3. What problem resolution and health restoration interventions by the population health nurse are appropriate at this time?
4. What roles might the population health nurse perform in dealing with this situation? What other public health personnel might the population health nurse collaborate with in addressing the situation?
5. How would you evaluate the effectiveness of interventions in this situation?

27 Chronic Physical Health Problems

Learning Outcomes

After reading this chapter, you should be able to:

1. Describe personal and population effects of chronic physical health problems.
2. Identify biological, psychological, environmental, sociocultural, behavioral, and health system factors that influence the development of chronic physical health problems.
3. Describe strategies for health promotion related to chronic physical health problems and analyze the role of the population health nurse related to each.
4. Discuss major foci in prevention of chronic physical health problems and identify related population health nursing roles.
5. Identify the major aspects of resolving existing chronic physical health problems and analyze population health nursing roles with respect to each.
6. Analyze population health nursing roles related to health restoration in relation to chronic physical health problems.

Fostering Research on Kidney Disease

In 1950, Ada and Harry DeBold's young son developed nephrosis, a condition for which there was no known cure. In an attempt to help their son, they initiated the Committee for Nephrosis Research, which became the National Nephrosis Foundation and in 1964 became the National Kidney Foundation (NKF). Despite her child's death at age four, Ada DeBold continued to raise funds for research and patient services. In 1956, the foundation undertook the first major national fund-raising campaign and raised \$400,000. Research led to the development of a Teflon shunt in 1960 that permitted dialysis treatment; converting kidney disease to a chronic condition, rather than a terminal illness. NKF continues to provide public- and patient-focused education, support for research, and advocacy for people with kidney disease. NKF has also been instrumental in the development of clinical practice guidelines for nephrology care and helped create an international program "Kidney Disease: Improving Global Outcomes," which published guidelines related to hepatitis C in the context of kidney disease. That effort was followed by publication of seven additional sets of guidelines. Education of health care providers regarding kidney disease is another significant focus for the foundation (National Kidney Foundation, n.d.).

Supplying Health Needs

Afya means "good health" in Swahili. *Afya* is also the name of a charitable organization that works to meet health resource needs in Africa and the Caribbean. Founded by physical therapist Danielle Butin, *Afya* focuses on supplying needed supplies, equipment, and humanitarian provisions to developing countries in these regions. Rather than just sending truckloads of supplies that may or may not meet local needs, *Afya* conducts in-county needs assessments to determine specific equipment and supplies needed. Needs are met through donations of surplus equipment and supplies from U.S. health care institutions, corporations, and private individuals. Individuals and families can donate home care equipment, such as walkers and wheelchairs, when it is no longer needed. Available goods are entered in a computer-based inventory from which health organizations and professionals can select items to meet specific needs (*Afya* Foundation, n.d.).

In addition, *Afya* supports other projects to meet identified needs. For example, in Haiti, plastic bottles gleaned from trash piles are used to create lightweight and portable beds and stools to help people keep themselves and their possessions out of the periodic flooding following heavy storms. Another project involved training "Rehab Techs" to deliver home care rehabilitation services and products in tent cities housing survivors of the 2010 earthquake in Haiti (*Afya* Foundation, n.d.).

Because of the effectiveness of control measures developed for many previously fatal communicable diseases, chronic health problems have largely replaced communicable diseases as the leading causes of death and disability in the United States and elsewhere in the world. Each year, millions of people worldwide experience the suffering and the economic costs associated with chronic health problems, and many die as a result. An estimated 145 million people in the United States, half of the total population, experience at least one chronic condition. This figure is

expected to increase by 1% per year to 171 million people by 2030 (Improving Chronic Illness Care, n.d.). Globally, non-communicable conditions account for 63% of all deaths and outstrip communicable disease mortality in all World Health Organization (WHO) regions except Africa (WHO, 2011).

A **chronic disease** is a condition that persists over a significant period of time that is not amenable to cure, but can be controlled (University of Michigan, Center for Managing Chronic Disease, 2011). Chronic conditions are characterized by uncertain or complex etiologies, multiple risk factors, typically long

periods of latency prior to symptom development, a prolonged course of illness, noncommunicability, functional impairment or disability, and an absence of a cure. The standard definition and characteristic features, however, are somewhat blurred by the advent of long-term communicable diseases such as tuberculosis, HIV/AIDS, and chronic forms of hepatitis. A more useful definition has been proposed by an organization called Improving Chronic Illness Care, which notes that a chronic condition is any condition that requires a protracted period of interaction with the health care system and ongoing lifestyle changes for those affected (Improving Chronic Illness Care, n.d.). Based on this definition, chronic conditions include diseases, injuries with lasting consequences, and other enduring abnormalities.

Chronic health problems may be either physical or emotional, and both types of chronic conditions are addressed in the national health objectives developed for the year 2020. These objectives and current levels of achievement may be viewed at the *Healthy People 2020* website. In this chapter, we address chronic physical health problems. Chronic emotional conditions are addressed in Chapter 28. Information on selected objectives and their achievement is included at the end of this chapter.

From a population health perspective, the goals of chronic disease prevention and control include reducing their incidence in the population or delaying their onset or the development of resulting functional disability. Additional goals include alleviation of suffering and improving the quality and length of life for those experiencing chronic physical health problems. Unfortunately, a number of deficiencies have been identified in chronic disease control efforts nationally and internationally. These deficiencies include failure to use established practice guidelines for the prevention and treatment of chronic conditions, lack of coordination of care, lack of active follow-up to determine the effects of care, and inadequate education of the public and those affected relative to prevention and self-management of chronic health problems (Improving Chronic Illness Care, n.d.). Population health nurses can be actively involved in resolving these deficiencies and in changing health care delivery from a reactive stance once problems develop to a proactive focus on prevention and effective management that minimizes consequences of chronic conditions.

Individual, Family, and Societal Effects of Chronic Physical Health Problems

Chronic health problems can arise from a variety of sources. For example, some people are born with chronic health problems. Conversely, a person might develop a chronic disability as a result of a serious accident or because of a disease such as arthritis, cardiovascular disease (CVD), chronic respiratory diseases, or cancer. Some chronic conditions, such as some cancers, may result in death. Others, such as arthritis, although not fatal, cause persistent pain and disability.

The effects of chronic health conditions are not only experienced by individuals. Families, population groups, and society at large are also affected by the consequences of chronic health problems.

Individual Effects

The advent of a chronic condition has many personal effects for individual clients. Possible long-term consequences of disease and injury include pain and suffering, hospitalization, disability, and diminished quality of life.

Pain and suffering are frequent accompaniments to chronic health problems, and chronic pain is itself considered an illness. According to the National Research Council (2011), approximately 100 million Americans experience chronic pain at an annual cost to U.S. society of \$560 to \$635 million. These costs are the result of medical care for pain and lost productivity among those affected. Pain has physical and physiologic effects as well as psychological and cognitive ones, and is a significant contributor to poor quality of life in people with chronic health problems. The constant battle with chronic pain can be disheartening and can lead to depression and possible suicide. Population health nurses can advocate for effective management of chronic pain and promote the use of appropriate pharmacologic and nonpharmacologic management strategies. Pain management with respect to chronic health problems is addressed in more detail later in this chapter.

Pain and other consequences of chronic health problems often lead to diminished functional capability and disability. The United Nations Convention on the Rights of Persons with Disabilities noted that disability is a fluid concept that reflects societal attitudes and environmental circumstances (Rutkow, Vernick, Tung, & Cohen, 2013). Conditions that result in disability for one person may not be disabling for another individual. WHO has delineated three dimensions of disability: the impairment of bodily structure or function, activity limitations, and consequent restrictions in participation in normal daily activities (Benjamin et al., 2013). The U.S. Census Bureau (2010) defined disability in the context of difficulty with any of six categories of function addressed in the American Community Survey (vision, hearing, ambulation, cognition, self-care, and independent living) within three domains of disability: communication, activities of daily living (ADLs), and instrumental activities of daily living (IADLs). WHO described **disability** as a complex phenomenon arising from interactions between one's physical health and functional status and the society in which one lives (2014). Disability results from impairments, activity limitations, and participation restrictions. **Impairment** involves an alteration in bodily structure or function, whereas an **activity limitation** is difficulty in performing a given task. **Participation restriction** is an inability to take part in ordinary social interactions (WHO, 2014). According to the U.N. Convention on the Rights of Persons with Disabilities, **disabled persons** are people with long-term physical, mental, intellectual, or sensory impairments that may

interfere with their ability to participate equally in the society in which they live (Rutkow et al., 2013). Disability results when health conditions and their interaction with contextual factors interfere with one's ability to function in ways that are expected or desired. For example, a person in a wheelchair whose workplace accommodates his or her mobility limitations is not disabled. The same person, however, might be considered disabled in another country where buildings have not been designed to facilitate wheelchair access.

An estimated 16% of U.S. adults (37.5 million people) have some form of disability, and 43% of them experience more than one functional limitation. Although the prevalence of disability tends to increase with age, more than a third of people with disabilities in the United States are between 45 and 64 years of age (Benjamin et al., 2013). According to the National Center for Health Statistics (NCHS, 2014b), in 2012, 45.6 million people 18 to 64 years of age in the United States had at least one limitation in basic activities of daily living, and 23.8 million had at least one complex activity limitation related to self-care, work, or social interaction. Among older adults (over age 65), 22.5 million experienced basic activity limitations and 12.8 million had complex activity limitations. For example, nearly 15% of women and 10% of men needed help with personal care activities (NCHS, 2011d). Based on 2012 National Health Interview Survey data, 16% of the U.S. population experienced hearing problems, 8.8% had vision problems, and more than 7% were unable to walk a quarter of a mile without difficulty (Centers for Disease Control and Prevention [CDC], 2014).

Some chronic health conditions may make a greater contribution to disability than others. For example, nearly 17% of people with diabetes experienced visual impairment in 2010 (Burrows, Hora, Li, & Saaddine, 2011), and stroke and arthritis are significant contributors to overall disability figures (CDC, 2012d, 2013e). In July 2005, the U.S. Surgeon General issued a *Call to Action to Improve the Health and Wellness of Persons with Disabilities*. The four goals of this initiative are to (a) promote public understanding of disability and the capabilities of persons with disability, (b) increase the capability of health care providers to provide holistic care to persons with disabilities, (c) assist persons with disabilities to promote their own health, and (d) enhance access to the care and services required to promote independence among those with disabilities (Office of the Surgeon General, 2005). Population health nursing intervention and advocacy will be required to accomplish these goals. For example, population health nurses may need to advocate for holistic care for people with disabilities that meets more than physical health needs. Political advocacy may also be needed to assure access to needed services or to promote environmental changes that limit the disabling effects of chronic conditions.

In addition to a diminished quality of life, the presence of disability may impede other health-related behaviors. For example, women with disabilities may be less likely than those without disabilities to receive Papanicolaou smears or mammograms due to mobility difficulties. People with disabilities are

also more likely than those without to report poor health, 39% versus 9% in one report (Benjamin et al., 2013). This leads to increased health care utilization, with people with disabilities accounting for almost 40% of emergency departments visits each year (Rasch, Gulley, & Chan, 2012).

Activity limitations engendered by disability often require a change in lifestyle. Individuals with arthritis, for example, may need to adjust to their inability to do some things that they have done in the past or may need to learn to use special implements to accomplish everyday tasks like closing a zipper or buttoning a shirt. Similarly, clients with chronic respiratory conditions may find that they are less able to engage in vigorous activity than in the past and may require more frequent rest periods. The client seriously injured in an automobile accident may need to adjust to using a wheelchair. Frequently, such physical limitations make it necessary to rely on others to perform routine tasks of daily living. This enforced dependence on others may, in turn, adversely affect an individual's self-image.

Even when activities are not restricted, the presence of a chronic health problem usually requires lifestyle adjustments. For the person with diabetes or a heart condition, for example, changes in diet are required. The person with diabetes may also need to make changes in eating patterns. This might mean not skipping meals or not eating on the run.

The pain, lifestyle changes, decreased activity levels, and impaired mobility associated with chronic conditions can contribute to social isolation. The chronically ill individual may be less able to interact with others in familiar patterns or be unable to engage in activities that friends and family enjoy. Consequently, this person may feel left out unless concerted efforts are made to incorporate him or her into family and community life. Advocacy may also be required to address integration of those with disabilities into the everyday life of society. The David L. Bazelon Center for Mental Health Law has developed a set of principles for societal integration of people with disabilities that include rights to the following:

- Opportunities to live like others with respect to residence, employment, and social interactions
- Control over their own lives and daily schedules
- Control over where and how they live
- Employment in nonsegregated workplaces with access to supports necessary to promote productivity
- Independent housing other than group homes
- Opportunities to make informed choices
- Government funding to support implementation of the principles. (David L. Bazelon Center for Mental Health Law, 2013)

Family Effects

Chronic health problems have effects on families as well as on the individual affected. Family members with chronic conditions may no longer be able to fulfill their normal family roles, necessitating role reallocation and possibly role overload for

other family members. Restructuring of family roles may also affect relationships among family members, changes in self-image and anger for the member with a chronic disease, and increased stress for other family members. Family members may also have to give up work to care for a disabled member, limiting both the opportunity for respite and family income.

Finally, chronic health problems often entail considerable financial burden for both individuals and families. Most chronic conditions require the individual to take prescribed medications for the rest of his or her life, and the cost can escalate rapidly. Add to this the cost of frequent visits to health care providers to monitor the condition and the effects of therapy. Moreover, many individuals with chronic conditions require expensive special equipment or services. Disabled individuals are more likely than those who are not disabled to put off needed health care because of costs and are more likely to live in poverty (Beckles & Truman, 2011). Population health nurses may need to advocate for services and financial assistance for families affected by chronic health conditions.

Societal Effects

Chronic conditions also affect the general population. These effects are reflected in financial costs to society, morbidity, and mortality.

FINANCIAL COSTS. Chronic health problems cost society millions of dollars each year, and the annual costs of disability related to chronic health conditions amount to approximately \$400 billion in health care costs alone (Benjamin et al., 2013). Societal costs of chronic health conditions include the direct medical costs of care, the indirect medical costs (e.g., home modification, special education), and other indirect costs such as productivity losses due to the inability to work, limitations on work ability, or premature death. Societal costs due to lost productivity may also apply to family caretakers who cannot be employed because of their caretaking responsibilities.

U.S. medical care related to stroke resulted in costs of \$18.8 billion in 2008, with half of this amount spent on hospitalization (Hall, Levant, & De Frances, 2012). Cancer costs in the United States amount to 1.7% of the total gross domestic product (GDP), but are higher in other countries. For example, in Hungary an estimated 3.05% of the GDP is spent on cancer care. Worldwide, an estimated \$180 billion is spent each year on cancers of the lung, bronchus, and trachea alone. In 2008, the total global cost of cancer in terms of premature death and disability and excluding direct treatment costs was an estimated \$895 million or 1.5% of the global GDP. Other chronic conditions account for significant costs as well. For example, the global costs of heart disease (excluding treatment costs) in 2008 was \$753 billion, with cerebrovascular disease costing \$298.2 billion, diabetes \$204.4 billion, and chronic obstructive pulmonary disease (COPD) \$203.1 billion (American Cancer Society, 2010).

In the United States, 2010 expenditures for cardiovascular diseases, including heart disease and stroke, amounted to \$444

billion (Farley et al., 2012), and direct medical care costs related to hypertension amount to \$47.5 billion per year (CDC, 2013a). In 2007, the direct medical costs for diabetes care were \$116 billion, with another \$58 billion related to disability, lost productivity, and premature mortality, for a total cost of \$174 billion (CDC, 2011a). Arthritis, the most common cause of disability, accounts for \$128 billion in expenditures per year (Cheng, Hootman, Murphy, Langmaid, & Helmick, 2010), and the medical costs for obesity amount to \$147 billion annually (Hootman, Helmick, Hannan, & Pan, 2011). Similarly, second-hand smoke exposure related to mortality and years of productive life lost amounted to \$6.6 billion in 2006 (Max, Sung, & Shi, 2012).

Accidental injuries also contribute a major portion of societal costs related to chronic conditions. In 2009, for example, productivity and lost wages costs for all unintentional injuries amounted to \$357.4 million, with another \$147.3 for medical costs (National Safety Council, 2011). According to a report prepared for the Institute of Medicine (IOM), the annual direct and indirect costs of epilepsy are estimated at \$15.5 billion (National Center for Chronic Disease Prevention and Health Promotion [NCCDPHP], 2011b), with direct medical costs amounting to \$9.6 billion per year. Indirect costs of epilepsy due to lost productivity and quality of life are believed to be far higher (England, Liverman, Schultz, & Strawbridge, 2012). It would seem clear from these cost figures alone that the United States can no longer bear the burden of chronic disease and must take steps to control these and other chronic conditions.

MORBIDITY AND MORTALITY. Societal costs of chronic health conditions are measured not only in dollars but also in terms of the extent of morbidity resulting from these conditions. Although some progress has been made in preventing mortality due to chronic conditions, their prevalence has been increasing over the years. Because the reporting of chronic health conditions is not mandatory, however, prevalence figures probably

Hypertension is one of the most prevalent chronic health problems. (Kurhan/Fotolia)

grossly underrepresent the extent of these conditions in the population.

Approximately half of all Americans are dealing with some form of chronic condition in themselves or in family members. Twelve percent of U.S. children have special care needs, and 23% of those children experience significant effects of their conditions. Among adults, 7% of those 45 to 54 years of age and 37% of those over age 75 are managing three or more chronic conditions (Ryan & Sawin, 2009). Chronic disease mortality also poses a significant burden in the United States and worldwide. In 2008, for example, noncommunicable diseases accounted for 63% of all deaths worldwide or 36 million deaths (WHO, 2011). U.S. age-adjusted heart disease mortality in 2010 was 179.1 per 100,000 population, while cerebrovascular mortality was 39.1 per 100,000, and mortality due to malignant neoplasms was 172.8 per 100,000. Mortality rates per 100,000 population for chronic lower respiratory diseases, unintentional injury, diabetes, and cirrhosis were 42.7, 38.0, 20.8, and 9.4 per 100,000 people, respectively (NCHS, 2014b). In 2010, an estimated 200,070 avoidable deaths occurred in the United States as a result of heart disease, stroke, and hypertension, a decline of 29% from 2001 (Schieb, Greer, Ritchey, George, & Casper, 2013). Similarly, declines in mortality for other conditions have been achieved. For example, in-hospital stroke mortality increased from 21% in 2005 to 23.7% in 2009, but ischemic stroke mortality declined from 6.2% to 5.1% (George, Tong, & Yoon, 2011). Age-adjusted cardiovascular mortality decreased by more than 30% from 1999 to 2009, and cancer mortality declined by almost 12% in the same time period (NCHS, 2011a).

In spite of these gains, however, the incidence and prevalence of chronic conditions continue to rise. Approximately one third of Americans have hypertension, and the self-reported prevalence of hypertension increased from nearly 26% to more than 28% from 2005 to 2009, with nearly 60% of people over 65 years of age affected (Fang, Ayala, Loustalot, & Dai, 2013). By 2009–2012, this figure had increased to 30% of the U.S. population (NCHS, 2014b). Based on data from the National Health and Nutrition Examination Survey (NHANES) from 2005 to 2008, less than 44% of people who have been diagnosed with hypertension have their blood pressure under control, with men less likely to achieve control than women (Keenan & Rosendorf, 2011). In addition, approximately 14 million Americans with hypertension are unaware of their disease status (CDC, 2013a). Hypertension accounted for 38.9 million medical office visits and 3.6 million outpatient department visits in 2010 and resulted in 26,634 deaths (NCHS, 2014c).

Hypertension is a major risk factor for heart disease and stroke (Fang et al., 2013). According to the 2009 Behavioral Risk Factor Surveillance Survey (BRFSS), a median of 5.9% of the population across the states had coronary heart disease (Li et al., 2011). Coronary heart disease prevalence decreased from 6.7% of the population to 6% between 2006 and 2010 (Fang, Shaw, & Keenan, 2011). Despite this decline, approximately 300,000 people experience an out-of-hospital cardiac arrest

each year, and 92% of them die. Part of the reason for this level of mortality is the failure of bystanders to provide CPR (only a third of cases from 2005 to 2010 received bystander CPR) or treat the arrest with an automated external defibrillator (AED) (3.7%) (McNally et al., 2011).

Over 6.2 million people in the United States have experienced a stroke, and stroke is the fourth leading cause of death. In 2010, the stroke mortality rate was 41.9 deaths per 100,000 population (NCHS, 2012). From 1999 to 2009 the rate of hospitalization for stroke declined by 20% for persons 65 to 74 years of age, 24% for those in the next decade, and 20% for those 85 years of age and older. Despite these gains, more than a million stroke hospitalizations occurred in 2009 (Hall et al., 2012).

Diabetes is another significant contributor to both heart disease and stroke. In 2010, 26 million people in the United States had diabetes, and another 79 million were prediabetics (CDC, 2012b). **Prediabetes** is a condition in which blood glucose and HgA1c levels are higher than normal, but not yet high enough for a diagnosis of diabetes. Only approximately 11% of those with prediabetes are aware of the condition and, without intervention and changes in lifestyle, are at risk for progression to diabetes (Li, Geiss, Burrows, Rolka, & Albright, 2013). Diabetes prevalence increased by more than 82% from 4.5% in 1995 to 8.2% in 2010 among people 18 years of age and older (Geiss et al., 2012). Diabetes incidence and prevalence data are available by state from the web-based atlas created by the Division of Diabetes Translation (2014). For further information about the atlas, see the *External Resources* section of the student resources site.

Cancer incidence across all types of cancers was 443.1 per 100,000 population in 2010 (NCHS, 2014b). In the 2009 BRFSS, a median of 9.9% of U.S. adults reported having had a diagnosis of cancer (Li et al., 2011), and 1.4 million invasive cancers were diagnosed that year (Singh, Henley, Wilson, King, & Ehemann, 2013). Survival rates have improved for most cancers. Survival rates reflect the number of people with a diagnosed condition who are still alive after a given period of time (usually 5 or 10 years for most cancers). From 1971, the number of U.S. cancer survivors increased from 3 million to 11.7 million from 1971 to 2007 (Rowland et al., 2011). One of the *Healthy People 2020* objectives is to increase overall 5-year cancer survival rates to 72.8% of those diagnosed. In 2009, 65.5% of those with a cancer diagnosis had survived for at least 5 years (U.S. Department of Health and Human Services [USDHHS], 2014a), and 39% of people with cancer responding to the 2009 BRFSS had survived for more than 10 years (Underwood et al., 2012). Reasons for increased survival rates include earlier diagnosis as a result of cancer screening programs, the availability of more effective therapies, prevention of secondary disease among persons with cancer, and a decrease in mortality from other causes, leading to longer survival with cancer. Care of cancer survivors will assume greater importance as this objective is achieved and will be addressed in more detail later in this chapter.

Asthma affects about 25.7 million adults and children in the United States, and the number of those affected increased by

nearly 3% per year from 2001 to 2010 (Moorman et al., 2012). In the 2006–2008 National Health Interview Survey, current asthma prevalence was 9% among children and 7.3% among adults (Moorman, Zahran, Truman, & Molla, 2011). As noted in Chapter 16, asthma accounts for more school absences than any other condition, and in 2008 children with asthma missed 10.5 million school days. Asthma is also a significant problem in the workplace, and one in six people with asthma experience a worsening of their condition due to occupational exposures. In addition, approximately 11 million U.S. workers are exposed to at least one asthmagen in the workplace (American Lung Association, 2014a). Typical asthma triggers at work include mold; dust; gases, fumes, and vapors; second-hand smoke; cleaning and personal care products; animal dander; and stress. Outdoor workers may also encounter air pollutants and vehicle exhaust (American Lung Association, 2014b). In 2008, 34% of workers with asthma missed at least 1 day of work for a total of 14.2 million work days lost (Akinbami, Moorman, & Liu, 2011).

Chronic lower respiratory disease, mostly due to chronic obstructive pulmonary disease or COPD, is the third leading cause of death in the United States and affects 5.1% of the adult population (Herrick et al., 2012). Nearly 30% of those with COPD have a history of asthma (Kosacz et al., 2012), but less than half (48%) report daily use of medications to improve respiratory function and only 82% have ever had a diagnostic breathing test (Herrick et al., 2012).

Arthritis is one of more than a hundred conditions affecting joints and connective tissue. Arthritis contributes to nearly a quarter of disability in older people (Hootman, Helmick, & Brady, 2012). Based on NCHS data for 2012, 22% of the noninstitutionalized population in the United States (51.8 million people) had arthritis, and an additional 303,000 nursing home residents (20%) were affected (NCHS, 2014a). In addition, a third of those with arthritis experience severe pain, and 11% are restricted in social interactions because of the disease (Benjamin et al., 2013). Arthritis also affects 300,000 children. By 2030, an estimated 67 million people will suffer from arthritis, and 25 million will experience activity limitations (CDC, 2012d).

Epilepsy is another chronic condition that contributes to morbidity and mortality in the United States and elsewhere. An estimated 2.2 million persons in the United States have epilepsy, and approximately 150,000 new cases are diagnosed each year. An estimated 1 in 26 people will develop epilepsy at some point in their lives (England et al., 2012). More than a third of people with epilepsy continue to experience seizures despite medications. Epilepsy has been linked to social stigma, lost productivity, and decreased quality of life for those affected (NCCDPHP, 2011b). In addition, people with epilepsy are at increased risk for premature mortality due to cardiovascular disease, stroke, hypertension, and respiratory diseases (Kadima, Kobau, Zack, & Helmers, 2013).

Chronic kidney disease (CKD) is the ninth leading cause of death in the United States (CDC, 2013b). An estimated

26 million people have chronic kidney disease, and millions more are at risk. Diabetes and hypertension are major risk factors for CKD (National Kidney Foundation, 2013).

Accidental injuries are another source of chronic disability, and their long-term consequences constitute chronic health conditions of concern to population health nurses. In 2010, for example, 21,000 deaths and 2.6 million nonfatal injuries occurred as a result of motor vehicle accidents (CDC, 2013c). Worldwide motor vehicle accidents kill 3,500 people each day and injure or disable 50 million more each year (CDC, 2012e), but traffic accidents are not the only cause of unintentional injuries. In 2010, in the United States, 120,589 unintentional injury deaths occurred for an age-adjusted mortality rate of 37.89 deaths per 100,000 population (National Center for Injury Prevention and Control [NCIPC], 2013a). In 2012, the age-adjusted rate for nonfatal unintentional injuries was 9,480.61 per 100,000 people, amounting to 29.4 million injuries (NCIPC, 2013c). NCIPC (2013b) has developed a reporting system for injury statistics that includes injury deaths, violent deaths, and nonfatal injuries that permits population health nurses to determine unintentional injury rates in their own areas and assist in designing appropriate control measures. For further information about the web-based Injury Statistics Query and Reporting System (WISQARS), see the *External Resources* section of the student resources site.

Some of the increase in incidence and prevalence figures for chronic health problems is attributable to better diagnosis as well as to the ability to prevent deaths due to these conditions. These and similar figures for other chronic conditions, however, indicate that Americans are making little progress in the prevention of chronic health problems.

Population Health Nursing and Chronic Physical Health Problems

Factors related to biological, psychological, environmental, sociocultural, behavioral, and health system determinants can increase the risk of an individual or a population group with respect to a particular chronic condition. Conversely, determinants may help protect against chronic health problems. In addition, the presence of a chronic health problem might affect factors in each of these areas.

Assessing Risks for and Effects of Chronic Physical Health Problems

Population health nurses assess both individual clients and populations for risk factors that contribute to the development of chronic physical health problems. They would also assess for the presence of chronic conditions and their effects at both individual and population levels. The assessment would be framed in the context of the six categories of determinants of health.

Global Perspectives

The Global Rise of Noncommunicable Diseases

In 2010, the World Health Organization (WHO) published its *Global Status Report on Noncommunicable Diseases* (WHO, 2011). Based on the report, nearly two thirds (63%) of all deaths worldwide in 2008 resulted from noncommunicable conditions, particularly cardiovascular disease, diabetes, cancer, and chronic respiratory diseases. In all regions of the world except Africa, noncommunicable conditions outstripped communicable diseases as a cause of death. Four-fifths of these deaths occurred in low- and middle-income countries, including more than 80% of deaths due to cardiovascular disease and diabetes, nearly 90% of COPD deaths, and two thirds of cancer deaths. In addition, deaths due to these conditions occur at younger ages in lower-income countries, with 29% of deaths occurring before age 60 in low- and middle-income countries compared to only 13% in high-income countries (WHO, 2011).

Four main behavioral risk factors contribute to the global burden of noncommunicable conditions: tobacco use, insufficient physical activity, harmful alcohol use, and unhealthy diet. Worldwide, 6 million deaths are attributed to tobacco use each year. By 2020, this number is expected to increase to 7.5 million, accounting for 10% of all deaths. Among men, smoking is more frequent in lower-middle-income countries, but prevalence is higher for the total population in higher-income countries due to greater participation by women. Physical inactivity causes approximately 3.2 million deaths per year, with those who are inactive having a 20% to 30% increase in their risk of all-cause mortality compared to those who engage in sufficient activity (WHO, 2011).

Harmful alcohol use results in 2.3 million deaths each year, more than half due to chronic conditions such as cancer, cardiovascular disease, and cirrhosis. High-income and upper-middle-income countries have higher per capita alcohol consumption rates than lower-income countries. Increased consumption of salt and saturated fats and trans-fatty acids has been linked to increased prevalence of noncommunicable diseases throughout the world (WHO, 2011).

Biological risk factors, such as elevated blood pressure, overweight and obesity, elevated cholesterol levels, and cancer-related infections also contribute to the global burden of noncommunicable diseases. Hypertension, for example, is estimated to cause 7.5 million deaths per year. Similarly, overweight and

obesity result in more than 2.8 million deaths annually, and raised cholesterol is implicated in 2.6 million deaths. Finally, about 18% of cancer deaths are the result of chronic infections with human papillomavirus (HPV), hepatitis B and C, and *Helicobacter pylori*, with a large portion of these deaths occurring in low-income countries (WHO, 2011).

A subsequent report addressed the national capacity of the world's nations to address the growing incidence and prevalence of noncommunicable diseases (WHO, 2012). The report noted that while some countries have some aspects of capacity for addressing noncommunicable conditions, many are woefully lacking in this respect. For example, only 80% of countries had funding available for treatment of these conditions; only 81% had funding for prevention activities. Similarly, although 92% of countries reported at least one policy, plan, or strategy to address noncommunicable conditions, only 79% had at least one operational policy and in only 71% of those countries was policy implementation funded (WHO, 2012).

