, Winston, Pratt, Robinson, & Narita, 2011).

Elements of the built environment beyond crowding may influence the development of communicable diseases. For example, the only two cholera epidemics to occur in the Americas in recent memory (Peru in 1991 and Haiti in 2010) both resulted from deteriorating water supply infrastructure. In Peru, a water main collapsed creating a sink hole and allowing sewage to contaminate the local drinking water supply. Similar conditions occurred in Haiti after the 2010 earthquake. Both events reinforce the need for clean water and sanitation and the risks of neglecting upkeep to essential infrastructures (Cerdia & Lee, 2013).

Another example of built environment factors contributing to disease incidence is found in the underlying cause of outbreaks of *Legionellosis* in Alcoi, Spain. After repeated outbreaks over a period of 4 years, an epidemiologic investigation determined that the source of infection was the water tank of a street paving machine. Whenever streets were repaved, microorganisms were propelled into the air to result in increased disease in people living in the area (Coscollá, Fenollar, Escribano, & González-Candelas, 2010).

The relationship between environmental factors and communicable diseases can be extremely complex. For example, the relationship between the environment and HIV infection

has been described as a syndemic one in which physical and social environmental factors interact with disease to worsen effects in all areas. Climate change increases migration among “climate refugees” (those leaving poor land conditions) and “conservation refugees” (those displaced from efforts to conserve protected environments). Migration tends to weaken the economy and diminish personal and societal resources to deal with illness and nutritional deficits, which, in turn, make the population more susceptible to HIV infection. Increased susceptibility may be the result of poor overall health or increased high-risk behavior (e.g., sex work) to support life. Conversely, HIV and AIDS decrease productivity among those affected and may lead to abandonment of the land, inability to grow crops due to reduced manpower, and use of natural resources to replace livelihoods (e.g., scavenging for edible foodstuffs or fuel), which depletes resources and leads to food shortages (Talman et al., 2013).

Multiple environmental determinants may contribute to the incidence and prevalence of communicable diseases in individuals and populations. The *Focused Assessment* questions below can assist population health nurses to identify environmental factors influencing communicable disease incidence in a particular population.

SOCIOCULTURAL DETERMINANTS. A variety of social and cultural factors influence the development and course of communicable diseases. For example, congregating with large groups of people indoors during the winter facilitates the spread of airborne diseases, and poverty and poor nutrition increase susceptibility to a variety of diseases, particularly TB. Congregate living in institutional settings also contributes to the spread of disease. For example, TB outbreaks frequently occur in correctional settings, as we saw in Chapter 24. College campuses and military installations experience frequent outbreaks of measles, mumps, pertussis, and meningococcal

FOCUSED ASSESSMENT

Assessing Environmental Determinants Influencing Communicable Diseases

- What effect, if any, do crowded living conditions have on the incidence of the disease?
- Do elements of the built environment serve as sources of contamination and exposure to disease (e.g., contaminated ventilation systems, aging sewer or water supply systems)?
- Can the disease be transmitted to humans by animals or insects?
- What environmental factors increase the risk of human exposure to animal or insect sources of disease (e.g., standing water where mosquitoes breed)?
- Is the disease spread by contaminated food or water?
- Does poor sanitation affect disease incidence?
- Are there seasonal variations in disease incidence? If so, when is the disease most likely to occur? What environmental factors are present at that time that contribute to disease incidence?
- Do environmental factors impede access to diagnostic or treatment services?
- Are there rural/urban differences in disease incidence? If so, what environmental factors contribute to those differences?
- What effects, if any, does the disease have on physical or social environments?

meningitis among young adults in close quarters who are not immunized or whose levels of immunity have declined over time. Outbreaks of communicable diseases are also common in conditions of civil unrest. For example, more than 5,000 people were affected in a Sudanese refugee camp due to poor sanitation and personal hygiene and drinking water contamination (Thomson et al., 2012). Similarly, a cholera epidemic broke out in Haiti and the Dominican Republic after an earthquake disrupted safe water supplies (Jenkins et al., 2010).

Poverty and unemployment, with consequent loss of health insurance, are social factors that may limit the ability of parents to have their children immunized or to provide prompt medical care when illness does occur, resulting in more serious consequences of disease. Pregnant women with low incomes might not receive prenatal care and are thus denied the opportunity to obtain screening and counseling for syphilis, HIV, HBV, and HCV infection or susceptibility to rubella. HIV infection among heterosexual populations in high prevalence areas has been associated with low socioeconomic status, lower education levels, unemployment, and poverty (Denning, DiNenno, & Wiegand, 2011). In one study, census tracts with high poverty levels and high population density accounted for three times more pediatric hospitalizations for influenza than low poverty/low density areas (Yousely-Hindes & Hadler, 2011). Likewise, the racial disparities in STIs noted earlier have been associated with income disparities (Owusu-Edusei, Chesson, Leichliter, Kent, & Aral, 2013). Population health nurses will need to function as political advocates to assure the availability of communicable disease prevention and treatment services for all segments of the population, particularly those of low socioeconomic status.

Policy and legal issues also influence communicable disease incidence and control. For example, in 2013, 63 countries criminalized HIV transmission (UNAIDS, 2013), and in the United States most states have laws criminalizing intentional failure to disclose HIV infection to prospective sexual partners, but such laws have little effect. For example, in one study in New Jersey, 51% of HIV-positive respondents were aware of the law, but awareness was not associated with abstinence, condom use, or disclosure. The study found that, while such laws do not seem to increase stigma associated with HIV infection, neither do they reduce disease transmission (Galletly, Glasman, Pinkerton, & Di Francisco, 2012).

Most states also have laws related to control of TB. CDC has suggested a set of standard provisions for state TB control laws that address general areas of case identification, case management, protection of individual rights, and interjurisdictional collaboration. Case identification provisions include mandated reporting of cases, screening, and investigation of both suspected cases and contacts. Case management provisions focus on state authority to implement control measures related to investigation, treatment, isolation of infectious cases, emergency detention, social distancing measures, penalties, and costs of services as well as “grants of authority to take any necessary action to protect public health” (Thombley & Stier,

2010, p. 53). Isolation or detention features of such laws permit state or local health jurisdictions to isolate infectious patients who refuse treatment under home isolation orders or through incarceration. Provisions related to individual rights address provision of due process, religious exemptions, and confidentiality of information (Thombley & Stier). Social distancing accomplishes the same goals, prevention of the spread of disease, but involves voluntarily staying away from others to avoid exposing them (Kumar, Grefenstette, Galloway, Albert, & Burke, 2013). For further information about the model law provisions, see the *External Resources* section of the student resources site.

Other examples of legal and policy issues that influence communicable disease incidence include mandatory immunizations, police interference with needle exchange programs for IDUs, and school policies on the availability of condoms for use by adolescents. All states mandate specific immunizations for school enrollment, although the specific requirements may vary slightly from state to state. As noted earlier, there are provisions for exemptions for medical, religious, or philosophical reasons. Population health nurses should be knowledgeable regarding immunization requirements in their areas. They should also be aware of the extent of exemption requests and reasons for them and help to educate parents regarding the need for mandated immunizations.

Mandatory HPV vaccination of children has been instituted in some jurisdictions, but has been resisted by some stakeholders on the grounds that immunity to HPV does not protect the general public, but protects the individual from a potential future condition (cancer) and should, therefore, be an individual decision rather than a legal mandate (Mah et al., 2011). During the 2009 H1N1 influenza epidemic, New York State mandated influenza vaccination for all HCPs. At the time, the mandate was resisted on grounds of violating civil liberties, but a significant case can be made for a moral and ethical imperative for immunization of HCPs to protect vulnerable patients (Ottenberg et al., 2011). Immunization of HCPs also helps to maintain the structural integrity of the health care system and its ability to respond to an epidemic.

Many jurisdictions have begun to authorize needle exchange programs and deregulation of syringe sales as a means of preventing the spread of HIV infection and other bloodborne diseases, such as hepatitis B and C and syphilis among IDUs. Unfortunately, local police may interfere with such programs even when they are legal due to lack of legal knowledge, fear of needlestick injuries, and overestimation of occupational risk to themselves (Beletsky et al., 2011).

Finally policies that promote or impede condom access by sexually active adolescents can influence rates of STIs as well as unintended pregnancy rates. Unfortunately, only 5% of U.S. school districts make condoms available to sexually active adolescents (Guttmacher Institute, 2014). Policies that promote STI education in the school setting also influence STI incidence, and population health nurses can advocate for both sexuality education and condom availability in schools.

As noted earlier, travel may be a significant sociocultural factor in the spread of communicable diseases. For example, more than 950,000 travelers enter the United States every day, anyone of whom might have a communicable disease. Legal immigrants and refugees are screened for TB and other diseases prior to entry, but approximately 125 people enter the country each year with active TB disease. Incidence rates for TB are 12 times higher in foreign-born persons than among U.S.-born residents (Kim et al., 2012). Each year, approximately 450,000 legal immigrants and 75,000 refugees enter the United States. In addition to the preentry screening, a medical assessment is recommended for refugees within 30 days after arrival. In 2009, the Electronic Disease Notification System notified state and local health departments of 21,319 refugees with a medical condition, 93% either had evidence of LTBI or X-ray evidence of suspected TB diseases. Approximately one third of the notifications were sent to three states: California, Texas, and New York. Nearly three fourths of notifications resulted in TB follow-up within 30 days of arrival (Lee et al., 2013).

When a report of communicable disease such as TB is received for persons arriving in the United States, an investigation is initiated. Federal isolation orders are issued until the person can be shown to be noncommunicable and travel is restricted. If the person arrived by air on a flight of 8 or more hours, contact investigation is initiated for passengers seated in the same row and two rows ahead and behind the source case (Kim et al., 2012). In an investigation of measles infection acquired during air travel, however, many of those who developed measles were seated more than two rows away from the source case, suggesting that exposure potential may extend beyond those limits. In addition, travelers may be exposed in jetways, departure terminals, or transit lounges (Hoskins et al., 2011). Some countries have instituted border screening based on self-report of symptoms and temperature for international arrivals, but these measures have not been shown to be effective in decreasing disease transmission (Priest, Jennings, Duncan, Brunton, & Baker, 2013).

Persons traveling from the United States to other countries may also become ill after exposures abroad. Approximately 8% of those traveling from developed to developing countries become ill. Diseases related to international travel are monitored by the GeoSentinel Surveillance System. The most commonly acquired diseases include acute unspecified diarrheas, bacterial diarrhea, febrile or systemic illness (approximately 19% of which is due to malaria), giardiasis, and dermatologic conditions (Harvey et al., 2013).

The magnitude of the potential for disease spread through international travel is reflected in many such events. In one case, a traveler returning from India with measles resulted in an outbreak with an additional 22 cases, most of which occurred in a large unvaccinated religious community. The outbreak resulted in over 1,000 persons exposed in various settings and required 2,200 hours of control efforts including written quarantine orders for 81% of susceptible contacts who did not receive vaccine within 72 hours of exposure and oral quarantine

orders of the remaining 18% at tremendous cost to the local health jurisdiction (Sullivan, Moore, & Fleischauer, 2013).

Language barriers, cultural beliefs and values, and lower education levels among some ethnic and socioeconomic groups may impede awareness of the need for immunization or other preventive measures for communicable diseases. In addition, the beliefs of some religious groups prohibit immunizations, thus increasing the size of the susceptible population among their members and in the community at large. Other factors related to religion may impede or promote communicable disease control. For example, a strong religious foundation among African Americans has been shown to be associated with an increase in the stigma attached to HIV infection for Black MSM and to impede disclosure of HIV status to prospective partners (Bird & Voisin, 2013). Conversely, a faith-based HIV prevention intervention for African American women has been associated with increased abstinence and safer sexual practices (Wingood et al., 2013).

In some cases, religious practices may actually contribute to the development of communicable diseases. For example, cases of amebic meningoencephalitis have been attributed to ritual nasal rinsing as part of ablution prior to prayer in some Islamic groups (Hunte et al., 2013).

Gender socialization may also play a part in risk factors that promote STIs, particularly among women. In one study of condom negotiation among sexually active women, participants were found to rely on their male partners to initiate condom use. They cited unequal gender dynamics and beliefs that they were in a monogamous relationship. Even when faced with an STI diagnosis, the women did not feel able to engage in condom negotiation, highlighting the need to consider gender factors in programs to promote condom use (East, Jackson, O'Brien, & Peters, 2010). Socialization and peer group position have also been found to influence high-risk behaviors among runaway homeless youth. In one study, for example, the extent of risk behavior was associated with the strength of a particular youth's

Women can be assisted to develop skills for negotiating condom use with their partners. (Petro Feketa/Fotolia)

connections to other youth engaged in high-risk behaviors (Rice, Barman-Adhukari, Milburn, & Monro, 2012).

Occupational factors are another part of the sociocultural dimension that may contribute to communicable diseases. Work with animals or animal products, for example, may contribute to transmission of zoonoses (Anderson et al., 2013) and sex work increases the potential for HIV infection and other STIs, as well as hepatitis B. Health care personnel and “first responders” (e.g., emergency personnel) are at increased risk for bloodborne diseases, and health care workers are frequently exposed to a variety of other communicable diseases. HCPs have the potential for both exposure to and transmission of diseases such as influenza, yet as noted earlier, vaccine coverage among health care personnel is relative low. As another example, hepatitis B and hepatitis C infections occur in HCPs after occupational exposures. Both employees and children are at risk for hepatitis A when outbreaks occur in child care settings. Certain occupations may contribute to the spread of disease as well as increased potential for exposure. For example, food service personnel may spread hepatitis A, and health care workers may expose clients to a number of communicable diseases.

Social stigma is another aspect of the sociocultural dimension that influences exposure to communicable diseases and attitudes to people who have them. Stigma may derive from fear of people who are different or from fear of exposure to disease, and affects people with communicable diseases in several ways. For example, stigma may increase the personal burden experienced

by those with the disease or prevent them from seeking health care when stigmatized diseases are suspected. Stigma may also attach to professionals and community volunteers who provide services to those with certain communicable diseases.