Surveillance was also an area of concern, with only 48% of countries collecting population-based mortality data, and 23% collecting morbidity data. Similarly, only 59% of countries reported collecting population-based data on chronic disease risk factors. With respect to clinical care activities, only 85% of countries provided prevention and 77% provided risk factor detection services within primary care systems. Even fewer provided self-management support (58%) or home-based care (50%). Although most countries reported having evidence-based practice guidelines for diabetes or hypertension care or nutrition counseling, less than a third had fully implemented any guidelines (WHO, 2012).

WHO (2012) recommended the use of several low-cost “best buys” or strategies that can rapidly contribute to better chronic disease control. Some of these strategies included tobacco and alcohol control, reduced sodium and trans-fat intake, hypertension control, early detection and treatment for cancer, and blood pressure and glycemic control and foot care for persons with diabetes. Recommendations for action also included a comprehensive approach that addresses prevention and treatment interventions; multisectoral action among government, civil society, and the private sector; and improved surveillance and monitoring (WHO, 2011).

BIOLOGICAL DETERMINANTS. Human biological factors related to age, gender, race and ethnicity, specific genetic inheritance, and physiologic function can increase one's risk of developing several chronic health problems. Factors in each of these areas will be addressed here.

Age, Gender, and Race/Ethnicity. Many people think of chronic health problems as occurring primarily among the elderly, despite the fact that approximately 8% of U.S. children experience some form of limitation related to a variety of chronic conditions, many of which were discussed in Chapter 16.

More than 50 million Americans under 65 years of age have one or more chronic health conditions (National Health Council, 2013), and both the incidence and prevalence of chronic conditions rise with increasing age. For example, in 2012, 26% of people 18 to 64 years of age had at least one complex activity limitation due to chronic conditions compared to nearly 59% of those over age 65 (NCHS, 2014b).

Both the young and the elderly are at higher risk than other age groups for accidental injuries and resulting disabilities. In part, this increased risk is due to maturational events of childhood and aging. The inability of a young infant to roll over or support his or her head contributes to suffocation as the leading cause of accidental death and disability in this age group. Similarly, normal toddler development involves a great deal of experimentation that may lead to accidental injury and disability if close supervision and safety precautions are not employed. The risk taking and feelings of invulnerability characteristic of preadolescent and adolescent development place young people at risk for motor vehicle accidents. Among the elderly, death and disabilities due to falls are of the greatest concern. In 2010, for example, falls among older adults resulted in 662,000 hospitalizations and 2.3 million nonfatal injuries treated in emergency departments at a cost of \$30 billion for direct medical care. In addition, unintentional fall injuries caused 21,700 deaths among the elderly in the United States (Division of Unintentional Injury Prevention, 2013). Leading

causes of fatal and nonfatal unintentional injuries by age are presented in Table 27-1. As can be seen in the table, falls are the leading cause of unintentional injury for all age groups. Population health nurses can help to educate families and the general public regarding age-appropriate safety measures to prevent injuries. They can also engage in political advocacy to promote safe living and working conditions (e.g., legislation mandating functioning smoke alarms in all residences).

Young children and the elderly are also at higher risk for epilepsy than other age groups. By age 80, for instance, 3% of the U.S. population will have a diagnosis of epilepsy (NCCDPHP, 2011b).

Some chronic conditions and their effects are more prevalent in adults. For example, despite the popular belief that people with arthritis are elderly, most cases of arthritis have their onset in the fourth decade of life. For women over age 45, for example, arthritis is the major cause of activity limitation. Older persons do, however, tend to experience greater disability as a result of this condition. The prevalence of COPD tends to increase dramatically in the fifth through the seventh decades of life, and approximately 12% of people 65 to 74 years of age in the United States experience COPD (Kosacz et al., 2012). The incidence of cancer also increases with increasing age. According to the National Cancer Institute's Surveillance, Epidemiology, and End Results (SEER) data, cancer incidence rates from 2005 to 2010 for people over 65 years of age were

TABLE 27-1 Leading Causes of Fatal and Nonfatal Unintentional Injuries in Order of Frequency, by Age Group

Age Group	Fatal Injuries	Nonfatal Injuries
Infants (birth–1 year)	Suffocation, motor vehicle accidents (MVA), drowning, fire/smoke, falls, poisoning, struck by/against an object	Falls, struck by/against an object, bite/sting, foreign body, fire/smoke, cut/pierced, inhalation/suffocation, MVA
1–4 years	Drowning, MVA, fire/smoke, suffocation, pedestrian, struck by or against an object, falls, poisoning, firearms	Falls, struck by/against an object, bite/sting, foreign body, cut/pierced, overexertion, fire/smoke, dog bite
5–9 years	MVA, fire/smoke, drowning, suffocation, other land transport, pedestrian, firearms, struck by or against an object	Fall, struck by/against an object, cut/pierced, bite/sting, pedalcyclist, overexertion, MVA, foreign body, other transports
10–14 years	MVA, drowning, other land transport, fire/smoke, poisoning, suffocation, firearms, falls, pedestrian, other transport	Falls, struck by/against an object, overexertion, cut/pierced, pedalcyclist, MVA, other transport, bite/sting, dog bite
15–24 years	MVA, poisoning, drowning, other land transport, falls, fire/smoke, firearms, pedestrian, other transport	Being struck by or against an object, falls, MVA, overexertion cut/pierced, bite sting, other transport, poisoning
25–34 years	MVA, poisoning, drowning, falls, other land transport, fire/smoke, suffocation, other transport, pedestrian	Falls, overexertion, struck by/against an object, MVA, cut/pierced, bite/sting, poisoning, other transport
35–44 years	Poisoning, MVA, falls, drowning, fire/smoke, suffocation, other land transport, other transport	Falls, overexertion, struck by/against an object, MVA, cut/pierced, poisoning, bite/sting, other transport
45–54 years	Poisoning, MVA, falls, fire/smoke, drowning, suffocation, other land transport	Falls, overexertion, struck by/against an object, MVA, cut/pierced, poisoning, bite/sting, other transport
55–64 years	MVA, poisoning, falls, fire/smoke, suffocation, drowning, other transport	Falls, struck by/against an object, overexertion, MVA, cut/pierced, poisoning, bite/sting, other transport
Over 65 years	Falls, MVA, suffocation, fire/smoke, poisoning, drowning, other land transport	Falls, struck by/against an object, overexertion, MVA, cut/pierced, poisoning, bite/sting, other transport

Data from: National Safety Council. (2011). *Injury facts 2011 edition*. Retrieved from http://www.nsc.org/Documents/Injury_Facts/Injury_Facts_2011_w.pdf

more than nine times higher than those for younger people (2,113.7 per 100,000 population and 224.2/100,000, respectively). Cancer mortality was almost twice as high for older people than for those under 65 years of age (104.1 and 56.1 per 100,000 population, respectively) (Howlader et al., 2013).

In 2010, an estimated 215,000 people under 20 years of age had type 1 or type 2 diabetes (Saydah, Geiss, & Gregg, 2012), less than 1% of this segment of the U.S. population (National Diabetes Information Clearinghouse, 2013). Among people over 18 years of age, the 2011 diabetes incidence rate was almost three times higher among persons 65 to 79 years of age than among those aged 18 to 44 years, and 63% of new cases were diagnosed between the ages of 40 and 64 years (Division of Diabetes Translation, 2013a, 2013b). Similarly, although a stroke can occur at any age, two thirds of strokes in the United States occur over 65 years of age, and the rate of hospitalization for stroke is two-and-a-half times higher in people over 85 years of age than in the 65 to 74 age group (Hall et al., 2012). Asthma affects all age groups with 7 million U.S. children and 18.7 million adults affected in 2010. Approximately 3.1 million Americans over 65 years of age also suffer from asthma (Moorman et al., 2012).

Gender can also influence the risk of developing a variety of chronic health conditions. Boys have a higher incidence of asthma than girls, but among adults, women are more likely to be affected than men (Moorman et al., 2012). Men have a higher incidence of coronary heart disease than women (7.8% vs. 4.8%), and invasive cancer incidence is higher in men than women (Singh et al., 2013). Similarly, diabetes prevalence is higher in men, 8.1 per 100,000 population compared to 7.7 per 100,000 for women (Beckles, Zhu, & Moonsinghe, 2011). Men also have higher incidence rates for cancers than women (502.6 per 100,000 men compared to 401 per 100,000 women in 2010) (NCHS, 2014b). With respect to hypertension, White men and women have similar mortality rates (15/100,000 population), but Black women have higher rates than Black men (50/100,000 compared to 40/100,000) (Hicken et al., 2012). Women, in general, experience more arthritis than men. According to the 2007–2009 National Health Interview Survey, 26% of women reported doctor-diagnosed arthritis compared to only 18% of men. Women were also more likely to report arthritis-related activity limitations than men (44% and 40%, respectively) (Cheng et al., 2010).

For many chronic conditions, race and ethnicity are associated with disparities in chronic disease morbidity and mortality. Race and ethnicity are probably markers for differences in health behaviors, access to health care, and other factors that contribute to the development of disease. **Risk markers** are factors that help to identify persons who may have an elevated risk of developing a specific condition but that do not themselves contribute to its development. For example, Black women have lower incidence rates for breast cancer, but have a 41% higher risk for mortality than White women. In part, this disparity is due to more advanced stage at diagnosis than among White women (Cronin et al., 2012). Overall invasive cancer incidence rates are highest in Blacks and lowest in the American

Indian/Alaska Native population (AI/AN) (Singh et al., 2013). Conversely, the AI/AN population is far more likely than other racial and ethnic groups to experience diabetes, with prevalence rates two times higher than those for non-Hispanic Whites (CDC, 2011b). In addition, diabetes mortality is three to four times higher in this population than in the overall U.S. population. Because diabetes is a significant factor in cardiovascular disease, increased diabetes prevalence in the AI/AN population also contributes to a cardiovascular mortality rate two-and-a-half times that of the White population.

Furthermore, cardiovascular deaths tend to occur at younger ages in this population (O'Connell, Wilson, Manson, & Acton, 2012). Both hypertension prevalence and mortality are higher among Blacks than Whites (Hicken et al., 2012). In large part, these differences are due to the degree of blood pressure control achieved in the two groups, with 33% of Whites having controlled their blood pressure compared to only 28% of African Americans (Cuffee et al., 2013).

Arthritis occurs with greater frequency among non-Hispanic Whites and AI/ANs than other groups in the United States. For example, arthritis prevalence is roughly 25% for AI/ANs and 24% for non-Hispanic Whites, followed by non-Hispanic Blacks at 19%. The lowest incidence is found among Hispanics (11%) and Asians/Pacific Islanders (8%). Racial and ethnic minority groups, however, are more likely than non-Hispanic Whites to experience arthritis-related activity limitations, work limitations, and severe pain (NCCDPHP, 2011a). For the most part, the disparities noted in the incidence, prevalence, and effects of chronic physical health problems among racial/ethnic groups are associated with differences in socioeconomic status, access to care, and health-related behaviors. Population health nurses can be actively involved in advocating and providing health promotion education and access to health care services to minimize racial and ethnic disparities in the incidence of chronic health problems.

Genetic Inheritance. Some chronic diseases seem to be associated with genetic predisposition. The Center for Surveillance, Epidemiology, and Laboratory Services (CSELS) has noted that genetic factors play a part in nine of the ten leading causes of death in the United States (CSELS, 2014a). Genetic contributions to chronic disease occur in one of three forms: single gene disorders, such as hemophilia, chromosomal abnormalities such as Down syndrome, and multifactorial disease (e.g., cancer or heart disease) in which genetic factors are one of several contributors to disease (Australian Institute of Health and Welfare, 2013).

Genetic factors primarily interact with environmental and behavioral risk factors to promote disease (CSELS, 2014a). Four mechanisms have been proposed for these gene–environment interactions. In the first mechanism, genetic make-up influences one's response to environmental stressors. Second, genetic factors may enhance one's sensitivity to favorable or adverse environmental conditions. In the third mechanism, some inherited characteristics may fit better with some

environments than others. Finally, inherited characteristics may only become manifest in certain challenging or favorable environments (Reiss, Leve, & Neiderhiser, 2013).

Genetic factors have been implicated in a variety of cancers. For example, 2% to 7% of women who develop breast cancer have evidence of hereditary BRCA1 or BRCA2 gene mutations, and 10% to 15% of women who develop ovarian cancer have such genetic mutations. Occasionally, other inherited genetic mutations will contribute to breast or ovarian cancer, but these mutations are not common. The majority of breast and ovarian cancer incidence, however, is not related to genetic mutations (CSELS, 2013c). Similarly, colorectal cancer also has a genetic component in which genes interact with behavioral factors such as obesity and physical activity to cause disease. In some rare cases, colorectal cancer is due to hereditary genetic mutations (CSELS, 2013b).

Genetic disorders may also contribute to heart disease. For example, familial hypercholesterolemia, a relatively common condition, increases levels of low density lipoprotein cholesterol (LDL), leading to greater risk of cardiovascular disease. An estimated 1 in 500 people are affected by this inherited condition (CSELS, 2014c). Genetic factors also play a part in stroke risk through contributions to related factors such as hypertension, heart disease, diabetes, and vascular conditions. For example, in one study, 86% of all early strokes occurred in 11% of families in Utah. Stroke may also occur as a complication of other genetic disorders, such as sickle cell disease (CSELS, 2013d).

In addition, genetic factors have been implicated in being overweight and obese, primarily as a result of responses to environmental factors. Genetic variations may affect hunger and food intake contributing to obesity. Genetic–environmental interaction theories of obesity suggest a mismatch between development of “energy-thrifty” genes in periods of restricted food supplies and today’s overabundance of food (CSELS, 2013a). Genetic testing has been suggested for several conditions with known genetic contributions. The Office of Public Health Genomics (CSELS, 2014b) has developed guidelines for genetic testing for specific conditions. For further information about the guidelines, see the *External Resources* section of the student resources site.

Population health nurses can obtain a family history of chronic diseases to help determine an individual client’s risk for these conditions. Clients may not be knowledgeable regarding family history of disease, and population health nurses can educate the public regarding the need for family health history information and guide them in its collection.

Physiologic Function. Assessment of physiologic factors related to chronic conditions focuses on three areas: presence of physiologic risk factors, physiologic evidence of existing chronic health problems, and evidence of physiologic consequences of chronic conditions.

Physiologic traits over which one has little control may predispose one to certain chronic illnesses. For example, having fair skin, red or blonde hair, or a tendency to sunburn easily

increases one’s risk for skin cancers. Preventive interventions (e.g., staying out of the sun, use of sunscreen) can, however, mitigate the effects of these risks.

Certain physiologic conditions may predispose one to develop some chronic health problems. Activity limitations and impaired balance and mobility, for example, may contribute to injuries with long-term consequences. Biomedical risk factors, such as overweight and obesity, hypertension, elevated cholesterol levels, and impaired glucose tolerance also contribute to several chronic health problems (Australian Institute of Health and Welfare, 2013).

Obesity, in particular, contributes to a variety of chronic health problems. Approximately 68% of the U.S. population are obese, and obesity affects one third of White women, 43% of Mexican American women, and more than half of Black women. Figures are slightly lower for men, but encompass about a third of U.S. men (Deputy & Boehmer, 2014; Reitzel et al., 2014). Obesity contributes to and worsens conditions such as heart disease, stroke, and diabetes. Obesity also contributes to asthma, worsens symptoms, and impedes asthma control. For example, in 2010, nearly 39% of people with asthma were obese compared to 27% of those without asthma (National Center for Environmental Health, 2013a). Obesity, in the presence of arthritis, has been linked to disease progression, activity limitations, disability, and diminished quality of life (Hootman et al., 2011). Obese adults with arthritis are 44% more likely to be physically inactive than those with obesity alone, increasing their risk for cardiovascular disease and other health problems (Hootman, Murphy, Helmick, & Barbour, 2011). Obesity has also been shown to decrease functional status in persons with COPD (Ade-Oshifogun, 2012), and childhood obesity is 38% higher in the presence of disability than among children without disability (Benjamin et al., 2013). Obesity also increases the risk for occupational injury. Hypertension, a chronic disease in and of itself, is also a major risk factor for heart disease and stroke (Fang et al., 2013). Hypertension is also one of the two main contributors (with diabetes) to CKD, and, in fact, blood pressure elevation is one of the key indicators of CKD, along with urine albumin and serum creatinine. CKD also causes hypertension (National Kidney Foundation, 2013). Arthritis risk and arthritis-related functional limitations are also increased in the presence of diabetes, and heart disease (Barbour et al., 2013).

Epilepsy also increases one’s risk of other chronic conditions. For example, persons who experience active seizures are at increased risk of injury. In addition, people with epilepsy have higher prevalence rates of cardiovascular and respiratory diseases, hypertension, asthma, arthritis, cancer, and peptic ulcer disease. Stroke risk for persons with active epilepsy is eight times that for persons without epilepsy; emphysema risk is more than three times higher, and chronic bronchitis rates are twice as high (Kadima et al., 2013).

Past infection may also be implicated in the development of some chronic conditions. For example, viral infection is suspected as a contributing factor in both cancer and diabetes.

A history of recurrent respiratory infections, particularly a history of severe viral pneumonias early in life, has been found to be associated with COPD. Respiratory allergy and asthma may also be predisposing physiologic factors in COPD, whereas viral infection may be a predisposing factor in childhood asthma. Human papillomavirus (HPV) infection in the form of genital warts has been linked to cervical cancer (Stanley et al., 2012). Hepatitis B and C are major factors in the development of liver cancer and cirrhosis, and there is evidence that HIV infection increases one's risk for myocardial infarction by 50% even when CD4 cell counts are controlled and other factors are accounted for (Freiberg et al., 2013).

Other physiologic conditions may be complicated by the existence of chronic illnesses. For example, diabetes places both the pregnant woman and her child at increased risk of adverse outcomes. Conversely, pregnancy complicates diabetes control. In addition, gestational diabetes mellitus (GDM) is an important contributor to later development of type 2 diabetes (Osgood, Dyck, & Grassman, 2011). GDM occurs in 2% to 20% of U.S. pregnancies and 35% to 60% of women with GDM will develop type 2 diabetes in the ensuing 10 to 20 years (CDC, 2011a).

People with chronic health problems may also develop secondary conditions as a result of their illnesses, and population health nurses caring for these clients should be alert to the development of signs of secondary conditions. For example, a client in a wheelchair may develop pressure ulcers, or a client with diabetes might develop diabetic retinopathy. Diabetes also increases the risk of lower extremity disease, often leading to amputation.

Other examples of secondary conditions include pain, sleep disturbances, fatigue, weight gain or loss, respiratory infections, and falls or injuries. When the nurse identifies the presence of secondary conditions, he or she will refer the client for appropriate medical therapy. Population health nurses can advocate for effective care for health problems to prevent the development of these and other secondary conditions. Tips for assessing the influence of biological factors on chronic health problems in the population are included in the *Focused Assessment* questions provided below.

PSYCHOLOGICAL DETERMINANTS. The major psychological factor contributing to chronic health problems is stress. Stress can result in carelessness and contribute to accidents that lead to chronic disability. Similarly, stress has been implicated as a contributing factor in the development of cancer and cardiovascular disease. Stress may also lead to poor compliance with control measures in persons with diabetes, resulting in diabetic complications. Depression and anxiety have also been associated with the onset of cardiovascular disease and with coronary heart disease survival. Conversely, myocardial infarction increases one's risk for major depressive disorder.

People with disability resulting from chronic conditions are more likely than those without disability to report poor mental health. For example, approximately one quarter of people with disabilities report poor mental health compared to only 6% of the general population (Benjamin et al., 2013).

Mental health status also affects treatment and control of chronic health problems. Conversely positive mental health is linked to better health outcome, such as lower cardiovascular disease risk and greater longevity (Perry, Presley-Cantrell, & Dhingra, 2010). Psychological factors may also influence engagement in risk behaviors for chronic conditions or adherence with treatment regimens for chronic health problems. For example, the concept of social resistance has been advanced as a possible contributing factor to the prevalence of high-risk behaviors among nondominant minority populations. **Social resistance** is a propensity to respond to perceived discrimination and alienation by engaging in everyday resistance behaviors, such as high-risk behaviors, in conscious or unconscious opposition to the majority group (Factor, Williams, & Kawachi, 2013). This perspective has received some preliminary research support, but further work is needed to determine its salience in explaining high-risk behaviors in some populations.

Psychological distress has also been found to play a part in exacerbation of symptoms among people who have asthma. Similarly, people with epilepsy have been shown to have higher rates of psychiatric comorbidity than the general population, particularly for depression and anxiety, often as a result of the social stigma attached to having epilepsy (Kadima et al., 2013).

FOCUSED ASSESSMENT

Assessing Biological Determinants Influencing Chronic Physical Health Problems

- What age groups within the population are most likely to develop specific chronic health problems? What age groups will be most seriously affected?
- Are there racial/ethnic or gender differences in disease incidence? What factors influence these differences?
- Is there a genetic predisposition to common chronic health problems in the population?
- Are there other physiologic conditions present in the population that increase the risk of developing chronic health problems?
- What are the signs and symptoms of the problem?
- What are the physiologic effects of specific chronic health problems? Do problems limit functional abilities or contribute to the development of other health problems?

Some chronic conditions have also been found to have effects on mental and emotional function. Alzheimer's disease comes most easily to mind, but traumatic brain injury may also contribute to personality changes and increased aggressiveness. Similarly, insufficient blood circulation to the brain in congestive heart failure has been suggested as an explanation for mental effects such as memory deficit, diminished learning ability, poor executive function, and decreased psychomotor speed.

Population health nurses can assist individual clients to identify personal psychological resources or refer them to support groups and other similar interventions. They can also advocate for access to psychological counseling, as needed, to help with adjustment to a chronic health problem. The *Focused Assessment* provided below can assist population health nurses in exploring factors related to chronic health conditions in individual clients and in population groups.

ENVIRONMENTAL DETERMINANTS. The effects of physical environmental conditions in terms of chronic illness were first observed in terms of scrotal cancer, the first identified occupational illness. Sir Percival Pott noted that English chimney sweeps had a high risk for cancer of the scrotum due to soot exposures while cleaning chimneys. More recently, chimney sweeps in Sweden have been found to have increased risk for ischemic heart disease, nonmalignant respiratory conditions, alcoholism and liver disease, and increased incidence of esophageal, liver, lung, bladder, hematopoietic, and colon cancers as a result of occupational soot and asbestos exposures (Hogstedt, Jansson, Hugosson, Tinnerberg, & Gustavsson, 2013).

Another obvious link to environmental exposures exists between chronic outdoor work and squamous cell carcinoma. Intermittent exposure, on the other hand, increases the risk of melanoma and basal cell carcinoma. In 2008, nearly 60,000 cases of melanoma were diagnosed, resulting in more than 8,000 deaths (CDC, 2012c). The risk of melanoma increases with the number of sunburns experienced in one's lifetime, and in the 2010 National Health Interview Survey, half of all U.S. adults and nearly two thirds of Whites 18 to 29 years of

age reported at least one sunburn in the prior year (Holman, Berkowitz, Guy, Saraiya, & Plescia, 2012). In addition, roughly 58% of White women and 20% of White men aged 18 to 25 years reported use of an indoor tanning device more than 10 times in the prior year (Hartman, Guy, Holman, Saraiya, & Plescia, 2012).

Differential exposure to environmental factors may explain some of the health inequalities among population groups (Degeling & Rock, 2012). For example, elevated blood lead levels have been associated with increased systolic blood pressure, among Blacks but not Whites. This difference has been associated with lower socioeconomic status and greater risk of lead exposures among Blacks (Hicken et al., 2012).

Urban and rural differences in disease incidence have also been noted. For example, cardiovascular disease prevalence is higher in rural than urban areas, primarily due to differences in risk behaviors such as smoking, obesity, and physical inactivity (Melvin et al., 2013). Urban density has been associated with lower body mass index (BMI) and more hours per week of physical activity (James et al., 2013). Conversely, the density of fast food restaurants has been associated with higher BMIs for low-income African Americans. Similarly, household proximity to a fast food restaurant was associated with higher BMI for all income groups, but particularly low-income households (Reitzel et al., 2014).

Physical environmental factors also contribute to chronic health problems such as long-term sequelae of accidents, cancer, and COPD. Road conditions, weather, dangerous conditions for swimming, and other physical safety hazards can contribute to accidents that result in permanent physical disability, and the nurse assesses the existence of these types of hazardous conditions in the community.

The population health nurse also assesses the environment for pollutants that may be carcinogenic. Air pollution, in particular, contributes to COPD and asthma. Other environmental factors that may influence chronic respiratory conditions, particularly those with an allergic basis, include house dust, mites, molds, tobacco smoke, and occupational exposures

FOCUSED ASSESSMENT

Assessing Psychological Determinants Influencing Chronic Physical Health Problems

- Does exposure to stress increase the risk of chronic health problems in the population?
- Do existing psychological problems increase the risk for chronic health problems in the population? If so, in what way does this influence occur?
- Does social resistance play a part in high-risk behaviors related to chronic health problems in the population?
- Do existing psychological problems complicate control of physical health problems? If so, how?
- What are the typical psychological effects of chronic health problems common in the population? Are there psychological effects for family members as well as for the person affected by the problem?
- What is the extent of adaptation to chronic health problems? What factors or conditions facilitate or impede adjustment?

Morbidity and mortality due to asthma are increasing each year.

(Spflaum/Fotolia)

to respiratory irritants. The effects of environmental pollution on health were addressed in more detail in Chapter 4∞.

Global climate changes also affect chronic health problems such as asthma. It is anticipated, for example, that global

warming will increase the growth of plant allergens and may prolong periods of seasonal asthma related to pollens.

Population health nurses should also be concerned with the concept of environmental justice. Many environmental hazards are located in low-income neighborhoods, further increasing the effects of poverty and other social factors on health. Advocacy is required to prevent the location of hazardous industries in low-income residential areas and to promote elimination of existing hazards.

The other aspect of the physical environment related to chronic health problems is its effect on the functional abilities of persons with existing chronic conditions. The *disablement process* is influenced by a variety of factors, including the pathology of disease and the environmental conditions that lead to disability in someone with a chronic health problem. For example, substandard housing conditions can lead to fear of falling in older persons with mobility limitations, resulting in social isolation and disability. Similarly, lack of adequate heat increases the growth of molds, exacerbating respiratory problems for people with asthma and other chronic conditions. Population health nurses examine personal and community environmental factors that promote disability in persons with chronic health problems. They may also need to educate clients on dealing with these environmental conditions or advocate for modification of conditions that contribute to chronic disease and/or disability in the population.

The *Focused Assessment* below provides tips for exploring physical environmental considerations as they affect the incidence, prevalence, and effects of chronic health problems in the population.

SOCIOCULTURAL DETERMINANTS. Sociocultural factors contribute to the development of chronic health problems primarily in terms of social conditions, policies, or mores that promote unhealthy behaviors or limit access to care. As some authors have noted, social factors incongruent with health may make it difficult for people to engage in healthy behaviors (Ryan & Sawin, 2009). Major sociocultural determinants to be

FOCUSED ASSESSMENT

Assessing Environmental Determinants Influencing Chronic Physical Health Problems

- Do environmental pollutants contribute to chronic health problems in the population?
- What effect, if any, do weather conditions have on the development or consequences of chronic health problems?
- Do features of rural or urban environments contribute to the development of chronic health problems in the population?
- What influence, if any, do elements of the built environment have on the development of chronic physical health problems in the population?
- Do environmental factors interact with genetic influences to contribute to chronic health problems?
- How do environmental conditions interact with other determinants of health to influence chronic health problems?
- Do chronic health problems in the population or among individuals necessitate environmental changes (e.g., installation of ramps for a wheelchair)?

addressed here include policy issues, employment and income factors, issues of discrimination and isolation, social marketing, and other social factors.

Policy issues. The main policy issue affecting chronic physical health problems is that of tobacco control; 2014 marked the 50th anniversary of the first U.S. Surgeon General's report on smoking and health (Warner, 2014). It is estimated that without the tobacco control efforts during that period, per capita cigarette consumption would be five times what it is today (Warner, Sexton, Gillespie, Levy, & Chaloupka, 2014). In addition, tobacco control policies have been credited with preventing 800,000 deaths from lung cancer alone. States, such as California and Massachusetts, that have most aggressively pursued tobacco control have reduced smoking levels well below averages (roughly 13% for California and 16% for Massachusetts compared to 19% for the nation in 2011 (CDC, 2012a). More recently, the Family Smoking Prevention and Tobacco Control Act of 2009 gave the federal Food and Drug Administration sweeping authority under the Center for Tobacco Products that could be used to control currently unregulated tobacco products such as snuff and little cigars and to mandate reduction of nicotine in cigarettes to nonaddictive levels (Warner, 2014).

Internationally, the World Health Organization's Framework Convention on Tobacco Control requires signatory countries to provide public information on the harm related to tobacco use. Under the convention, warnings on cigarette packages are expected to meet specific criteria related to the size of the message (30% to 50% of the package's principal display area), visibility, and legibility. Warnings are also expected to employ multiple rotating messages and be in the country's main language(s). The 2008–2010 Global Adult Tobacco Survey, conducted in 14 convention countries, indicated that 90% of smokers reported noticing the warnings. In addition more than 50% of those who noticed warnings in six countries considered quitting smoking as a result, and more than 25% considered quitting in all but one of the other countries. Based on these and similar results, WHO has identified package warnings as a "best buy" intervention to promote smoking cessation (Caixeta et al., 2011; 2013a). Warnings have been implemented in 209 countries and have been suggested as a means of reducing disparities related to knowledge of tobacco harm in low literacy groups (Sanders-Jackson, Song, Hiilamo, & Glantz, 2013). The convention has been signed by 177 countries representing 88% of the world's population. Unfortunately, the United States is a notable exception, due to pressure from the tobacco industry (Warner, 2014).

Policies controlling the sale and promotion of tobacco use to minors are also effective in limiting smoking initiation and extent of smoking. In 1992, the Symar amendment to the federal Alcohol, Drug Abuse, and Mental Health Administration Reorganization Act mandated withholding federal funds from states that did not prohibit sales of tobacco to minors. Youth

access policies vary from state to state, but generally include warning signs in businesses about youth tobacco purchases and penalties for failure to post such signs, vending machine restrictions, identification requirements, repackaging and free distribution restrictions, and statewide enforcement authority. Most state regulations also include clerk intervention requirements that store clerks retrieve tobacco products from areas other than public-access shelving. Studies have indicated that restricted access during youth results in less smoking in adulthood, but only for women. No single policy has proven to have a significant effect, but it has been suggested that having the full array of policies in effect might reduce lifetime smoking among women by 14%, with a 29% reduction in heavy smoking among those who smoke (Gruzka, Plunk, Hipp, Cavazos-Rehg, & Krauss, 2013). Bans on tobacco product and signage displays have also been effective in reducing tobacco use (Cohen et al., 2011).

Community smoke-free policies and promotion of smoke-free homes are other policy initiatives that can significantly reduce smoking as well as exposure to second-hand smoke (Vijayaraghavan, Messer, White, & Pierce, 2013). In 2000, only one of the 50 largest cities in the United States was covered by comprehensive smoke-free laws. By 2012, this figure had increased to 60%. In 2012 only 20 cities were not covered by either local or state laws, mostly in the South and often in states with laws that preempted local restrictions on smoking (Hopkins et al., 2012). Such laws are not only effective in reducing smoking behavior but also in reducing tobacco-related illnesses. For example, implementation of a statewide smoking ban in Arizona resulted in a significant decrease in hospitalizations for stroke, acute myocardial infarction, angina, and asthma (Herman & Walsh, 2011).

Increased cigarette prices, often through increased taxes, also decrease smoking behaviors. For example, in one study, high cigarette prices (more than \$4.50 per pack) were associated with less consumption at all income levels (Vijayaraghavan et al., 2013). From 2010 to 2011, eight states increased their cigarette taxes for a mean state tax of \$1.46 per pack. Per pack taxes ranged from a low of 17 cents in Missouri to \$4.35 in New York (Tynan, Promoff, & MacNeil, 2012). Some authors caution, however, that increased cigarette taxes may lead to "tax avoidant" behaviors with smokers purchasing untaxed cigarettes "on the street" rather than from authorized dealers. They note a need to pair tax increases with efforts to limit the entry of untaxed cigarettes into the jurisdiction (Coady, Chan, Sacks, Mbamalu, & Kansagra, 2013).

Another policy issue that influences tobacco use includes the current failure to regulate prices and sales of new smokeless tobacco products such as snus (spitless moist snuff), dissolvable oral forms of tobacco in lozenges or breath strips, and electronic cigarettes that vaporize nicotine (Choi, Fabian, Mottey, Corbett, & Forster, 2012). Similarly, the amount of funding available for tobacco control efforts limits the effectiveness of interventions. In 2014, CDC established a minimum nationwide per capita expenditure of \$7.41 for tobacco control efforts,

with a recommended per capita expenditure of \$10.53. Specific expenditure targets have also been established for each state based on the state's socioeconomic outlook. By 2011, however, only two states had met the recommended expenditure targets proposed in 2007 (Office on Smoking and Health, 2014), so concerted effort will be required to meet the new higher recommendations to address tobacco control.

Access to tobacco cessation services is another policy issue that affects smoking prevalence. The Community Preventive Services Task Force (CPSTF, 2014d) has recommended policy changes to limit out-of-pocket expenses for smoking cessation, including medication and counseling. Systematic reviews have indicated that evidence-based cessation strategies increase quit rates and attempts, decrease the prevalence of tobacco use, and can achieve an estimated savings of \$2,349 per quality-adjusted life year (QALY) saved. Additional savings related to disability life years averted range from \$7,695 to \$16,559.

Policy issues influence other factors that contribute to chronic physical health problems. For example, physical activity is known to reduce the risk of multiple chronic problems, yet access to spaces and facilities for physical activity may be limited. One limitation stems from the inability of community members to use school grounds for physical activities due to liability concerns. These concerns can be addressed through careful planning related to community access. For example, school districts can enter into joint use agreements with community organizations that limit school liability. Schools should also address any safety issues in play equipment and facilities through inspection and maintenance (Zimmerman, Kramer, & Trowbridge, 2013).

Income and employment. Economic factors influence both the development of chronic disease and disability and the ability to seek care for existing problems. WHO estimates there are more than 1 billion people with disabilities throughout the world, 200 million of whom have significant functional limitations. Based on World Health Survey data, mean disability levels are higher in low- and lower-middle-income countries than in high-income countries. Even within specific countries disability levels are significantly higher for the poorest segments of the population than the richest (Hosseinpoor et al., 2013).

In the United States, links between socioeconomic status and chronic disease have been established for many illnesses. For example, diabetes prevalence is highest in people living below poverty level (11.7 per 100,000 population) and lowest in those with incomes 400% above poverty (5.5 per 100,000) (Beckles et al., 2011). Similarly, current asthma prevalence among the poor is 11.2% compared to 6.7% for those 450% above the poverty level (Moorman et al., 2012).

Higher income levels are associated with better access to care and better outcomes. For example, the probability of receiving colorectal cancer screening for people at 600% of poverty level is twice as high as for those with incomes below poverty (Huang & Kandi, 2012). Similarly, 21.5% of working adults below poverty level did not get a needed prescription

filled due to cost compared to less than 4% of those at 400% of poverty level and above in 2010 (NCHS, 2011b). The effects of poverty are not only experienced at the individual level, but also at the community level. For example, low-income areas are associated with increased risk of asthma rehospitalization and caregiver psychological distress (Beck, Simmons, Huang, & Kahn, 2012). Population health nurses can assess the effects of socioeconomic status on chronic disease incidence and prevalence in the community as well as on access to care.

Occupation, of course, is closely related to income and socioeconomic status, but as we saw in Chapter 23, work can also contribute directly to the development of chronic health problems. As one example, nearly 7% of people with asthma, 6% of those with skin conditions, and 69% of those with carpal tunnel syndrome have been told that their condition is work-related (NCHS, 2011c). Safety hazards in the work environment can result in accidents that lead to chronic disability. Clients' occupations may also increase their potential for exposure to various carcinogens found in the workplace. Repetitive movements involved in some jobs can lead to joint injuries and subsequent arthritis. Occupations involving exposure to organic and inorganic dusts or noxious gases increase the probability of COPD. Work-related stress has also been shown to increase the risk of some chronic health problems. Population health nurses can assess for occupations and working conditions that contribute to chronic health problems in the population or that exacerbate existing problems.

Discrimination, Stigma, and Social Isolation. Perceptions of everyday discrimination have been associated with increased incidence of chronic health problems. Similarly, **racism-related vigilance**, or the expectation that one will be discriminated against as a result of one's race or ethnicity, has been associated with an increase in hypertension risk among African Americans and Hispanics, but not Whites. It is believed that the stress of anticipating discrimination is a contributing factor in hypertension in nondominant groups (Hicken, Lee, Morenoff, House, & Williams, 2014). Perceived racial discrimination may also affect adherence to hypertension medications leading to poor control (Cuffee et al., 2013).

Discrimination may stem from stigmatization of easily recognizable disabilities and other chronic conditions. **Stigmatization** is a social process of attaching unfavorable meaning to behavior and individuals on the basis of certain traits or characteristics. Some chronic health conditions create visible physical evidence, such as the malformed joints often seen in arthritis or the need to use a wheelchair or other assistive devices. The presence of other conditions, such as seizure disorder or developmental disability, may be perceived as evidence of inferiority.

People with disabilities routinely experience social justice issues related to stigma and discrimination. They may be denied the right to make decisions or to marry, and may be subjected to involuntary institutionalization. They also experience lower educational and literacy and higher poverty and

unemployment levels than the general population. Stigma is particularly common with respect to epilepsy, which is poorly understood by the general public, and epilepsy is frequently stigmatized in both work and educational settings (NCCDPHP, 2011b).

Stigma and discrimination, as well as functional limitations may contribute to social isolation. Social isolation, in and of itself, has been identified as a significant predictor of illnesses, such as hypertension, and unhealthy behaviors, such as smoking, as well as overall mortality (Pantell et al., 2013). Recent research has shown genetic interactions with social isolation that lead to up-regulation of inflammatory responses and down-regulation of antiviral responses and antibody formation. Ultimately this increases one's risk of inflammatory-type diseases, such as heart disease, neurodegenerative diseases, and some cancers, and decreased immune response to vaccines and viral infections (Cole, 2013).

Conversely, there is convincing evidence that strong social ties may be as influential in preventing mortality as hypertension, smoking, and sedentary lifestyle are in contributing to it. This association is often perceived as one of social support, in which social support from others improves one's health and well-being. Some research, however, suggests that being on the giving, rather than receiving, end of support is beneficial and that actively helping others provides a buffer for the effects of stress in one's own life (Poulin, Brown, Dillard, & Smith, 2013). Further evidence for the effects of social ties lies in findings that increased ethnic density (and potentially increased support networks) is associated with lower cardiovascular disease rates among older African Americans and Mexican Americans (Alvarez & Levy, 2012).

Social marketing. Social marketing strategies have been used extensively to promote unhealthy behaviors such as smoking. For example, tobacco companies have attempted to counteract smoke-free environments policies with the introduction of smokeless tobacco products targeted toward young people. These products are often flavored to attract a younger consumer group and may be gateways to cigarette smoking or substitute for smoking in smoke-free environments (Choi et al., 2012). In 2011, tobacco companies spent 90% of a \$8.4 billion budget on advertising and promotion. Point of sale displays have been found to be highly effective in promoting initiation of smoking among youth and in increasing smoking levels in adults. Much of this social marketing has targeted minority and young adult neighborhoods producing environmental triggers to smoking initiation and continuation in these populations (Cantrell et al., 2013). As we saw in Chapter 11, however, social marketing strategies can be equally effective in promoting healthy behaviors. Population health nurses can advocate with local and national media for support of health-promoting rather than illness-promoting messages. They may also engage in political advocacy regarding media messages. For example, population health nurses in one community were actively involved in the development of a local ordinance to prohibit billboards

advertising tobacco products within a specified distance of elementary and secondary schools.

Cultural factors. Cultural factors may also influence the incidence and consequences of chronic physical health problems. For example, culture may play a role in the extent of support for healthy or unhealthy behaviors that influence the development of chronic health conditions. In many cultures, for instance, use of alcohol is discouraged, so the risk of chronic liver disease due to alcohol intake is reduced. Conversely, nondrinkers would not benefit from the potential positive effects of moderate alcohol intake on cardiovascular disease risk. Cultural factors such as language may influence knowledge of risk factors and health-promoting activities. For example, reading and speaking a language other than English or more fluently than English has been linked to decreased use of screening and preventive services.

Cultural factors may also influence compliance with treatment regimens for chronic conditions. For example, in some cultural groups, health care providers are expected to provide remedies that resolve a problem immediately and group members have difficulty conceiving of conditions that require lifelong use of medications. Similarly, as discussed in Chapter 5, traditional cultural remedies may counteract or potentiate the effects of medications prescribed for chronic health conditions.

Tips for assessing the relationship of sociocultural factors to chronic health problems in the community are included in the *Focused Assessment* on the next page.

BEHAVIORAL DETERMINANTS. Behavioral factors are the major contributors to the development of most chronic health problems. Behavioral considerations to be assessed by the nurse include tobacco and alcohol use, physical activity, nutrition, and other health-related behaviors. Usually we think of behavioral factors as negative risk factors that contribute to disease. Research, however, has indicated a positive effect for healthful behaviors. For example, people with four low-risk health behaviors (never smoking, healthy diet, adequate physical activity, and moderate alcohol use) have been found to have significantly lower all-cause mortality risk and mortality risk due to cancers and cardiovascular disease than people who exhibited none of these behaviors (Ford, Zhao, Tsai, & Li, 2011). Whether we focus on health-promoting behaviors or high-risk behaviors, the discussion below highlights the need to modify behaviors related to chronic physical health problems.

Tobacco use. Despite advances in tobacco control, smoking has contributed to 20 million U.S. deaths since 1964 (Warner, 2014). In 2006, 42,000 deaths occurred as a result of second-hand smoke exposure. Nine hundred of those deaths occurred in infants due to in utero exposure to maternal smoking (Max et al., 2012). Although the prevalence of smoking had decreased, the risk of death for smokers compared to nonsmokers increased by more than 25% from 1987 to 2006 (Mehta & Preston, 2012). Worldwide smoking accounts for 6 million deaths per year with

FOCUSED ASSESSMENT

Assessing Sociocultural Determinants Influencing Chronic Physical Health Problems

- Do social norms support behaviors that increase the risk of developing chronic health problems (e.g., smoking)?
- How do policy issues affect the development of chronic health problems in the population? What policies are in place for tobacco control? For addressing other risk factors for chronic health problems?
- What effect does socioeconomic status have on the development or effects of chronic health problems?
- Do occupational factors influence the incidence or consequences of chronic physical health problems?
- What are societal attitudes to specific chronic health problems? Do they hamper control efforts? Is there social stigma attached to having the problem? What social support systems are available to people with the problem?
- What is the extent of stigma, discrimination, and social isolation related to chronic health problems? What effects do these conditions have on people with chronic health conditions?
- What effect, if any, do social marketing strategies have on behaviors related to chronic health problems?
- What effect, if any, do cultural beliefs and behaviors have on the incidence of the problem? On treatment of the problem?
- What effect, if any, does legislation have on risk factors for the problem?

600,000 due to second-hand smoke exposure. By 2030, smoking is expected to cause 8 million deaths per year (CDC, 2013d).

Tobacco use is costly to society. For example, U.S. smoking-related costs are approximately \$96 billion per year for direct medical care and another \$97 billion in lost productivity costs (Agaku, King, & Dube, 2012). Smoking is also costly in terms of property damage. In one study, for example, mean smoking-related costs in California multiunit housing complexes were \$4,935 per year in 2008–2009. At that time, slightly more than a third of multiunit housing complexes had completely smoke-free policies, and it was estimated that statewide implementation of such policies would save more than \$18 million per year (Ong, Diamant, Zhou, Park, & Kaplan, 2012).

Some headway has been made in controlling tobacco use. For example, the percentage of the U.S. population 18 to 24 years of age who had never smoked increased from 65% in 1999–2001 to 76% in 2011–2012 (NCHS, 2013). Smoking prevalence is highest among persons 26 to 34 years of age and lowest among those over age 65 (Garrett, Dube, Trosclair, Caraballo, & Pechacek, 2011). In spite of laws controlling minors' access to cigarettes, nearly 7% of middle school students and 23% of high school students reported current tobacco use in 2012, and use of cigars, electronic cigarettes, and hookahs increased in these age groups (Arrazola, Dube, & King, 2013).

Use of smokeless forms of tobacco, in general, has been increasing, while cigarette consumption has declined. For example, little cigar sales increased by 221% from 2000 to 2011. Cigar smoking is particularly common among young adults, with first cigar smoking occurring at a mean age of 20.5 years and 11% of people aged 18 to 25 years in the United States reporting smoking little cigars (Cantrell et al., 2013). Similarly, based on the California Tobacco Survey, hookah or bubble pipe use increased more than 40% from 2005 to 2008 and close to 25% of young men in the survey reported ever using a hookah.

Hookah smoking is often part of social gatherings. Although there is no research data yet, hookah smoking may be even more harmful than cigarette smoking, but may be perceived as less harmful (Smith et al., 2011). Although advertised as smoking cessation aids, electronic cigarettes or e-cigarettes (battery powered devices that deliver doses of nicotine and other addictive substances by means of an aerosol) are not regulated by the FDA and there are no restrictions on sales to minors. As a result, current use of e-cigarettes increased from 1.1% to 2.1% of 6th- to 12th-grade students from 2011 to 2012 (Corey et al., 2013).

Tobacco use is associated with education level, with college graduates less likely to use tobacco than people with 9 to 11 years of education (7.5% and 36.7%, respectively). Smoking prevalence is highest among the AI/AN population (31.5%), followed by Whites (21%), Blacks (19%), and Hispanics (13%). Lower prevalence among Hispanics is attributed to fewer women smokers in this group (Warner, 2014). Drug use and mental illness are also associated with tobacco use. In fact, people with mental illness (including drug abusers) account for 40% of all tobacco sales in the United States (Hunt, Gajewski, Jiang, Cupertino, & Richter, 2013).

Smoking cessation prior to age 35, results in mortality risks similar to those of nonsmokers. In 2010, nearly 69% of smokers reported wanting to quit and 52% had actually attempted to quit (Malarcher, Dube, Shaw, Babb, & Kaufmann, 2011). Among people with particular needs to stop smoking, fewer than desired have done so. For example, 21% of people with asthma smoke (National Center for Environmental Health, 2013c). Similarly, people with disabilities are more likely to smoke than those without disabilities in some studies (Benjamin et al., 2013), and little change in smoking rates before, during, and after pregnancy occurred from 2000 to 2010 (Tong et al., 2013). Population health nurses can assess the level of tobacco use in the population and its effects on chronic

health problems. They can also advocate for and provide education on the harm related to tobacco and provide assistance with smoking cessation. In addition, they can advocate for effective tobacco control policies.

Alcohol use. Alcohol use also contributes to the development of certain chronic health problems and their consequences. For example, alcohol is implicated in motor vehicle accidents, bicycling accidents, fires, falls, and boating accidents, many of which result in chronic disability. Alcohol abuse also contributes to mortality due to chronic liver disease, but moderate alcohol use may have a protective effect for coronary heart disease.

Binge drinking, in particular, has been associated with adverse health outcomes. According to the 2009 BRFSS, more than 20% of men and 10% of women engaged in binge drinking. Men also reported greater frequency of binge drinking and a larger number of drinks per episode than women. Overall prevalence of binge drinking in the U.S. population was 15%. Prevalence was higher among the nondisabled, but frequency and intensity (number of drinks) were higher among disabled individuals (Kanny, Liu, & Brewer, 2011). Population health nurses can assess the extent of alcohol use in the population and its effects in terms of chronic physical health conditions.

Physical activity. Physical activity may enhance the control of diabetes or contribute to hypoglycemic reactions. Physical activity also improves control of arthritis and limits its disabling effects. Both aerobic and strengthening exercises have been linked to improved physical function and decreased disability. Physical activity has also been shown to be directly related to the incidence of heart disease. Several studies have documented that adults with active lifestyles have significantly lower risk of developing heart disease than their less active contemporaries. A sedentary lifestyle, on the other hand, is closely associated with obesity, a risk factor for cardiovascular disease, diabetes, stroke, and arthritis.

An estimated 3.2 million people die each year from the effects of physical inactivity, and inactivity contributes to a 20% to 30% increased risk of all-cause mortality (WHO, 2011). In the United States, a median of just over half of adults engaged in moderate to vigorous physical activity across all states in 2009 (Li et al., 2011). Men were more likely than women to meet aerobic activity and muscle strengthening guidelines, but less than 25% of either gender or any racial/ethnic group did so (Howie, 2013).

Physical activity is beneficial in preventing a number of chronic health problems and in mitigating their effects. Among young adults 25 to 30 years of age, for example, greater levels of physical activity were associated with decreased incidence of hypertension (Parker, Schmitz, Jacobs, Dengel, & Schreiner, 2007). Despite the beneficial effects of physical activity for people with arthritis, however, a 2011 survey indicated that 53% of people with arthritis did no walking, and a median of 66% across states walked less than 90 minutes per week (Hootman, Barbour, Watson, & Fulton, 2013).

Physical activity helps prevent multiple chronic health problems.

(Spotmatikphoto/Fotolia)

As we saw in Chapter 4, elements of the built environment may foster or impede physical activity for the general public. The same is true for individuals with existing chronic illness. For example, some walking trails have exercise stations that promote movement of other muscles than those used in walking. Fewer such trails, however, have activities or facilities designed to promote exercise for someone in a wheelchair or with other limitations. Population health nurses may need to actively advocate for opportunities for physical activity for all segments of the population, including those with disabilities.

Nutrition. Poor dietary patterns contribute to chronic diseases such as diabetes and cardiovascular disease and to obesity, which is a risk factor for these and other chronic conditions. In addition, elevated sodium intake increases the risk for hypertension, heart disease, and stroke. The 2010 Dietary Guidelines for Americans recommended sodium intake less than 2,300 mg per day for the general public, and less than 1,500 grams per day for people over age 50, Blacks, and people with hypertension, diabetes, or CKD. According to the 2005–2008 National Health Assessment and Nutrition Examination Survey (NHANES), 98% of those who should restrict their sodium intake to the lower level failed to do so, and more than 88% of the general population had intake levels above the 2,300 mg recommendation (Loria et al., 2011).

Diet has also been implicated in the development of some forms of cancer. Baseline data for the national health objectives for 2020 indicate that few people meet the targets for 1.1 cup of vegetables per 1,000 calories of dietary intake or 0.6 ounces of whole grains per 1,000 calories. Similarly few people meet the objectives to reduce solid fat and sugar consumption to 16.7% and 10% of daily calories, respectively. Finally, few people achieve the goal of 1,300 mg of calcium per day (USDHHS, 2014b).

Other behavioral factors. Use of complementary and alternative therapies (CAT) is another consumption pattern that should be considered in chronic disease risk and management.

Use of CAT was discussed in Chapter 5∞. Population health nurses should assess the use of these therapies in terms of their interaction with medications prescribed for chronic diseases and educate clients and the public regarding their safe use. They can also advocate for and conduct research regarding the effectiveness of CAT in controlling chronic health problems, particularly for pain relief.

Another lifestyle behavior that might influence the development and course of chronic conditions includes the use of safety devices and precautions. The use of safety devices and safety precautions can prevent accidents that may result in chronic disability. For example, seat belt use is an important behavioral factor in preventing motor vehicle fatalities. Other safety factors to be considered include the use of bicycle or motorcycle helmets, occupational safety equipment, and so on. Population health nurses would also explore the presence or absence of legislation mandating their use and the extent to which such legislation is enforced.

Other behaviors can contribute to or prevent skin cancer. For example, reducing direct exposure to sunlight (particularly from 10 A.M. to 4 P.M.), using sunscreen protection, and wearing a broad-brimmed hat and other protective clothing can minimize the risk of malignant melanoma.

Another aspect of the behavioral dimension of chronic physical health problems is their effect on client behaviors. Earlier we explored the relationships among chronic illness and functional limitations and disability. The presence of chronic disease may prevent or make it more difficult for people to engage in specific activities. One area that is often neglected is the effect of chronic disease on sexual function. People with asthma and other respiratory conditions may be particularly likely to report sexual limitations. Other conditions that result in fatigue, such as cardiovascular disease and cancer, may also affect sexual function. Finally, as noted in Chapter 17∞, many medications used to treat chronic conditions may cause sexual dysfunction, particularly among men.

Questions to guide the examination of behavioral influences on the incidence and prevalence of chronic health problems in the population are included in the *Focused Assessment* below.

HEALTH SYSTEM DETERMINANTS. Health system factors may contribute to the development of chronic health problems or influence their course and consequences. Major health system determinants include capacity to address chronic health problems, lack of access to care, lack of a preventive focus, failure to engage in evidence-based practice, and client–provider relationships.

Health system capacity. The World Health Organization (WHO, 2012) has reported limited worldwide capacity to address the problems of noncommunicable diseases, particularly in low- and middle-income countries. It has identified several priorities for improving capacity. These include more effective use of existing health care infrastructures, better surveillance related to morbidity, mortality, and risk factor occurrence, funded policy changes to better support chronic disease control and development of innovative funding strategies, and the development and use of evidence-based guidelines for chronic disease management (WHO, 2012). In the United States, the Council of State and Territorial Epidemiologists (2009) has noted a similar, but less extensive, lack of capacity to monitor chronic disease epidemiology, with less than two thirds of states reporting substantial to full capacity in this area.

Access to care. Access to care is another health system determinant influencing the development and outcomes of chronic physical health problems. This includes lack of access to health care in general and lack of access to disease-specific specialty care. In 2012, for example, nearly 28% of people under 65 years of age with a basic or complex activity delayed or did not receive needed medical care due to cost, and 20.5% did not get a needed prescription filled (NCHS, 2014b). Similarly, in the

FOCUSED ASSESSMENT

Assessing Behavioral Determinants Influencing Chronic Physical Health Problems

- Does smoking contribute to the incidence of chronic physical health problem in the population?
- Does alcohol or drug use contribute to chronic physical health problems? What effect does alcohol or drug use have on the development and course of problems?
- What effect does physical activity have on the incidence of chronic physical health problems in the population?
- Do dietary factors influence the incidence of chronic health problems in the population? Does having specific health problems necessitate dietary changes?
- Do chronic physical health problems common in the population necessitate regular medication use or other disease management behaviors (e.g., glucose monitoring)? What is the availability of these treatment modalities? What is the level of compliance with them?
- What effects do self-care behaviors have on the course of chronic physical health problems?
- What effect do safety precautions have on the incidence of chronic physical health problems in the population? To what extent does a common problem necessitate special safety precautions?

2009 National Health Interview Survey, more than half of adults with epilepsy were not seen by a neurological specialist in the prior year (Kobatu, Luo, Zack, Helmers, & Thurman, 2012). Furthermore, people with disabilities are more likely than those without to report not having seen a provider due to cost (Benjamin et al., 2013). People with asthma have also been found to experience cost barriers to adequate care, particularly medications, even when they are insured (National Center for Environmental Health, 2013b). Lack of disability-specific services is another issue with access to care. Some authors have suggested that dental care visits are a good opportunity for oral evaluation for systemic diseases (Strauss, Alfano, Shelley, & Fulmer, 2012), but that presupposes that people obtain dental care, which may not be the case.

Lack of preventive focus. The failure of health care professionals to educate their clients and the general public on the effects of diet, exercise, smoking, alcohol, and other factors in the development of chronic health problems contributes to the increased incidence of these conditions. To some extent this failure may be attributed to time constraints in today's health care system. Some studies have indicated that brief interventions in primary care settings accompanied by telephone counseling and medication assistance have been effective in promoting smoking cessation (Malarcher et al., 2011). A study of screening for tobacco use and cessation advice in 17 countries found wide variation in the extent of provider involvement in these activities (Caixeta, 2013b). Population health nurses and others may need to advocate for changes to reimbursement policies to promote better education for self-management of chronic illnesses.

The extent of screening services for existing chronic conditions may influence their course and effects. The extent to which low-cost screening procedures for various forms of cancer are available varies considerably throughout the country. Although screening services may be obtained from private health care providers, they are often costly, and many low-income people are prevented from taking advantage of them.

Evidence-based practice. Health care system factors influence the availability and quality of treatment obtainable for persons with chronic conditions. For example, provider knowledge and expertise may affect the recognition and treatment of chronic health conditions. Similarly failure to engage in evidence-based practice may also influence the quality of care provided. For example, in the 2009 National Health Interview Survey, only about a third of people with asthma had received a written asthma action plan and just over two thirds had been taught about appropriate responses to symptoms. Likewise, only one third of adults and children with asthma had been given long-acting corticosteroids (Zahran, Bailey, & Garbe, 2011).

Clinical practice guidelines vary in terms of the strength of their underlying evidence base. In one study, the majority of state diabetes programs disseminated a variety of practice guidelines from subspecialty organizations, but had not prioritized them or adapted them for use in specific populations.

In addition, 71% of the states indicated that they did not have the capacity to provide guideline-concordant care (Sarkar, Lopez, Black, & Schillinger, 2011). Similarly, in 2009, data from seven states with federally funded stroke registries reported on data related to quality care indicators. According to the report, only 73% of hospitals engaged in dysphagia screening, 70% provided stroke education, and 93% engaged in deep vein thrombosis prophylaxis. In addition, only 57% of hospitals provided intravenous TPA in the event of stroke. Overall, only 69% of the institutions provided "defect-free" in-patient care for ischemic stroke, 57% for hemorrhagic stroke, and 57% for response to transient ischemic attacks (TIAs). In addition, only 72% provided defect-free discharge care for ischemic stroke (George et al., 2011).

Poor quality care occurs in other areas of chronic disease care, as well. For example, methadone is commonly used for chronic noncancer pain relief, yet methadone is responsible for nearly 40% of single opioid deaths, suggesting that providers are not as knowledgeable as they should be in its use for pain relief (Paulozzi, Mack, & Jones, 2012). In other instances, providers may engage in poor care practices even when they know they are inappropriate. For example, two outbreaks of *Staphylococcus aureus* were reported in 2012, both due to multiple injections of pain medications from single dose vials. Reasons given for the inappropriate practice were the inability to obtain single dose vials in the correct dosage amounts and unwillingness to waste medication after first use (Anderson et al., 2012).

Provider failure to provide appropriate screening and preventive services also influences the incidence and course of many chronic physical health problems. The aggressiveness of treatment received also affects the outcome of chronic health conditions. Some studies, for example, suggest that poorer cancer survival rates among low-income populations may be related to reduced access to care. The quality of treatment received for diabetes may also vary widely and affect the consequences of this disease. Medical care, on the other hand, has greatly reduced mortality from cardiovascular and cerebrovascular diseases. This is largely due to a concerted effort to control hypertension, smoking, and diet.

Client-provider relationships. Client-provider relationships are another health system determinant that affects chronic health problems, particularly with respect to adherence to treatment recommendations. Studies have indicated that trust in the medical system in general have been associated with hypertension medication adherence (Cuffee et al., 2013; Elder et al., 2012). Conversely, distrust has been associated with low breast and cervical cancer screening participation (Yang, Matthews, & Hillemeier, 2011) and other health-related behaviors. The *Focused Assessment* on the next page provides questions to guide the examination of health system factors influencing chronic health problems in the population.

Risk factors related to biological, psychological, environmental, sociocultural, behavioral, and health system determinants all influence the development and outcomes of chronic

FOCUSED ASSESSMENT**Assessing Health System Determinants
Influencing Chronic Physical Health Problems**

- Do health system factors contribute to the development of chronic physical health problems in the population?
- What health promotion and illness and injury prevention services are available to prevent chronic health problems in the population? Are they widely used? To what extent do health care providers educate the public regarding prevention of chronic health problems?
- Are screening services available for chronic health problems? If so, are persons at risk for the problem adequately screened?
- Are diagnostic and treatment services for chronic health problems available and accessible to those who need them?
- To what extent is evidence-based practice used in the control of chronic physical health problems? Are there alternative therapies that may contribute to the control of problems? Do alternative therapies pose health risks themselves?
- What is the attitude of health care providers to persons with chronic health problems? What is the level of trust accorded to the health care system and health care providers in the population? What effect does trust have on the effectiveness of measures to control chronic physical health problems in individuals and in the population?

physical health problems. Population health nurses use their assessment skills to assess for determinants that contribute to chronic health problems and for existing chronic conditions and their effects. In addition to assessing individual clients for the presence of risk factors for chronic health problems, the population health nurse examines the incidence and prevalence of these risk factors in the general population to determine the potential for chronic health problems in the community. Nurses can also obtain family histories and construct genograms for specific families as described in Chapter 14. A *Chronic Disease Risk Factor Inventory* is available on the student resources site to assist the population health nurse in assessing individual and population risk for chronic physical health problems.