Social norms that contribute to high-risk behaviors also foster the spread of some communicable diseases. For example, relaxed sexual mores have led to greater sexual promiscuity and increased risk of exposure to HIV infection, STIs, and some forms of hepatitis. Similarly, a social environment in which it is relatively easy to obtain drugs for injecting drug use promotes infection with HIV, syphilis, and hepatitis B, C, and D.

In addition to social factors that contribute to disease, communicable diseases may have social effects. For example, congenital rubella syndrome and congenital syphilis lead to long-term consequences in newborns that have extensive costs for society. Similarly, treatment of persons with chronic hepatitis or HIV infection imposes a costly burden on society, and care of children orphaned by parental death due to AIDS poses another social dilemma. On the other hand, social conditions may have positive effects on the incidence and prevalence of communicable diseases. For instance, raising the taxes on alcohol and increasing the age for legal consumption have been associated with lower incidence of gonorrhea. Alcohol lowers inhibitions to risky sexual behaviors, so control of alcohol use can minimize such behaviors. Sociocultural factors influencing communicable disease incidence in the community can be identified using the *Focused Assessment* questions provided below.

FOCUSED ASSESSMENT

Assessing Sociocultural Determinants Influencing Communicable Diseases

- Does society condone behaviors that increase the risk of disease (e.g., sexual activity)?
- How does socioeconomic status influence disease incidence?
- Does social interaction increase the risk of the spread of disease?
- Is the disease spread easily in congregate living situations? What factors in congregate living situations contribute to the spread of disease?
- What are societal attitudes to the disease? Do they hamper control efforts? Is there social stigma attached to having the disease?
- Does gender or other socialization influence disease incidence?
- Does travel increase the potential for exposure to the disease?
- What influence do policy or legal issues have on incidence of the disease or its control?
- What effect do media messages have on attitudes to the disease? On behaviors that contribute to disease? On willingness to seek care for the disease?
- Do occupational factors influence the incidence of the disease?
- Does socioeconomic status affect risk for the disease? Consequences of the disease?
- Is the disease more common in the homeless population?
- What effect, if any, do language and cultural beliefs and behaviors have on the incidence of the disease?
- How, if at all, do religious beliefs and practices influence the disease?
- What effect does education level have on disease incidence?
- To what extent does gender socialization contribute to disease incidence?
- Is the disease more common in immigrant populations?
- What effects do war and social unrest have on disease incidence, if any?
- What are the social effects of having the disease for the individual or of increased incidence of the disease for the population?
- Does the disease have potential for use as a biological weapon?

BEHAVIORAL DETERMINANTS. Major behavioral determinants that influence the development of communicable disease are related to diet, sexual activity, and injecting drug use. Malnutrition makes people more susceptible to a number of diseases, particularly TB and childhood diseases in unimmunized populations. Malnutrition may also contribute to more severe disease and a greater chance of complications.

Sexual activity obviously increases the risk of STIs, but hepatitis B and D are also spread by sexual activity. Hepatitis C is usually transmitted via percutaneous exposure, but MSM who engage in high-risk sexual behaviors (e.g., anogenital and orogenital sex, use of sex toys, and group sex) are at risk for HCV (Fierer et al., 2011). Similarly, hepatitis A may be transmitted through orogenital sexual activity, particularly among MSM. Sexual transmission of *Shigella* has also been reported among MSM (Adams et al., 2013).

Roughly 27% of new HIV infections in 2009 were acquired by heterosexual activity (Miles et al., 2013), but the bulk of new infections occur in MSM. In 2011, for example, MSM accounted for 78% of all new HIV infections among men in 2011 (Harris et al., 2013). Young Black MSM are at particular risk for infection, and from 2001 to 2006, there was a 93% increase in new HIV infections in this group (Biedrzycki et al., 2011). Youth in general are also at higher risk for HIV infection through sexual activity than other groups. Risk factors for sexual acquisition of HIV infection among youth include early initiation of sexual activity, unprotected intercourse, older partners, sexual abuse, and the presence of other STIs (Division of HIV/AIDS Prevention, 2011).

MSM also account for most new cases of syphilis. For example, 70% to 80% of cases of syphilis in California occurred among MSM, and 57% of MSM with syphilis were also infected with HIV. In addition, California Syphilis Surveillance System data indicated that nearly 6% of MSM in California had repeated primary or secondary syphilis infections within 2 years (Cohen et al., 2012). MSM who seek sexual partners online are more likely than other MSM to be exposed to syphilis due to higher numbers of partners and more anonymous partners (Ng et al., 2013).

Globally, female sex workers are 13.5 times more likely than other women to develop HIV infection (UNAIDS, 2013). Factors contributing to risk for HIV and other STIs among female sex workers include large numbers of partners, unsafe working conditions, inability to negotiate condom use, and criminalization of sex work, which impedes STI screening and treatment (HIV/AIDS Programme, 2012). Transgender women who engage in sex work are also at high risk for HIV infection. In San Francisco, for example, HIV prevalence among transgender females who also engage in injecting drug use is 51% (Rapues et al., 2013).

Women who have sex with women (WSW) are also at greater risk for some STIs. For example, *Chlamydia trachomatis* infection is more prevalent among WSW and those who have sex with both men and women than among strictly heterosexual women. In the National Survey of Family Growth, 11% of

U.S. women between the ages of 15 and 44 reported same sex behavior at some point in their lives, and more than 90% of self-identified lesbians have had sex with men as well as women increasing their risk for STIs. WSW are at higher risk for HPV, HIV, herpes, trichomoniasis, and bacterial vaginitis than heterosexual women (Singh et al., 2011).

Combining sexual activity with drug and alcohol use (other than IDU) also increases the risk for STIs. For example, 40% of HIV-infected adults reported illicit drug use other than marijuana in the prior 12 months. In addition, 40% reported heavy alcohol or crack cocaine use, 14% used stimulants, and 38% used marijuana. Drug use is associated with increased numbers of sexual partners and unprotected sexual activity increasing the risk for STIs (Mimiaga et al., 2013).

Concurrent sexual partnerships also increase one's risk for STIs. Concurrent partnerships are those that overlap in time, and are a significant factor in the spread of sexually transmitted infections. Based on data for the National Survey of Family Growth, 5.7% to 8.3% of U.S. women engaged in concurrent relationships (Adimora, Schoenbach, Taylor, Kahn, & Schwartz, 2011). Studies among men who have sex with men in China (Ha, Liu, Liu, Cai, & Feng, 2010) and New York City (Tieu et al., 2014) reported concurrent sexual partners, and 38% of the men in the Chinese study had concurrent partnerships with both men and women. Concurrent partnerships among women have been associated with younger age and younger age at first intercourse; being formerly married, rather than single or currently married; having a nonmonogamous partner, having sex while under the influence of drugs or alcohol; binge drinking; and cocaine use (Adimora et al., 2011). Men with concurrent partnerships were considerably more likely to report inconsistent condom use (Ha et al., 2010; Tieu et al., 2014), but did not perceive themselves as being at any higher risk for HIV than those with single partners (Ha et al., 2010).

Another behavior that increases the potential for HIV exposure and other STIs (e.g., chronic HBV) is the failure of infected persons to disclose their status to sexual partners. Conversely, use of condoms is a behavioral factor that can protect against exposure to STIs. Unfortunately, the prevalence of condom use by sexually active persons waxes and wanes. Among adolescents, access to condoms may influence their use, but many people are reluctant to provide condoms to sexually active young people out of a fear of promoting sexual activity. Population health nurses may educate sexually active clients, particularly adolescents, about the use of condoms. They may also need to advocate for condom availability to those who are sexually active.

Injecting drug use is another behavioral determinant that influences the incidence of several communicable diseases. For example, globally, IDUs are 22 times more likely to develop HIV infection than the general population in reporting countries (UNAIDS, 2013). In fact, because of easy access to the bloodstream, IDU is more efficient than sexual contact in spreading HIV; however, harm reduction strategies, such as

needle exchange programs among IDUs can decrease percutaneous transmission, making sexual transmission more significant. In addition, use of certain drugs increases the potential for unsafe sexual activity (Des Jarlais et al., 2011). In 2010, 8% of new HIV infections occurred in IDUs, and only 19% of IDUs reported participating in risk reduction interventions (Smith, Martin, Lansky, Mermin, & Choopanya, 2013).

HCV prevalence among IDUs is estimated at 50% (Iverson et al., 2013), and IDUs engaged in sex work are more likely than non-sex workers to develop syphilis. IDUs are also at higher risk than nonusers for several bacterial infections, particularly wound infections such as anthrax, botulism, and *Clostridium* (Hope et al., 2012). In addition, the self-neglect and poor nutrition that frequently accompany injection drug use increases the risk for a variety of other diseases such as tuberculosis, influenza, and pneumonias.

Drug abuse, particularly opiate use, may also result in anergy, reducing the validity of tuberculin tests as a screening tool in these high-risk populations. **Anergy** is an inability to react to antigens commonly used in TB skin testing due to a weakened immune system (Division of Tuberculosis Elimination, 2011). Anergy also occurs in the presence of HIV infection, making it more difficult to diagnose TB in HIV-infected individuals.

Smoking, breast-feeding, and tattooing are other examples of behavioral determinants that may increase one's risk for communicable diseases. Smoking may result in respiratory irritation, increasing the potential for respiratory diseases. Breast-feeding can promote vertical transmission of HIV infection from mother to infant, but transmission is prevented when mothers receive ART. Tattoos may contribute to a variety of skin infections. For example, an outbreak of nontuberculous mycobacterial skin infections was attributed to contamination of tattoo ink (Bedard et al., 2012). The *Focused Assessment* below includes questions that can assist population health nurses to identify behavioral factors influencing communicable disease incidence in population groups or individuals.

HEALTH SYSTEM DETERMINANTS. Factors related to the health care system may also influence the development and course of communicable diseases. For example, charging fees for immunizations may limit the ability of people in lower socioeconomic groups to become adequately immunized. Similarly, missed opportunities for immunizations and provider failure to give immunizations because of mythical contraindications (e.g., presence of mild fever) also increase the risk of communicable diseases.

Health care providers may also fail to provide screening or health education related to communicable diseases. For example, providers often fail to elicit a sexual history thereby missing clients who are at risk for STIs (Satterwhite et al., 2011). Even among providers caring for clients with communicable diseases, the frequency of preventive counseling may be low. The lack of national guidelines for routine health promotion and wellness activities for young men has been cited as a cause of missed opportunities for health promotion, preventive interventions, and screening (Lanier & Sutton, 2013).

Health care providers may also fail to recognize atypical forms of illnesses or emerging or reemerging diseases and treat them effectively. For example, because of its relative infrequency in modern society, providers may lack clinical experience with pertussis or fail to consider it as a possible diagnosis. Similarly, they may fail to consider a diagnosis of HIV in a client with no known risk factors. Health care providers who are unfamiliar with the symptoms of anthrax or other rarely seen conditions may misdiagnose them, leading to inappropriate treatment and greater spread of disease. Providers may also be unfamiliar with recommended treatment guidelines for certain communicable diseases. For example, gonorrhea treatment guidelines were modified in 2006, but a study conducted in 2008 found that the revised guidelines were followed approximately 20% of the time in primary care settings and only slightly more often in STI clinics (28%) (Dowell et al., 2012).

FOCUSED ASSESSMENT

Assessing Behavioral Determinants Influencing Communicable Diseases

- Does diet play a part in the incidence of the disease (e.g., malnutrition as a risk factor for TB)? Does nutritional status influence the consequences of the disease?
- Does alcohol or drug use contribute to the incidence of the disease?
- Does sexual activity increase the risk of the disease? Do specific sexual behaviors increase or decrease the risk of the disease?
- Are people with the disease likely to disclose their infection to others? What barriers to disclosure exist? What effect does willingness to disclose have on controlling spread of the disease?
- Does breast-feeding increase the risk of infection in young children?
- Does smoking increase the risk of disease?
- What other behaviors contribute to the development of disease (e.g., tattooing)?

In addition, inappropriate use of antibiotics by providers may contribute to the development of resistant strains of microorganisms. For example, approximately 258 million courses of antibiotics are prescribed in the United States each year, many of them inappropriate for the conditions being treated. Half of all hospitalized patients receive some form of antibiotic, and nearly half of those are unnecessary or inappropriate (CDC, 2013c).

Health system factors may also contribute more actively to communicable diseases and their effects. For example, **nosocomial infection** (disease spread as a result of exposure in a health care setting) is a significant factor in the spread of communicable diseases. For example, an outbreak of hepatitis B occurred in an assisted living facility due to assisted monitoring of residents' blood glucose levels using inappropriate lancets (Rossheim et al., 2013). An outbreak of *Streptococcus pneumoniae* in another assisted living facility highlighted the need for effective infection control processes in assisted living facilities (Bamberg et al., 2013). In other instances, methylprednisolone injections have resulted in outbreaks of spinal and paraspinal fungal infections and meningitis due to contaminated medication received from compounding pharmacies (Finks et al., 2013; Peterson et al., 2013). As we saw earlier, transfusion and organ transplantation are other health care procedures that may contribute to the development of blood-borne diseases in recipients.

Measles exposure in a hospital emergency department (ED) led to an outbreak that necessitated 4,000 contact investigations and resulted in cases of measles in four other patients and one ED physician. In this particular outbreak, 43% of potentially exposed employees had no documented measles immunity putting them and their patients at risk for disease (Green et al., 2012).

As noted earlier, HCPs are at particular risk for developing and spreading communicable diseases. This is particularly true of HCPs with chronic HBV infection. HBV infection, however, does not preclude health care practice by infected individuals if adequate precautions are taken. U.S. recommendations for preventing HBV exposure of patients by HCPs include screening all providers who engage in exposure prone procedures, vaccinating those who do exposure prone procedures, using safer devices to minimize risk of exposure, and implementing safe work practice controls (e.g., not recapping needles) (Holmberg, Suryaprasad, & Ward, 2012). Similarly, recommended procedures for investigating possible infections associated with health care, such as HBV or HCV, have also been developed (Bornschelegel, Dentinger, Layton, Balter, & France, 2012).