Population health nurses are actively involved in efforts to control chronic physical health problems and their effects in individuals and population groups.

Diagnostic Reasoning and Control of Chronic Physical Health Problems

Nursing diagnoses are derived from information collected relative to the incidence and prevalence of chronic health problems in the population and the factors contributing to these conditions. These diagnoses may relate to individual clients or to the general population. Examples of nursing diagnoses related to an individual client are “potential for cardiovascular disease due to smoking and sedentary lifestyle” and “uncontrolled diabetes due to inability to adhere to diabetic diet.” At the group level, the nurse might derive diagnoses such as “increased prevalence of lung cancer due to smoking and occupational exposure to carcinogens.” In each case, the nursing diagnosis contains a statement of the probable cause or etiology of the problem that directs interventions designed to resolve it.

Planning and Implementing Control Strategies for Chronic Physical Health Problems

Planning interventions related to chronic health problems for individual clients or population groups is based on the understanding of contributing factors derived from the assessment. It is particularly important to involve the client and his or her family or the community in planning solutions to chronic health problems because they will be responsible for implementing the plan or for using services designed. By involving the client/family or community, the nurse can tailor the plan of care to the specific circumstances influencing chronic disease. It is important to remember that the presence of a chronic health problem affects many facets of life. Effective planning accounts for these effects and minimizes the consequences of chronic illness for those affected.

CDC’s *Healthy Communities Program* (formerly *Steps to a Healthier US*) is designed to assist local communities to reduce risk factors for chronic diseases and attain health equity within the population. The initiatives are aimed at reducing the incidence and prevalence of heart disease, stroke, diabetes, cancer, obesity, and arthritis. In addition, initiatives focus on reduction of risk factors such as tobacco use and exposure, insufficient physical activity, and poor nutrition (Division of Community Health, 2013). The initiative has produced a series of tools to promote community action related to these chronic conditions. For further information about the tools, see the *External Resources* section of the student resources site.

THE CHRONIC CARE MODEL. The chronic care model was developed to delineate the elements of high-quality chronic disease care and to foster effective interaction between informed clients and providers with the needed expertise to

address chronic health issues. Elements of the model include the following:

- A community that mobilizes resources to meet population health needs and fosters partnerships between health care systems and community organizations to enact policies and provide resources needed for effective chronic disease control.
- A health system that embraces change and care improvement, provides incentives for change, and fosters communication and data sharing, evaluation, and correction of errors.
- Self-management support that empowers and prepares patients to manage their health care and engage in assessment, goal-setting, action planning, problem solving, and follow-up. Such support includes information, emotional support, and skill development, and fosters client-provider collaboration in problem definition, priority setting, goal setting, treatment planning, and problem solving.
- A delivery system design with a proactive focus on keeping people healthy that incorporates elements of case management, health literacy, cultural competency, and care coordination and makes routine follow-up part of the standard of care.
- Decision support for health care providers that promotes evidence-based care and use of evidence-based practice guidelines through provider education regarding evidence-based practice and coordination of primary and specialty care.
- Clinical information systems that assure access to key data at individual and population levels to facilitate performance monitoring and quality improvement (Improving Chronic Illness Care, n.d.).

A health system designed around this model will engage in effective care for chronic illness control at all four levels of health care delivery, health promotion, illness and injury prevention, resolution, and health restoration.

HEALTH PROMOTION. General health promotion is aimed at making people healthier and reducing their chances of developing a variety of health problems, including chronic conditions. Health promotion at both the individual and group levels involves promoting a healthier lifestyle and political activity to create conditions that promote health.

Promoting healthy lifestyles. Strategies to promote healthy lifestyles as a means of preventing chronic health problems focus on diet, exercise, and coping skills. The nurse employs the principles of health education discussed in Chapter 11 to educate both individual clients and the general public on basic nutrition and specific nutritional requirements based on age and activity level. For example, to prevent obesity the nurse would teach parents about the nutritional needs of infants and young children and encourage a well-balanced diet with minimal amounts of junk food. Similarly, the nurse would teach a pregnant woman, a nursing mother, or a physically active person

about their specific nutritional needs. The nurse would also try to inform the general public about proper nutrition.

Access to healthy foods has also been associated with healthier diets. Access to foods such as fruits and vegetables is often related to socioeconomic level. Healthy foods, such as fruits and vegetables, tend to be more expensive when purchased at small neighborhood stores than at supermarkets, thus lessening the ability of low-income families to afford them. Population health nurses may advocate for access to healthy foods in neighborhood stores and may assist local families in cooperative buying to decrease prices. In some areas, nurses may help communities to establish community gardens to improve consumption of fresh produce.

Physical activity is another area in which health education may be required, and nurses would plan to inform both individual clients and the general public about the need for regular physical activity. The nurse might also assist clients to plan ways to incorporate physical activity into their daily routine or develop plans for exercise programs in the community or for employees of local businesses. For example, a simple means of motivating people to climb stairs is to display posters at stairwell entries encouraging use of stairs rather than elevators.

Exercise is also beneficial for people with existing chronic illnesses, and there is a growing emphasis on including people with disabilities in health promotion activities. This includes incorporating them into mainstream programs whenever possible, using approaches common across multiple disabilities (e.g., reduction of physical barriers), and a condition-specific health promotion focus when needed (Benjamin et al., 2013). People with arthritis can be assisted to engage in pain control strategies prior to physical activity and those with COPD can be helped to develop a progressive activity regimen that strengthens their functional capabilities. Population health nurses can help people with these and other chronic conditions to identify avenues for physical activity that are within their capabilities. For certain conditions, such as cardiovascular disease, nurses may suggest a thorough medical evaluation prior to undertaking a rigorous exercise regimen.

Teaching general coping skills is another way for population health nurses to promote health and prevent chronic health problems that are influenced by stress. In this respect, the nurse might assist a harried mother of several small children to develop ways of coping with stress, or the nurse might assist school personnel to develop a program to teach basic coping skills as part of elementary and secondary school curricula. Another approach might be to plan a program to foster adequate coping among employees of local businesses.

Technology provides new avenues for promoting healthy lifestyles among the general public and in clients with chronic diseases. Experts have identified several points at which clients may turn to the Internet for information related to their health. Many people seek information on basic health promotion and health maintenance activities. When symptoms arise, people may seek information on the possible meaning of symptoms,

or they may seek to validate a treatment regimen as the appropriate option after diagnosis. Clients may also use the Internet to search for information about their conditions or about specific treatment regimens or options, to identify possible side effects, or to participate in support groups. Population health nurses can make active use of Internet technology to educate clients for health-promoting lifestyles and for self-care when illness occurs. Nurses can also refer clients to credible sources of information and educate them regarding mechanisms for evaluating the credibility of information retrieved from Internet sources.

Political advocacy. Sometimes educational interventions are aimed at informing health policy makers and promoting legislative and regulatory strategies to control chronic illness in the population. Political activity related to health promotion focuses on measures to foster access to health promotion services and to create a healthful environment. Nursing involvement in efforts at this level includes the planning of strategies to influence health policy making discussed in Chapter 9. For example, population health nurses might campaign for better access to prenatal care for pregnant women or legislation to prevent or reduce pollution so as to prevent its contribution to chronic respiratory conditions and other chronic health problems.

Political activity by population health nurses might also be required to establish and enforce policies and legislation that foster healthful behaviors. For example, failure to enforce laws related to the sale of tobacco products to minors has enabled youngsters to purchase tobacco. Conversely, enforcement of seat belt legislation has significantly reduced motor vehicle accident fatalities.

ILLNESS AND INJURY PREVENTION. WHO has identified several “best buy” prevention strategies for noncommunicable diseases. These strategies include the following:

- Protection from second-hand smoke and development of smoking bans
- Education on the dangers of tobacco use
- Banning tobacco advertising, promotion, and sponsorship
- Increasing tobacco taxes
- Restricting access to retail alcohol
- Instituting bans on alcohol advertising
- Increasing alcohol taxes
- Reducing salt intake and sodium content in foods
- Replacing trans fats with polyunsaturated fats
- Immunization for hepatitis and HPV (WHO, 2011)

Additional prevention strategies for chronic physical health problems include preventing obesity, promoting tobacco use cessation, and injury prevention.

In the United States, the National Prevention Council developed the *National Prevention Strategy* in 2011. The overall goal of the strategy is to increase the number of people who are healthy at every stage of their lives. The strategy encompasses four strategic directions and seven priorities.

The strategic directions include healthy and safe community environments, provision of clinical and community preventive services, empowerment of people for healthful living, and elimination of health disparities among segments of the population. The seven priorities for action are promoting tobacco-free living, preventing drug abuse and excessive alcohol use, promoting healthy eating and active living, and promoting injury and violence-free living, reproductive and sexual health, and mental and emotional well-being (National Prevention Council, 2011). Several of the strategic directions and priorities are relevant to chronic disease prevention and are discussed below.

Preventing obesity. Dietary changes, weight loss, and moderate physical activity can prevent diabetes, obesity, and other related health problems. Increasing food taxes may be a helpful strategy in preventing obesity. Two types of taxes have been suggested: nutrient taxes and category taxes (Franck, Grandi, & Eisenberg, 2013). Nutrient taxes focus on foods that have higher than recommended percentages of fats or sugars (e.g., sugar sweetened fruit juices). Category taxes are taxes assessed on specific categories of foods or beverages. Examples would be a tax on sodas, candy, or snack foods.

Development of modified food products also assists in controlling fat intake. Population health nurses can encourage the food industry to pursue research on food modification. They can also campaign for legislation to require accurate labeling of food packages and disclosure of food contents.

Specific programs for reducing or preventing obesity might focus on increasing physical activity levels. For example, safe walking routes to school and walking school bus programs have been initiated to promote physical activity among children before and after school. In these programs, students walk together to and from school under adult supervision. After-school recreation programs or activity programs in business are other ways of promoting physical activity and preventing obesity.

Smoking cessation assistance. Another approach to preventing multiple chronic health problems is to promote smoking cessation among smokers or prevent smoking initiation among nonsmokers, particularly youth. Efforts to decrease tobacco use constitute one of the most intensive public health initiatives in the last 50 years (Warner, 2014). As effective as these initiatives have been, they are not enough, and even decreasing smoking to 10% of the U.S. population (the *Healthy People 2020* target) will result in more than 100,000 smoking-related deaths per year over the next few decades (Warner, 2014).

Rockland County, New York, has framed its tobacco control efforts in the context of the essential public health services discussed in Chapter 1. Application of the essential services model is depicted in Table 27-2. Application of the model has resulted in a decline in adult smoking prevalence from 16% in 2003 to 9.7% in 2009. In the same time frame smoking prevalence declined to less than 10% among high school students and less than 4% among 8th grade students (Lieberman et al., 2013).

Evidence-Based Practice

Misplaced Evidence

In 2002, the Women's Health Initiative terminated its study of estrogen and progestin due to adverse effects noted in women receiving the study drug Prempro. Because the treatment was often referred to as "hormone therapy" or "estrogen therapy," the study's findings were inappropriately generalized to all forms of hormone replacement, including for women without a uterus who were excluded from the original study. Over a period of 18 months, use of hormone replacement therapy (HRT) for postmenopausal women decreased by about 50%. Both women and providers were anxious to avoid use of HRT despite subsequent findings that estrogen alone provided a protective effect against coronary heart disease for women who had had a hysterectomy. As a result, anywhere from 18,601 to 91,610 women died prematurely as a result of estrogen therapy avoidance (Sarrel, Njike, Vinante, & Katz, 2013).

A similar response was engendered by the results of ethically questionable testing of homeless alcoholic men on New York's Skid Row for prostate cancer in the 1950s and 1960s. A physician recruited members of this vulnerable population in a study to determine the prevalence of prostate cancer using open perineal biopsies. When cancerous cells were found, the surgeons performed radical prostatectomies and orchiectomies with minimal consent, followed by diethylstilbestrol treatment. This practice contributed to the current screen-and-treat paradigm for prostate cancer still in vogue today, despite current evidence that routine screening and radical treatment of prostate cancer are not warranted (Aronowitz, 2014).

These two stories highlight the dangers of relying on the results of one or a few studies and on inappropriate generalization of study findings as a foundation for practice. Population health nurses need to not only keep current with research findings, but also need to examine the strength of the evidence for or against a particular intervention or treatment approach before advocating specific strategies. One strategy to promote the use of evidence-based interventions is to critically evaluate clinical practice guidelines using evaluation guidelines such as SELECT. SELECT is a mnemonic that stands for a six-step process for evaluating and implementing clinical practice guidelines. The six steps are as follows:

- Search: Examination of the practice setting to identify care issues and concerns that suggest a need for a practice change
- Explore the evidence: Identify evidence validating the identified concerns and potential solutions
- Locate existing clinical practice guidelines for best practice interventions relevant to the issue
- Evaluate: Evaluate the process used to develop the practice guidelines and the strength of the evidence base supporting them
- Choose and customize: Select the best guideline recommendations and tailor them to your practice setting
- Translate the guidelines into practice and evaluate their effects (American Professional Wound Care Association, 2010)

TABLE 27-2 Application of the Essential Public Health Services Model to Tobacco Control, Rockland County, New York

Essential Public Health Services	Application
Diagnose and evaluate	Monitored state and local data to set realistic goals
Inform, educate, and empower	Developed student advocacy programs against tobacco industries, created local media campaigns and a smoke-free home campaign
Mobilize community partnerships	Developed a four-county consortium and partnered with multiple local organizations
Develop policies	Created smoke-free school campuses, parks, playgrounds, housing units
Enforce laws	Conducted compliance checks at retail tobacco facilities, bars, and restaurants
Link to/provide care	Provided counseling in multiple languages and links to quitlines
Ensure competent workforce	Trained providers in brief cessation counseling techniques
Evaluate	Conducted an annual tobacco use telephone survey
Monitor	Monitored attitudes and behaviors using an expanded BRFSS survey and a 5-year community assessment

Data from: Lieberman, L., Diffley, U., King, S., Chanler, S., Ferrara, M., Alleyne, O., & Facelle, J. (2013). Local tobacco control: Application of the essential public health services model in a county health departments to Put It Out Rockland. *American Journal of Public Health, 102*, 1942–1948. doi: 10.2105/AJPH.2013.301284

As can be seen in the table, the initiative employed a number of different strategies that have been found to be effective in deterring smoking initiation and promoting smoking cessation among those who smoke. Such strategies include increasing tobacco prices, graphic media campaigns, smoke-free laws, and barrier-free access to cessation assistance (Agaku et al., 2012). CPSTF (2014b) also recommends mass-reach health communications, which have been shown to be effective in decreasing the prevalence of tobacco use, increasing cessation and the use of cessation resources, and decreasing tobacco use initiation. A systematic review of related literature found that mass-reach campaigns resulted in a median increase in quitline calls, decreased median state per capita tobacco consumption to 15 cigarettes per person per year, and increased successful cessation by 2.2% (CPSTF, 2014b). Similarly, CDC's annual national tobacco education campaign resulted in a 75% increase in weekly quitline calls and a 38-fold increase in visitors to its tobacco cessation website (Bright et al., 2013).

Quitlines are effective strategy for promoting smoking cessation, providing information, advice on quitting, and referrals for cessation assistance as well as counseling and support. California was the first state to implement a statewide tobacco quitline, but similar resources are now available in each state and each Canadian province. There have also been calls for the mandatory inclusion of national toll-free quitline numbers on cigarette packages (Leischow et al., 2012). Quitlines are easy to access, cost-free, and can be tailored to individual needs. In addition, they are cost effective, resulting in savings of \$2,012 per QALY saved. Even when free cessation assistance medications are included (e.g., nicotine patches), there is a net savings of \$795 per QALY (CPSTF, 2014c).

Medications are an important adjunct to smoking cessation that is often neglected in primary care. Studies indicate that people with hypertension are nearly 33 times more likely to receive appropriate medications for their hypertension than smokers are to receive smoking cessation medications. Similarly, diabetes, hyperlipidemia, asthma, and depression are more likely to be treated with medication than smoking. Provider counseling is also more likely for hypertension, diabetes, and hyperlipidemia than for smoking (Bernstein, Yu, Post, Dziura, & Rigotti, 2013).

Tailored interventions may be needed to promote tobacco use cessation in specific target groups. For example, mass media campaigns, insurance coverage of smoking cessation treatment, 100% smoke-free policies, and increased tobacco excise taxes have been particularly recommended for preventing smoking uptake among youth and promoting cessation among pregnant women (Tong et al., 2013). Drug users are another group that needs tailored interventions. As many as 77% to 90% of drug users smoke cigarettes and more than 1 million enter treatment programs each year, but few drug treatment centers provide tobacco cessation treatment. In one study of 405 drug treatment facilities, only 14% provided nicotine replacement therapy, and only two thirds reported their capacity to deal with tobacco addiction as adequate to very good.

Similarly, only half had staff with training in tobacco cessation and only one third had protocols, procedures, or curricula in place for addressing smoking. Finally, only 20% reported having the financial resources needed to provide tobacco counseling for their clientele (Hunt et al., 2013).

Population health nurses can be actively involved in providing tobacco cessation counseling or in referring clients for cessation services. They can also advocate for insurance coverage of cessation services and for inclusion of free medication in conjunction with existing tobacco quitlines. Finally, they can be involved in the development of mass media campaigns for the general public or for specific targeted populations such as pregnant women and youth.

Population health nurses may also be involved in political activity to limit smoking. Legislative and regulatory activities to control smoking can be of two types: legislation controlling smoking in public places and taxation of tobacco sales. Public smoking bans and smoke-free workplace policies not only affect smoking behaviors but also limit exposure to *second-hand* or *involuntary* smoking (also called environmental tobacco smoke).

Preventing cardiovascular disease. Prevention of cardiovascular disease has also become a priority in the United States. For example, the *Million Hearts Initiative* was established to prevent 1 million heart attacks by 2017. The initiative is a public-private partnership to decrease cardiovascular disease using evidence-based practice. Two goals of the initiative are to reduce the need for treatment for cardiovascular disease by empowering people to make healthy lifestyle choices and to improve preventive care employing the ABCS (aspirin use for those at risk, blood pressure control, cholesterol management, and smoking cessation). Foci include decreasing tobacco use and second-hand smoke exposure, reducing sodium intake, eliminating artificial trans fats, and providing workplace wellness and media campaigns. Other areas of emphasis are increasing the use of evidence-based practices among health care providers and increasing use of health information technology (Farley et al., 2012).

A similar program, *Healthy Heart, Healthy Family*, has been created to address cardiovascular disease in African Americans, AI/ANs, Filipinos, and Latinos (USDHHS, 2012). The program includes a series of educational materials, heart healthy recipes, and community health worker manuals to minimize cardiovascular disease risk factors in these populations (National Heart, Lung, and Blood Institute [NHLBI], n.d.). For further information about these materials, see the *External Resources* section of the student resources site.

In addition, the CPSTF (2013b) has recommended reducing out-of-pocket costs for treatment for hypertension and hypercholesterolemia to include low- or no-cost medication, behavioral counseling (particularly for weight loss), and behavioral support for gym memberships and weight management programs. In its systematic reviews, the task force found that reducing out-of-pocket costs increased medication adherence and decreased blood pressure and cholesterol levels.

Population health nurses can be involved in educating the public and health care providers regarding interventions to lower cardiovascular disease risk. They can also advocate for better insurance coverage of the cost of preventive strategies.

Injury prevention and other prevention strategies. Other strategies may also help to prevent chronic physical health problems. Injury prevention at home and in occupational settings is one effective approach to the prevention of long-term consequences of unintentional injuries. In addition the “Click It or Ticket” campaign, a national police crackdown on unbelted drivers and passengers conducted every Memorial Day weekend has been shown to be one of the most effective seat belt use strategies.

The use of safety devices and other safety precautions can modify risk factors for accidents that may lead to chronic disability. Population health nurses can encourage clients to install smoke detectors in residences, provide adequate supervision for small children, store hazardous items appropriately, and remove hazards that contribute to falls in the elderly. They can also promote the use of seat belts in vehicles and campaign for legislation that makes seat belt use mandatory in all vehicles (e.g., school buses). Population health nurses can promote use of safety devices and safety precautions in the work setting to prevent accidental injury. Programs to prevent sports and occupational injuries will also help to prevent arthritis. Fall prevention through balance training, correcting visual impairment, limiting medication side effects, and environmental changes can also help to prevent injury, particularly in older populations. Finally, population health nurses can motivate clients to use sunscreen, sunglasses, and protective clothing to prevent melanoma and cataracts. In 2012, the USPSTF recommended counseling for children and young adults to age 24 years on skin cancer prevention (USPSTF, 2012). In addition, CPSTF has developed several recommendations related to parent and caregiver education, policy approaches, and community wide initiatives to promote skin cancer prevention (CPSTF, 2013a).

Modifications of environmental conditions that contribute to chronic health problems may also help to control them. For example, population health nurses can advocate for enforcement of clean-air legislation and promote measures that prevent contamination of drinking water by heavy metals and other agents that cause chronic health problems. Control of environmental conditions, such as radon emissions and air pollution, are particularly important in preventing some forms of cancer. Similarly, nurses and others can campaign for traffic control measures that minimize motor vehicle accidents and subsequent disability. Nurses can also advocate for environmental designs that promote physical activity.

Although usually considered a preventive strategy for communicable diseases, selected immunizations may also prevent chronic diseases. For example, the Advisory Committee on Immunization Practices (ACIP) has recommended hepatitis B vaccine for all adults 19 to 59 years of age with diabetes, and at

the discretion of providers for those over age 60 (Sawyer et al., 2011). Similarly, people with chronic diseases are at particular risk for disease and complications due to influenza and pneumococcal pneumonia and should receive the relevant vaccines. In addition, HPV vaccine can prevent genital warts and subsequent cervical cancer and varicella zoster vaccine (VZV) can prevent shingles, particularly in the elderly.

Innovative strategies may need to be employed to inform the public about prevention strategies for chronic health problems. One such strategy is the development of a radio novella series in Spanish “Promesas y Traiciones,” produced in Alabama, that focused on chronic disease risk factor reduction. In this project, community members helped develop, implement, and evaluate a series of 48 episodes to address salient chronic disease issues (Frazier, Massingale, Bowen, & Kohler, 2012).

Population health nurses may be involved in educating individual clients and the general public about the need for and availability of vaccines or in designing and providing immunization services. They may also need to advocate for accessible immunization services and coverage of routine immunization under health insurance plans. Health promotion and illness and injury prevention goals in the control of chronic physical health problems and related population health nursing activities are summarized in Table 27-3•.

RESOLVING EXISTING CHRONIC PHYSICAL HEALTH PROBLEMS.

Population health nurses are also involved in activities aimed at dealing with chronic health problems once they have occurred. Three major foci in resolving existing chronic conditions are screening and surveillance, early diagnosis, and prompt treatment.

Screening and surveillance. Screening involves identifying individuals who are either at high risk for chronic health problems or who may already have them. Surveillance, on the other hand is a process of monitoring the incidence and prevalence of chronic health problems in the population in order to establish priorities for control efforts. WHO identified three essential components of noncommunicable disease surveillance. These include monitoring exposures and risk factor prevalence, monitoring disease outcomes (e.g., morbidity and mortality), and monitoring health system response. A WHO report on noncommunicable disease capacity indicated that these three components are lacking in most national health information systems and should be integrated into existing systems to promote more effective control of chronic physical health problems (WHO, 2011).

Although the prevalence of many chronic conditions in the population has been increasing, there is less evidence of both upper and lower body limitations that may lead to disability. In all likelihood, this improvement in health status despite increased incidence of disease is due to earlier diagnosis and more effective disease management. Screening is the first step in early diagnosis of many chronic health problems.

Screening tests are available for several chronic health problems but the extent of screening varies across population

TABLE 27-3 Goals for Health Promotion and Injury and Illness Prevention and Related Population Health Nursing Interventions in the Control of Chronic Physical Health Problems

Health Promotion Goal	Nursing Interventions
1. Provide prenatal care.	1. Educate clients and public about the need for prenatal care. Refer to or provide prenatal care.
2. Maintain appropriate body weight through adequate nutrition. <ul style="list-style-type: none"> • Breast-feed infants. • Delay introduction of solid foods. • Avoid use of food as pacifier or reward. • Establish healthy food habits from childhood. 	2. Educate clients and public about adequate nutrition. <ul style="list-style-type: none"> • Obtain diet history and identify poor food habits. • Assist with breast feeding. • Assist with menu planning and budgeting. • Refer for food-supplement plans as needed. • Encourage use of nonfood reward systems.
3. Engage in graduated program of exercise.	3. Educate public about need for exercise. Assist clients to plan appropriate exercise programs.
4. Develop coping skills.	4. Teach coping skills.
Illness and Injury Prevention Goals	Nursing Interventions
1. Decrease obesity prevalence. <ol style="list-style-type: none"> a. Decrease dietary intake of saturated fats, cholesterol, sodium, and alcohol. b. Provide access to healthy food. c. Modify foods to decrease unhealthy constituents. 	1. Educate clients and the public regarding the contribution of obesity to chronic health problems. <ol style="list-style-type: none"> a. Educate and help clients plan adequate nutritional intake. Foster self-help groups for overeaters. b. Advocate for access to low-cost healthy foods (e.g., fruits and vegetables). c. Advocate for control of fat, sugar, salt content of foods. Promote modification of foods to decrease unhealthy constituents.
2. Decrease tobacco use. <ol style="list-style-type: none"> a. Prevent initiation of smoking and increase smoking cessation. 	2. Educate clients and the public regarding the harm from tobacco <ol style="list-style-type: none"> a. Foster self-help groups for smokers. <ul style="list-style-type: none"> • Educate nonsmokers about the hazards of smoking. • Promote no-smoking policies in public places and in the workplace. • Promote smoke-free homes.
3. Decrease cardiovascular disease incidence. <ol style="list-style-type: none"> a. Identify and treat existing health problems that are risk factors for chronic illness (hypertension, obesity). b. Increase use of evidence-based practices. c. Increase compliance with treatment for diseases contributing to CVD. 	3. Educate clients, the public, and providers on strategies to prevent cardiovascular disease. <ol style="list-style-type: none"> a. Screen for and refer clients with existing conditions. <ul style="list-style-type: none"> • Educate clients regarding therapy for existing disease. • Educate clients and providers regarding the ABCS of CVD prevention. • Adjust therapy to client's situation when possible. • Monitor for compliance, therapeutic effects, and side effects.
4. Prevent long-term consequences of unintentional injury.	4. Eliminate risk factors for unintentional injury. <ul style="list-style-type: none"> • Educate client and the public regarding safety hazards and safety precautions. • Advocate for safety legislation and its enforcement. • Prevent occupational and sports injuries through use of safety equipment and practices. • Identify caretaker injury risk factors and plan appropriate interventions. Educate caretakers for injury prevention. Refer for help in obtaining client management equipment and assistive devices. Advocate for funding to provide needed caretaker assistance to prevent injuries.
5. Eliminate environmental pollutants contributing to chronic conditions. <ol style="list-style-type: none"> a. Decrease exposure to sources of radiation (X-ray, sunlight). b. Eliminate occupational exposure to hazardous substances. 	5. Educate public about pollution. Become politically active on environmental legislation. <ol style="list-style-type: none"> a. Educate public about risks of radiation. <ul style="list-style-type: none"> • Discourage sunbathing. • Encourage use of sunscreen and protective clothing. b. Monitor occupational safety conditions.
6. Eliminate or modify effects of emotional stress. Avoid stressful situations when possible.	6. Assist clients to identify stressful situations. Explore with clients ways of decreasing stress.
7. Increase immunization to prevent chronic health problems.	7. Educate clients and the public on the need for immunizations that prevent or minimize effects of chronic health problems. Refer for or provide immunization services. Advocate for the availability of immunization services.

groups and conditions. The U.S. Preventive Services Task Force (USPSTF) has recommended several screening tests for chronic health problems many of which have been addressed in other chapters for specific populations (see Chapters 16∞, 17∞, 18∞, and 19∞). Recently, the USPSTF also recommended annual lung cancer screening using computerized tomography for current smokers 55 to 85 years of age or those who quit smoking within the last 15 years who have a 30-pack-year history of smoking (USPSTF, 2013).

Creative strategies may be needed to promote screening in some populations. For example, the emergency department has been suggested as an effective setting to educate clients regarding mammography screening. In one study, for instance, three fourths of respondents indicated their willingness to listen to mammography promotion materials while waiting to be seen (Hatcher, Rayens, & Schoenberg, 2010). Expansion of Medicaid-funded family planning services also served to increase receipt of breast and cervical cancer screening services in low-income populations (Wherry, 2013). Similarly, interventions using tailored motivational messages and peer support by trained volunteers increased mammography screening rates among African American women (Fouad et al., 2010).

Most people with prediabetes are unaware of their status, yet awareness can lead to lifestyle changes that may prevent progression to type 2 diabetes (Li et al., 2013). The latest USPSTF recommendation is for diabetes screening for individuals with treated or untreated blood pressures over 135/80 (USPSTF, 2008), but some authors have recommended routine screening of high-risk populations in emergency departments.

Population health nurses play an important role in screening for chronic illness. They are conversant with the prevalence of various risk factors in the community and can plan screening programs to detect conditions related to the most prevalent risk factors. They may also plan to motivate client participation in screening by educating the public regarding the need for screening. Knowledge of risk factors alone does not motivate the general public to seek screening opportunities, so motivational activities must go beyond educational campaigns. For example, population health nurses may be actively involved in referring clients for screening services and linking disease prevention to other goals valued by clients (e.g., the ability to continue working).

Interpretation of test results and referrals for further diagnosis and treatment of suspected conditions are also functions of population health nurses in relation to chronic health problems. Screening is only effective if clients understand the results of the screening test and the need for further diagnostic evaluation when screening tests are positive. Misunderstanding of screening reports may lead to increased anxiety or failure to act. Population health nurses can be instrumental in helping clients understand the results of screening tests and in educating them regarding next steps when tests are positive.

At the population level, population health nurses may need to advocate for available and accessible screening services for underserved segments of the population. For example, people

lacking health insurance were twice as likely as those with insurance not to be screened for colorectal cancer (Klabunde, Joseph, King, White, & Plescia, 2013). Similarly, only 38% of women without health insurance had received a mammogram in the past 2 years in the 2010 National Health Interview Survey, compared to 80% of those with private insurance and 67% with public insurance coverage (Khajuria, 2013). Population health nurses may also need to educate and motivate providers to recommend screening procedures to their clients since provider recommendation has been shown to be a strong predictor of screening for many health conditions.