Even routine health care interventions such as immunization may result in unintended illness. For example, rare cases of vaccine-associated paralytic poliomyelitis may occur in persons who receive oral polio vaccine or their close contacts. Such vaccine-associated cases may contribute to outbreaks in populations with low oral polio vaccine (OPV) coverage.

Once worldwide polio eradication has been achieved, OPV use can be discontinued and inactivated polio vaccine (IPV) used to maintain vaccination coverage (Polio Eradication Department, WHO, 2012). Although the risk of vaccine-induced disease occurs, it is lower than the risk of exposure through travel to endemic areas, and immunization prior to travel is recommended.

Other medical treatment interventions have also been associated with communicable diseases in their recipients. For example, medical treatment for conditions such as asthma and autoimmune diseases that require immunosuppressive therapy places individuals at greater risk for complications of influenza. In addition, inappropriate prescription of antimicrobials by health care providers has led to the development of antibiotic-resistant strains of several microorganisms, which will be discussed in more detail later in this chapter.

Provider attitudes to persons with stigmatizing diseases may also influence care. Such attitudes may be reflected in refusal of care, blaming and humiliation, poor quality of care, or violation of confidentiality (Li et al., 2013). Lack of infrastructure support and drug shortages are other health system factors that may influence communicable disease control. For example, a 2010 survey of state health departments indicated that many states lacked sufficient capacity to effectively investigate foodborne disease outbreaks due to delays in notification, lack of personnel, and lack of epidemiologic expertise (Boulton & Rosenberg, 2011). With respect to drug shortages, 178 impending shortages were reported to the Food and Drug Administration (FDA) in 2010. Shortages are most often due to recall of medications due to poor quality or to difficulty procuring raw materials for manufacture. Early FDA notification of anticipated shortages can often help to circumvent them (e.g., through authorization of purchase of foreign-made drugs or other strategies) (Seaworth et al., 2013). Currently, drug shortages are being experienced for both first-line and second-line antituberculosis drugs.

Potential questions for exploring health system determinants in the development of communicable diseases are presented in the *Focused Assessment* on the next page. A communicable disease risk inventory for assessing the risk of communicable diseases in population groups is included on the student resources site.

Diagnostic Reasoning and Control of Communicable Diseases

The population health nurse may derive a variety of nursing diagnoses related to communicable diseases. These diagnoses may reflect the health needs of individuals, families, or population groups. Diagnoses may also reflect the potential for infection or the presence of active disease. For example, the nurse working with a family may diagnose “inadequate immunization status due to poor knowledge of children’s immunization needs.” Possible nursing diagnoses related to individual

FOCUSED ASSESSMENT

Assessing Health System Determinants Influencing Communicable Diseases

- What preventive measures are available for the disease? Are they widely used?
- To what extent do health care providers educate the public on prevention of the disease?
- Is there a vaccine available for the disease? Do vaccine-associated cases of the disease occur? If so, what is the incidence of vaccine-associated disease?
- To what extent are health care personnel immunized against the disease?
- Is there a screening test for the disease? If so, are persons at risk for the disease screened?
- How is the disease diagnosed?
- To what extent are health care providers conversant with the signs and symptoms of the disease?
- To what extent are health care providers conversant with recommended treatments for the disease?
- To what extent do health care providers report cases of the disease? Do they engage in contact notification?
- To what extent do health care settings or provider behaviors contribute to the development of disease? What is the extent of nosocomial infection in the community?
- To what extent do routine medical interventions contribute to the incidence of communicable disease?
- Is there an effective treatment for the disease? Are diagnostic and treatment services for the disease available and accessible to infected persons?
- Are the drugs needed to treat the disease available?
- Do health care systems have the capacity needed to investigate outbreaks of disease?
- To what extent do health care providers engage in practices that might lead to the development of drug-resistant microorganisms?
- Do health care personnel with the disease engage in effective infection control practices?
- Do health care facilities engage in effective infection control practices?
- What are the attitudes of health care providers to persons with the disease? How do these attitudes affect willingness to seek diagnostic and treatment services? To what extent do they affect the quality of care provided?

clients might include “potential for infection with tetanus due to increased risk of occupational injury and lack of recent immunization,” or “failure to obtain routine immunizations due to lack of transportation.” A diagnosis related to the presence of active disease might be “probable tuberculosis as evidenced by symptoms of cough, weight loss, and night sweats and a history of recent travel to an endemic area.”

Nursing diagnoses related to communicable diseases may also be derived for population groups. Diagnoses at the community level may reflect the current incidence of disease or the potential for spread of infection. Examples of such diagnoses are “increased incidence of HCV due to injection drug use” and “potential for increased transmission of HIV infection due to widespread use of unsafe sexual practices among MSM.”

Nursing diagnoses may also reflect the presence of risk factors that affect the development of communicable diseases in individuals or population groups. For example, the nurse may diagnose an “increased risk of hepatitis A due to shellfish contamination in local waters” or “increased risk of tuberculosis transmission from refugees emigrating from endemic areas.”

Planning and Implementing Control Strategies for Communicable Diseases

Many previously known as well as emerging communicable diseases contribute to a significant worldwide burden

of disease, death, and suffering. Control of communicable diseases rests on an understanding of the factors that lead to their development and knowledge of interventions to prevent or treat them. Such understandings allow population health nurses and others to engage in effective control strategies related to health promotion, illness prevention, resolution of existing communicable diseases, and health restoration.

HEALTH PROMOTION. Basic health promotion strategies can reduce susceptibility to communicable diseases in individuals or in population groups. Adequate nutrition is an essential facet of health promotion with respect to communicable diseases. As we saw earlier, malnutrition is a significant contributor to communicable disease morbidity, and particularly mortality, throughout the world. Similarly, maintaining one’s health through adequate rest and physical activity can also reduce one’s susceptibility to illness. Finally, promotion of good coping skills can reduce the contribution of stress to the development of chronic diseases. Population health nurses can educate individuals, families, and population groups regarding good nutrition, rest and exercise, and coping. In addition, they can advocate for the availability of adequate resources to promote overall health.

ILLNESS PREVENTION. Major emphases in preventing communicable diseases include immunization, contact tracing

and notification, pre- and postexposure prophylaxis, and other preventive measures specific to particular communicable diseases.

Immunization. Immunization is the most effective method of preventing the occurrence of communicable diseases for which vaccines are available. The modern concept of immunization originated with William Jenner, and the first smallpox vaccine was developed in 1796, but its use did not become widespread for more than 100 years. Similarly, four other vaccines (rabies, cholera, typhoid, and plague) were developed between 1885 and 1897 but were not widely used (Immunization Action Coalition, 2013). Based on U.S. immunization recommendations, discussed in Chapter 16, children should receive a recommended set of vaccines before the age of 2 years. These immunizations are intended to protect them from multiple diseases. Immunization with selected vaccines is also recommended for adults, as noted in Chapters 17, 18, and 19, and for members of specific groups at high risk for infection. For example, people in certain occupational categories (e.g., health care providers) are at high risk for exposure to a variety of pathogens, and inmates in correctional settings are at increased risk for diseases such as HIV/AIDS, TB, and hepatitis (see Chapters 23 and 24 for more in-depth discussion of immunization needs in these populations). Other immunizations are recommended for people traveling to areas with a high incidence of specific diseases. For example, a booster dose of polio vaccine is recommended for travel to countries with high polio risk (World Health Organization, Division of Global Migration and Quarantine, 2013a). Similarly, the Advisory Committee on Immunization Practices has recommended use of the Japanese Encephalitis vaccine (JE-VC) for persons (including young children) traveling to JE-endemic areas (e.g., rural areas in Asia and the western Pacific), whose planned activities promote exposure to mosquito bites (Bocchini, Rubin, Fischer, Hills, & Staples, 2013). As another example, meningococcal vaccine is recommended for all adolescents, but also for military recruits and travelers to or residents of hyperendemic or epidemic areas (Cohn et al., 2013).

Influenza vaccine is recommended for people over 6 months of age in the United States (Grohskopf et al., 2013) and worldwide (WHO, Collaborating Center for Surveillance, Epidemiology, and Control of Influenza, 2013), but is particularly important for young children, the elderly, and persons with chronic illnesses who are at high risk for complications of influenza. Unfortunately, vaccine efficacy is reduced in the elderly due to suboptimal immune responses (Sagawa, Kojimahara, Otsuka, Kimura, & Yamaguchi, 2011), so immunization of health care workers in long-term care facilities is even more critical than in other health care settings. Health care worker immunization is fostered when employers provide onsite availability at no cost to employees (Ball et al., 2013).

Overall, influenza vaccine effectiveness during the 2012–2013 season was estimated at 56% (Jackson et al., 2013). Despite variability in preventing disease, vaccination has been found to be effective in preventing death and hospitalizations

Immunization is a highly effective preventive measure for many communicable diseases. (casanowe/Fotolia)

among those at risk of complications. In one cost-benefit analysis, influenza immunization for the general population resulted in cost savings of \$6 per vaccination to employers, rising to \$83 per person vaccinated among those with high-risk comorbidities and \$107 per person among older adults (Duncan, Taitel, Zhang, & Kirkham, 2012). Similarly, the New York Department of Health (2013) estimated a cost savings of \$13 per vaccination among health care providers.

HBV vaccine is recommended for all U.S. children under 19 years of age, and WHO has recommended that all countries incorporate HBV vaccine into their routine childhood immunization. Immunization of pregnant women prevents approximately 90% of mother-to-child transmission of HBV. Some countries, however, target vaccine delivery to high-risk women and children born to HBV-positive mothers leaving other children at risk for later development of HBV (Børresen et al., 2012).

Updated tetanus vaccination is particularly recommended for persons with diabetes, IDUs, and those over 65 years of age, who may never have been immunized (Tiwari et al., 2011). Similarly, Tdap is recommended for pregnant women, health care providers, and others who will be caring for young infants to protect them from exposure. Reimmunization may occur as soon as 2 years after a prior dose in this situation (Miller et al., 2010; Sawyer et al., 2013).

Persons who have immune deficiencies can and should receive many of the recommended vaccines. For example, MMR can be given to HIV-positive individuals without severe immunosuppression, and HIV-exposed infants should be re-vaccinated after initiation of ART (McLean et al., 2013).

HPV vaccine is now recommended for both boys and girls after age 11 (Guttmacher Institute, 2014). The vaccine is relatively expensive, costing approximately \$390 for the three-dose series. Fortunately, vaccine coverage will be required of private insurers under ACA, and the Vaccines for Children Program

covers vaccine costs for Medicaid enrollees. State Children's Health Insurance Programs (SCHIP) separate from Medicaid are also required to provide coverage. Internationally, the Global Alliance for Vaccines and Immunization (GAVI) is expected to support HPV vaccine in 28 countries by 2017 (Henry J. Kaiser Family Foundation, 2014).

Bacille Calmette–Guerin (BCG) vaccine is used for TB prevention in some parts of the world, but has been found to be only partially effective. In addition, use of BCG vaccine causes tuberculin skin tests to become reactive and invalidates skin tests as a screening measure for tuberculosis. New vaccines for TB are being developed, and several are currently being tested in animals, so a more effective vaccine may be available in the future. An effective vaccine for malaria may also be available soon. International trials have been promising and the vaccine has been shown to be safe (Ogwang et al., 2013). At present, there are no vaccines for most STDs, for hepatitis C or D, or for HIV infection. There is a vaccine available for HEV, but it is not used in the United States due to the relatively low incidence of the disease, and is not widely used elsewhere in the world (Thomson et al., 2012).

Widespread use of vaccines is a 20th-century phenomenon, but barriers still exist to the use of immunization services. Some of these barriers include lack of access to services (e.g., due to cost), lack of knowledge regarding the need for immunization, parental concerns regarding the discomfort associated with administration of some vaccines (e.g., localized swelling with DTP), and health system limitations such as differences in school entry requirements across jurisdictions, poor enforcement of immunization requirements, and poor data management. Other system barriers are the failure of providers to encourage immunizations other than those required for school entry and missed opportunities for immunization in the course of providing other services. Population health nurses can advocate for the availability of immunization services to all segments of the population and can educate the public and providers on the need for immunization as well as possible adverse reactions. In fact, in some studies, information provided by nurses was the most significant factor in parental decisions to immunize their children (Austvoll-Dahlgren & Helseth, 2010).

Several of the 2020 national health objectives are related to increasing immunization coverage for a variety of communicable diseases (U.S. Department of Health and Human Services, 2014). Some of these objectives with baseline data, current status, and 2020 targets are presented later in this chapter. Additional objectives may be viewed on the *Healthy People 2020* website. For updates on immunization recommendations, see the *External Resources* section of the student resources site.

The problem of data management has also been addressed in the *Healthy People 2020* objectives with the recommendation to develop population-based immunization information systems (IISs) to consolidate records and generate reminders of subsequent immunization needs. IISs record and consolidate confidential information regarding immunizations given

by multiple providers. In 2011, 84% of U.S. children under 6 years of age were included in an IIS (Cardemil, Pabst, & Gerlach, 2013). Immunization levels in the community are fostered by systems that can generate reminder messages. For example, text messages reminding parents of their children's need for immunizations have improved immunization rates, particularly in low-income populations (Stockwell et al., 2012). Similarly, population-based recall systems generated by state IISs have been even more effective in promoting up-to-date immunizations than reminders generated by individual provider offices (Kempe et al., 2013). Population health nurses can advocate for the development of local IISs where they do not already exist and for health care provider participation in existing IISs.

The extent of vaccine coverage in a population is affected by a number of variables, including perceptions of vaccine effectiveness and fear of possible adverse consequences of immunization. Vaccination coverage is also influenced by vaccine availability and distribution. Some authors have questioned the advisability of adding new vaccines into routine immunization schedules in developing countries for fear of overwhelming vaccine storage and delivery infrastructures and causing problems with access to previously required immunizations (Lee et al., 2012). Population health nurses in these countries can help to ascertain the potential effects of the addition of new vaccines to immunization schedules and collaborate in addressing infrastructure constraints. Population health nurses educate the public regarding the need for immunizations. They are also frequently involved in planning, implementing, and evaluating immunization campaigns and in giving immunizations to susceptible individuals. When nurses actually provide immunizations, they are also involved in educating clients regarding normal reactions to vaccines and comfort measures that may be taken to address them (e.g., nonaspirin antipyretics for fever or pain following DTP immunization) as well as signs of potential adverse reactions.