Early diagnosis. The effects of many chronic health conditions can be minimized when they are diagnosed and treated early in the course of the disease. Positive screening test results are always an indication of a need for further diagnostic testing. Persons with obvious symptoms associated with chronic diseases should also be referred for diagnostic evaluation.

Population health nurses frequently engage in case finding with respect to chronic diseases, identifying community members with possible symptoms of disease and referring them for diagnosis and treatment as appropriate. Population health nurses are also active in educating clients and the general public regarding signs and symptoms of chronic diseases and the need for medical intervention. Population health nurses who are nurse practitioners may also be involved in making medical diagnoses of chronic illnesses.

At the population level, early diagnosis may also involve surveillance for increasing incidence of specific chronic diseases and detection of “outbreaks” in particular populations. For example, a four-step process had been suggested by CDC and the Council of State and Territorial Epidemiologists for investigating reports of cancer clusters. This process includes the following:

- **Initial response:** Data collection to determine the credibility of the concern and referral to the appropriate agency unit for investigation. Includes exploration of the nature of the concern, demographics of those affected, and any history of prior reporting and response.
- **Assessment:** Determining if incidence or prevalence figures represent a statistically significant excess of cases, developing a case definition, identifying the population involved and local environmental concerns.
- **Major feasibility study:** An epidemiologic study of cancer cases and environmental factors of concern, and
- **Etiologic investigation of contributing factors** (Abrams et al., 2013).

Population health nurses may need to advocate for available and accessible low-cost diagnostic services for chronic health problems. They may also refer individual clients for those services. In addition, they may need to assist clients to deal with the anxiety and uncertainty that accompany the diagnostic process. A systematic review of available research has indicated that increased distress during the diagnostic phase for breast

cancer can affect treatment outcomes particularly for women with low education levels and high levels of trait anxiety. It has been suggested that providers may need to engage in interventions to reduce distress from the first mention of a possible cancer diagnosis (Montgomery & McCrone, 2010).

Prompt treatment. The third aspect of resolving chronic health problems is the treatment of existing conditions. The primary public health role in this area lies in promoting and monitoring treatment standards for chronic disease in the personal health care sector. Treatment considerations in chronic conditions include engaging in evidence-based disease management, pay for performance, and promoting and supporting client self-management.

Evidence-based disease management. Unfortunately, many people with chronic illnesses do not receive effective evidence-based clinical services. For example, the percentage of people with self-reported hypertension who reported being treated only increased from 61% in 2005 to 62% in 2009 (Fang et al., 2013) and from 2003 to 2010, only 60% of people with stage 2 hypertension were treated with medication (Valderama, Gillespie, & Mercado, 2013). Similarly, from 2009 to 2010, 17.2% of U.S. adults with diabetes had HgA1c levels indicative of good glycemic control (USDHHS, 2012).

A 2013 report for the Institution of Medicine identified elements of quality cancer care that can be adapted to other chronic health problems as well. The first element is engaged patients who are adequately informed and included in decision making regarding their health and health care. The second element is an adequate health professional workforce that includes coordinated services from generalist and specialist providers who possess core competencies. Use of evidence-based care strategies is the third element of quality care. A fourth element is a “learning” information technology system that supports care decision making, while the fifth element is the translation of evidence into quality care that is supported by quality measurement and performance improvement strategies. The final, and most critical, element is access to affordable care for all who need it. This last element will need to be achieved through reimbursement system reforms and elimination of waste as well as through elimination of disparities in care quality (Levit, Balogh, Nass, & Ganz, 2013). Population health nurses may be involved in evaluating the extent to which chronic care systems address these elements of quality care. They can also be active in advocating changes in care delivery system to promote quality care.

Effective treatment of chronic illness can be facilitated with disease management and decision support systems. The CPSTF defined disease management as “an organized, proactive, multicomponent approach to health care delivery for people with a specific disease, such as diabetes. Care is focused on and integrated across the spectrum of the disease and its complications, the prevention of comorbid conditions, and the relevant aspects of the delivery system” (2014a, para 1). Disease

management emphasizes prevention and client–provider collaboration and includes the following components: identification of affected populations; use of evidence-based practice guidelines; collaborative practice including the primary provider, client, and other health care professionals; education of clients for self-management; process and outcomes evaluation; and routine feedback to providers and clients. Disease management has been shown to result in better client health outcomes for several chronic health problems.

Disease management has been shown to be particularly effective in the control of asthma. In 2007, the National Heart, Lung, and Blood Institute (NHLBI) developed expert guidelines for the management of asthma that addressed four essential elements of asthma management: assessment and monitoring, education for a partnership of client and provider in asthma control, control of environmental factors and comorbid conditions, and pharmacologic therapy. The guidelines were subsequently expanded as practice implementation recommendations (NHLBI, 2008). For example, the education guideline was amplified to incorporate collaborative development of an individualized asthma action plan, and pharmacologic recommendations included the use of both rescue medications for acute exacerbations and long-term use of inhaled corticosteroids for better control. Similarly, the assessment and monitoring guideline was operationalized in recommendations for measures of asthma severity, degree of control, and scheduled follow-up visits. Environmental control measures included recommendations for elimination of asthma triggers as well as prevention of comorbidities through influenza immunization. Similar disease management guidelines have been developed for other chronic diseases such as diabetes, cardiovascular disease, and COPD.

Pay for performance. One approach to promoting effective care for chronic physical health problems is to provide incentives for quality care and achievement of specific health outcomes. The Health Care Incentives Improvement Institute has created an innovative reimbursement model called Prometheus that is similar to the Medicare system of diagnosis-related groups (DRGs), but that rewards health systems and providers for prevention of avoidable complications of disease. Approximately one in five Medicare hospitalizations is for potentially avoidable complications of chronic diseases that could be prevented with more effective evidence-based care (de Brantes, Rastogi, & Painter, 2010). An estimated 40 cents of each dollar spent on chronic disease care and 20 cents spent on each hospitalization is the result of potentially avoidable complications (Health Care Incentives Improvement Institute, n.d.b).

Prometheus stands for Provider Payment Reform for Outcomes, Margins, Evidence, Transparency Hassle Reduction, Excellence, Understandability and Sustainability. The Prometheus payment model creates a reimbursement system based on a budget for an entire care episode for a particular disease tailored to a specific patient based on the severity and complexity of their disease. Reimbursement is based on an evidence-informed

case rate (ECR), which is a reimbursement rate for a specific package of covered services based on clinical guidelines or expert opinion in the treatment of a particular condition. Whereas Medicare's current practice is to not reimburse providers and health care systems for "never events" or potentially avoidable complications, Prometheus factors in an allowance for these events based on their typical rates of occurrence. Providers would be paid the lump sum based on the ECR including that allowance. If no complications occur, however, the provider retains the allowance as a net gain, thereby rewarding effective care (Health Care Incentives Improvement Institute, n.d.a). It has been estimated that use of such a reimbursement system for six major chronic diseases (congestive heart failure, coronary artery disease, diabetes, hypertension, COPD, and asthma), could reduce the costs of care by approximately 4% (de Brantes et al., 2010), but actual results remain to be seen.

Other approaches to pay for performance are based on the extent to which providers adhere to best practices in disease management. For example, providers would be reimbursed based on whether or not they provide nutrition counseling to diabetic clients or the percentage of patients with asthma who receive a written asthma action plan. Such mechanisms, however, address provider activities, but do not consider actual patient care outcomes.

Promoting and supporting self-management. Another approach to the treatment of chronic physical health problems lies in client self-management. **Self-management** of chronic health problems involves the ability to manage risk factors and deal effectively with symptoms and treatment regimens and to adjust to the physical and psychological effects of a chronic condition. Self-management also requires knowledge of when to seek medical assistance. The impetus for the current emphasis on self-management by clients with chronic health problems lies in the economic burden posed for society by these conditions. Self-management encompasses three phenomena: a process, a program, and outcomes. Self-management programs are intended to prepare clients to assume responsibility for managing their illness or engage in health promotion behaviors. From an outcomes perspective, self-management should result in better control of the chronic condition and better quality of life for the person affected (Ryan & Sawin, 2009).

Self-management differs from self-care, which is the performance of activities of daily living independent of the health care system (Ryan & Sawin, 2009). Rather, self-management involves self-monitoring, decision making, and action. Monitoring includes both awareness and measurement of one's health status and condition, while symptom management includes awareness of and response to physiologic, cognitive, or functional changes (Richard & Shea, 2011). Self-management skills include problem solving, decision making, resource utilization, formation of effective relationships with providers, development of an action plan, and tailoring the plan to address personal needs and conditions. Common self-management

foci across multiple chronic conditions include symptom management, medication adherence, recognition of acute episodes, promoting good nutrition and physical activity, smoking cessation, stress reduction, interaction with health care providers, obtaining information, adapting to work, managing relations with others, and managing emotions (Ryan & Sawin, 2009).

Some authors have cautioned against an overemphasis on self-management, suggesting that a focus on client responsibility for managing their own conditions may lead to a greater emphasis on cost-containment than quality of services (Baumann, 2012). Others have noted that health care providers are often ill-equipped to assist clients in the acquisition of self-management knowledge and skills (Ryan & Sawin, 2009).

Effective control of chronic health problems should incorporate both evidence-based disease management by health care providers and appropriate self-management by clients. Population health nurses and other health professionals can support clients in the development of needed self-management skills. The Agency for Health Care Research and Quality (AHRQ, 2014) has collected a number of resources to assist health care providers to promote clients' self-management of chronic conditions. For further information about the AHRQ materials, see the *External Resources* section of the student resources site.

Monitoring treatment effects. Another important aspect of resolving chronic physical health problems for individual clients involves monitoring treatment effects. This includes monitoring both therapeutic effects and side effects of treatment. For instance, the nurse may obtain or review periodic blood pressure measurements for the client with hypertension. If the nurse determines that antihypertensive therapy has not noticeably affected the client's blood pressure, the nurse would make sure that the client is taking the medication appropriately and refer the client to his or her primary provider for further follow-up. The nurse also monitors clients for the presence of side effects related to treatment. For example, the nurse may note that a client is experiencing postural hypotension due to antihypertensive medications and will then educate the client about the need to change position gradually and will continue to monitor blood pressure levels to be sure that they do not drop too low.

At the population level, population health nurses will monitor the effects of health care delivery programs in reducing the incidence of chronic health problems or in promoting their control in the population. The goal of monitoring the therapeutic effectiveness of interventions may also require population health nurses to advocate for routine treatment-monitoring services. For example, although effective diabetes management includes annual dilated eye examinations, foot examinations, and glycosylated hemoglobin (HbA1c) determinations, clients with diabetes may not receive these services. Goals for resolving chronic physical health problems and related population health nursing interventions are summarized in Table 27-4.

TABLE 27-4 Goals for Resolving Existing Chronic Physical Health Problems and Related Population Health Nursing Interventions

Goal	Nursing Interventions
1. Screening <ol style="list-style-type: none"> Perform periodic health examinations. Periodically screen for chronic disease. 	1. Screen for existing chronic diseases. <ol style="list-style-type: none"> Educate public about need for health examinations. Provide periodic examinations. Educate public about need for periodic screening. Plan and implement screening programs for high-risk groups.
2. Early diagnosis	2. Educate public about warning signs and symptoms of chronic disease. <ol style="list-style-type: none"> Engage in case finding and refer for diagnosis as appropriate. Prepare client for diagnostic procedures (physically and emotionally). Conduct diagnostic tests as appropriate.
3. Prompt treatment <ol style="list-style-type: none"> Stabilize condition as soon as possible. Establish treatment regimen. <ul style="list-style-type: none"> Medication Radiation Chemotherapy Surgery Provide evidence-based disease management. Promote and support self-management. Prevent disease progression. 	3. Assist with management of chronic disease. <ol style="list-style-type: none"> Provide emergency care as needed. <ul style="list-style-type: none"> Educate public to provide emergency care (CPR). Refer for further treatment. Prepare client for treatment procedures (physically and emotionally). <ul style="list-style-type: none"> Carry out treatment regimen. Provide supportive measures during treatment (relief of pain). Educate clients about medications: dosage, side effects, etc. Encourage client compliance with treatment. Educate providers for evidence-based disease management. <ul style="list-style-type: none"> Disseminate evidence-based clinical guidelines. Advocate for pay-for-performance reimbursement mechanisms. Educate and motivate clients for self-management. Monitor therapeutic effects of treatment. <ul style="list-style-type: none"> Monitor side effects. Refer for follow-up as needed.

HEALTH RESTORATION. The aim of health restoration with respect to chronic physical health problems in individual clients is to promote the client's optimal level of function despite the presence of a chronic health problem. This entails preventing further loss of function in affected and unaffected systems, restoring function, monitoring health status, assisting the client to adjust to the presence of a chronic condition, and providing palliative and end-of-life care as needed.

Preventing loss of function in affected systems. Chronic health problems frequently result in some loss of function in organ systems affected by the condition, and health restoration activities should be planned to restore function or prevent further loss of function in these systems. Activities may be planned to minimize losses or to eliminate risk factors that might lead to adverse consequences of the condition. Such activities on the part of the population health nurse might include motivating client adherence to treatment recommendations and assisting clients to identify and change risk factors that may lead to further loss of function. For example, the client who has had a myocardial infarction may be assisted to plan a regimen of diet

and exercise that will prevent future infarcts. Population health nurses can advocate for the development of and access to restoration services for those in need of them. In addition, nurses can promote clients' active participation in rehabilitation activities for myocardial infarction as well as for stroke, COPD, and other chronic health problems.

Clients with arthritis may be assisted to identify safety factors in the home that might contribute to falls, leading to further mobility limitation. Other interventions aimed at preventing further loss of function in people with arthritis include weight and physical activity counseling and education to address pain management and other problems leading to disability. Population health nurses can provide counseling and education in these areas or refer clients for these services. They may also advocate for access to these services by promoting coverage under health insurance plans or fostering the development of such services for the uninsured.

Pain management may be another intervention that helps to limit loss of function in both affected and unaffected body systems. Pain management will be discussed in more detail in the section on promoting adjustment to chronic health problems.

Preventing loss of function in unaffected systems. Chronic health problems may also result in loss of function in other physical and nonphysical systems not directly affected by the condition. For example, the client with arthritis may develop skin lesions due to limited mobility, or the client with COPD may become malnourished because meal preparation is too exhausting.

Nursing interventions will be directed toward preventing both physical and social disability. Physical complications of chronic conditions may be prevented by activities such as teaching breathing exercises to clients with COPD and providing good skin care and teaching foot care for clients with diabetes. Clients may also need help in managing fatigue, a frequent effect of chronic health problems, particularly COPD and asthma. Prevention of additional physical effects may also entail immunization. Clients with diabetes and COPD, for example, are in particular need of influenza and pneumonia immunizations. The use of statewide immunization information systems to send reminders regarding influenza vaccine for children with chronic diseases has helped to limit comorbidity in this population (Dombkowski et al., 2014).

Other measures to prevent loss of function in people with diabetes include tight glycemic control, control of hypertension, and lipid management as well as screening for diabetic retinopathy (CPSTF, 2014a). Laser therapy for early diabetic eye disease can minimize the risk of severe vision loss, and foot care can reduce the risk of amputation by 50% to 60% (CDC, 2011a). Population health nurses will be actively involved in educating clients with diabetes regarding strategies to control hyperglycemia (e.g., medication use, diet, exercise, glucose monitoring) and prevention of hypoglycemic reactions. They will also assist in monitoring clients' blood pressure and referring them for treatment if needed. In addition, they will educate clients regarding dietary fat intake and treatment measures for hyperlipidemia if prescribed. Population health nurses also educate clients with diabetes regarding skin and foot care and appropriate footwear. In addition, advocacy may be required to assure the availability of these and other services to all segments of the population. Population health nurses can also refer clients to sources of services to prevent deterioration in other body systems.

Nurses can also help prevent social disability by encouraging clients to interact with others, assisting clients to maintain their independence as much as possible, assisting with necessary role changes within the family, and referring the client to appropriate self-help groups. At the group level, population health nurses can work to prevent social isolation of those with chronic illnesses by advocacy and political activities to assure access to services. They can also work to educate the public and to develop positive attitudes to persons with chronic or disabling conditions. Nurse-led clinics have been found to be an effective approach to preventing further loss of function in clients with many chronic health problems (Melville, 2011). Use of community outreach workers is another effective strategy for controlling chronic health problems such as asthma

(Hootman et al., 2012) and diabetes (McEwen, Pasvogel, Gallegos, & Barrera, 2010; Spencer et al., 2011). For clients with cancer, navigation services have resulted in improved patient outcomes. The addition of weatherization interventions to community health worker home visits has also improved asthma outcomes. Examples of weatherization interventions included promoting air tightness, heating system cleaning and maintenance, dealing with moisture-related problems, replacing carpets, and installing stove and dryer hoods (Breyse et al., 2014). For some clients and populations, telemedicine case management can improve function and chronic disease outcomes (Shea et al., 2013).

Cancer navigation involves assisting people to obtain timely access to necessary cancer-related screening, treatment, and survivorship services (Nguyen, Tran, Kagawa-Singer, & Foo, 2011). Nurse navigators, in particular, have been shown to result in better emotional support and feeling better informed and better able to manage care (Brooks, 2013). Navigators can also promote influenza and pneumonia vaccine for cancer survivors (Underwood et al., 2012).

Restoring function. Specific rehabilitation services are needed to offset the consequences of many chronic health conditions, including accidental injury, stroke, and myocardial infarction. Unfortunately, many clients in need of rehabilitation services do not receive them. Population health nurses can refer clients to rehabilitation programs or advocate for their accessibility to those in need. They can also help design programs that meet the perceived needs of the client population.

Particular areas to be addressed in rehabilitation programs include functional status related to activities such as positioning, range of motion, transfer abilities, dressing, bowel and bladder control, hygiene, locomotion, and eating. Other functional considerations include vision, hearing, speech, mental ability, and capacity for social interaction. The nurse, together with the client and his or her significant others, can foster renewed abilities to perform these functions. For example, the nurse may develop a plan and teach the client and family how to reestablish bowel control following a stroke, or the nurse might assist the client with passive and active range-of-motion exercises to restore function after a broken arm has healed. Other considerations include teaching stress management, dealing with the limitations imposed by a chronic condition, and addressing the financial burden of disease that may limit clients' abilities to regain function.

Other interventions may necessitate referral to other health care providers. For example, clients may need physical therapy to regain lost function after a stroke. Clients may also need rehabilitation services following myocardial infarction or to minimize the effects of arthritis or stroke. Population health nurses may assist individual clients to obtain these services or advocate for their availability and accessibility in the community.

Promoting adjustment. Movement to an optimal level of health entails adjustment to the constraints of a chronic physical

health problem. Areas for special consideration in promoting adjustment to chronic health problems include functional and psychological adjustment, pain management, and survivorship care.

Adjustments to the presence of a chronic disease occur in both functional and psychological realms. Functional adjustments reflect changes in lifestyle necessitated by the illness. Such changes may involve diet, activity patterns, restrictions (e.g., limiting alcohol use or caloric intake), and the need to take medications. Some diseases necessitate learning special skills. For example, insulin-dependent diabetic clients need to learn to give themselves insulin injections, and hypertensive clients may need to learn how to take their blood pressure. In other chronic conditions, such as arthritis, there may be a need for special apparatus to assist in performing routine activities. The need for medication may also necessitate budgetary changes that the client must adjust to.

Adjustment in the work setting is a special consideration for many people with chronic conditions. Promoting adjustment in the work setting usually combines a variety of approaches. First, population health nurses in occupational settings can enhance the employee's personal ability to cope with illness. This might be accomplished through education regarding medication management or self-monitoring skills or other interventions. Second, the nurse can advocate for the support of management or colleagues for self-care activities (e.g., scheduling flexible breaks or meals) and advocate for working conditions that accommodate any limitations or special needs (e.g., redesign of work stations to prevent exacerbation of carpal tunnel syndrome, assuring wheelchair access to all areas of the work setting). Third, nurses can connect employees to support groups and services outside the work setting, and finally, the nurse can assure adequate access to care and advocate for insurance benefits to cover the costs of care. Case management is also an effective approach to keeping employees with chronic health problems on the job. Disease management programs may also be helpful for groups of employees with similar conditions.

Psychological adjustments are also necessary. Psychological adjustment to a chronic condition may be required in a number of areas. Self-esteem is one of these areas. A chronic disease may make a client more dependent on others and less able to engage in activities that promote a positive self-image. For example, the client may need to stop working or begin to rely on others for assistance with basic functions such as eating and toileting. This dependence may be demeaning to one who has been self-reliant. The nurse should encourage the client to maintain as many functions as possible and help families to see the client's need for independence.

Loss of independence also necessitates adjustments in one's sense of control. Clients may feel they are not in control of events when the food they eat or the activities they perform are dictated in part by the chronic health problem. For some clients, noncompliance with recommendations might be an attempt to regain control over their own lives. Nurses can help prevent noncompliance by providing the client with other

avenues for exercising control. Ways of doing this include involving the client in planning interventions and providing, whenever possible, choices in which the client can exercise control over actions and outcomes. Population health nurses may also help clients obtain assistive technology devices (e.g., braces, chairlifts, railings, shower seat, grab bars) that can decrease their dependence on the assistance of other.

Another area that may require adjustment for clients with chronic conditions is that of intimacy. Among men, for example, some chronic conditions or their treatments may result in impotence. In other cases, pain or changes in self-image may limit a client's ability to maintain intimate relationships with others. Another potential problem may be the withdrawal of significant others. Clients and their families can be encouraged to discuss intimacy issues openly, and significant others can be assisted to find ways of fulfilling intimacy needs that are congruent with the presence of a chronic health problem.

Stigma is another psychological issue in adjustment to a chronic health problem. Many chronic health conditions are stigmatized by the general population. Clients with visible evidence of disease may attempt to deal with stigma by minimizing the perceived consequences of the disease or covering them up as much as possible while still acknowledging their existence. Those whose condition is invisible are faced with decisions of whether to disclose their chronic illness, how much to disclose, and to whom. Clients who fear rejection on the basis of stigma attached to the disease may attempt to pass themselves off as healthy, but then endure the stress of possible discovery and loss of credibility as well as rejection. Population health nurses can assist clients to deal with perceptions of stigma and to make decisions regarding disclosure. For clients suffering from the psychological effects of stigmatization, referrals for counseling services may be warranted. Nurses may also engage in public education campaigns to diminish the stigma attached to certain chronic conditions.

Population health nurses may also need to help clients and their families deal with caregiver burden. **Caregiver burden** is the effect of the stress of caring for a family member with a physical or mental illness on those providing the care. Caregiver burden can stem from the extent of care required or from behaviors exhibited by the family member receiving care. For example, caregiver burden may be increased when the person to whom care is given exhibits behavioral disturbances.

Population health nurses can refer clients and caregivers to self-help groups or other community agencies that provide assistance in dealing with problems arising from chronic health conditions. When self-help groups are not available in the local area, population health nurses may be involved in their development. Nurses may also advocate for the provision of services to promote functional and psychological adjustment to chronic health problems. For example, they may advocate for funding for homemaker assistance to permit people with disabilities to remain in their homes. Or they may advocate for insurance coverage for psychological counseling for clients with chronic physical health problems or for respite for caregivers.

Pain management. Pain management is an important component of management of chronic physical health problems. Effective pain management is important not only for improving the quality of life of individual clients, but also for decreasing the economic costs of chronic health problems for society in general. According to an Institute of Medicine report, an estimated 37% of the adult population in 10 countries experience chronic pain. In the United States, this figure rises to 43%. The prevalence of pain is increasing and is anticipated to continue to increase, primarily due to diabetic neuropathies and orthopedic problems. The overall cost of pain in the United States is conservatively estimated to be between \$560 and \$635 billion each year when medical care costs and lost productivity costs are considered (National Research Council, 2011).

Goals of pain management in chronic illness include preventing pain whenever possible, reducing the severity or frequency of pain, improving physical function, reducing psychological distress, and improving the overall quality of life. Health care providers often prescribe pharmacologic agents for pain management, but population health nurses may be able to assist clients to find other means of dealing with pain. For example, they can refer clients for acupuncture services, which have been shown to be effective in decreasing some types of chronic pain. Population health nurses can refer clients for these services. They may also advocate for reimbursement for nonpharmacologic pain management strategies under insurance coverage.

Population health nurses can work to educate health policy makers, providers, legislators, clients and their families, and the general public regarding the need for effective pain control and appropriate pain management strategies. They can also advocate for changes in laws or insurance coverage to promote effective pain management. In addition, population health nurses can assess the pain management needs of individual clients with chronic illnesses. *Partners Against Pain* (n.d.) provides a number of pain assessment tools and pain management tools. An information resource regarding the tools is provided in the student resources site for this book.

Survivorship care. Survivorship is another aspect of health restoration care for people with some chronic health problems. **Cancer survivors** include persons with cancer from the time of diagnosis through the balance of their lives as well as their families, friends, and caregivers (Levit et al., 2013). The vast majority of cancer survivors will need some level of continuing care for the rest of their lives because of their increased risk for recurrent cancers. Survivors may also need assistance in dealing with the psychosocial effects of their diagnosis. The concept of survivorship care was developed to address these ongoing needs. Although the concept was developed in relation to cancer survivors, elements of survivorship care are relevant to other health conditions that threaten life and have long-term consequences for survivors (e.g., HIV/AIDS and severe traumatic injuries).

Survivorship care encompasses care provided not only to clients who survive life-threatening conditions, but also to families, friends, and caregivers who are affected by the condition. Life for

all of these people is irrevocably changed. Survivors and those around them who are affected by their condition are subjected to physical, emotional, social, spiritual, and financial issues that require long-term care. Additional needs may include dealing with pain or side effects of treatment, many of which may occur well after treatment is completed. Psychological issues of anxiety and depression may also need to be addressed. Cancer survivors may also have special nutritional needs or increased susceptibility to infection. Survivors also need information about health promotion activities such as exercise and weight control as well as ongoing surveillance and periodic screening for recurrent cancer, although the type and frequency of screening recommendations will vary with the type of cancer involved.

Survivorship care includes:

- Prevention of recurrent and new cancers and late treatment effects
- Surveillance for recurrent or new cancer and medical or psychological effects of the cancer and its treatment
- Interventions to address the consequences of disease and treatment
- Coordination of care between oncology specialists and primary care providers to assure that all the health needs of survivors are met (Levit et al., 2013)

Survivorship care should be grounded in a *survivorship care plan* that includes information about the cancer diagnosis, treatment received, and possible consequences; recommended follow-up interventions (e.g., screening for cancer recurrence, reconstructive surgeries, dietary recommendations); recommendations for health promotion; information on legal protections related to employment and health insurance; and referral for psychosocial services (e.g., financial assistance, job training) as needed.

Population health nurses can be instrumental in developing cancer survivorship plans for clients or for assuring that assistance in developing such plans is available. They may also need to advocate for insurance coverage for plan development services and services needed to implement the survivorship plan. There is also a need to develop clinical practice guidelines for survivorship care for specific types of cancer, and population health nurses can advocate for or conduct research in this area. Nurses may also need to engage in political advocacy to promote insurance reforms that prohibit denial of health insurance based on a past history of cancer and to include coverage of survivorship care as an integral part of cancer care.

Palliative and end-of-life care. A few chronic physical health problems are terminal in nature, and population health nurses may be involved in providing care to clients who are facing death, and to their families. In other instances, care is directed primarily toward palliation of symptoms, with no real expectation of improvement in the condition. Palliative and hospice care were addressed in Chapter 13 in the context of home health care and home visiting.

The National Consensus Project for Quality Palliative Care (2013) has developed clinical practice guidelines for quality

palliative care. The guidelines address seven domains of practice that encompass structure and processes of care with an emphasis on an interdisciplinary approach; physical aspects of care, including multidimensional symptom management; psychological and psychiatric aspects of care, including bereavement services for families; and social, spiritual, and cultural aspects of care. Additional domains include end-of-life care, including communication and documentation of signs and symptoms of the dying process, and ethical and legal aspects of palliative care. For further information about the palliative care practice guidelines, see the *External Resources* section of the student resources site.

Another consideration in end-of-life care is attending to clients' care wishes. In one study, 60% of people surveyed indicated that they wanted their end-of-life wishes respected, yet only one third of them had completed an advance directive. Many people were not knowledgeable regarding advance directives and others indicated that they were not yet ready to execute one. It is estimated that greater use of advance directives could reduce health care costs considerably, since approximately a quarter of costs are related to unnecessary care provided in the last few months of life (Morhaim & Pollack, 2013). Population health nurses can educate clients and the general public regarding advance directives and can assist clients in their completion. They can also advocate for making provider discussion of advance directives a reimbursable health care activity and promote such discussions with clients.

Health restoration goals for end-of-life care and other aspects of chronic disease care and related nursing interventions are summarized in Table 27-5.

Evaluating Control Strategies for Chronic Physical Health Problems

Evaluating control strategies for chronic health problems is done in terms of care outcomes. Care may be evaluated in relation to the individual client or to a population group. In the case of the individual client, the nurse evaluates the status of the chronic condition as well as the client's adjustment to having a chronic health problem. If medical, nursing, or self-management interventions have been effective, the condition will be controlled or may even be improving. Failing improvement, the condition will provide the least disruption possible to the life of the client and his or her significant others. Evaluative criteria reflect both the client's physiologic status and his or her quality of life.

Evidence of success in controlling chronic health problems at the community or population level lies primarily in changes in morbidity and mortality figures. Are there fewer cases of hypertension or cardiovascular disease in the population now than before the initiation of control efforts? Are there fewer disabilities due to accidental injuries? Do those individuals with diabetes live longer or have fewer hospitalizations for diabetic complications? Based on the evaluative data, decisions can be made regarding the need to attempt other control strategies or to continue with current measures.

Evaluation of population-based control strategies may focus on the status of national objectives for 2020 for selected chronic diseases. Baseline and target information and the current status of several of these objectives are presented on the next page.

TABLE 27-5 Goals for Health Restoration and Related Community Health Nursing Interventions in the Control of Chronic Physical Health Problems

Goal	Nursing Interventions
1. Prevent further loss of function in affected systems. Decrease risk factors for recurrence, exacerbation, or development of crises.	1. Motivate client to comply with treatment regimen. Assist client to identify risk factors amenable to change. Assist client to identify ways of decreasing risk factors.
2. Prevent loss of function in unaffected systems. a. Prevent physical disability. b. Prevent social disability.	2. Assist client to maintain function in unaffected systems. a. Prevent physical complications of illness through: <ul style="list-style-type: none"> • Breathing exercises • Skin care • Range-of-motion exercises and physical activity • Adequate nutrition and fluids Provide physical care as required. Refer for assistance with physical care as needed. b. Accept client as a unique person. Encourage interaction with others. Assist significant others to deal with feelings about client's illness. Assist client to maintain independence as much as possible. Assist with identification of need for changes in family roles. Work to change public attitudes toward the disabled. Promote legislation to aid chronically ill to maintain their independence.
3. Restore function.	3. Assist with planning and implementation of programs to regain function (bowel training, physical therapy). Teach client and others to carry out program and evaluate effects.

TABLE 27-5 (Continued)

Goal	Nursing Interventions
<p>4. Promote adjustment.</p> <p>a. Deal with feelings about disease.</p> <p>b. Adjust lifestyle to accommodate chronic disease and its effects.</p> <p>c. Adjust environment to meet changed needs.</p> <p>d. Adjust self-image.</p> <p>e. Adjust to expense of chronic care.</p> <p>f. Deal with stigma.</p> <p>g. Effectively manage pain.</p>	<p>4. Assist client to adjust to presence of chronic disease.</p> <p>a. Accept client at his or her level of development and acceptance of disease. Encourage client to discuss fears and apprehensions. Refer to self-help groups as appropriate.</p> <p>b. Assist client to identify needed changes in lifestyle. Assist client to plan and carry out lifestyle changes.</p> <p>c. Identify need for self-help devices and help client obtain them. Identify environmental changes needed to foster independence. Assist client to make necessary environmental changes.</p> <p>d. Assist client to adjust to change in self-image. Refer for counseling as needed.</p> <p>e. Refer for financial aid as needed.</p> <p>f. Assist with decisions regarding disclosure. Assist client to cope with effects of stigma. Educate public to minimize stigma.</p> <p>g. Accurately assess client pain levels. Assist in identifying appropriate pharmacologic and nonpharmacologic approaches to pain control. Refer for pain management services, as needed. Educate clients, family, providers, and the public regarding effective pain control. Advocate for available and accessible pain management services and insurance coverage for services. Monitor the effectiveness of pain control strategies.</p>
5. Meet survivorship care needs.	5. Identify survivorship care needs and participate in developing a survivorship care plan. Refer clients and families for survivorship care services as needed. Advocate for insurance coverage of survivorship care planning and needed survivorship care. Conduct research to identify care needs and best practices in survivorship care.
6. Adjust to impending death.	<p>6. Provide end-of-life care.</p> <p>a. Provide pain management.</p> <p>b. Provide comfort care.</p> <p>c. Provide palliative care.</p> <p>d. Encourage advance directives.</p> <p>e. Refer to hospice services as needed.</p>

Healthy People 2020

Selected Health Objectives Related to Chronic Physical Health Problems

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
AOCBC-1. Reduce the mean level of joint pain in adults with doctor-diagnosed arthritis	5.6 (on a 10-point scale) (2006)	5	5.7 (2009)	National Health Interview Survey (NHIS), CDC/ NCHS
AOCBC-2. Reduce the proportion of adults with doctor-diagnosed arthritis with limitation in activity	39.4% (2008)	35.5%	40.5% (2011)	NHIS, CDC/ NCHS
AOCBC-10. Reduce the proportion of adults with osteoporosis	5.9% (2005–2008)	5.38%	NDA	National Health and Nutrition Examination Survey (NHANES), CDC/ NCHS
CKD-1. Reduce the proportion of the population with chronic kidney disease	15.1% (1994–2004)	13.6%	NDA	US Renal Disease System (USRDS), NIH/NIDDK
CKD-8. Reduce the rate of new cases of end-stage renal disease (per million population)	358.9 (2007)	323	349.7 (2010)	USRDS, NIH/NIDDK

Healthy People 2020 (Continued)

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
CKD-9.1. Reduce kidney failure due to diabetes (per million population)	154.6 (2007)	139.1	150.6 (2010)	USRDS, NIH/NIDDK
D-1. Reduce the annual number of new cases of diabetes in people aged 18–64 (per 1,000 population)	8 2006–2008	7.2	7.3 (2010–2012)	NHIS, CDC/ NCHS
D-3. Reduce the diabetes death rate (per 100,000 population)	74 (2007)	66.6	70.7 (2010)	National Vital Statistics System—Mortality (NVSS-M), CDC/NCHS
D-14. Increase the proportion of persons with diagnosed diabetes who receive formal diabetes education	56.8% (2008)	62.5%	58% (2010)	Behavioral Risk Factor Surveillance System (BRFSS), DCD/PHSPO
HDS-2. Reduce coronary heart disease deaths (per 100,000 population)	129.2 (2007)	103.4	113.6 (2010)	NVSS-M, CDC/NCHS
HDS-3. Reduce stroke deaths (per 100,000 population)	43.5 (2007)	34.8	39.1 (2010)	NVSS-M, CDC/NCHS
HDS-5.1. Reduce the proportion of adults with high blood pressure	29.9% (2005–2008)	26.9%	NDA	NHANES, CDC/ NCHS
HDS-7. Reduce the proportion of adults with high total blood cholesterol levels	15% (2005–2008)	13.5%	NDA	NHANES, CDC/ NCHS
HDS-12. Increase the proportion of adults with high blood pressure whose blood pressure is under control	43.7% (2005–2008)	61.2%	45.9% (2009–2010)	NHANES, CDC/ NCHS
NWS-8. Increase the proportion of adults who are at healthy weight	30.8% (2005–2008)	33.9%	NDA	NHANES, CDC/ NCHS
PA-1. Reduce the proportion of adults who engage in no leisure-time physical activity	36.2% (2008)	32.6%	31.6% (2011)	NHANES, CDC/ NCHS
RD-4. Reduce activity limitations among persons with asthma	12.7% (2008)	10.2%	10%* (2012)	NHIS, CDC/ NCHS
RD-7.1. Increase the proportion of persons with asthma who receive written asthma management plans	33.4% (2008)	36.8%	NDA	NHIS, CDC/NCHS
TU-1.1. Reduce cigarette smoking by adults	20.6% (2008)	12%	19% (2011)	NHIS, CDC/NCHS
TU-2.1. Reduce use of tobacco products by adolescents (grades 9–12) (last month)	26% (2009)	21%	23.4% (2011)	Youth Risk Behavior Surveillance System (YRBSS), NCHHSTP

CHAPTER RECAP

Chronic physical health problems have largely replaced communicable diseases as the major contributors to death and disability, and significant morbidity and mortality due to chronic physical conditions are seen throughout the world. Factors related to each of the six categories of determinants of health contribute to the development and/or control of chronic physical

health problems. Population health nurses are actively involved in efforts to educate the public to prevent these diseases as well as in the design, implementation, and evaluation of programs to provide diagnostic, treatment, and support services for persons with existing disease.

CASE STUDY

Reducing Hypertension Incidence

You have just started working as a population health nurse for the Wachita County Health Department in Mississippi. During your employment interview, the nursing supervisor mentioned that one of your responsibilities would be to participate in developing plans for dealing with the high rate of hypertension in the county. The incidence rate for hypertension here is three times that of the state and twice that of the nation. The population of the county is largely African American, with high unemployment rates and little health insurance. Folk health practices are quite common, one of them being drinking pickle brine for a condition called “high blood.” Although this condition is not related to high blood pressure, the two terms are frequently confused by lay members of the community and professionals alike. Dietary intake is typical of the rural South, consisting of a variety of fried foods, beans and other boiled vegetables, and corn bread.

Most of the adult members of the community work in service industry jobs that involve little vigorous physical activity. In addition, few community members engage in leisure time physical activity. The local Baptist and Methodist churches are interested in initiating health ministries, but have not made much headway in organizing related activities yet. Few health services are

available in the county itself, although there is a major hospital 50 miles away. There are two general practitioners in the area and one pediatrician. Both of the general practitioners are older physicians, and you doubt that they are incorporating current practice guidelines for hypertension control. The health department holds well-child, immunization, tuberculosis, and family planning clinics regularly, and all are well attended. Transportation is a problem for many community residents.

1. What are the biological, psychological, environmental, sociocultural, behavioral, and health system factors influencing the incidence and prevalence of hypertension in this county?
2. Write two objectives for your efforts to resolve the county's problem with hypertension.
3. What health promotion, illness prevention, problem resolution, and health restoration activities might be appropriate in dealing with the problem of hypertension? Which of these activities might you carry out yourself? Which would require collaboration with other community members? Who might these other people be?
4. How would you evaluate the outcome of your interventions?

28 Mental Health and Mental Illness

Learning Outcomes

After reading this chapter, you should be able to:

1. Define mental health and mental illness.
2. Analyze the personal, family, and societal impact of mental illness and mental health problems.
3. Analyze factors influencing the development of mental health problems.
4. Identify symptoms characteristic of common mental health problems.
5. Describe strategies for promoting mental health and analyze the population health nurse's role in each.
6. Analyze the role of the population health nurse in strategies to prevent mental health problems.
7. Discuss approaches to resolving mental health problems and analyze the population health nurse's role in each.
8. Describe areas of emphasis in health restoration related to mental health problems and analyze the role of the population health nurse in maintenance.

Dorothea Dix and Asylum Reform

Dorothea Lynde Dix was born to parents who had mental health problems, although the exact nature of those problems is debated in various sources and includes alcoholism, depression, or mental retardation (Bumb, n.d.; Casarez, 2000; Dorothea Lynde Dix, 2014). At a young age, she began teaching young girls in schools supported by her grandmother. She was first exposed to the inhumane conditions in which both prisoners and the mentally ill were kept when she volunteered to teach a Sunday school class to inmates at the jail in East Cambridge, Massachusetts. Appalled by what she saw, she went to court and was successful in securing heat for the inmates (Dorothea Dix, 2014). She then embarked on a fact-finding tour that took her to most of the jails, almshouses, and houses of correction within the state. She compiled her findings in a report presented to the Massachusetts legislature that led to funding for an institution specifically for the mentally ill (National Women's Hall of Fame, 2011). She extended her efforts throughout the United States and in Europe and was responsible for multiple changes in how the mentally ill were perceived and treated, including the establishment of several hospitals for the mentally ill (Dorothea Dix, 2014).

When she volunteered at the beginning of the U.S. Civil War, Dix was made Superintendent of Nurses for the Union Army (Prison and Asylum Reform, n.d.). In that capacity, although she had no nursing background, she was responsible for the administration of military hospitals and supplies as well as for recruiting nurses. She was the first woman to serve in a high-level federally appointed role (Dorothea Lynde Dix, 2014). After the war, she continued to be politically active in advocating for humane care of the mentally ill.

Advocating for Mental Illness Treatment

The Treatment Advocacy Center is a national nonprofit organization that advocates for access to timely treatment for persons with mental illness. The organization works to influence legislation and policy related to mental health treatment and supports research on innovative treatments for mental disorders. Organizational activities have resulted in changes in commitment and treatment laws in 22 states. Foci for activities include educating policy makers about mental illnesses and their treatment, assisting grassroots activism for effective legislation, promoting innovative strategies for preventing diversion of mentally ill people to correctional facilities, and promoting strategies to enhance treatment adherence after hospital discharge (Treatment Advocacy Center, 2011).

Mental health and mental illness are not mutually exclusive and have been conceptualized as dual continua: one reflecting mental health and the other reflecting mental illness. Mental health is a state of flourishing, characterized by positive emotions and high levels of psychological and social function. Mental illness, on the other hand, is a state of languishing, characterized by feelings of emptiness and stagnation accompanied by specific symptoms. Some level of mental illness may be present even in the context of general mental health and vice versa (Perry, Presley-Cantrell, & Dhingra, 2010).

A 1999 U.S. Surgeon General's report defined **mental health** as "a state of successful performance of mental function,

resulting in productive activities, fulfilling relationships with people, and the ability to adapt to change and to cope with adversity" (quoted in Keyes, Myers, & Kendler, 2010, p. 2379). The World Health Organization's (WHO) definition of mental health encompasses achievement of one's potential and abilities to cope with life's stresses, work productively, and contribute to society (2014a). The Surgeon General's definition incorporates two aspects: feeling good and functioning well (Keyes et al., 2010), whereas the WHO definition addresses emotional (feelings of happiness and satisfaction), psychological (effective individual function), and social well-being (effective social function) (Fledderus, Bohlmeijer, Smit, & Westerhof, 2010). The absence of positive mental health has

been linked to increased risk of all-cause mortality (Keyes & Simoes, 2012).

Mental illness or mental disorder is defined as “health conditions that are characterized by alterations in thinking, mood, or behavior (or some combination thereof) associated with distress and/or impaired functioning” (National Institute of Mental Health [NIMH], 1999, p. 5). **Serious mental illness** is defined by the U.S. federal government as “a diagnosable mental, behavioral, or emotional disorder of sufficient duration to meet diagnostic criteria specified within the *Diagnostic and Statistical Manual of Mental Disorders (DSM)-III-R*, (4) that has resulted in functional impairment which substantially interferes with or limits one or more major life activities” (Insel, 2013, para 3). **Mental health problems** involve signs and symptoms of mental distress that are of insufficient duration or intensity to qualify as mental disorders diagnosed on the basis of accepted criteria. **Community mental health problems** are those that occur with sufficient frequency in the community or population group to be of serious concern in the overall health status of the population. In this chapter we use the term *mental health problems* to refer to the composite of mental and emotional conditions that result in impaired function.

Individual, Family, and Societal Effects of Chronic Mental Health Problems

Mental health problems have burdensome effects for individuals and their families as well as for society as a whole. Some of these effects will be presented here.

Personal Effects

Suffering and disability are the two most prominent effects of mental health problems for the individuals they affect. There is no objective measure of the suffering endured, but measures of disability are discouraging. Depression is one of the top three disabling conditions in high-income countries throughout the world (Smith & Bielecky, 2012). Although disability related to chronic health problems has decreased in recent years, mental illness-related disability has increased. For example, mental health disability increased from 2% of the U.S. non-elderly adult population in 1997–1999 to 2.7% in 2007–2009, affecting approximately 2 million people (Mojtabai, 2011).

Mental health problems not only result in mental disability but also cause physical and social impairments. Mental illness may result in worsening of physical health problems due to inability or lack of motivation for effective self-care. On average, people with serious mental health problems die 25 years earlier than those without mental health problems (Shim & Rust, 2013).

Family Effects

Mental health problems also exact a toll on the families of people that experience them. The family costs of mental disorders are both economic and emotional. In Chapter 19, we

reviewed the effects of caregiving on family members with Alzheimer’s disease. Other chronic mental health problems also have family effects. For example, families in which one member has schizophrenia may not progress through the normal stages of family development described in Chapter 14 due to the difficulty people with schizophrenia have with separating from home and becoming independent. Parents of a child with schizophrenia may find themselves extending the parental role indefinitely.

The increasing move to treat mental health problems in community settings has increased the burden of care for families. The presence of a family member with a mental illness creates demands and stress for families that can affect family interactions and the physical, emotional, and social health of family members (Lowenstein, Butler, & Ashcroft, 2010). The effects of mental illness in a family member include denial and feelings of anxiety and hopelessness. Family members may also suffer the burden of caring for someone who is not fully capable of caring for him or herself. In addition, families may experience the stigma associated with mental illness or suffer with stigmatized family members.

Clients with mental illness may have difficulty holding a job because of the impairments resulting from their conditions. Unemployment and underemployment may lead to poverty for the individual and the family. In addition, family caretakers may be forced to take time from work or even stop working, further diminishing family income. Major mental disorders may also prevent family members from carrying out their expected family roles. Mental illness in a family member often increases stress for the entire family and may contribute to family communication problems and perceptions of social stigma for both client and family.

Strategies that have been suggested for dealing with the burden of caring for family members with mental illness include educating themselves about the disease and becoming involved in the treatment process, seeking out resources, having realistic expectations, reaching out for support, and working closely with the treatment team (Tartakovsky, n.d.). The National Alliance on Mental Illness (NAMI) has developed a family education course, *Family-to-family*, designed to provide support to families with loved ones with mental illness (NAMI, n.d.c). Research on program effectiveness has indicated that it improves knowledge about the illness and fosters empowerment, problem-focused coping, and increased acceptance of the illness, as well as reducing stress (Dixon et al., 2011). For further information about the *Family-to-family* program, see the *External Resources* section of the student resources site.

Societal Effects

Mental illness and less severe mental health problems also pose a burden for society in general. Mental disorders are the leading cause of disability worldwide and account for a substantial portion of the global disease burden. For example, in 2004, depression was the third leading cause of disease

burden worldwide and is expected to rise to the second leading cause by 2020. Much of this burden is related to decreased productivity as well as the direct treatment costs for mental health problems (Centers for Disease Control and Prevention [CDC], 2010). Overall, mental health conditions account for 37% of healthy life years lost due to noncommunicable diseases. Unipolar depression alone accounts for nearly a third of mental health disability-adjusted life years lost, and bipolar disorder and schizophrenia account for another 15% (Bloom et al., 2011).

In addition to the burden of disability posed by mental disorders, society experiences considerable economic burden as well. For example, overall costs of mental health care in 2006 amounted to \$57.5 billion, equal to the amount spent on cancer care (Insel, 2011). A 2011 World Economic Forum report estimated global costs for mental health in 2010 at \$2.5 trillion. These costs are expected to rise to \$6 trillion by 2030, about two thirds of which are due to indirect costs, such as lost economic productivity (Bloom et al., 2011).

The importance of chronic mental health problems in the United States is highlighted by the number of objectives related to these disorders in the national health objectives for the year 2020 (U.S. Department of Health and Human Services [USDHHS], 2014). Some of these objectives are presented at the end of this chapter. The complete set of objectives for mental health and mental disorders can be viewed on the *Healthy People 2020* web page.

Trends in Mental Health Problems

WHO estimates that one quarter of all the people in the world who utilize health services have at least one mental health problem (Bloom et al., 2011). Together mental health and substance abuse disorders constitute the second leading cause of worldwide disease burden and disability (Shim & Rust, 2013). In addition, the Organisation for Economic Co-operation and Development (OECD) estimates that 20% of the working age population in OECD countries has a clinical mental disorder, and the lifetime prevalence is estimated at 50% of the world's population. By conservative estimates, mental illness costs account for 3% to 4% of the gross domestic product (GDP) of the European Union, and one third to one half of all disability claims result from mental health problems (OECD, 2011).

The majority of mental illnesses, or common mental disorders (CMDs), are mild or moderate in their effects, but all can evolve to severe mental disorders (SMDs). In addition, most mental illness is recurrent. For example, recurrence occurs in 40% to 80% of people with depression even with medication. An individual may also experience a variety of co-occurring mental disorders as well as comorbidity with chronic physical health problems, with comorbid conditions being more disabling than a single condition (OECD, 2011).

In the United States an estimated quarter of adults experience a diagnosable mental illness in any given year, and approximately two thirds of them do not seek care (Center for Surveillance, Epidemiology, and Laboratory Services [CSELS], 2012). In 2011–2012, 3.1% of the U.S. population reported serious psychological distress within the prior 40 days (National Center for Health Statistics [NCHS], 2014), and in the 2009–2011 National Survey on Drug Use and Health, nearly 20% of U.S. adults over 18 years of age had a mental illness (Gfroerer et al., 2013). According to the 2007–2008 National Ambulatory Medical Care Survey, 5% of all ambulatory care visits in the United States were related to mental health disorders, primarily depression, psychoses, and anxiety disorders. The rate of hospitalization with a primary diagnosis of mental illness was 97.9 per 10,000 population but this rate decreased with increasing age (Reeves et al., 2011).

Prevalence figures for specific mental disorders are equally alarming. Periodic depression, “feeling down” or “having the blues,” is a common occurrence in all people, but major depression is not a normal phenomenon. A milder, chronic, ongoing form of depressed mood that prevents one from functioning well or feeling good is called **dysthymia** (Mayo Clinic Staff, 2012). Bipolar disorder is another form of depression. In bipolar disorder, also known as manic-depressive disorder, people experience unusual shifts in mood, energy, and functional ability. Most people with bipolar disorder cycle through periods of depression alternating with periods of energy, excitability, and irritability called *mania*. Symptoms gradually flow through a continuum from severe mania and hyperactivity through hypomania, characterized by mild to moderate manic symptoms, followed by a normal mood state. Normal mood eventually shifts into mild depression and then into severe depression. Some people exhibit symptoms of both mania and depression simultaneously in a mixed state (NIMH, n.d.b). Both major depression and bipolar disorder are risk factors for suicide. Symptoms of depression and mania are presented in Table 28-1 •.

Depression may lead to suicide attempts. (Chalabala/Fotolia)

TABLE 28-1 Mood and Behavior Changes Characteristic of Depression and Mania

Depression	Mania
Mood Changes: <ul style="list-style-type: none"> • Persistent sadness or despair • Loss of interest in formerly pleasurable activities (including sex) 	Mood Changes: <ul style="list-style-type: none"> • Persistent feelings of euphoria, overly happy, or outgoing • Irritability
Behavior Changes: <ul style="list-style-type: none"> • Feeling fatigued or “slowed down” • Problems concentrating, remembering, or making decisions • Restlessness, irritability • Changes in eating, sleeping, or other habits • Thinking of death or suicide, attempting suicide 	Behavior Changes: <ul style="list-style-type: none"> • Talking fast, jumping from one topic to another • Psychomotor agitation • Decreased sleep • Racing thoughts and distractibility • Poor judgment and impaired impulse control, engaging in high-risk behaviors • Increasing activities or projects • Unrealistic perceptions of one’s abilities

Data from: National Institute of Mental Health. (n.d.b). *Bipolar disorder*. Retrieved from <http://www.nimh.nih.gov/health/topics/bipolar-disorder/index.shtml>

The lifetime risk of major depression in the United States is 16.5% and approximately 3.5% of the population will experience bipolar disorder (NIMH, n.d.c, n.d.e). In the 2008 Behavioral Risk Factor Surveillance System (BRFSS), more than 8% of the population reported current depression, and similar figures were reported in the National Health and Nutrition Examination Survey (NHANES) from 2007 to 2010 (NCHS, 2012a). In 2009, people responding to the BRFSS reported an average of 3.5 mentally unhealthy days in the last month. Postpartum depression occurs in 14.5% of women after delivery and ranges from 10% in women aged 30 to 39 years to 23% in those less than 19 years of age (Reeves et al., 2011).

Schizophrenia is generally conceived of as a disease of abnormality in the brain. Schizophrenia is characterized by three types of symptoms: positive symptoms, negative symptoms, and cognitive symptoms. Positive symptoms are unusual thoughts or perceptions that are not present in “normal” people. Negative symptoms are an absence of normal behaviors and emotional states, and cognitive symptoms reflect deficits in attention, memory, and executive functions that permit planning and organizing thoughts and behaviors (NIMH, 2013). Positive, negative, and cognitive symptoms of schizophrenia are summarized in Table 28-2. Schizophrenia affects approximately 1% of the general public (NIMH, 2009b). This amounts to about 2.4 million people in the United States (Wexner Medical Center, Ohio State University, n.d.).

Anxiety disorders are a group of illnesses that result in chronic and overwhelming fear and anxiety that tend to grow progressively worse with time. Anxiety disorders include panic disorder, obsessive-compulsive disorder (OCD), post-traumatic stress disorder (PTSD), phobias, and generalized anxiety disorder. Panic disorder is characterized by episodes of intense fear without any identifiable basis. Panic is manifested in cardiac, respiratory, and gastrointestinal symptoms of distress (e.g., shortness of breath, palpitations) or fear of dying. Approximately 6 million people in the United States experience panic disorders. Full-blown recurrent panic attacks can be extremely disabling, particularly when those affected begin

to avoid places or situations in which attacks have occurred (NIMH, 2009a).

OCD manifests as persistent upsetting thoughts (obsessions) and the use of rituals (compulsions) to control the resulting anxiety. For example, an obsession with dirt may lead to constant hand washing. Performance of these rituals is distressing and interferes with daily life, but those affected cannot desist. OCD may be accompanied by other mental health problems such as eating disorders, depression, and other anxiety disorders (NIMH, 2009a).

PTSD, another form of anxiety disorder, arises in response to experiencing or witnessing a traumatic event and is characterized by nightmares, flashbacks, irritability, depression, and poor concentration. About 70% of the U.S. population has experienced at least one major traumatic event in their lives. Approximately 20% of these people develop PTSD. PTSD affects approximately 5% of the U.S. population or 1.5 million people at any given time and will affect about 8% of adults over their lifetimes (PTSD Alliance, n.d.). PTSD is characterized by the presence of three clusters of symptoms present for at least

Panic attacks can strike without warning and usually get worse over time. (David Stuart/Fotolia)

TABLE 28-2 Positive, Negative, and Cognitive Symptoms of Schizophrenia

<p>Positive symptoms: Symptoms present in people with schizophrenia that are not present in the general population</p> <ul style="list-style-type: none"> • Hallucinations: Seeing, hearing, smelling, or feeling things that no one else does • Delusions: Unchanging false beliefs that are not part of one's culture • Thought disorders: Unusual or dysfunctional ways of thinking, difficulty organizing thoughts or presenting them coherently, loss of thoughts, creation of meaningless words (neologism) • Movement disorders: Agitated or repetitive body movements or lack of movements and response (catatonia)
<p>Negative symptoms: Disruptions of normal emotions and behaviors</p> <ul style="list-style-type: none"> • "Flat affect": Lack of facial expression or monotonous voice • Lack of pleasure in everyday life • Lack of ability to begin and sustain planned activities • Speaking little, even when forced to interact
<p>Cognitive symptoms: Inappropriate thought processes</p> <ul style="list-style-type: none"> • Poor executive function: Inability to understand information and use it to make decisions • Trouble focusing or paying attention • Problems with working memory: Inability to use information immediately after learning it

Data from: National Institute of Mental Health. (2013). *Schizophrenia*. Retrieved from <http://www.nimh.nih.gov/health/topics/schizophrenia/index.shtml>

6 months. Symptom clusters include reliving the traumatic event through flashbacks or nightmares; avoiding thoughts, people, places, and things that recall memories of the event; and hypervigilance (PTSD Alliance, n.d.). Hypervigilance may manifest as irritability, aggression, or being easily startled (NIMH, 2009a). According to the National Institute for Mental Health (NIMH, 2009a), an estimated 7.7 million U.S. adults experience PTSD.

Phobias are the most common anxiety disorders and include social phobia and specific phobias. People with social phobia, or social anxiety disorder, feel overwhelming anxiety, embarrassment, or self-consciousness that make them incapable of interacting comfortably with others in everyday social situations. Social phobias may be related to one specific type of social interaction (e.g., speaking in public) or to broad categories of interaction. Specific phobias are extreme and unreasonable fears of something that pose little real danger (e.g., heights, being closed in). Approximately 15 million U.S. adults are affected by social phobias, and 19.2 million experience specific phobias (NIMH, 2009a).

Finally, general anxiety disorder is characterized by constant and excessive worry about everyday events. General anxiety disorder affects about 6.8 million U.S. adults (NIMH, 2009a). A given person may experience more than one type of anxiety disorder, and anxiety disorders frequently co-occur with other mental health problems such as depression, eating disorders, and substance abuse.

Eating disorders result in serious disturbances of one's everyday diet. Three types of eating disorders are common: anorexia nervosa, bulimia nervosa, and binge eating disorder. Anorexia nervosa is characterized by a strong resistance to maintaining a minimal weight for one's height and body type, by intense fear of gaining weight, and by a distorted body image that leads one to perceive oneself as fat even when significantly underweight (NIMH, 2011b). An estimated 1% to 4.2% of U.S. women experiences anorexia nervosa in their lifetimes,

with prevalence three times higher among women than men (Ekern, 2014).

Bulimia nervosa is characterized by frequent episodes of eating unusually large amounts of food followed by compensatory purging or other behaviors to prevent weight gain that usually occur at least twice a week. Because of the compensatory behaviors, many people with bulimia are able to maintain a normal weight (NIMH, 2011b). Approximately 1.5% of U.S. women and 0.5% of men have bulimia at some point in their lives (Ekern, 2014). Excessive overeating without compensatory purging and other behaviors is referred to as binge eating disorder. Binge eating contributes to obesity and the resulting increased risk for cardiovascular disease, hypertension, and other chronic physical health problems (NIMH, 2011b). An estimated 2.8% of the U.S. adult population engages in binge eating in their lifetimes, including 3.5% of women and 2% of men (Ekern, 2014).

Borderline personality disorder (BPD) is characterized by rapidly changing moods and resulting difficulty with interpersonal relationships and an inability to function effectively in society. BPD affects 1% to 2% of the U.S. population (NAMI, n.d.a). The characteristic mood changes of people with BPD occur rapidly, over a period of hours rather than days as is the case with depression or mania. The impulsivity that accompanies these mood changes may lead to self-injury or suicide, impulsive spending, or sudden shifts in attitudes toward others (e.g., from idealization to anger and dislike). People with BPD may see routine absences of significant others as evidence of rejection and abandonment and may resort to threats of self-harm or suicide in response (NIMH, n.d.d).

Autism spectrum disorders (ASDs), also called pervasive developmental disorders, tend to occur in young children and may be diagnosed as early as 18 months of age. Autism is characterized by persistent difficulties with social interaction and communication and restricted repetitive patterns of behavior or activity. Children with ASD have difficulty learning to

TABLE 28-3 Characteristic Symptoms of Selected Mental Disorders

Disorder	Characteristic Symptoms
Anxiety disorders <ul style="list-style-type: none"> • Panic disorder • Obsessive compulsive disorder • Post-traumatic stress disorder (PTSD) • Phobias • General anxiety disorder 	Symptoms: Feelings of fear/dread, trembling, restlessness, muscle tension, rapid heart rate, dizziness, lightheadedness, increased perspiration, cold hands and feet, shortness of breath
Autism spectrum disorders <ul style="list-style-type: none"> • Asperger syndrome • Rett syndrome • Childhood disintegrative disorder 	Symptoms: Deficits in social interaction and verbal and nonverbal communication, repetitive behaviors or interests, unusual response to sensory stimulation, delayed development
Borderline personality disorder	Symptoms: Chronic instability of moods with intense anger, depression, and anxiety lasting only hours, may be accompanied by periodic aggression, self-injury, or substance abuse, frequent changes in life goals and plans, impulsivity
Eating disorders <ul style="list-style-type: none"> • Anorexia nervosa • Binge eating • Bulimia nervosa 	Symptoms: Intense fear of gaining weight, altered body image, infrequent menses, recurrent and uncontrolled eating followed by purging, misuse of laxative, diuretics, enemas

Data from: National Institute of Mental Health, n.d.a, n.d.c, 2009a, 2011b. (See references at the end of this chapter for full citations.)

interpret social cues from others, which makes communication difficult. They may also under- or overreact to stimuli. Approximately one in 88 children is affected by ASD (NIMH, n.d.a).