Population health nurses may also advocate for access to immunization services for all segments of the population and may be involved in the enactment and enforcement of immunization policies designed to protect the general public. For example, population health nurses might advocate requirements that college entrants provide evidence of measles immunity or that rotavirus immunization be required for preschool or elementary school entry.

Contact investigation and notification. Contact investigation and notification is a prevention strategy used for some communicable diseases with a relatively long incubation period. **Contact investigation and notification** involves identifying people who might have been exposed to someone with a case of a particular disease, making them aware of the exposure and offering prophylactic treatment and/or screening for the disease. Typically, the source case is interviewed and names of persons who might have been exposed to the disease are elicited. Who constitutes a contact depends on the mode of transmission of

the disease. For example, sexual contacts would be elicited in the case of a sexually transmitted disease, while persons who might share needles and other drug paraphernalia would be obtained from an IDU with syphilis or HIV, HBV, or HCV infection. For airborne diseases, such as TB or measles, family members, coworkers, or school classmates would be considered contacts. People identified are then located and informed of their exposure status. In many instances, they may be required to submit to testing for the disease or be shown to be noncommunicable. For example, health care providers whose children develop streptococcal infection are frequently required to have negative cultures or be placed on antibiotic therapy before they will be allowed to return to work.

Contact notification can be an expensive undertaking, so contacts should be prioritized in terms of the likelihood of developing the disease. For example, TB contacts would be prioritized on the basis of the infectiousness of the source case, the age and immune status of the contacts, and the intensity and duration of exposure. The World Health Organization has suggested that each person with infectious TB will have at least three close contacts and that approximately 2.5% of those contacts will also have active TB. Routine contact investigation could promote early identification of 300,000 cases of TB per year permitting early treatment and minimizing the spread of disease (WHO, 2012). Many more people may have latent TB and, with treatment, can be prevented from progressing to active disease. As we saw earlier, some people with communicable disease may have significantly more contacts who may have already spread the disease to others leading to widespread and costly contact investigations.

Contact investigation may be more effective when those exposed can be screened on the spot rather than having to go to a health care setting for screening and treatment. For example, the use of rapid HIV screening kits in the field when contacting sex and needle-sharing partners of HIV-positive individuals in New York City increased the percentage of partners screened from 52% to 76% (Renaud et al., 2011).

Population health nurses are frequently involved in contact investigation and notification. They may interview clients with communicable diseases to elicit the names of relevant contacts. In addition, they are often the ones to notify contacts of their status and offer them needed screening and treatment services. Nurses involved in contact investigations may make home visits or approach contacts at work or any other place where they can be located. When they approach contacts, nurses should speak to them in a setting that ensures privacy and inform them that they have been exposed to a communicable disease. Nurses frequently need to exercise creativity to protect both the confidentiality of the source case and the contact and prevent others from knowing why the person is being contacted by a nurse.

Pre- and postexposure prophylaxis. One of the advantages of contact identification and notification is the ability to offer treatment to people prior to exposure to or development of a

particular disease. **Preexposure prophylaxis (PrEP)** involves provision of treatment to people who have not yet been exposed to a disease, but who are at high risk for exposure. For example, IDUs and MSM in areas of high HIV infection prevalence might be offered prophylactic ART to prevent them from becoming infected. CDC recommends daily ART preexposure prophylaxis to prevent HIV infection in MSM, IDUs, and heterosexual men and women in high prevalence areas (Leibowitz, Parker, & Rotherham-Bonus, 2011; Smith et al., 2013).

Postexposure prophylaxis (PEP) was defined in Chapter 23 and involves the use of medications or vaccines to prevent the onset of disease in exposed individuals. When individuals are prevented from developing symptomatic disease, they are usually also prevented from spreading the disease to others. PEP has been used for a variety of diseases. For example, people at high risk for complications, pregnant women, and infants exposed to measles should be given MMR vaccine or measles immune globulin to prevent disease (McLean et al., 2013). Similarly, varicella immune globulin is recommended for persons exposed to varicella who have no evidence of immunity and are at high risk for severe disease (CDC, 2012a; Marin, Bialek, & Seward, 2013). PEP is also used for rabies and meningococcal disease exposures (Cohn et al., 2013; Rupprecht et al., 2013).

Postexposure prophylaxis has been used extensively to prevent contacts to cases of tuberculosis and persons with latent TB infection from developing active disease (Miramontes et al., 2013). Traditional contact notification for STIs may be replaced by a newer strategy of **expedited partner therapy (EPT)**, which involves providing an individual with a STI with medication to be given to his or her sexual partners without an examination or screening test. CDC recommends EPT for treatment of partners of persons infected with gonorrhea and *Chlamydia trachomatis* (Division of STD Prevention, 2014). Other recommendations are to advocate for legal support of EPT through exceptions to prescription laws, promoting professional support of EPT, and advocating for third-party reimbursement for EPT.

Health care workers are often the recipients of PEP after occupational exposures to a variety of organisms. PEP is highly recommended for health care workers with LTBI and for those with HIV exposures, as well as for HBV and HCV exposure. Population health nurses may need to advocate for effective PrEP and PEP policies for specific vulnerable populations (e.g., homeless persons or inmates in correctional settings). They may also need to advocate for funding for and development of easily accessible services for the general public.

Other prevention measures. Other prevention strategies for communicable diseases may be directed toward the mode of transmission of specific diseases. Prevention for tetanus due to puncture wounds, for example, involves educating clients on the use of protective clothing (e.g., gloves, boots) to prevent injuries and the need for adequate cleansing of wounds with soap and water when injuries do occur. Effective wound care is also critical in preventing rabies after animal bites. Vaccine-laden bait can

also be used to immunize wildlife against rabies in high prevalence areas (Kellogg et al., 2013). Disinfection of equipment in health care settings also helps to prevent the spread of communicable diseases.

For STIs, refraining from sexual activity is the most effective means of preventing diseases. For those who are sexually active, however, use of condoms and refraining from unsafe sexual practices may limit exposure to disease. MSM and others who engage in high-risk sexual behaviors (e.g., with multiple partners, anal receptive intercourse) should also be encouraged to use condoms. Population health nurses can advocate for condom use with sexually active clients who engage in high-risk behaviors. They may also educate clients on the correct use of condoms or may advocate for condom availability to special groups like adolescents or correctional inmates. Population health nurses can also inform clients who engage in oral–genital intercourse as a mode of contraception that they continue to be at risk for STI transmission.

Serosorting is another effective strategy for preventing the spread of HIV infection among MSM. As we saw in Chapter 20, serosorting involves limiting one’s sexual partners to people who are of the same HIV status as oneself (Eaton, Cherry, Cain, & Pope, 2011). Population health nurses can encourage serosorting among MSM without steady partners. Another approach to STI prevention involves focusing on the ABCs of abstinence, being faithful, and condom use promulgated by the United States President’s Emergency Plan for AIDS Relief (PEPFAR, n.d.), although such strategies may be difficult for women in unequal power relationships.

WHO has identified several additional strategies to prevent STIs in sex workers, thereby preventing the spread of disease in the general public. Recommendations include decriminalizing sex work, providing health service access for sex workers, preventing violence against sex workers, empowering this segment of the population to advocate for themselves, and providing periodic screening for STIs and HIV infection. Additional prevention strategies include providing presumptive STI treatment for asymptomatic sex workers in high prevalence settings,

Sexually transmitted infections, as well as unwanted pregnancies, can be prevented with condom use. (Urbanhearts/Fotolia)

providing ART for HIV-infected sex workers, engaging in harm-reduction strategies for sex workers who inject drugs, and providing HBV vaccinations (HIV/AIDS Programme, 2012).

Preventing bloodborne diseases such as HIV/AIDS and hepatitis B, C, and D involves prevention of drug use or promotion of harm-reduction strategies such as needle exchanges and education on safer drug use procedures. Because these strategies are often not acceptable to the general public or to health policy makers, population health nurses may be involved in advocacy to establish needle exchange programs and other harm-reduction strategies. Infection through occupational exposure to bloodborne diseases can be prevented by means of universal precautions for the handling of blood and other bodily secretions and excretions. Unfortunately, many persons in these occupations fail to use universal precautions, increasing their risk of disease. Screening of blood and tissue donors for HIV and for hepatitis B, C, and D has virtually eliminated transmission of these diseases by means of transfusion.

For foodborne and waterborne diseases, control measures are aimed at improving sanitation, protecting food and water from contamination, and promoting adequate hand washing. Washing fruits and vegetables before eating, boiling contaminated water, and discouraging use of human waste as fertilizer may also serve to prevent diseases in developing countries. Population health nurses can educate people regarding adequate hygiene and the need to wash fruits and vegetables before eating them, particularly those imported from other countries. They can also discourage consumption of shellfish retrieved from contaminated waters and promote environmental policies that prevent contamination of shellfish beds. In addition, nurses can advocate for safe water supplies, effective sanitation and enforcement of food processing techniques that minimize the potential for bacterial contamination (Honish et al., 2013). Promotion of good hygiene and sanitation in areas where animals are kept can also help to prevent the spread of zoonoses (Collier et al., 2011).

Population health nurses may also collaborate with environmental specialists to address issues of food or water contamination with pathogens. For example, the nurse might alert water authorities regarding a sudden increase in diarrheal diseases in a particular neighborhood, suggesting that water sources may be contaminated. Or the nurse might identify unsanitary conditions in a restaurant and notify the appropriate inspectors.

Prevention of crowding is a control measure for conditions such as TB and influenza. Other primary prevention measures include the use of adequate ventilation and ultraviolet light in areas that increase the risk of TB transmission. For example, areas in which aerosol sputum specimens are collected provide an environment conducive to the spread of disease that can be modified using these measures. Providing appropriate facilities for isolating infectious clients in hospitals and other institutions also minimizes the risk of transmission to health care personnel. Population health nurses can work with environmental engineers to address such problems or collaborate with

housing authority personnel to address housing conditions conducive to diseases. Grouping patients with drug-resistant strains of microorganisms and personnel caring for them can also help prevent the spread of drug-resistant infections (Jacob et al., 2013).

Prevention of tickborne diseases involves use of tick repellents, avoidance of tall grass and other vegetation, and use of protective clothing. Daily inspection of people and pets for ticks is also recommended. Wearing light-colored clothing may make ticks more visible. Environmental measures for preventing exposure to tickborne diseases include use of pesticides on lawns, removal of brush and leaf litter from around homes, and creating buffer zones of wood chips or gravel between wooded or brushy areas and human habitations. Similarly, removal of standing water and other breeding grounds for mosquitoes can help prevent mosquito-borne diseases such as WNV infection. Pregnant women, in particular, should avoid mosquito exposure, use insect repellent, wear long sleeves and long pants, and avoid being outdoors at dawn and dusk to minimize the risk of WNV infection for themselves and their infants. Use of long-lasting insecticide treated bed nets and indoor spraying can minimize the spread of malaria (Cullen & Arguin, 2013; Mace et al., 2011). Population health nurses often work with environmental specialists and veterinarians to address diseases transmitted from animals to humans.

Other measures that aid in the control of communicable diseases include legislation requiring screening for specific diseases in high-risk groups, mandatory reporting of cases of communicable disease with contact notification and follow-up, and regulation of potential vehicles of transmission such as insects. Population health nursing involvement in other control measures for communicable diseases generally lies in educating the public and individual clients regarding prevention and in identifying and helping to eliminate risk factors for exposure and disease.

Pandemic and bioterrorism preparedness. One further aspect of prevention related to communicable disease addresses preparation for a possible pandemic or bioterrorist event. As we saw in Chapter 25, population health nurses are actively involved in identifying the potential for and probable community effects of such disasters. For example, they would identify risk factors for infection in the population in the event of a pandemic (e.g., segments of the population with poor nutritional status that puts them at particular risk for serious disease). They would also be involved in planning for community response to a pandemic or bioterrorist attack. In addition, population health nurses would be actively involved in informing the public regarding preventive measures or other appropriate responses to the threat of a pandemic or bioterrorist event.

Bioterrorism and pandemic preparedness are important not only because of the potential for significant morbidity and mortality resulting from either event, but also because of other population effects that might occur. For example, either a pandemic or a bioterrorist-caused epidemic might cause severe

economic effects as a result of business closures to prevent spread of the disease. Availability of food and other essential goods might also be impaired if production and transportation systems are severely affected. Short-term educational effects might also be noted if schools are closed for extended periods of time. One of the most serious effects might be the burden placed on an already overburdened health care system if significant numbers of health care personnel become ill. There is also the problem of inadequate facilities and supplies (including drugs and vaccines) needed to address widespread communicable disease incidence. Preparedness will help to mitigate these potential effects, although it is unlikely that they can be prevented altogether. Health promotion and disease prevention strategies for communicable diseases, including pandemic and bioterrorism preparedness, are summarized in Table 26-3.

RESOLVING EXISTING PROBLEMS OF COMMUNICABLE DISEASE. Resolution activities in relation to communicable diseases include case finding and surveillance, screening, diagnosis and reporting, and treatment.

Case finding and surveillance. Because they serve large segments of the population who may not receive care from other health care providers, population health nurses are in a unique position to identify possible cases of communicable diseases. Once a person with a potential communicable disease has been identified, the population health nurse may make a referral for further diagnosis and treatment. In some cases, the nurse may be involved in diagnosing and treating communicable diseases on the basis of medically approved protocols. The case finding function of the population health nurse was discussed in general in Chapter 1.

To identify a possible case of a communicable disease, population health nurses need to be familiar with the signs and symptoms of communicable diseases commonly seen in their area. They should also be familiar with the signs and symptoms of diseases that may result from bioterrorist activities.

Case finding related to outbreaks of communicable diseases within populations may require some creative strategies. For example, electronic messaging and other media were used to find cases of *Cyclospora* during an outbreak in Iowa. Alerts were also sent to all hospitals, emergency departments, public health agencies, and providers to alert them to the possibility of a *Cyclospora* diagnosis in patients with symptoms of watery diarrhea, nausea, anorexia, abdominal cramping, fatigue, and weight loss. Similarly, e-mail press releases were sent to news media to alert the public (Kalas & Quinlisk, 2013). Contact tracing may also be used to find cases of disease.

Case finding at the population level contributes to surveillance. As we saw in Chapter 1, surveillance involves the gathering and analysis of data that reflect trends in disease incidence and prevalence as well as information on the effects of disease within the population. Population health nurses may collect surveillance data or identify cases of disease that are reported to local epidemiologists for inclusion in surveillance

TABLE 26-3 Health Promotion and Prevention in Communicable Disease Control

Health Promotion Foci	Population Health Nursing Interventions
Nutrition	<ul style="list-style-type: none"> • Educate clients and the public on good nutrition • Advocate for access to adequate nutrition sources
Rest and physical activity	<ul style="list-style-type: none"> • Promote adequate rest and physical activity to maintain health
Coping	<ul style="list-style-type: none"> • Model and teach effective coping strategies to minimize stress • Advocate for living conditions than minimize stress
Disease Prevention Foci	Population Health Nursing Interventions
Immunization	<ul style="list-style-type: none"> • Educate clients and the public regarding the need for immunizations • Refer clients for immunization services • Provide immunization services • Advocate for access to immunization services for all segments of the population • Ascertain the potential effects of introducing new vaccines in constrained environments and collaborate to address infrastructure issues
Contact investigation and notification	<ul style="list-style-type: none"> • Educate providers regarding the legal requirements for reporting communicable diseases • Interview clients with communicable diseases for names and locating information for close contacts • Inform contacts of their exposure to a communicable disease • Refer contacts for testing and PrEP or PEP as needed • Educate clients regarding preventive measures and the need to prevent the spread of disease to others • Advocate for and plan effective contact notification services • Promote contact notification by other health care providers and educate them regarding contact notification • Advocate for/provide field screening services for contacts
Pre- and postexposure prophylaxis	<ul style="list-style-type: none"> • Refer clients for services as needed • Provide PrEP/PEP under established protocols • Monitor and promote compliance with PEP among contacts • Monitor for adverse effects and side effects of PEP and refer for medical evaluation if needed • Advocate for the availability of PEP for clients in need • Provide expedited partner therapy (EPT) • Advocate changes in prescribing laws and for insurance coverage of EPT
Other primary prevention measures	<ul style="list-style-type: none"> • Educate clients and the public regarding effective wound care • Educate clients and the public on safe sexual practices, use of condoms, etc. • Prevent drug abuse or refer clients for drug abuse treatment • Promote harm-reduction strategies to prevent infection among IDUs • Promote use of universal precautions for bloodborne diseases • Promote adequate hand washing, washing of produce, etc. • Advocate for adequate sanitation and safe water supplies • Advocate for policies and processes that prevent contamination of food and water supplies • Promote adequate housing to prevent crowding and allow for adequate ventilation • Promote use of ultraviolet light in settings where exposure to pathogens is common • Advocate for preventive education and services • Advocate for STI prevention strategies among commercial sex workers and for decriminalization of sex work
Pandemic and bioterrorism preparedness	<ul style="list-style-type: none"> • Assist in identifying the potential for a pandemic or bioterrorist event • Assist in identifying particularly vulnerable populations and factors influencing their vulnerability • Participate in planning community response to a pandemic or bioterrorist event • Educate the public and other health care providers regarding prevention of illness or self-care during a pandemic or bioterrorist event • Educate the public regarding the signs and symptoms of disease resulting from a pandemic or bioterrorist event and sources of treatment

systems. Analysis of surveillance data is usually undertaken by epidemiologists or health information system specialists and the results of the analysis conveyed to public health officials and other health policy makers.

Screening. Screening is presumptive identification of asymptomatic persons with disease. Screening may involve either selective or mass screening. **Selective screening** is screening directed toward persons exhibiting risk factors for a particular disease. **Mass**

screening involves screening an entire population regardless of the level of risk among individuals. For example, prior screening recommendations for HCV infection were risk-based, focusing screening activities on persons at risk for HCV (e.g., IDUs; hemodialysis, transfusion, and transplant recipients; exposed health care workers, and children born to HCV-positive mothers). More recent recommendations have added a one time mass screening of persons born between 1945 and 1965 (Mahajan et al., 2013; U.S. Preventive Services Task Force [USPSTF], 2013a).

Screening is not generally done for communicable diseases that have a short incubation period such as measles, rubella, influenza, and so on. Screening tests are available, however, for diseases such as HIV/AIDS, hepatitis A, B, and C, TB, and STIs such as gonorrhea, syphilis, *Chlamydia*, and HSV infection.

Screening for HIV infection is recommended for all pregnant women at entry into prenatal care or during labor if HIV status is unknown. In addition, screening is routinely recommended for all people aged 15 to 65 years in the United States and persons over age 65 if at risk (e.g., sexually active or IDUs) (USPSTF, 2013b). Overall, in 2010, 9% of U.S. adults had been screened for HIV in the prior year (Cohen et al., 2011). Based on National HIV Behavioral Surveillance (NHBS) system data, 25% of heterosexual participants in high HIV prevalence areas had never been tested for HIV until they participated in the survey. Slightly over 2% of participants were found to be HIV-positive, and increased screening outreach was particularly recommended for low-income, low-education groups in high prevalence areas (Miles et al., 2013).

HIV screening is least effective during the period between the appearance of HIV RNA and detection of HIV-specific antibodies in the blood. For this reason, a new diagnostic algorithm has been suggested, in which those with negative immunoassay screening results receive RNA testing. The availability of rapid screening tests makes provision of same-day screening results possible, increasing the number of HIV-positive individuals who are referred for treatment services (Geren et al., 2013).

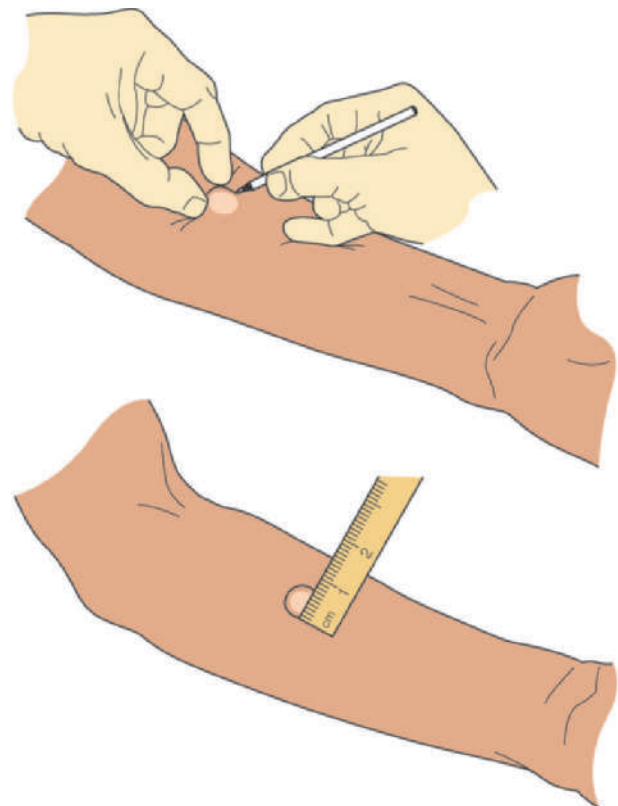

One strategy that has been suggested to improve identification of those with undiagnosed HIV infection is social networking. A social network strategy involves using HIV-infected clients and those at high risk for infection to recruit people from their social, sexual, and drug-use networks for HIV screening, counseling, and referral for treatment, if needed. This strategy has been particularly effective in promoting HIV screening among MSM, but because of its resource-intensive nature, research is needed to determine its cost-effectiveness in this and other populations (McCree et al., 2013).

Opt-out testing is another strategy that is recommended for certain populations (e.g., correctional inmates). In opt-out testing, screening for HIV is performed at entry unless the inmate specifically refuses testing as opposed to opt-in testing in which inmates are offered the test and must choose to receive it, or testing on request initiated by the inmate. CDC recommends opt-out testing in correctional settings (Strick, McGowan, & Belcher, 2011).

Screening of all sexually active women 24 years of age and under and pregnant women of all ages for *Chlamydia*

trachomatis infection is also recommended (Singh et al, 2011). In fact, *Chlamydia* screening has been identified by the USPSTF as “one of the 10 most beneficial and cost-effective preventive services” (Satterwhite et al., 2011, p. 370), but is greatly underutilized. In 2009 for example, less than 60% of women under 25 years of age were screened. The Los Angeles County Health Department initiated the use of free home screening kits for *Chlamydia* and gonorrhea as a means of fostering screening for these STIs among sexually active women. In the first year of the program, nearly 3,000 kits were dispensed and more than half were returned with testable specimens. Among those with positive screening results, 88% retrieved their results and confirmed treatment (Rotblatt et al., 2013). Population health nurses can advocate for screening of sexually active women for a variety of STIs during routine health promotion visits. They may also be involved in educating other health care providers regarding the need for screening or in promoting self-screening programs like that initiated in Los Angeles.

There are two approaches to identification of tuberculosis—a tuberculin skin test (TST) or use of interferon γ release assay (IGRA). A positive or significant reaction to TST is based on the degree of induration that results. **Induration** is a palpable, hard, raised area around the injection site with clearly defined margins. *Induration* does not refer to redness around the injection site. In a person without known risk factors, an area of induration of 15 mm or greater is considered a significant reaction. For recent immigrants, IDUs, residents or employees of

A positive TB skin test showing induration (National Medical Slide).

congregate settings, mycobacteriology lab personnel, those at high risk for disease, children under 4 years of age, and children and adolescents exposed to adults at high risk, 10 mm or more induration is considered positive, and 5 mm is considered a positive reaction for persons with HIV infection or other cause of immunosuppression, transplant recipients, close contacts to an infectious case of TB, or persons with chest X-ray results consistent with prior untreated TB (Division of Tuberculosis Elimination, 2011). A positive tuberculin skin test is shown in the picture on the previous page. The area of induration in the picture is demarcated with ink on all four sides.

There is a shortage of TST antigens in some areas, so IGRA, a more expensive test, can be used instead if available. IGRA has the advantage of being of use with people who have received BCG vaccine as BCG invalidates TST results. In areas with limited supplies of TST antigens or IGRA capacity, screening should be prioritized to those at greatest risk for developing TB (Jereb, Mase, Chorba, & Castro, 2013).

Reaching people at greatest need for TB screening can sometimes be difficult. One suggestion to reach immigrant populations is to offer screening in adult education centers that provide services to immigrants. One such project, for example, found 18.5% of program participants to have positive TSTs (Wieland et al., 2011). Another approach was used by a Texas county health department. Incidence data were used to identify the two neighborhoods with the highest incidence and density of TB cases and persons with LTBI. Outreach workers then went door to door offering TSTs. Results were read in the homes in the appropriate timeframe, and positive reactors were escorted by outreach workers to a mobile clinic for X-ray, clinical evaluation, and treatment services. Using this approach 57% of the population of the two areas was tested, with nearly 18% testing positive. Treatment was initiated for 147 people who might otherwise not have been found. Over the subsequent 10 years, no new cases of TB disease were reported from either neighborhood (Cegielski et al., 2013). Congregate living settings, such as correctional facilities and homeless shelters, are other places in which TB screening is warranted.

Because of the complex interaction between TB and HIV infection, persons with HIV infection should be screened for TB. Conversely, people with TB disease or latent TB infection at risk for HIV infection, should be screened. Population health nurses should keep in mind, however, that people with HIV infection or AIDS may have negative sputum smears for TB and up to a third of them may have normal chest X-rays. In addition, persons with HIV infection are more likely to develop extrapulmonary TB (Getahun et al., 2012).

In resource-constrained settings, WHO has recommended screening all individuals with HIV/AIDS for three symptoms: cough, fever, and night sweats. If none of the three are present, the individual should be offered a 6-month course of isoniazid prophylactic treatment (IPT) for TB. If a tuberculin skin test is positive, but none of the three symptoms is present, IPT should also be considered for 6 months. IPT may be continued for life if feasible. Finally, if any of the three symptoms is present, a TB diagnostic workup should be conducted (Getahun et al., 2012).

HBV screening is recommended for all pregnant women at the first prenatal visit (USPSTF, 2009) and for those at risk of disease (e.g., exposed health care workers, IDUs, sexual or drug contacts to infected persons). As noted earlier, HCV screening is recommended for persons at high risk of exposure as well as those born between 1945 and 1965. This age cohort accounts for approximately 75% of HCV infections in the United States and 73% of HCV-related mortality. One time screening is recommended for this group followed by a brief screening for alcohol abuse and referral for care if needed (Smith et al., 2013). It is anticipated that cohort-based screening of this age group could prevent 120,000 deaths with subsequent treatment with antiviral therapy (Mahajan et al., 2013).

Because of the link between HCV and injecting drug use, drug treatment programs have been suggested as an ideal setting in which to conduct HCV screening. Unfortunately, only 34% of drug treatment programs responding to a national survey offered HCV screening (Frimpong, 2013).

Population health nurses may need to actively advocate for screening as a regular practice in correctional and drug treatment settings. They may refer individuals at risk for disease to appropriate screening resources. Many population health nurses may also be involved in conducting screening examinations and tests and in counseling clients regarding test results and their implications. Population health nurses may also need to advocate for the availability of screening services and for follow-up and treatment (therapeutic or prophylactic) of persons with positive screening tests.

Diagnosis and reporting. Diagnosis of many communicable diseases relies on serologic evidence of disease markers or the actual presence of causative organisms. For example, diagnostic tests for syphilis and hepatitis A, B, C, and D rely on the presence of specific antibodies in the blood of infected persons. More sophisticated tests for syphilis, on the other hand, are based on demonstration of the presence of the actual causative organism in the bloodstream and are used when antibody-based tests are inconclusive. Similarly, tests for gonorrhea involve cultures of urine or urethral, vaginal, anal, or pharyngeal specimens for growth of *Neisseria gonorrhoeae*, and diagnostic tests for *Chlamydia* infection include culture of specimens for *Chlamydia trachomatis*. Diagnosis of many childhood diseases is based on physical signs and symptoms, with laboratory confirmation for some diseases (e.g., measles, pertussis, diphtheria, tetanus, etc.).