In all likelihood, the figures presented here underrepresent the actual prevalence of mental illness in the United States and the world. Due to stigma, lack of knowledge, and lack of access to care, many people with mental health problems do not seek care and remain undiagnosed. This gap between the true prevalence of mental health disorders and those treated, or treatment prevalence, is referred to as the **treatment gap** (Henderson, Evans-Lacko, & Thornicroft, 2013). Symptoms characteristic of autism and other mental illnesses are presented in Table 28-3•.

Population Health Nursing and Mental Health and Illness

Population health nurses may play a significant part in the control of mental health problems with individuals and with population groups. Effective control includes assessment of risks for and factors influencing mental health problems, as well as the planning, implementation, and evaluation of health care programs directed toward mental health.

Assessing Mental Health Status

Factors related to each of the six categories of determinants of health influence the risk for and course of mental health problems for individuals and populations. Population health nurses will be actively involved in assessing for these risks as well as for the presence of mental illness in individual clients and in the population as a whole. Knowledge of factors in each of the categories will enable population health nurses to better promote mental health and contribute to control strategies for community mental health problems.

BIOLOGICAL DETERMINANTS. Biological factors influencing mental health problems include age, gender, and race or ethnicity; genetic inheritance; and physiologic function.

Age, gender, and race/ethnicity. Age influences mental health problems primarily in terms of the typical age at first onset of symptoms. Both children and adults develop mental health problems. One in three or four children has a mental disorder, and one in ten experiences serious mental disturbances. Over the course of their lifetimes one in four to five children can expect to meet criteria for a mental disorder with severe impairment. *The National Comorbidity Survey Replication—Adolescent Supplement* indicated a lifetime prevalence of 32% for anxiety disorder in adolescents and 19% for behavioral disorders. In addition, 40% of those who develop a mental disorder will experience more than one disorder, and 22% will experience severe distress or impairment (Merikangas et al., 2010).

Different mental disorders have their typical age of onset at different ages. For example, the median age for onset of anxiety among children and adolescents is 6 years of age, compared to 11 years for behavior disorders, 13 years for mood disorders, and 15 years for substance use disorders. The median age for all mental disorders is 14 years of age, and 75% of disorders develop before the age of 24. Only mood disorders typically start at older ages with onset typically in the 30s and 40s. There is an estimated 12-year gap between symptom onset and initiation of treatment for most people with mental disorders (OECD, 2011). Given the relatively young age of onset of these disorders, some authors have called for a greater focus on mental health promotion and prevention of mental illness rather than on treatment (Merikangas et al., 2010).

Depression is more common in older age groups than in children and adolescents. As much as 6.6% of U.S. elderly experience a major episode of depression in any given year. In

Children also experience mental health problems. (Tatyana Gladskih/Fotolia)

this age group, in particular, depression may complicate treatment for other chronic physical health problems (Akincigil et al., 2012).

Generally speaking, women are more likely than men to develop most mental disorders. One exception is ASDs, which occur five times more often in boys than girls (CSELS, 2013). Similarly, while equally prevalent in men and women, men develop symptoms of schizophrenia at earlier ages than women (late teens to early 20s vs. 20s and 30s for women) (NIMH, 2009b; Wexner Medical Center, n.d.). Schizophrenia rarely has its onset in childhood or over age 45, but there may be a prodromal period during adolescence characterized by withdrawal and increases in unusual thoughts and suspicions. This prodromal period is more apt to occur in adolescents with a family history of psychosis (NIMH, 2009b). Both social phobias and OCD may manifest in childhood, and approximately a third of people with OCD first developed symptoms as children (NIMH, 2009a). Eating disorders can manifest throughout life, but often begin in adolescence or young adulthood (NIMH, 2011b).

Women are less likely than men to be exposed to traumatic events at some point in their lives (51% vs. 61%) (Vogt, 2014), but are more than twice as likely as men to develop PTSD (PTSD Alliance, n.d.). The estimated prevalence for PTSD in women is 9.7% compared to 3.6% for men. Women are more vulnerable to sexual assaults and molestation, more likely to have experienced childhood neglect or abuse, and more likely to be affected by domestic violence or the sudden death of a loved one. It has been proposed that women's increased vulnerability to the effects of these traumas is because women's

sense of well-being is closely tied to the character of their relationships with others (Vogt, 2014).

In the 2007–2010 NHANES, women were more likely to report current depression at every age than men (NCHS, 2012b), and in the 2010–2011 National Health Interview Survey, 22% of women and 17% of men reported often feeling worried or anxious (NCHS, 2012a).

Although Blacks generally have a lower risk of substance abuse and mental disorders, such as depression and anxiety than Whites, this is not true among some subgroups of the population. For example, the prevalence of mental illness is higher in Caribbean-born Black men than U.S.-born Black men, but the reverse was found to be true for women. Similarly, mental illness rates were found to be lower among Somali-born Blacks than either U.S.-born Blacks or Whites. Among the elderly, however, African Americans were less likely than White elders to receive a diagnosis of depression even in the face of symptoms and were less likely to receive treatment (Akincigil et al., 2012). This finding suggests that there may be less difference in actual occurrence of disease than in its recognition.

Genetic inheritance. Genetics also appear to influence the incidence of some mental health problems. Various studies of families, twins, and adopted children provide strong evidence that some people have a genetic predisposition to develop schizophrenia. Apparently an inherited chemical imbalance in the brain is necessary for schizophrenia to develop, but its development is influenced by the probable interaction of multiple genetic and environmental factors. Siblings of persons with schizophrenia have a 7% to 8% risk of developing the disease, and the risk increases to 10% to 15% of children whose parents have schizophrenia. Risk of disease also increases with the number of family members affected (NIMH, 2009b; Wexner Medical Center, n.d.).

Genetic contributions to vulnerability are implicated in other mental health problems as well. For example, ASDs are believed to be influenced by multiple gene–environment interactions (Johnson, Giarelli, Lewis, & Rice, 2013). The effects of genetic influence, however, are apparent in findings that the chance of an identical twin whose sibling has ASD developing the condition is 35% to 90%. Risk decreases to 0% to 31% of non-identical twins. In addition, parents who have one child with ASD have a 2% to 28% chance of having a second child that is affected (CSELS, 2013).

The heritability of major depressive disorder is estimated at 31% to 42%, but no specific genes influencing transmission have yet been identified (Schutte, Davies, & Goris, 2013). Risk of depression may be as much as three to five times higher for people with a first-degree relative affected than for the general population, and risk seems to increase if the affected relative became symptomatic before 25 to 30 years of age. Similarly, a child of a parent with depression has a 5% to 30% risk of developing the disease. If both siblings and parents have depression, the estimated risk of developing the disease in other children is 50% for bipolar disorder and 30% to 40% for major depression.

Families with a history of depression may also have a history of other comorbid conditions, such as alcohol abuse and eating disorders. There is some evidence, however, that the genetic risk of major depression is mitigated by higher education and upward social mobility (Mezuk, Myers, & Kendler, 2013).

Genetic inheritance may also play a part in Alzheimer's disease and other irreversible dementias. For example, to date, three specific gene mutations have been associated with some forms of Alzheimer's disease (Schutte et al., 2013). Similarly, there is some evidence that genes may play a role in creating fear memories that lead to PTSD. There is also a suggestion that changes in the prefrontal cortex may modify responses designed to control stress when stress is perceived to be controllable. It is hypothesized that these changes may be activated by trauma, head injury, or mental illness, or modified by personality factors such as optimism or negativity or the availability of social support (NIMH, 2012a).

On the positive side, there is also some evidence that factors related to psychological well-being may also be heritable. Genetic influences have been noted with respect to emotional and social well-being (Keyes et al., 2010).

Physiologic Function. The interaction between mental health and physiologic factors is complex. The presence of physiologic conditions may increase one's risk for mental health problems. Conversely, mental health problems may pose risks for physiologic effects. Finally, the presence of either mental or physical conditions may complicate control of problems in the other realm.

There is considerable evidence that some mental health problems have a physiologic basis in brain chemistry and that the resulting neurophysiologic deficits are a major contributor to mental illness. For example, deficits in sensory processing result in the sensory-based behaviors typical of ASDs (Marco, Hinkley, Hill, & Nagarajan, 2011). Similarly, the presence of chronic physical illness, infection, malnutrition, and the effects of hormones and physical trauma have all been shown to play a part in the development of mental health problems. Infectious agents such as human immunodeficiency virus (HIV) and syphilis, for example, are implicated in the development of some forms of dementia. In addition, depression has been associated with declining CD4-T cell counts in people with HIV infection, speeding progression to AIDS and increasing mortality risk (Tsai et al., 2013). Physiologic differences also account for differential effects of psychotropic drugs in different racial and ethnic groups.

Mental health problems may also increase one's risk for physical illness. For example, anxiety and depression have been shown to increase the risk for the onset of coronary heart disease (CHD) and to affect survival in persons with existing CHD. Conversely, people recovering from myocardial infarction are at increased risk for major depressive disorders. Depression may also be implicated in falls among the elderly. Treatment for depression may also increase fall risk and fallers may be prone to anxiety and depression.

Pregnancy, as a physiologic condition, has been found to influence the incidence of depression. Although pregnancy is often considered a joyful event and depression is more often associated with the postpartum period, an estimated 10% to 20% of women experience some level of depression during pregnancy. Depression during pregnancy is also known as antepartum depression. A woman's risk for antepartum depression is increased by relationship problems, a past history of depression (or family history of depression), prior pregnancy loss, and other stressful life events. Depression during pregnancy may be misinterpreted as hormonal imbalance, and population health nurses may need to educate pregnant women, health care providers, and the public about antepartum depression. They may also need to advocate for access to counseling and treatment services for those affected. For example, although many health insurance plans cover care for the pregnancy itself, they may not provide coverage for counseling services related to antepartum depression.

Depression in the postpartum period is more common and better recognized than antepartum depression and may occur in one of three forms: postpartum blues, postpartum depression, or puerperal or postpartum psychosis. Postpartum blues are a mild form of depression characterized by tearfulness and anxiety. They are time-limited, and usually do not require treatment beyond emotional support. Postpartum depression and psychosis are more serious conditions that require treatment. Miscarriage, menstrual cycle difficulties, and menopause may also trigger depression, particularly in the context of a family history of depression.

Receiving a diagnosis of a chronic illness may also lead to depression or anxiety (Al-Modallal, Abuidhail, Sowan, & Al-Rawashdeh, 2010). Conversely, mental health problems of all kinds may interfere with treatment adherence for physical health conditions (Perry et al., 2010). The presence of some chronic physical health problems may also impede recognition of mental health problems. For example, people who are culturally Deaf (meaning they have been deaf from a young age, use American Sign Language [ASL], and perceive themselves to be members of a unique cultural group) may not be recognized as having depression. Many words for depression have no equivalent in ASL, and depression screening tools have not been normed on this population. In addition, some signs used to connote depression are unrecognizable even to people who use ASL. In focus groups with culturally Deaf people, use of signing interpreters was considered intrusive in mental health encounters, and most participants reported never having been asked about depression even in the face of obvious symptoms (Sheppard & Badger, 2010). Similarly, other people who have difficulty with communication (e.g., those with aphasia or dementia) may have unrecognized depression or other mental health problems. The *Focused Assessment* below provides some questions for evaluating the contribution of biological determinants to community mental health problems.

FOCUSED ASSESSMENT

Assessing Biological Determinants Influencing Mental Health and Illness

- Is there a family history of mental health problems?
- Is there evidence of heritable personality traits that promote mental health (e.g., optimism)?
- Are there any existing physical health conditions that may contribute to mental health problems? What effects do personal physical health conditions or those of family members have on mental health? Do physical health problems or their treatment cause signs and symptoms suggestive of mental health problems?
- Does the presence of a mental health problem complicate treatment of physical health conditions?
- Does the present of physical health problems impede recognition of mental health concerns?

PSYCHOLOGICAL DETERMINANTS. Psychological considerations to be addressed relative to community mental health problems include psychological risk factors, psychiatric comorbidity, coping skills, and suicide potential.

Psychological risk factors for mental health problems.

Personality traits, difficult temperament, experience of stressful life events, and below-average intelligence are some of the psychological factors that have been associated with the development of mental health problems. Some people's personalities appear to place them at increased risk for mental health problems. For example, people who are excessively critical or who have difficult temperaments may alienate others, receiving less social support for dealing with everyday sources of stress that we all encounter.

Psychological stress appears to play an important part in the development of mental disorders (CSELS, 2012). Stress and an emotionally charged environment are also implicated in symptomatic relapses in clients with schizophrenia. Conversely, decreasing stress and increasing personal and interpersonal competencies appear to contribute to mental health and to control of existing mental health problems. Stressful life events may contribute to situational depression or exacerbate major depressive disorders.

Psychiatric comorbidity. Clients with one mental disorder may concurrently experience other disorders. This co-occurrence of two mental disorders is referred to as psychiatric comorbidity. **Dual diagnosis** is the term commonly used to indicate the co-occurrence of a substance abuse disorder with one or more other psychiatric diagnoses. Several forms of comorbidity may occur. For example, preexisting depression and anxiety disorders increase one's risk for PTSD following a traumatic event (Vogt, 2014). Similarly, PTSD, depression, and anxiety disorders frequently co-occur with substance abuse disorders (NIMH, 2009a). Co-occurring PTSD and depression may also be linked to increased suicide risk in some populations. People with borderline personality disorder also have high rates of co-occurring depression, anxiety disorders, substance abuse, and

eating disorders, and are at high risk for suicide (NIMH, n.d.d). Similarly, people with panic disorder often experience depression and/or substance abuse as well (NIMH, 2009a).

The presence of comorbidity complicates treatment for any given mental illness, and population health nurses working with clients with comorbid conditions or dual diagnosis may need to assure that clients receive treatment for all the disorders that they experience. Similarly, the combination of HIV infection, depression, and homelessness increases the difficulty of treating depression as well as HIV infection (Tsai et al., 2013).

Coping skills. The extent of an individual's coping abilities mediates the effect of stress on both physical and mental health. Coping strategies are culturally determined, and different cultural groups may display different approaches to coping with life's stress. Specific types of coping strategies have been linked to various mental disorders. For example, adolescents with schizophrenia frequently use emotion-focused coping, particularly in the face of anxiety and fear (Lee & Schepp, 2011). Development of problem-focused coping, however, contributes to mental health and may help in dealing with symptoms associated with mental illness. Negative thinking, excessive worry, and a sense of lack of control of one's life are personal traits that have been associated with depression.

Some clients with mental health problems may turn to substance use or abuse as a coping strategy, which may contribute to the potential for dual diagnosis. Other clients may engage in other, more or less adaptive coping strategies for dealing with stress or with symptoms. Research has indicated, for example, that clients with schizophrenia have fairly well developed coping skills for controlling their symptoms. Some of these coping strategies are healthier than others and can be encouraged by population health nurses working with clients with schizophrenia and their families. One category of coping skills displayed by schizophrenic clients dealt with behavior control by means of distraction (e.g., listening to music, reading, playing an instrument or writing), physical activity (e.g., running), asking for help or interacting with sympathetic others, prayer, and meditation. Other coping strategies include avoiding thinking about

or ignoring misperceptions, shifting one's attention to other thoughts, engaging in future planning or problem solving. An innovative suggestion is to engage selectively with voices, informing them that they are not welcome unless they have useful information and requesting that they make an appointment and treat the patient with respect. Other strategies, such as telling voices to "shut up" or doing as told by voices are less healthy approaches to dealing with symptoms of schizophrenia. Similarly, passive acceptance of hallucinations may result in hallucinations consuming one's life. Mindfulness, on the other hand, is a healthier approach in which the client acknowledges voices, but does not agree to be guided by them, relying on his or her own decision-making abilities (Brichford & Jones, 2009).

Suicide potential. Both the stress that contributes to the development of mental disorders and the hopelessness often associated with having a mental disorder place clients at increased risk for suicide, and population health nurses must be particularly alert to evidence of suicidal ideation in clients with mental health problems. Depression, in particular, whether due to major depressive, unipolar, or bipolar disorder or to situational factors, increases the potential for suicide (NIMH, n.d.b). Suicide risk is also increased among people with schizophrenia with about 10% of those affected attempting suicide (NIMH, 2009b). Those with PTSD and borderline personality disorder are also at increased risk for suicide (NIMH, n.d.c, 2009a). The nurse should explore with the client any suicidal tendencies or thoughts of suicide. Suicide tends to occur most frequently when clients are recovering from an episode of depression; this is because the severely depressed client probably does not have the energy to commit suicide. Suicide is addressed in more depth in Chapter 30. Possible questions to assist population health nurses in identifying psychological factors contributing to mental health and illness are included in the *Focused Assessment* below.

ENVIRONMENTAL DETERMINANTS. Physical environmental factors influence the development and course of some mental health problems. Chronic exposure to lead and other toxins may cause mental retardation and other forms of mental illness. Cataclysmic environmental events may also contribute

to PTSD and depression. For example, many survivors of hurricane Katrina evacuated from New Orleans experienced PTSD for several years after the event. PTSD was also associated with depression, particularly in people with debilitating physical illnesses. For instance, 24% of people with end-stage renal diseases affected by the hurricane developed PTSD and depression (Edmondson et al., 2013). Disasters may also interrupt treatment for many forms of mental illness.

Seasonal changes may also contribute to mental health problems, as in the case of seasonal affective disorder. **Seasonal affective disorder (SAD)** is a form of depression that varies with the seasons, resulting in depression in the fall and winter when exposure to natural light is diminished. For some people, experience of symptoms is reversed, with depression occurring in the spring and summer. The incidence of SAD increases at greater distances from the equator, and some people with bipolar disorder may experience a degree of mania in spring or summer (Mayo Clinic Staff, 2011). Environmental considerations in mental health problems are addressed in the *Focused Assessment* provided on the next page.

SOCIOCULTURAL DETERMINANTS. A number of sociocultural determinants influence risk for and treatment of mental health problems. These factors include societal disorganization, economic factors, family relationships and social support, culture, and societal attitudes, stigma, and societal policies related to mental health and illness.

Societal disorganization and immigration. As noted in Chapter 25, social upheaval such as war and disaster increases the incidence of mental health problems in the populations affected, particularly when the effects are long-lasting. Immigration, which may result from social upheaval, has also been linked with a high incidence of mental disorders. Research has suggested that the circumstances of immigration, for instance, if it was planned or unplanned, influence its effects on mental health and illness. In one study of Latinos, for example, being forced to immigrate was associated with increased distress, particularly among women, Cubans, and Puerto Ricans (Torres & Wallace, 2013). Immigration from Mexico to the United States has been associated with increased risk of mental illness, particularly in

FOCUSED ASSESSMENT

Assessing Psychological Determinants Influencing Mental Health and Illness

- What life stresses is the client experiencing? Does stress contribute to or exacerbate mental health problems? How does the client cope with stress?
- What signs and symptoms does the client exhibit that suggest the presence of mental health problems?
- What is the extent of adaptation to the mental health problem? How does the client cope with the problem?
- Is there existing psychiatric comorbidity? If so, what form does it take?
- Is the client at risk for suicide as a result of the mental health problem?

FOCUSED ASSESSMENT

Assessing Environmental Determinants Influencing Mental Health and Illness

- Have environmental disasters contributed to the incidence and prevalence of mental health problems in the population?
- Have environmental disasters complicated treatment for existing mental health problems?
- Do environmental pollutants contribute to the incidence of mental health problems?
- Are there seasonal fluctuations in the incidence or severity of particular mental health problems? If so, when do these fluctuations occur?

third generation or higher Mexican Americans, who may have twice the risk of mental illness as non-immigrants (Orozco, Borges, Medina-Mora, Aguilar-Gaxiola, & Breslau, 2013). Immigration is associated with multiple stressors, including discrimination, issues related to legal status, and separation from family support systems. Discrimination, in particular, may lead to mental health problem among immigrants.

Mental health problems are also influenced by more contained social events. For example, the risk of depression increases with recent divorce or separation, unemployment, and bereavement. Inability to work and stresses associated with low income have also been associated with mental illness, as have overcrowding and living in an area with a high rate of disorganization.

Socioeconomic Factors. Economic and employment factors may also influence one's mental status. The Center for Surveillance, Epidemiology, and Laboratory Services (2012) has indicated that poverty and other economic circumstances are potential contributors to mental illness. For example, mortgage delinquency was associated with depression as well as less access to care during the height of the mortgage foreclosures in 2009 (Alley et al., 2011).

Employment factors may also influence mental health and mental illness. Job strain and an increase in the psychological demands of one's job have been linked to the incidence of major depression (Smith & Bielecky, 2012). Similarly, jobs that entail exposure to trauma are also associated with mental health problems. For example, health care workers who respond to trauma victims are at risk for PTSD (PTSD Alliance, n.d.). Likewise, military personnel exposed to combat conditions are at risk for a variety of mental disorders (Maguen, Bosch, Marmar, & Seal, 2010). Becoming suddenly unemployed is a risk factor for depression, which may be intense at first due to "unemployment shock," then taper off, and then become worse if the length of unemployment extends and job searches are fruitless (OECD, 2011).

Mental health problems may also interfere with work. Worldwide, 60% to 70% of people with common mental health problems (CMDs) are employed compared to 75% to 85% of those without mental health problems. Employment rates are closer to 45% to 55% among those with severe mental disorders (SMDs). Most people with mental health problems want

to work but may have difficulty finding or keeping a job. People with CMDs are two to three times more likely to be unemployed than those without problems, and those with SMDs are six to seven times more likely to be unemployed. They may also be employed in low paying jobs that combine high psychological demands and low decision latitude (OECD, 2011).

Mental health problems may contribute to workplace absences and reduced productivity. For example, 80% of people with SMDs in one international study reported reduced productivity in the prior 4 weeks, compared to 69% of those with CMDs and only 26% of people without mental health problems. There is also a worldwide increase in the rate of disability claims related to mental health issues. In addition, people may move to disability benefits too soon or be on them too long without attempts to find or fit them for successful employment. For example, an estimated half of people with SMDs receive disability benefits and the other half receives some other form of benefits. The Organisation for Economic Cooperation and Development (2011) has indicated a need for sickness monitoring and early intervention for people with mental health problems to minimize the personal and societal effects of mental illness.

Employment is often beneficial for mental health and may aid recovery in the face of mental illness. Key workplace variables that have been identified as preventing worsening of mental health problems among the mentally ill include good management characterized by support, adequate feedback, and recognition of effort. Unfortunately, such conditions are only experienced by about 60% of people with SMDs and 70% of those with CMDs (OECD, 2011). Population health nurses in occupational settings can help to identify employees with mental disorders and advocate for assessment of work capacity and meeting of support needs.

Family relationships and social support. Family interactions may also influence the development and course of mental health problems. For example, women experiencing parenting stress are more likely to report poor mental health than those without such stress. High levels of negative emotional expression have also been associated with anorexia nervosa and depression. Conversely, warmth and positive family relationships may have a protective effect against mental health problems or

assist family members to cope more effectively when problems do occur.

Social support may assist clients to cope with the stresses of life and prevent mental health problems. Lack of social support, on the other hand, may increase the risk of mental illness, contributing to the feelings of isolation and poor social skills common among people with mental health problems.

Abuse may also contribute to the development of mental health problems. For example, gender abuse resulting from atypical gender presentation and transgression of gender norms has been linked to high levels of depression in male-to-female transgender individuals. Gender abuse may occur both within and outside of the family constellation (Nuttbrock et al., 2013). Spouse abuse has also been linked to depression, anxiety disorders, and substance abuse (Al-Modallal et al., 2013). Trafficking and sexual exploitation are also associated with PTSD, depression, and anxiety disorders. Abuse and trafficking will be addressed in more detail in Chapter 30.

Cultural factors. The effects of culture on mental health are many and pervasive. Culture defines what constitutes mental illness for members of a group, and that definition may not always conform to the diagnostic criteria established in the *DSM-5*. What may be seen as abnormal behavior or feelings in one culture may be perfectly normal in another. Similarly, culture mediates one's experience of distress and how one expresses that distress. Culture, for example, creates what are known as "idioms of distress" or typical ways of expressing mental discomfort. In many cultural groups, for example, mental distress is expressed in terms of somatization. **Somatization** is the expression of mental or emotional distress in terms of physical symptoms. Diagnostic criteria contained in the *DSM-5* are based on Western-Anglo experience, and it is unclear how applicable diagnostic criteria are to members of other cultural groups. Some cultures also have recognized culture-bound syndromes generally reflecting concepts of mental illness that are culture-specific and fall outside Western psychiatric practice. Culture-bound syndromes were discussed in Chapter 5.

Cultural differences in diagnostic criteria, expressions of distress, and meanings and value attributed to different symptoms may result in misdiagnosis in cross-cultural encounters. For example, in a qualitative study among African American men, participants described life events that resulted in stressors and led to "the funk" or depression. If not resolved, the funk resulted in a "breakdown," but the men rarely sought assistance for these feelings (Bryant-Bedell & Waite, 2010). In another study, Jordanian women who experienced depression as a result of spousal abuse rarely identified their emotional response as depression and so did not seek care (Al-Modallal et al., 2010). Language barriers between provider and client also increase the potential for misdiagnosis, as do diagnostic measurements that are not linguistically or culturally sensitive.

Culture also influences expectations regarding treatment that may enhance or impede compliance with therapy.

Members of many cultural groups engage in the use of herbal remedies. For this reason, they may expect psychotropic medications to act rapidly, as most herbals do. The need to build effective blood levels of medications may be difficult for clients in these cultural groups to understand. Inability to see immediate results may lead to discontinuation of pharmacotherapy. Herbal therapies may also interact with prescription medications to impede or enhance their effects, contributing to therapeutic ineffectiveness or adverse reactions to medications. Increasing use of complementary and alternative medicine (CAM) has been reported among persons with psychotic disorders. In one study, for instance, 88% of people with schizophrenia had used CAM in their lifetimes, and 68% in the prior 12 months (Hazra et al., 2010). In another study, 45% of Asian Americans with probable psychiatric diagnoses had used CAM alone, 26% used CAM in conjunction with conventional mental health services, and 29% had used conventional services alone (Choi & Kim, 2010).

Societal attitudes, stigma, and policy issues. Culture also contributes to the way people view mental illness and to the degree of stigmatization encountered by those who experience mental illness. Stigmatization is characterized by bias, distrust, stereotyping, fear, embarrassment, anger, and avoidance. Stigmatization has the effect of reducing willingness to seek help and thereby reduces access to needed care.

The response to perceived stigma is mediated by culture. For example, members of many ethnic groups may fail to seek care for psychological problems as a result of perceived stigma or because of perceived incongruence between group cultures and the Western mental health care system. Cultural barriers to obtaining mental health services include racial and cultural biases and inappropriate services, philosophical differences regarding disease causation or treatment, cultural attitudes to seeking help, language barriers, a lack of bilingual and culturally sensitive providers, and clients' lack of knowledge about available services. Clients from ethnic cultural groups may also be subjected to *language discrimination*, being treated unfairly because of language differences or accented speech. As we saw earlier, such factors also influence recognition of depression among the culturally Deaf.

Stigmatization of the mentally ill may also decrease their access to needed resources and opportunities, such as those related to employment or housing. For the individual, stigma leads to low self-esteem, hopelessness, and social isolation. Clients with mental illness are faced with the same kinds of decisions regarding disclosure that were discussed in the context of sexual orientation and gender identity in Chapter 20. At the population level, stigmatization influences public willingness to pay for services for the mentally ill or to locate treatment facilities in residential neighborhoods.

Stigma and the discrimination that results from belonging to a stigmatized group may also contribute to mental health problems. As we saw in Chapter 20, the stigma attached to nonheterosexual orientation has been associated with higher

rates of suicide and depression. Discrimination has been reported by 21% of gay, lesbian, and bisexual individuals and is linked to higher incidence rates for mental illness in these populations than in the heterosexual population. Similarly, racism experienced in the general community and homophobia among heterosexual friends have been linked to depression and anxiety disorders in African American, Asian American and Pacific Islander, and Latino men who have sex with men (Choi, Paul, Ayala, Boylan, & Gregorich, 2013).

Stigma encompasses four social-cognitive processes that influence people's perceptions of and behavior toward those who are different, including those with mental illness. These four processes include cues, stereotypes, prejudice, and discriminatory behavior. Cues may be physical symptoms (e.g., tics or repetitive behaviors), social skills deficits, physical appearance (e.g., flat affect), or labels (e.g., a mental illness diagnosis) that trigger cognitive associations with stereotypes. Stereotypes may include some of the core perceptions reported below, such as incompetence, violence, or tendencies to criminal behavior that one believes are typical of people with a particular mental illness or of mental illness in general. These stereotypes then lead to prejudice against people with mental illness that are often acted upon in discriminatory behaviors (Cummings, Lucas, & Druss, 2013).

Stigma occurs at three levels: institutional, community, and individual. Institutional stigma results in discriminatory legislation, funding, and availability of services (Henderson, et al., 2013). Evidence of societal attitudes and the stigma associated with mental illness lies in the number of the mentally ill who are incarcerated in correctional facilities. Mental illness may contribute to unlawful behaviors or to incarceration as an alternative to mental health care. A study by the Treatment Advocacy Center described U.S. corrections institutions as the "new mental hospitals" (Torrey, Kennard, Eslinger, Lamb, & Pavle, 2010). The report further noted "We have now returned to the conditions of the 1840s by putting large numbers of mentally ill persons back into jails and prisons" (Torrey et al., 2010, p. 1). In 2010 in North Dakota, for example, an equal number of mentally ill persons were incarcerated as were hospitalized. In states like Arizona and Nevada, the number of incarcerated mentally ill was 10 times the number hospitalized. Overall, from 1980 to 2009, the U.S. prison population increased fivefold (Nicosia, MacDonald, & Arkes, 2013). In part, these figures are the result of massive closures of psychiatric hospital beds. From 1955 to 2005, for example, the rate of psychiatric beds decreased from one bed per 300 population to one per 3,000 (Torrey et al., 2010). These closures were well intentioned and resulted from a move to treat persons with mental illness in community settings. Unfortunately, community treatment capacity has never been equal to the demand for services (Torrey et al., 2010), and the per capita bed rate has receded to 1850 levels with 14 beds per 100,000 population in 1850 and 14.1 beds per 100,000 in 2010. In 2010, the number of beds available was less than 28% of the estimated need (Treatment Advocacy Center, 2012).