Population health nurses may refer suspected cases of communicable diseases for diagnostic confirmation. In addition, nurses may educate clients regarding the types of diagnostic procedures likely to be used. Population health nurses may also be involved in conducting some diagnostic tests for communicable diseases. For example, population health nurses in some agencies routinely draw blood for diagnostic tests for syphilis and collect urine samples for gonorrhea testing.

Diagnosis of TB is of particular concern worldwide, and the Tuberculosis Coalition for Technical Assistance (2014), a group composed of several national and international agencies, has developed *International Standards for Tuberculosis Care*, which

address diagnostic and treatment standards, standards for addressing comorbid conditions, and standards for public health and prevention. Elements of the standards are summarized in Table 26-4.

In the United States, diagnosis of TB is most often based on X-ray findings. However, given the lack of reliability of X-rays in diagnosing TB in persons with HIV infection, newer diagnostic tests have been developed. For example, the Xpert MTB/RIF assay of unprocessed sputum or concentrated sediments can provide a diagnosis of TB within 2 hours. The assay can also detect rifampin-resistant strains of *Mycobacterium tuberculosis*. Because of its relatively high cost, it is not used routinely for people for whom X-rays provide definitive

results (Division of Tuberculosis Elimination, 2013; Getahun et al., 2012).

Diagnosis of viral hepatitis is frequently based on the presence of viral antibodies and rapid testing is available for HCV using the OraQuick® HCV Rapid Antibody Test (Getchell et al., 2013). In order to determine if positive results are due to past or current HCV infection, HCV RNA testing is required. In one large study of newly reported cases, just over half of them were current infections (Bornschlegel et al., 2013).

Effective control of communicable diseases requires that diagnoses of many communicable diseases, including TB, be reported to local public health authorities. These reports are then forwarded to state and federal agencies. In the case of some

TABLE 26-4 Summary of International Standards for Tuberculosis Care

Focus	Related Standards
Diagnosis	<ul style="list-style-type: none"> • Clinician awareness of risk factors and prompt testing of persons with symptoms • TB evaluation for all persons with unexplained cough two weeks or longer or radiographic findings suggestive of TB • Submission of two sputum specimens for smear microscopy by all patients capable of producing sputum, including children. Performance of Xpert MTB/RIF tests performed as the initial diagnostic test for those with HIV risk, risk of resistance, or who are seriously ill • Diagnostic specimens collected from relevant sites for persons suspected of extrapulmonary TB, including children. Use of Xpert MTB/RIF testing for suspected tuberculous meningitis • Use of sputum culture for all those suspected of TB who have negative sputum smears. Initiation of antituberculin treatment in persons with negative smears with strong clinical evidence for TB disease after cultures are collected • Use of smear microscopy and/or culture of respiratory secretions (via expectorated or induced sputum or gastric lavage) for all children with suspected intrathoracic TB
Treatment	<ul style="list-style-type: none"> • Prescription and monitoring of appropriate treatment for all diagnosed cases of TB • Use of first-line WHO-approved quality assured drugs for all patients who have not been previously treated and do not have risk factors for drug resistance • Use of a patient-centered approach to promote treatment adherence, improve quality of life, and relieve suffering • Monitoring of treatment effects with follow-up sputum smears after 2–3 months with sensitivity testing for continued positive smears • Assessment of the likelihood of drug resistance with sensitivity testing and changes in therapeutic regimens as indicated • Use of specialized treatment regimens with quality drugs for persons likely to have drug-resistant TB • Maintenance of systematic records of treatment, including medications given, response, and adverse reactions for all clients
Addressing comorbidities	<ul style="list-style-type: none"> • HIV testing and counseling for all clients with suspected TB in the absence of HIV testing in the last 2 months. Use of integrated TB and HIV treatment approaches in high HIV prevalence areas • Initiation of ART within 2 weeks of TB treatment initiation in those with HIV and TB with profound immunosuppression, unless TB meningitis is present and within 8 weeks for all others with HIV and TB infection • Treatment of persons with HIV infection for presumed latent TB for at least 6 months • Thorough assessment for other comorbid conditions that could affect TB treatment response or outcomes and provision of additional services as needed
Public health and prevention	<ul style="list-style-type: none"> • Evaluation and appropriate management of all persons in close contact with persons with infectious TB, with special emphasis on children, immunocompromised persons, persons with symptoms suggestive of TB, and contacts to patients with MDR/XDR TB • Treatment for latent TB for all children and persons with HIV infection who do not currently have active TB • Development of infection control plans to prevent the spread of disease to others, including health care workers • Reporting of new and re-treatment of cases of TB and treatment to local health authorities

Data from: Tuberculosis Coalition for Technical Assistance. (2014). *International standards for tuberculosis care: Diagnosis, treatment, public health* (3rd ed.). Retrieved from <http://www.thoracic.org/assemblies/mtpi/resources/istc-report.pdf>

diseases, national agencies report diagnosed cases to WHO. The list of reportable diseases varies somewhat from one jurisdiction to another (usually at the state level), and population health nurses should inform themselves regarding the reportable diseases in their own locale. Laboratories are required to report positive test results for reportable diseases to official public health agencies, and health care providers who make the actual diagnosis are also required to submit a disease notification report. Reports are usually completed by the physician, nurse practitioner, or other health care provider who makes the diagnosis, but in some settings, reports may be made by population health nurses or other nurses.

In the United States, three categories of diseases are reportable at the national level. The first category includes diseases that are extremely urgent and should be reported to CDC within 4 hours by telephone, followed by electronic submission of a report the next business day. Extremely urgent diseases include anthrax, botulism, plague, paralytic polio, SARS-associated coronavirus, smallpox, tularemia, and viral hemorrhagic fevers. Urgent diseases are to be reported by telephone within 24 hours, with an electronic report with the next regularly scheduled electronic data submission. The final category encompasses diseases to be reported in the next regular reporting cycle. An information resource for diseases in each category from the Council of State and Territorial Epidemiologists (2012) is provided on the student resources site.

There are also two categories of communicable disease reports: case reports and outbreak reports. Case reports are those related to the diagnosis of individual cases of a particular disease (e.g., measles or HIV infection). Outbreak reports address an increased incidence in the number of cases of a particular disease above that normally expected in the population. Outbreak reports may include diseases that are not normally officially reportable in a given jurisdiction or diseases of unknown etiology in the case of emerging infectious diseases. For example, outbreak reports of an unusual respiratory disease among people attending a Legionnaires' convention in Philadelphia led to the identification of Legionnaires' disease.

Some diseases are also reportable to WHO under the *International Health Regulations* (IHR). Mandatory reporting under IHR includes any single case of smallpox, poliomyelitis due to wild poliovirus, a new subtype of influenza, and severe acute respiratory syndrome (SARS). In 2005, however, the IHR were revised to include mandatory investigation of "events involving epidemic-prone diseases of special national or regional concern which 'have demonstrated the ability to cause serious public health impact and to spread rapidly internationally.'" Notification occurs based on a decision algorithm contained in the IHR document (WHO, n.d., p. 2). The revised IHR also require nations to respond to requests for information regarding such events and to designate an IHR focal point and contact person to interface with WHO. Additional requirements include development of basic public health capacities to detect, report, and respond to potential public health emergencies and to implement control measures at airports and other

international border points (WHO, 2008). Unfortunately, several WHO member states have not yet fully developed their surveillance, reporting, and control capacities and have requested an extension of capacity development deadlines until 2014 or beyond (WHO, 2013a).

Treatment. Many communicable diseases are treated with antibiotics or antiviral medications, but some diseases such as varicella and uncomplicated measles are treated symptomatically. Antimicrobial treatment is recommended for tickborne diseases as well as for TB, HIV, hepatitis, sexually transmitted diseases, and influenza. Pertussis is another disease for which treatment is available. Treatment guidelines for selected communicable diseases commonly encountered by population health nurses are available from CDC.

In many instances, treatment for communicable diseases is highly effective, both for the infected individual and in terms of preventing the spread of the disease to others. For example, treatment of all HIV-infected pregnant women can reduce transmission of HIV infection to their infants to less than 5%. Unfortunately, in 2011, only 57% of HIV-infected pregnant women received treatment in low- and middle-income countries (Chimbwandira et al., 2013). HIV treatment is often dependent on CD4 cell counts, but many developing countries do not have the laboratory capacity to monitor eligibility for treatment. To address this issue, the recommendation is to provide all pregnant and breast-feeding women in these countries with lifelong ART. This new approach, which is supported by PEPFAR, has increased the number of pregnant and breast-feeding women on treatment by nearly 75%, with 77% of those continuing treatment beyond 1 year.

In the United States, approximately 77% of HIV-infected persons who were aware of their status were linked to care and just over half of them remained in care. In addition, 45% of those in care received counseling on transmission prevention, 89% received ART, and 77% achieved viral suppression (Cohen et al., 2011). ART reduces infectiousness and improves health for those with HIV infection; however, these outcomes require at least 85% adherence to suppress viral replication and avoid drug resistance (Kalichman et al., 2011). Because drug abuse is associated with ART adherence, concurrent drug abuse treatment services are particularly important for those IDUs with HIV infection (Mimiaga et al., 2013). Integrated behavioral interventions focusing on adherence support, sexual risk reduction, and amelioration of risk compensation resulted in increased ART adherence, less unprotected sexual activity, and fewer new STIs in one study (Kalichman et al., 2011).

Treatment for tuberculosis disease and LTBI relies primarily on the strategy of directly observed therapy. **Directly observed therapy (DOT)** is a medication administration strategy in which a client takes his or her medication in the presence of a nurse or other health care provider. Recommended treatment for LTBI consists of weekly DOT with isoniazid (INH) and rifampine for 12 weeks. This is a considerably shortened time frame and is more likely to promote compliance

than the prior recommended 9 months of therapy (Jereb et al., 2011). Standard treatment for active infection incorporates a combination of four first-line drugs: INH, rifampin, pyrazinamide, and ethambutol for 6 months (Burzynski et al., 2013). Treatment of multi-drug-resistant TB requires an 18- to 24-month course of five to six drugs that are less effective, more toxic, and more expensive, with less effective outcomes (Seaworth et al., 2013). DOT is credited with saving 7 million lives globally since 1990 (Getahun et al., 2012).

Population health nurses are often involved in providing DOT as well as monitoring clients for adherence and for adverse drug effects. Population health nurses are actively involved in supervising DOT and in motivating clients to continue compliance with therapy. In addition, population health nurses are often involved in locating clients who are noncompliant and encouraging them to continue therapy. Promoting continued compliance often requires that population health nurses assist clients to deal with factors that interfere with compliance. For example, they may assist a homeless client in his or her search for shelter or employment to eliminate life circumstances that impede DOT compliance. They may also need to be actively involved in promoting access to DOT or to other needed services that support DOT compliance.

Antiviral agents are recommended for treatment of persons with severe influenza, those at high risk for complications, and children under 1 year of age. Antivirals may also be provided to those without risk factors if available and provided within 48 hours of symptom onset (Fiori et al., 2011). Treatment of HCV with antiviral medications can also achieve a sustained response in 40% to 70% of cases (Drobnik et al., 2011). Unfortunately, there has been little use of HCV treatment among IDUs who are at greatest risk for long-term consequences of the disease (Iverson et al., 2013).

Other approaches have been taken in treating other communicable diseases. For example, treatment of malaria with artemisinin-based combination therapy has been shown to cure the disease as well as limit transmission to others (Mace et al., 2011). In addition, WHO has developed a strategy to address all of the major causes of child mortality that integrates services for malaria, pneumonia, and diarrheal disease through case management, strengthened health care systems, and promoting family and community health practices. In combination with insecticide-treated nets, this integrated approach has decreased malaria mortality in intervention areas where it has been implemented (Rowe, Onikpo, Lama, Osterholt, & Deming, 2012). Annual mass medication administration to entire populations has been recommended by WHO for treatment of lymphatic filariasis in endemic areas. This strategy has been implemented in Port-au-Prince in Haiti, one of only four countries in the Americas with endemic filariasis. It is estimated that annual coverage of 65% of the population for 5 years will interrupt disease transmission (Streit et al., 2013). Finally, voluntary isolation of infected persons, first aid for lesions, manual extraction of worms, and use of occlusive bandages have been used to treat dracunculiasis (Hopkins et al., 2013).

Some disease-causing agents are becoming resistant to some of the antimicrobials used in treatment. CDC and WHO recommend that a specific drug no longer be used to treat communicable diseases when 5% of cases in a given population are drug resistant. For example, fluoroquinolone was no longer recommended for treatment of gonorrhea in Hawaii as of 2000. By 2002, the recommendation of nonuse of the drug had extended to California and to MSM by 2004. As of 2007, fluoroquinolone is no longer recommended for treatment of gonorrhea at all (Dowell et al., 2012). Gonorrhea has a long history of developing resistance to successive antimicrobials beginning with sulfonamides, and progressing to penicillin, tetracycline, and fluoroquinolone. Current treatment recommendations are for the use of increased doses and combination therapy with ceftriaxone and either azithromycin or doxycycline (Adams et al., 2013). There is some suggestion, however, that resistance to this regimen has surfaced in Asia and may be occurring in the United States as well (Hook et al., 2013).

Similarly, a growing proportion of TB is caused by multi-drug-resistant (MDR) strains. MDR TB is resistant to at least INH and rifampin. Extensively drug-resistant TB (XDR TB) is also resistant to fluoroquinolone and at least one of three injectable antituberculin drugs. In 2011, there were an estimated 630,000 cases of MDR TB worldwide, with nearly 4% of those occurring as new cases and 20% in persons previously treated for TB. XDR TB has been found in 84 countries and affects an estimated 9% of persons with TB. The mortality rate for drug-resistant TB is about 15% (Mase, Chorba, Lobue, & Castro, 2013).

Antibiotic resistance is fostered by inappropriate use of antibiotics, and population health nurses can be actively involved in educating the general public and health care providers to minimize inappropriate use. They can also advocate for completion of recommended antibiotic therapies (e.g., for TB) to prevent development of resistant microorganisms.