The loss of in-patient psychiatric beds has also resulted in patients with mental illnesses being shunted to other sectors of

society. For example, the number of in-patient beds for mental illness in the Veterans Administration (VA) declined from 43,894 in 1999 to 40,928 in 2007 despite increases in veterans from Iraq and Afghanistan who experience myriad mental health problems. In addition, the average length of stay decreased from 33 to 19 days. This decline has been termed the "disaster of the past," and has resulted in a process of **transinstitutionalization**, or movement from one category of institution to another. Increased rates of incarceration are one example of transinstitutionalization. In the VA system, persons with mental illness were relegated to nursing homes that were ill-equipped to deal with mental illness treatment (Bowersox, Szymanski, & McCarthy, 2013). Transinstitutionalization results in a significant negative impact on correctional systems, emergency departments, and other segments of society. There is also an association between bed availability and violent crime, including homicide, further adding to the societal costs of not addressing mental health issues (Treatment Advocacy Center, 2012).

Community stigma, the second level of stigma attached to mental illness, is reflected in public attitudes and behaviors (Henderson et al., 2013). An international study conducted in 16 countries indicated that while large segments of the population believe that mental illness reflects disease processes and that the mentally ill can be helped, the majority of people exhibited several core elements of prejudice against people with schizophrenia. These elements of prejudice centered on not wanting those affected to associate with children (e.g., as teachers or child caretakers), not wanting them to marry into one's family, and perceptions of unpredictability or tendencies to violence against self or others. Less widely held, but still significant prejudices, related to perceptions of unproductivity, unsuitability for leadership positions or public office, and perceptions that the mentally ill were difficult to interact or communicate with (Pescosolido, Medina, Martin, & Long, 2013).

At the individual level, persons with mental illness may experience discrimination or stigma. In addition, people with mental illnesses may internalize stigma, and begin to self-stigmatize. Self-stigma may interfere with help-seeking behaviors, treatment adherence, feelings of self-efficacy, and the ability to achieve personal goals. Some authors have suggested that a process of "coming out" or disclosure of one's mental illness may be liberating and empowering, as suggested by the experience of persons in gender minority groups. Assistance with coming out employs a cognitive behavioral approach in which people are guided to frame self-stigma as irrational self-statements to be challenged and to invalidate through examination of one's personal strengths, acceptance of self, and mindfulness. Research has indicated that, like members of gay, lesbian, bisexual, and transgender groups, persons with mental illness who identify with a mental illness support group are more likely to participate in peer support activities (Corrigan, Kosyluk, & Rüsck, 2013).

As noted by some authors, the primary challenge is to identify and implement interventions to change attitudes and decrease discrimination against those suffering from mental

illness (Pescosolido et al., 2013). Legislation has made some strides in overcoming institutional stigma by prohibiting discrimination. Three major pieces of legislation have been enacted in the United States that attempt to prevent discrimination against people with mental illnesses. Each of the three have in common expansion overtime to include persons with mental illness, differential protections for persons with mental illness, implementation challenges related to label avoidance, and an explicit exclusion of substance abuse disorders from protective provisions. **Label avoidance** is the failure to seek the protections afforded by antidiscrimination legislation for fear of being further stigmatized and discriminated against if one admits to membership in a protected group (Cummings et al., 2013).

The first piece of legislation was the Education for All Handicapped Children Act of 1975. Initially drafted to encompass only certain physical handicaps, the Act was later amended to include psychologically handicapping conditions as well. Amendments also expanded coverage to preschool children and to conditions such as attention deficit hyperactivity disorder (ADHD). The second legislative effort to curb discrimination was the Americans with Disabilities Act of 1990, which prohibited workplace discrimination against people with disabilities. Again, the original legislation did not include disabilities due to mental health problems or those that were controlled by medication until amended in 2008. Finally, the Mental Health Parity and Addiction Equity Act of 2008 was expanded by the Affordable Care Act to mandate incorporation of mental health and substance abuse coverage in essential health insurance benefits packages. Unfortunately, the original

provisions of the law only applied to large employers and state insurance exchanges (Cummings et al., 2013).

The Community Preventive Services Task Force (CPSTF) conducted a systematic review of research on the effects of legislation to increase parity in mental health services as compared to physical health services. The task force found sufficient evidence to recommend passage of comprehensive mental health parity legislation, noting that such legislation increased access to care, decreased out-of-pocket spending for mental health services, increased service utilization among those in need, increased treatment access, decreased the percentage of people who reported poor mental health, and decreased suicide rates without causing substantial increases in insurance costs for services. At the time of the review, 49 states and the District of Columbia had enacted some form of mandatory parity legislation for mental health services. In 2014, the Affordable Care Act expanded federal parity requirements to new health insurance plans in individual and small group markets (CPSTF, 2014).

Unfortunately, legislation can only address one aspect of stigma—outright discrimination. Legislation may also have a certain symbolic value in that it indicates that those with mental illness should not be discriminated against and may help to change societal values and perceptions. Antidiscrimination laws must be combined with anti-stigma campaigns that are directed to the community and individual levels of stigma (Cummings et al., 2013). One such initiative is the California Mental Health Services Act of 2004, which funds statewide programs designed to reduce the stigma of mental illness (California Department of Mental Health, 2009). The initiative is described in the *Evidence-Based Practice* feature below. The *Focused Assessment*

Evidence-Based Practice

Reducing Stigma

The California State Mental Health Services Act, passed in 2004, was designed to fund a series of evidence-based initiatives throughout the state to decrease the stigma of mental illness. Initiatives funded by the Act employ multiple evidence-based strategies related to social marketing, creating public awareness, promoting cultural competence among providers, and capacity building among those affected by mental illness (Clark et al., 2013).

Funded initiatives are supported by a 1% tax on people with annual incomes over \$1 million, and 20% of funding is directed toward prevention and early intervention strategies. The intent of the legislation was to improve attitudes toward the mentally ill, decrease stigma, and promote help-seeking behavior. By 2008, more than 100,000 people had participated in planning efforts for programs to reduce stigma. The initiative applies scientific evidence to the development of interventions in one of four strategic directions designed to reduce the stigma attached to mental illness (Clark et al., 2013).

The four strategic directions, as laid out in the *California Strategic Plan on Reducing Mental Health Stigma and Discrimination*, include:

- Creating a supportive environment with social norms that acknowledge that mental health is an integral component of well-being and creating widespread public understanding of mental health and mental illness.
- Promoting changes that encourage respect for and protection of the rights of those with mental illness.
- Upholding and advancing laws that identify and eliminate discriminatory policies and practices.
- Increasing knowledge of programs and practices that effectively decrease discrimination and stigma and incorporate community participation in related activities (California Department of Mental Health, 2009).

FOCUSED ASSESSMENT

Assessing Sociocultural Determinants Influencing Mental Health and Illness

- How does the population define mental health and mental illness? Do these definitions hamper recognition of mental health problems or help-seeking behaviors?
- What are the effects of mental health problems on social interactions (with family and others)?
- What are the economic effects of mental health problems on those affected? On the overall population?
- What are societal attitudes to mental health problems? Do they hamper control efforts?
- Is there social stigma attached to having particular mental health problems? What effect does stigma have on clients' willingness to seek care? On public willingness to fund care?
- What effect, if any, do cultural beliefs and behaviors have on mental health problems?
- Do mental health problems contribute to the risk of homelessness for those affected?
- What social support systems are available to persons with mental health illness? What support is available to their families?
- How do social factors (e.g., unemployment) influence mental health problems?
- How do the mental health problems affect community members' ability to work?

above includes questions to assess sociocultural determinants influencing community mental health and illness.

BEHAVIORAL DETERMINANTS. Personal behaviors also influence the development and course of mental health problems, but it is often difficult to determine the direction of influence. In some cases, people engage in drug, alcohol, and tobacco use as a means of coping with symptoms of mental illness. Other times, substance use contributes to mental illness or affects treatment. All that is known for sure is that people with mental illness tend to engage in more substance use than those without illness.

In 2009–2011, 36% of people with mental illness smoked, compared to 21% of those without mental illness. In addition, people with mental illness smoked 31% of all cigarettes consumed in the United States (Gfroerer et al., 2013). In the 2007, National Health Interview Survey, smoking rates increased with the number of comorbid psychiatric conditions, and mental illness was associated with lower quit ratios and less success with smoking cessation (McClave, McKnight-Eily, Davis, & Dube, 2010). Regular smoking has been linked to increased risk of new onset mood or anxiety disorders, particularly among people 18 to 49 years of age. In addition, the level of risk increases with the number of cigarettes smoked (Mojtabai & Crum, 2013). Among people with schizophrenia, 75% to 90% are nicotine addicted, and smoking may reduce the effectiveness of antipsychotic medications (NIMH, 2009b). Alcohol and drug use also have implications for mental illness. For example, veterans who are problem drinkers have been found to have a risk of PTSD 2.7 times that of nondrinkers. Problem drinking has also been linked to depression and chronic fatigue syndrome in this group (Coughlin, Kang, & Mahan, 2011). Conversely, men with PTSD are also at risk for substance abuse disorders although this association has not been demonstrated in women (Vogt, 2014).

Physical activity and sexual activity are two other behavioral considerations in an assessment of mental health problems. For example, clients with mental illness have been shown to be less physically active and have a greater risk for obesity than those without illness. On the other hand, increased physical activity has been associated with improvements in anxiety and depression (NAMI, n.d.b).

Sexual activity is an area that is often ignored in the care of clients with mental illness. Attention should be given to meeting sexual needs as well as to assessing high-risk sexual behaviors that may be exhibited by some mentally ill individuals. Sexuality issues are complicated by possible links with childhood sexual abuse, the sexual content of positive symptoms in clients with schizophrenia, sexual disinhibition in some conditions, and medication side effects such as diminished libido and disabling extrapyramidal effects that promote distancing and social isolation by other people. Use of safe sexual practices and contraception are other sexual behaviors that should be assessed. Sexual orientation and gender identity have also been linked to mental illness, particularly to depression and anxiety disorders. For example, a meta-analysis of relevant research indicated that the lifetime incidence of depression and anxiety disorder was 1.5 times higher in the lesbian, gay, and bisexual population than in the general population, and suicide risk was nearly 2.5 times higher (Choi et al., 2013). Depression related to gender abuse has also been linked to high-risk sexual behaviors (Nuttbrock et al., 2013). The *Focused Assessment* on next page addresses behavioral determinants influencing mental health problems.

HEALTH SYSTEM DETERMINANTS. The health care system is fragmented with respect to mental health promotion and illness prevention. The care provided targets SMDs, and much of the treatment evidence and knowledge addresses this

FOCUSED ASSESSMENT

Assessing Behavioral Determinants Influencing Mental Health and Illness

- Does alcohol or drug use influence mental health problems or their effects in the population? Are alcohol or drugs used in an effort to self-manage symptoms?
- What effect, if any, does exercise have on mental health problems in the population?
- Does smoking influence mental health problems?
- What effect do mental health problems have on self-care behaviors among those affected?
- To what extent do mental health problems or their treatment influence sexual activity?

end of the disease spectrum rather than the more commonly encountered, less severe forms of disease. Worldwide, an estimated 80% of people with CMDs receive no treatment, and as much as 50% of those with SMDs do not seek or receive care. Those with CMDs who do receive treatment, primarily receive medications, which are not very effective. Pharmacotherapy for SMDs, on the other hand, is more effective, but frequently does not completely control symptoms (OECD, 2011). Furthermore, there are wide discrepancies in treatment among subgroups in the population, with some groups receiving little to no treatment.

The issue of parity with respect to health insurance coverage of mental health treatment was addressed earlier. Lack of parity, however, is one contributing factor in lack of service access. People with mental health problems tend to use emergency departments (EDs) for acute psychiatric emergencies, injuries, or illness related to their mental illness or when primary care is unavailable. In one study, for example, 10% of all ED visits in North Carolina were related to mental illness diagnoses, with 61% of those visits related to stress, depression, or anxiety. Persons with mental illness seen in EDs are admitted to the hospital twice as often as those without mental illness, and the rate of hospitalization is above 50% for older people with mental illness (Hakenewerth, Tintinallis, Waller, Ising, & DeSlem, 2013).

It has long been noted that people who do seek care for mental health problems most often do so in primary care settings. In part this may relate to greater ease of access, but may also be the result of perceptions of stigma attached to mental illness care. Competing demands in the primary care setting make attention to mental health issues difficult. In addition, managed care carve-outs for mental health services increase institutional level stigma due to unequal funding for services. As a result, some authors have called for better integration of primary care and behavioral health care in one setting. It is often argued that integrated care is too expensive, but fragmented care is actually more costly and results in suboptimal outcomes. Advantages to the integration of primary care and mental health services include primary prevention of mental illness, early risk factor identification and modification, early recognition and treatment of mental illness, and potentially better outcomes (Shim

& Rust, 2013). Integrated treatment services could also increase the use of evidence-based treatment approaches by clinicians who are more knowledgeable regarding mental illness treatment.

A report from the Institute of Medicine (2006) indicated that many providers failed to use evidence-based practices in treating mental disorders. Other problems identified in the report included medication errors; excessive use of restraints and seclusion resulting in 150 deaths each year; and failure to provide needed mental health treatment even for people who have access to health care services (IOM, 2006). Additional system flaws include coercion of clients into treatment, a poorly developed structure for assessing treatment outcomes, limited use of information technology to coordinate care, and an educationally diverse workforce (IOM, 2006). Based on the report, the IOM made two overarching recommendations for strengthening the mental health care system in the United States.

These recommendations included treatment services for mental and substance abuse disorders grounded in an understanding of mind—body interactions and tailoring of strategies for health system redesign recommended in *Crossing the Quality Chasm* to the care of mental health problems (Institute of Medicine, 2006).

Other, more specific recommendations include support for client decision making; lack of coercion; dissemination of evidence-based practice information; development of quality assessment instruments and outcome measures; better linkages between health care organizations, providers, and systems; and coordination of health and social services to best meet client needs. In addition, mental health care should be addressed as fully as care for physical health problems, and the Congress and state legislatures should mandate standard health insurance benefits that improve mental health care coverage. Computer technology should be used to standardize billing and information processes, and attention should be given to developing an adequate mental health workforce (IOM, 2006).

Tips for assessing health system factors influencing risk for mental health problems are presented in the *Focused Assessment* on next page. A tool for assessing the broad range of factors contributing to mental health problems is included on the student resources site.

FOCUSED ASSESSMENT

Assessing Health System Determinants Influencing Mental Health and Illness

- What are the attitudes of health care providers to persons with mental health problems?
- Are health care providers alert to signs and symptoms of mental health problems?
- What treatment facilities are available to persons with mental health problems? How adequate are they? What types of therapy are available? How effective are they?
- Are diagnostic and treatment services available and accessible to persons with mental health problems?
- To what extent are primary care and mental health care services integrated in the health care system?
- Is there parity in health insurance coverage for mental health services?
- Does the individual client exhibit treatment side effects or adverse effects?
- Does treatment for other health problems cause or exacerbate mental health problem in the population?

At the individual client level, the population health nurse would assess clients for evidence of mental health problems and for individual characteristics and circumstances that may be contributing to mental health difficulties. For example, the nurse might identify poor coping skills, unemployment, or family dysfunction as factors contributing to depression in a particular client. At the population level, the nurse would assess the incidence and prevalence of biological, psychological, environmental, sociocultural, behavioral, or health system determinants influencing mental health and illness.

Diagnostic Reasoning and Mental Health and Illness

Population health nurses may make a variety of nursing diagnoses related to mental health and mental illness. These diagnoses can reflect the mental health status of an individual client, the client's family, or a population group. For example, the nurse might diagnose "high levels of mental health" for an individual client or family or in a population group. Conversely, the nurse might diagnose "impaired reality orientation due to schizophrenic episode" in an individual client or an "exacerbation of depression due to family stress." Another nursing diagnosis at this level might reflect "disruption of family function due to exhibition of symptoms of schizophrenia" on the part of one member.

Nursing diagnoses may also be made that reflect mental health problems affecting population groups. For example, the population health nurse might diagnose an "increased incidence of schizophrenia in the homeless population" or "inadequate treatment facilities for persons with chronic mental health problems due to reduced program funds."

Planning and Implementing Strategies Related to Mental Health and Illness

The Surgeon General's report on mental health (NIMH, 1999) made several recommendations with respect to mental health care in the United States. These recommendations

included the need to reduce the stigma attached to mental illness, improve public awareness of the availability of effective treatment for most mental health problems, assure the supply of providers and services for those in need, and ensure the use of state-of-the-art treatments. Additional recommendations addressed the need to tailor treatment to the age, gender, race, and culture of those affected; to facilitate early entry into treatment; and to reduce financial barriers to treatment (NIMH, 1999). Although these recommendations were made a number of years ago, they remain relevant to efforts to control community mental health problems, and population health nurses can be actively involved in efforts to address these recommendations.

MENTAL HEALTH PROMOTION. Prevention of mental illness through risk reduction has not been effective in reducing the incidence or prevalence of mental health problems, so many authors are suggesting a need to focus on active promotion of mental health in addition to specific prevention endeavors. Positive mental health has been linked to less mental illness, decreased ADL limitations, fewer missed work days, better physical health, and less use of health care services and prescription drugs. Gains in mental health over time predict lower risk for future mental illness. Conversely, diminished mental health predicted an increased risk for mental illness (Keyes, Dhirra, & Simoes, 2010).

Promotion of mental health involves moving from a risk reduction model of mental illness control to a competence enhancement model (Fledderus et al., 2010). WHO has defined **mental health promotion** as the creation of conditions that support mental health and adoption of healthy lifestyles (WHO, 2014a). The goal of mental health promotion is to enhance both individual competencies and community assets to prevent mental health problems and improve quality of life (Kobau et al., 2011). General strategies to foster mental health include health-enhancing public policy related to employment and antidiscrimination, creating supportive environments, strengthening community action, developing personal skills,

and reorienting health services to address mental health needs (Kobau et al., 2011).

Mental health is also referred to as positive psychology and consists of four aspects. The first aspect is positive emotions which have been shown to reduce autonomic arousal and promote effective engagement with one's environment. Positive emotions have been found to be linked to better immune function, decreased risk of injury and illness, speedier recovery from illness, healthier behaviors, and increased longevity (Kobau et al., 2011).

The second aspect of positive psychology is reflected in individual traits of optimism and resiliency, creativity, bravery, kindness, and perseverance, all of which tend to buffer against psychological disorder. Development of positive relationships with others is the third aspect of positive psychology, and the last is the existence of enabling institutions, such as schools that prohibit bullying, that foster positive psychological outcomes (Kobau et al., 2011).

Psychological flexibility is one specific competency that has been linked to mental health. **Psychological flexibility** involves an attitude of acceptance of negative experiences, rather than attempting to avoid or control them, and engaging in behavior based on personal values. Two approaches can be used to increase psychological flexibility: acceptance and commitment therapy (ACT) and mindfulness. ACT involves learning to detach oneself from negative experiences and focus on behaviors that support personal values. Mindfulness involves awareness of and attention to experiences as they occur in a nonjudgmental and accepting way. Research has indicated that a combination of the two approaches is even more effective in increasing psychological flexibility (Fledderus et al., 2010).

Promotion of coping abilities and resilience also foster mental health. **Resilience** is the ability to withstand chronic stress or to recover from traumatic and stressful events. Population health nurses can assist individual clients to develop coping skills that will increase their resilience in the face of adversity. In addition, nurses can be instrumental in developing programs that promote coping in school, work, or other settings. Population health nurses might also organize stress management education programs as part of a school health curriculum or in a work setting.

Strategies to promote mental health should be employed across the life span. For example, strategies to promote mental health in young children include support for effective parenting and improved parent-child interaction, both of which may require attention to parental stressors such as poverty, unemployment, and so on. Effective strategies include parental education, home visiting and support programs, and child care programs outside the home. During the school years, programs that develop personal coping and social skills and foster inclusion, identity, and connectedness have been shown to enhance mental health. Other successful strategies include improving problem-solving ability and self-control, addressing learning problems, bullying prevention, promotion of self-awareness

and self-esteem, and programs to foster social and emotional skills.

For adults, mental health promotion focuses on two primary areas: prevention of unemployment and dealing with work-related stress. Job training programs and assistance with employment can help to promote mental health. Similarly, programs to reduce work stress and burnout, creation of balance between job demands and skills, promoting job control and decision latitude, and creating work climates that are socially and emotionally supportive can also enhance mental health in adults. Noise reduction, relaxation training, and conflict management strategies can also be helpful. For older adults, climates of respect and emotional and material support that help to maintain independence can enhance mental health. Prevention of social isolation and loneliness can also foster mental health. Population health nurses can be actively involved in the development of community programs to promote mental health at all age levels or can refer individuals to existing programs. Table 28-4 • summarizes foci and strategies for mental health promotion.

ILLNESS AND INJURY PREVENTION. Prevention of mental health problems and mental disorders involves reduction of risk factors. Population health nurses may be actively involved in risk-reduction efforts. The support provided to clients with mental distress and efforts to ameliorate or eliminate sources of stress may prevent the occurrence of mental health problems. Population health nurses can assist individuals and families to identify sources of stress and plan strategies to eliminate or minimize them. For example, referral for financial assistance may alleviate economic stresses that can contribute to depression. The nurse may also refer clients experiencing situational stressors such as divorce or care of a chronically ill family member to support groups to help them deal with stress. Assisting clients and families to expand social support networks may also prevent mental health problems.

Population health nurses can also assist clients with chronic physical health problems to cope effectively with their illnesses and refer them for counseling when they are experiencing adjustment difficulties. Referral for family counseling may also help to prevent mental health problems arising out of poor family dynamics. Families can also be assisted by population health nurses to develop communication and interaction patterns that promote the mental health of family members.

At the population level, population health nurses can advocate for societal conditions that minimize stress and prevent mental illness. They can assist communities to identify and develop strategies to address existing sources of stress for community members. For example, population health nurses in one community were actively involved with other community members in advocating for a local ordinance mandating a living wage for people working for organizations that received city contracts to minimize the stress of poverty.

TABLE 28-4 Mental Health Promotion Foci and Strategies

Health Promotion Focus	Strategies
Promote positive personal traits	<ul style="list-style-type: none"> • Advocate for programs that promote creativity and kindness. • Role model perseverance.
Promote positive relationships with others	<ul style="list-style-type: none"> • Teach and role model effective communication and relationship skills.
Develop institutions that foster positive psychological outcomes	<ul style="list-style-type: none"> • Assist in the development and implementation of mental health promotion curricula in schools. • Advocate for policies that promote inclusiveness and connectedness. • Advocate for anti-bullying programs and policies.
Promote coping skills and resilience	<ul style="list-style-type: none"> • Teach and role model coping skills. • Advocate for coping education in schools.
Promote psychological flexibility	<ul style="list-style-type: none"> • Assist clients to accept negative events and to engage in personal responses consistent with personal values. • Promote mindfulness and attention to experiences and behavioral responses consistent with personal values.
Promote effective parenting	<ul style="list-style-type: none"> • Teach parenting skills. • Assist with development of parenting programs. • Role model effective parent–child interaction. • Modify parental stressors. • Advocate for parenting support programs.
Prevent unemployment	<ul style="list-style-type: none"> • Advocate for and refer clients to job training programs and employment services.
Reduce work-related stress	<ul style="list-style-type: none"> • Advocate for or implement worksite stress-reduction programs. • Advocate for job control and decision latitude in the work setting. • Promote noise reduction in work settings. • Advocate for strategies that improve work–family balance. • Provide relaxation training in workplaces. • Assist with conflict management in the workplace.
Provide emotional and material support for older clients	<ul style="list-style-type: none"> • Advocate for programs that provide material support for the elderly. • Make referrals to prevent social isolation. • Assist older clients to maintain independence.

Interventions may also be undertaken to prevent postpartum depression (PPD). Population health nurses often work with pregnant women so they are in an ideal position to take steps to prevent PPD. Interventions that may help to prevent PPD include good nutrition, development of social support networks, exercise, discussion of and education about parenting expectations, promoting coping skills, and assisting parents to seek the help of others in dealing with other household tasks. Population health nurses can also engage in campaigns to change public perceptions of “good parents” to incorporate more realistic parenting expectations and to change policies that require women to return to work soon after delivery. Cultural pressures to regain one’s figure may also lead to excessive dieting, nutritional imbalance, and increased risk for PPD. Women may also need to have avenues for processing feelings about perceived birth trauma and population health nurses may help to create groups or programs that allow this processing to occur. Supportive home visits by health professionals have also been shown to be helpful in preventing PPD and population health nurses can advocate for and create home visiting programs for all mothers, not just those with high-risk infants, where such services do not exist.

There is also a need to promote health in clients with existing mental health problems. For example, second-generation

antipsychotic medications increase the risk of weight gain and metabolic disorder, and people taking these drugs for schizophrenia need preventive interventions to control weight, such as diet instruction and encouraging physical activity. Population health nurses can educate clients regarding the effects of psychotropic drugs and assist them to minimize these effects through counseling and structured physical activity programs. In addition, population health nurses can advocate for smoking cessation assistance for people in mental illness facilities (Gfroerer et al., 2013).

At the population level, clients with mental health problems should have access to routine health promotion services tailored to meet their needs. For example, walk-in services may be needed for clients who, because of cognitive or emotional deficits, have difficulty making or keeping appointments. Conversely, routine health promotion and illness prevention services (e.g., influenza immunization) could be provided in the context of mental health services to promote ease of access. Population health nurses can educate clients with mental health problems about the need for immunization as well as use of safety precautions and avoidance of high-risk behaviors such as substance abuse, mixing psychotropic medications with alcohol, or driving when taking certain medications or under the influence of drugs or alcohol. Population health

TABLE 28-5 Illness and Injury Prevention Foci and Strategies Related to Mental Health

Focus	Strategies
Modifying risk factors for mental illness	<ul style="list-style-type: none"> • Assist with identification of risks for mental illness. • Assist clients to modify sources of stress. • Refer clients for counseling to deal with situational stressors as needed. • Promote adjustment to chronic physical health problems. • Teach effective family interactions. • Promote employment and social support strategies.
Preventing postpartum depression	<ul style="list-style-type: none"> • Advocate for and provide support to new mothers. • Promote realistic expectations of parenthood. • Promote physical activity and good nutrition. • Assist in identification or development of social support networks.
Preventing or modifying treatment side effects	<ul style="list-style-type: none"> • Assist clients to deal with medication side effects.
Preventing other illnesses	<ul style="list-style-type: none"> • Promote smoking cessation. • Promote immunization.
Preventing injury	<ul style="list-style-type: none"> • Educate clients about safety issues. • Prevent high-risk behaviors.
Providing accessible health promotion and illness prevention services	<ul style="list-style-type: none"> • Advocate for and refer clients to mental health promotion and illness prevention services.

nurses can also assist in the development of mental health services that address health promotion and illness prevention as well as therapy for mental illness. Finally, they can advocate for accessible health promotion and illness prevention services for people with mental illness. Table 28-5 • summarizes illness and injury prevention strategies related to mental health.

RESOLVING EXISTING MENTAL HEALTH PROBLEMS.

Resolution of existing mental health problems involves screening and treatment interventions.

Screening. Early entry into treatment for mental disorders requires identification of those in need of treatment. Although there are no specific screening examinations for most mental illnesses as there are for some communicable diseases or chronic physical health problems, two aspects of screening are important in identifying clients who are in need of and will benefit from mental health services. The first aspect of screening is a mental health evaluation that includes a client's psychiatric history, use of current psychotropic drugs, presence of suicidal ideation or suicide attempt, drug and alcohol use, and a history of sex offenses, victimization, or violence. Additional components of the mental health evaluation for an individual client include a history of special education placement, history of traumatic brain injury, incarceration, and evidence of mental retardation.

The second aspect of screening is assessment of a client's motivation for treatment. Areas to be considered include perceptions of the seriousness of mental health problems, desire for and perceived importance of treatment, and past attempts at treatment and their effects.

There are screening tools for selected mental health problems. For example, the U.S. Preventive Services Task Force has recommended routine depression screening in adults when mechanisms are in place for dealing with positive screening

results (CDC, 2010). Tools for screening for depression and other conditions in the elderly were addressed in Chapter 18∞. The Edinburgh Postnatal Depression Scale (EDPD) is available for screening for postpartum depression, although the American College of Obstetricians and Gynecologists (2010) has found insufficient evidence for its use in routine screening for pregnant and postpartum women. The need for better screening tools for PTSD, as well as means of tracking disease incidence in mass trauma survivors has been identified, and approaches have been suggested for guiding self-evaluation and referral in the general public (NIMH, 2012a). Similarly, researchers are looking for biomarkers that may identify ASDs, but this effort is complicated by the number of gene expressions implicated in recent research (Johnson et al., 2013). Once population health nurses have identified people in need of and desiring assistance with mental health problems, they can help them find appropriate diagnostic and treatment services. Population health nurses should ensure that any screening tools used for mental health conditions are culturally and age appropriate to the populations for which they are being used. Population health nurses should be knowledgeable about and alert to signs and symptoms of mental illness. They can also educate the general public regarding signs and symptoms of conditions such as depression to promote self-screening or recognition of problems in friends or family members.

Treatment. Primary treatment goals for depression include relief of symptoms and return to effective function (Katon & Ciechanowski, 2014). Additional goals include preventing personal and societal effects of mental health problems, improving the client's (and family's) quality of life, and preventing suicide. These goals can be adapted to the treatment of other mental health problems.

Several general approaches may be implemented for the treatment of mental illness. These approaches include

pharmacotherapy, individual or group psychotherapy, family intervention, and use of self-help groups. Multimodal therapy involves a combination of approaches. It is beyond the scope of this book to discuss these therapeutic approaches in detail, but each will be addressed briefly.

Pharmacotherapy relies on the use of medications alone or in conjunction with other treatment approaches to mental illness. Most pharmacologic agents used in the treatment of mental disorders alter the action of neurotransmitters in the brain, either increasing or decreasing their activity. Major categories of pharmacotherapeutic agents include antipsychotics (neuroleptics), antidepressants, stimulants (used for ADHD), mood stabilizers, anxiolytics, and cholinesterase inhibitors (used for