Population health nurses can be active in advocating national policies that support international treatment initiatives for a variety of diseases. For example, U.S. nurses can advocate for federal assistance to international AIDS endeavors. In addition, nurses may be involved in the efforts of non-governmental organizations to support HIV, malaria, or other therapies through their churches or other social organizations. Nurses involved at the international level can assist in the development of policies and procedures that address concerns related to access to care. In the United States, population health nurses can be involved in research that tests various approaches to treatment for communicable diseases that may have implications for international implementation.

In addition to referring clients and assisting with treatment of communicable diseases with antimicrobial agents, population health nurses may provide supportive care for clients with self-limiting diseases that have no specific treatment. Supportive care may include educating clients and families about measures to reduce fever or enhance comfort until the disease has run its course. For example, parents should be

informed of the dangers in giving aspirin for fever in children. Other supportive measures may include encouraging a low-fat diet for clients with hepatitis A to deal with nausea.

Population health nurses may provide treatment for some communicable diseases under medical protocols, but are more likely to be involved in educating clients about treatment and promoting compliance. The role of population health nurses in treating communicable diseases may also involve political activity and advocacy. For example, the nurse might be actively engaged in efforts to assure access to health care for persons with AIDS or to change policies for providing treatment to drug users with chronic HCV infection. Strategies for resolving problems of communicable disease are summarized in Table 26-5.

HEALTH RESTORATION. Health restoration with respect to communicable diseases may occur with individual clients or with population groups. At the individual level, emphasis is on preventing complications and long-term sequelae, monitoring treatment compliance and effects, monitoring treatment side effects and assisting clients to deal with them, and providing assistance in dealing with long-term consequences of some communicable diseases.

Population health nurses can educate clients to prevent complications of communicable diseases with their attendant long-term sequelae. For example, clients with influenza can be

encouraged to rest and to refrain from resuming normal activities until they are recovered. Similarly, parents can discourage scratching in children with varicella to prevent secondary infection in lesions and encourage clients with hepatitis to refrain from alcohol use to prevent further liver damage.

Population health nurses also monitor clients with HIV infection for signs and symptoms of opportunistic infections and refer them for treatment when OIs are suspected. Nurses may also be involved in assisting clients with prophylactic regimens to prevent opportunistic infections. The Panel on Opportunistic Infections in HIV-exposed and HIV-infected Children (2014) has developed guidelines for the prevention and treatment of opportunistic infections in HIV-exposed and infected children. Similar guidelines for adults and adolescents have been developed by the Panel on Opportunistic Infections in HIV-infected Adults and Adolescents (2014). For further information about the guidelines, see the *External Resources* section of the student resources site.

Clients with HIV infection may also experience a number of nutritional difficulties that may require nursing intervention. For example, weight loss and wasting may occur as a result of reduced food or calorie intake due to anorexia, nausea and vomiting, changes in taste or smell, fatigue, or painful oral or esophageal lesions. Weight loss, loss of muscle mass, and vitamin deficiencies may also result from malabsorption due to lactose or fat intolerance, gastrointestinal infection, malignancies,

TABLE 26-5 Strategies for Resolving Problems of Communicable Disease

Focus	Population Health Nursing Strategies
Case finding and surveillance	<ul style="list-style-type: none"> • Recognize symptoms of communicable diseases in clients and refer them for diagnostic and treatment services as needed • Educate the public regarding signs and symptoms of specific communicable diseases • Recognize signs of disease outbreaks in the population • Collect surveillance data regarding communicable disease incidence, prevalence, contributing factors, and effects
Screening	<ul style="list-style-type: none"> • Recognize and refer possible cases of communicable diseases • Educate clients and the public regarding the need for screening for communicable diseases • Provide selective screening services • Plan and implement mass screening programs • Advocate for screening availability for populations at risk for communicable diseases
Diagnosis and reporting	<ul style="list-style-type: none"> • Refer clients for diagnostic procedures as needed • Educate clients regarding diagnostic procedures • Provide diagnostic services • Interpret diagnostic test results and counsel clients accordingly • Advocate for the availability of needed diagnostic services • Report cases of communicable diseases in accord with local, state, or national regulations • Educate other health care providers regarding reporting requirements • Follow up on reports of communicable diseases to obtain relevant epidemiologic information
Treatment	<ul style="list-style-type: none"> • Provide antimicrobial therapies • Educate clients regarding antimicrobial therapy • Supervise DOT • Educate clients and their families for supportive care • Educate health care providers, clients, and the public to prevent inappropriate use of antimicrobials and development of drug-resistant organisms • Advocate for the availability of needed treatment services for all segments of the population

and so on. Finally, HIV-infected clients may experience metabolic alterations due to HIV, medications, and other circumstances. Population health nurses engaged in health restoration activities would assist clients to overcome these nutritional deficiencies through nutritional counseling, promoting food and water safety, dealing with medication side effects, and suggesting complementary and alternative nutritional therapies such as the use of nutritional supplements. Population health nurses may also work closely with public health social workers and mental health counselors to address the health restoration needs of clients with HIV/AIDS and other conditions (e.g., hepatitis C). Although ART has increased health and quality of life and workforce participation among people with HIV/AIDS tremendously, unemployment continues to be a significant problem in this group. Population health nurses may need to engage in political advocacy to assure the availability of health restoration services for clients with these diseases. This may include services needed to address psychosocial as well as physical consequences of disease (e.g., unemployment, housing, discrimination).

Another issue related to HIV infection that requires intervention involves resumption of high-risk sexual or drug use behaviors. Because many people perceive ART to be a “cure” for HIV infection, treatment may lead to continuation or reinitiation of behaviors that may transmit the disease to others. Resumption of unsafe sexual practices may be the result of several factors. Treatment may lead to improved health and functional status, increasing sexual activity as well. In addition, treatment may give rise to unrealistic expectations regarding the potential for disease transmission, leading those with HIV infection to be less cautious in their sexual practices. Prevention case management, however, has led to a decrease in transmission risk behaviors. Prevention case management involves providing follow-up counseling and educational services to clients as well as assistance in dealing with other psychosocial effects of HIV infection.

Population health nurses also monitor communicable disease treatment compliance and treatment effects, particularly in diseases such as tuberculosis and HIV infection that require long-term therapy. Treatment of chronic hepatitis B, C, or D may also involve prolonged use of medications. In addition, population health nurses monitor the occurrence of adverse effects of treatment. For example, antituberculin drugs may result in hepatitis or visual disturbances, and the nurse should be alert to signs and symptoms of adverse effects. Treatment for other diseases may result in medication side effects as well, and population health nurses should educate clients regarding these effects and what clients should do about them.

Promoting treatment adherence in the face of multiple side effects can be difficult. Some strategies that may be effective in promoting compliance include reducing side effects where possible, simplifying the regimen to include fewer doses and fewer pills, establishing client trust in the efficacy of treatment, and tailoring therapy to fit the client’s lifestyle whenever possible. Additional approaches may include clarifying treatment instructions and making sure that clients understand them,

simplifying distribution systems (e.g., providing easy access to medication refills), and providing frequent follow-up.

Rehabilitation may be required following some communicable diseases. For example, rehabilitation may be needed to strengthen affected muscles or to promote individual and family adjustment to permanent disabilities from paralytic poliomyelitis. Active and passive range of motion may help restore muscle strength and prevent contractures. Maintaining skin integrity for clients with braces or those confined to a bed or wheelchair is also important. Observation for recurrent disease (even many years later) is also needed. Families may also require assistance in financing rehabilitative care and procuring needed equipment and appliances, and population health nurses may collaborate with public health social workers in efforts to address these needs. In addition, population health nurses may need to be involved in political advocacy to assure that needed services are available to clients and their families.

Population health nurses may also need to help clients deal with the long-term consequences of communicable diseases. For example, children with anomalies or developmental disabilities due to congenital rubella syndrome or congenital syphilis will need ongoing care, and their families will need emotional support and assistance in finding resources to deal with their children’s disabilities. Support may also be needed for long-term behavior changes required to prevent infecting others with HIV or hepatitis. Population health nurses may also need to function as advocates to prevent stigmatization and discrimination and to foster clients’ integration into the community to the extent permitted by their health status. For example, nurses may need to educate those who interact with HIV-infected clients about how HIV infection is and is not transmitted. Similarly, when working with children with AIDS, advocacy by the population health nurse may necessitate planning activities that foster normal growth and development in each child.

Assistance may also be needed in dealing with the financial impact of HIV infection and other diseases that have long-term treatment needs. The population health nurse can help in this respect by referring clients and their families to sources of financial assistance. Advocacy by population health nurses may be required to ensure client eligibility for financial assistance programs. This may involve political advocacy for health policy changes at state or national levels.

For a few communicable diseases, health restoration with individual clients entails preventing reinfection. This does not apply to the majority of the diseases discussed in this chapter because they result in immunity. For example, hepatitis A confers immunity against reinfection with hepatitis A, but does not provide immunity to other forms of hepatitis. Similarly, varicella, measles, and mumps usually confer immunity, and clients do not become reinfected. Some diseases, however, do not produce immunity, and reinfection is possible and even likely if clients do not change risk behaviors. For example, clients may be reinfected with gonorrhea or *Chlamydia* as a result of continued unprotected sexual activity. Similarly, reinfection

with syphilis is possible unless the disease has progressed to the point of immunity, by which time the risk for long-term complications is quite high. Population health nurses need to educate clients about the potential for reinfection and the need for behavior changes to reduce the risk of reinfection. For example, nurses might educate clients about the need for condoms during sexual intercourse or educate IDUs on harm-reduction strategies such as not sharing needles or other drug paraphernalia.

Health systems must also be in place to meet the health restoration needs of clients with communicable diseases. At the level of public policy, population health nurses may need to engage in political advocacy to assure necessary funding for assistance programs for clients experiencing long-term needs related to the effects of communicable diseases.

Health restoration at the community level is directed toward preventing the spread of disease and providing access to long-term care services. Measures to prevent the spread of disease in the population include many primary prevention measures for individuals such as immunization and identification, notification, and prophylactic treatment of contacts. Changes in risk behaviors among persons who are chronic carriers of infection can also serve to prevent dissemination of disease.

Isolation or quarantine of infected or exposed persons may also prevent further spread of some communicable diseases within the community. **Isolation** is the process of limiting the movement and interactions of people who have a communicable disease to prevent the spread of the disease to others. **Quarantine**, on the other hand, is a restriction on the movements of healthy people who have been exposed to a particular disease. In both strategies, people who have the disease or have been exposed to it are kept separated from the well population.

Both isolation and quarantine may be voluntary procedures in which people who are infected or exposed self-limit their activities to prevent the spread of the disease to others. Staying home from work or school when one is ill is a simple example of voluntary isolation. Isolation or quarantine may also be mandated by legal authority at local, state, or national levels. As we saw in Chapter 20, quarantine was initiated as a strategy for containing the spread of epidemics from one population to another. The length of the period of quarantine varies from disease to disease, but generally is for a period of time equal to the farthest limits of the incubation period for the disease. For example, the incubation period for diphtheria is 2 to 5 days. Adults who work with unimmunized children or handle food are restricted from work for 7 days or until treated and found not to be carriers by means of nose and throat cultures. In other instances, quarantine may only be imposed until people exposed to a microorganism such as aerosolized anthrax spores can be *decontaminated* through a shower and a change of clothes. Quarantine and isolation may also be imposed on a long-term basis for certain diseases. For example, people with communicable TB who refuse treatment may be forcibly isolated from others.

Population health nurses may need to be advocates for long-term isolation of people who pose a risk of communicable disease to the public and initiate isolation procedures

when absolutely necessary. At the same time, they need to be advocates for those with communicable diseases to be sure that mandatory isolation and quarantine procedures are warranted, that designated legal processes are followed, and that neither process is used to discriminate against vulnerable population groups. For example, population health nurses have been actively involved, with other civil rights activists, in resisting proposed efforts to quarantine or isolate people with HIV/AIDS.

Outbreak response is another strategy for controlling the spread of communicable diseases in the population. Outbreak response is the corollary to epidemic or bioterrorism preparedness discussed in relation to primary prevention and is initiated once an outbreak has occurred. The two facets of a response to an outbreak of communicable disease are the management of those with the disease and interrupting disease transmission in the population. Steps in an outbreak response include verifying the diagnosis, confirming the existence of an outbreak, identifying those affected and factors contributing to their illness, defining the population at risk, identifying the source and factors contributing to the spread of the disease, and containing the outbreak. Verification of diagnosis may involve the collection of specific specimens from those believed to have a particular disease. For example, population health nurses may collect stool specimens from neighborhood residents who exhibit diarrhea. The existence of an outbreak is confirmed by examining incidence figures in light of past trends in disease incidence. This step in the response to an outbreak is most often carried out by public health officials or epidemiologists rather than population health nurses.

Population health nurses are often involved, however, in obtaining case histories of those affected to determine factors contributing to disease. They may also be actively involved in identifying additional cases of disease. For example, nurses may go door to door asking about family members who have recently experienced diarrhea in an outbreak of diarrheal disease. The data gathered from these disease investigations can then be used by epidemiologists and others to identify persons at risk for the disease and to assist in the determination of the source of infection and factors influencing its spread. Population health nurses may be involved in identifying the source of the infection by collecting samples of suspected food or water sources and conveying them for laboratory testing.

Population health nurses are also actively involved in strategies to control the disease. Control may include managing cases of illness in those affected, and population health nurses are involved in educating people regarding disease management and referring them for medical care as needed. They are also involved in educating the public on measures to prevent the spread of disease or on the need for mass immunization or PEP if available. Population health nurses may also be involved in surveillance for evidence of disease among people at risk, with follow-up care for those who become symptomatic.

Social distancing is a third approach to preventing the spread of communicable diseases within the population. **Social distancing** involves voluntarily limiting one's interactions with others in order to prevent potential exposure to pathogenic

microorganisms (Thombley & Steir, 2010). Social distancing measures taken by individuals (e.g., avoiding crowded places during an epidemic or disease outbreak, not sharing food or beverages or personal items with others, wearing a mask in public places, washing hands) would be a form of illness prevention. Some people may also choose to engage in *reverse* quarantine, in which well persons may choose to avoid contact with others as much as possible.

Social distancing measures taken at the population level would be interventions aimed at preventing the spread of existing disease in the community. Population-based examples of social distancing include closing schools and businesses or restricting access to certain places. For example, hospitals might be closed to all but essential personnel in the event of an avian influenza epidemic, minimizing the exposure of well people to those who are ill. Canceling public events that would promote interaction among groups of people is another example of social distancing at the population level.

Population health nurses can educate individuals regarding relevant social distancing strategies to prevent exposure to disease. They may also participate in policy decisions related to population-level social distancing activities when these are warranted by the mode of transmission of a particular disease. They can also help to avoid excessive response to the threat of communicable diseases by educating the public and policy makers regarding factors influencing disease transmission. For

example, participation in the gay bar scene has been associated with increased risk of HIV infection, but closing gay bars would not be an appropriate social distancing strategy for preventing the spread of HIV infection in the gay population. Strategies for health restoration related to communicable diseases, including social distancing, are summarized in Table 26-6.

Evaluating Communicable Disease Control Strategies

Evaluating prevention related to communicable diseases with individual clients is based on the prevention of occurrence of disease. If drug users educated for harm reduction do not develop HBV or HIV infection, intervention has been successful. At the population level, the effectiveness of prevention of communicable diseases is reflected in declining incidence and prevalence rates.

The effectiveness of resolution strategies is reflected in communicable disease mortality and continued morbidity. For example, ART for HIV infection has decreased HIV/AIDS-related mortality and prolonged survival time for infected persons. Similarly, the effectiveness of TB therapy is reflected in the number of clients whose TB has been cured.

Evaluation of health restoration measures focuses on the extent to which complications of communicable diseases have been prevented, the extent to which reinfection occurs for those diseases where reinfection is possible, and the extent of

Focus	Population Health Nursing Strategies
Monitoring compliance	<ul style="list-style-type: none"> • Monitor client compliance with therapy • Promote compliance with treatment regimens • Locate noncompliant clients and promote reinitiation of therapy
Monitoring treatment effects	<ul style="list-style-type: none"> • Monitor side effects and adverse effects of therapy and refer for medical evaluation as needed • Monitor treatment effects by referring clients for follow-up testing as needed
Dealing with consequences	<ul style="list-style-type: none"> • Prevent complications of communicable diseases • Refer clients with complications to rehabilitation services as needed • Promote adjustment to long-term consequences • Advocate for the availability of long-term services as needed
Preventing reinfection	<ul style="list-style-type: none"> • Educate clients and the public regarding safe sexual practices • Refer clients for drug abuse treatment, as needed • Promote/advocate for harm-reduction strategies for IDUs
Preventing the spread of disease	<ul style="list-style-type: none"> • Plan and conduct mass immunization campaigns • Engage in contact notification • Promote screening of blood and tissue donors • Advocate for and provide screening and treatment for infected pregnant women • Promote behavior change to decrease subsequent exposure risks • Promote isolation/quarantine of infected persons when required and educate them regarding the need for quarantine • Prevent the use of isolation and quarantine as discriminatory procedures against vulnerable populations • Advocate for and participate in effective response to disease outbreaks, including case identification and investigation, specimen collection, source identification, disease management, and control strategies • Educate the public regarding social distancing strategies to prevent exposure to disease • Participate in decisions regarding population-based social distancing strategies and educate policy makers regarding their advisability and utility in specific diseases

disability and adverse consequences resulting from communicable diseases. Evaluation at each of the levels of health care is also reflected in the national objectives related to communicable diseases discussed earlier in this chapter. The current status of some of these objectives is presented in the *Healthy People 2020* feature below.

In addition, the Joint United Nations Program on HIV/AIDS (UNAIDS) has developed reporting indicators that can be used to evaluate country-level progress in meeting targets for HIV/AIDS control established in a 2011 “Political Declaration on HIV/AIDS” by the United Nations General Assembly High Level Meeting on AIDS. These targets, intended to be achieved by 2015, include the following:

- Reducing sexual transmission of HIV by 50%
- Reducing HIV transmission via injecting drug use by 50%
- Eliminating new HIV infection among newborns and reducing AIDS-related maternal deaths
- Providing ART to 15 million people
- Reducing tuberculosis mortality in people with HIV/AIDS by 50%
- Increasing annual global funding for HIV/AIDS control to \$22 billion to \$24 billion in low- and middle-income countries
- Eliminating gender-based abuse and increasing women’s abilities to protect themselves from HIV
- Eliminating stigma and discrimination among people living with HIV through legislative provisions
- Eliminating HIV-related restrictions on entry, stay, and residence in other countries, and
- Strengthening integration of AIDS response into global health and development efforts (UNAIDS, 2014)

Healthy People 2020

Selected Objectives Related to Communicable Diseases

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
HIV-4. Reduce new AIDS cases among adolescents and adults (per 100,000 population over age 13)	13.8 (2007)	12.4	13 (2010)	National HIV Surveillance System (NHSS), CDC/NCHHSTP
HIV-6. Reduce new AIDS cases among adolescent and adult men who have sex with men	15,966 cases (2007)	14,369	16,796 (2010)	NHSS, CDC/NCHHSTP
HIV-7. Reduce new AIDS cases among adolescents and adults who inject drugs	5,638 cases (2007)	5,074	4,497*	NHSS, CDC/NCHHSTP
HIV-8.2. Reduce new cases of perinatally acquired AIDS	34 (2007)	31	18* (2010)	NHSS, CDC/NCHHSTP
HIV-11. Increase the proportion of persons surviving more than 3 years after a diagnosis with AIDS	84% (2006)	92.4%	NDA	NHSS, CDC/NCHHSTP
HIV-12. Reduce deaths from HIV infection (per 100,000 population)	3.7 (2007)	3.3	2.6* (2010)	National Vital Statistics System—Mortality (NVSS-M), CDC/NCHS
HIV-14.1. Increased the proportion of adolescents and adults tested for HIV in the past 12 months	17.2% (2006–2010)	18.9%	NDA	National Survey of Family Growth, CDC/NCHS
HIV-14.3. Increase the proportion of pregnant women tested for HIV in the past 12 months	72% (2006–2010)	79.2%	NDA	National Survey of Family Growth, CDC/NCHS
HIV-15. Increase the proportion of adults with TB tested for HIV	73.3% (2008)	80.6%	NDA	National TB Surveillance System (NTSS), CDC/NCHHSTP
HIV-17.1. Increase the proportion of unmarried sexually active females aged 15–44 years who use condoms	35.1% (2006–2010)	38.6%	NDA	National Survey of Family Growth, CDC/NCHS

Healthy People 2020 (Continued)

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
HIV-17.2. Increase the proportion of unmarried sexually active males aged 15–44 years who use condoms	45.8% (2006–2010)	50.4%	NDA	National Survey of Family Growth, CDC/NCHS
IID-1. Reduce, eliminate, or maintain elimination of cases:				National Notifiable Disease Surveillance System (NNDSS). CDC/PHSPO
1.1. Congenital rubella syndrome	0/100,000 (2008)	0.0	0.0 (2011)	
1.2. <i>Haemophilus influenzae type b</i> (Hib)	0.3/100,000 (2008)	0.27	0.18* (2010)	
1.3. Hepatitis B (2–18 years)	0.1/100,000 (2007)	0.0	NDA	National Health Interview Survey (NHIS), CDC/NCHS
1.4. Measles (U.S. acquired)	115 cases (2008)	30	142 (2011)	
1.5. Mumps	421 cases (2008)	500	376* (2011)	
1.6. Pertussis (children <1 year of age)	2,777 cases (2004–2008)	2,500	2,744 (2006–2010)	
1.8. Wild poliovirus	0/100,000 (2008)	0.0	0.0 (2011)	
1.9. Rubella	10 cases (2008)	10	2 (2011)	
1.10. Varicella (<18 years)	586,000 cases (2008)	100,000	266,000 (2011)	
IID-2. Reduce early onset group B <i>Streptococcal</i> disease	0.28/1,000 newborns (2008)	0.25	0.27 (2010)	National Vital Statistics System- Natality (NVSS-N). CDC/NCHHSTP
IID-3. Reduce meningococcal disease	1,215 cases (2004–2008)	1,094	1,051* (2006–2010)	NNDSS, CDC/PHSPO
IID-8. Increase the proportion of vaccination coverage among children 19–35 months for DTaP, polio, MMR, Hib, hepatitis B, varicella, & PCV	44.3% (2009)	80%	68.5% (2011)	National Immunization Survey (NIS), CDC/NCHS
IID-12.12. Increase the percentage of persons 18 years of age and older vaccinated against influenza annually	38.1 (2010–2011)	70%	39.2% (2011–2012)	NIS, CDC/NCHS
IID-12.13. Increase the percentage of health care personnel vaccinated against influenza	55.8% (2010–2011)	90%	61.5% (2011–2012)	NIS, CDC/NCHS
IID-12.14. Increase the percentage of pregnant women vaccinated against influenza	DEV	DEV	NDA	Pregnancy Risk Assessment Monitoring System (PRAMS), CDC/NCCDPHP
IID-15.3. Increase hepatitis B vaccine coverage in health care personnel	64.3%	90%	NDA	National Health Interview Survey (NHIS), CDC/PHSPO
IID-23. Reduce new cases of hepatitis A	1/100,000 (2007)	0.3	NDA	NNDSS, CDC/PHSPO
IID-25. Reduce new cases of hepatitis B in persons 19 years of age and older	2.0/100,000 (2007)	1.5	NDA	NNDSS, CDC/PHSPO
IID-26. Reduce new cases of hepatitis C	0.28/100,000 (2007)	0.25	NDA	NNDSS, CDC/PHSPO
IID-29. Reduce new cases of tuberculosis	4.8/100,000 (2005)	1.0	3.4 (2011)	NTSS, CDC/NCHHSTP

* Objective has achieved target. NDA = No data available

Data from: U.S. Department of Health and Human Services. (2014). *Healthy people 2020: Topics and objectives*. Retrieved from <http://healthypeople.gov/2020/topicsobjectives2020/default.aspx>

For further information on achievement of these goals in specific countries, see the *External Resources* section of the student resources site.

As of 2013, 172 countries had reported their progress on meeting the HIV/AIDS control targets. Overall, 35.3 million people were infected with HIV in 2012, but new infections had declined 33% from 2001. HIV/AIDS mortality had also decreased from 2.3 million deaths in 2005 to 1.6 million in 2012. Increases were seen in the use of safer sexual practices, but little progress had been made among sex workers and MSM. From 2009 to 2012, a 35% decrease in the number of newly infected children was achieved. ART coverage among 62% of pregnant women with HIV infection contributed to the reduction in new HIV infections in children. Similarly, some progress has

been made in the provision of ART to HIV-infected individuals, with 9.7 million infected people receiving therapy in 2012, but more work in this area is needed. TB mortality among HIV-infected individuals declined by 36% from 2004 to 2012, but only two countries with large populations of people with comorbid TB and HIV infection provided treatment to more than 50% of those affected. Finally, the global funding available for HIV/AIDS control in 2012 was \$18.9 billion, with increased domestic spending in many countries (UNAIDS, 2014).

Population health nurses may be involved in collecting evaluative data regarding communicable disease control, including HIV/AIDS control measures. They may also contribute to the interpretation of those data and their use in developing and implementing new control strategies.

CHAPTER RECAP

Communicable diseases occur through a process that involves a “chain of infection” in which the causative organism is transmitted from an infected host through a specific mode of transmission that involves defined portals of entry and exit. Communicable disease control can involve interruption of this chain of events anywhere along the way.

Disease transmission occurs through airborne, fecal–oral, direct contact (including sexual contact), direct inoculation, insect or animal bite, or other mechanisms. Each mode of transmission involves specific portals by which the disease causing organism enters and leaves a host. Communicable diseases also vary in terms of their incubation periods and the presence or absence of a prodromal period.

Population health nurses assist in determining factors related to each of the six categories of determinants of health that contribute to the development and extent of a particular

communicable disease in the population. They are also actively involved in general health promotion strategies and illness prevention strategies to prevent communicable diseases in individuals and populations. When communicable diseases do occur, population health nurses may be involved in their identification and treatment. They are also involved in strategies to restore health following a communicable disease or to prevent reinfection. Finally, population health nurses are actively involved in evaluating the effects of communicable disease control measures.

Although remarkable progress has been made in controlling communicable diseases, they remain significant contributors to morbidity and mortality in the United States and throughout the world. Population health nurses can be actively involved in preventing communicable diseases and in identifying and treating them when they do occur.

CASE STUDY

A Communicable Disease Outbreak

Jane is an 18-year-old college student. She lives in the dorm with her roommate, Sally. Shortly after Jane returned from Christmas vacation, she developed a fever and severe cough. Sally persuaded her to see a doctor. Because it was Saturday, Jane went to the emergency department (ED) of the local hospital. The physician there made a diagnosis of pertussis. Later that night, he and the nurses in the ED became very busy with victims of a

multivehicle accident. As a result, no one completed the health department form reporting Jane’s pertussis until 2 days later.

By the time a population health nurse contacted Jane to complete a pertussis case report, Sally and several other girls in Jane’s dorm had also developed pertussis. Sally gave it to her boyfriend, who exposed those in his classes. One of the women in his English class just had a baby a month ago.

The university has a policy that all students provide verification of immunizations on admission before enrolling in classes. The student health center reviews student immunization records and notifies students of any deficiencies. They do not, however, follow up on whether the deficient immunizations were obtained. There is also no mechanism for creating a registration “hold” for students with deficient immunizations. A review of cases in this outbreak indicated that approximately three quarters of those affected, including the woman with the new baby, had not received a pertussis booster as adolescents and the remaining quarter had never been immunized for pertussis.

1. Based on the information presented in the case description, what biological, psychological, environmental, sociocultural, behavioral, and health system factors are operating in this situation? What additional determinants might influence

the situation? How might you assess for the presence or absence of these determinants?

2. What preventive measures could have been employed to prevent this situation? What prevention measures are appropriate at this point?
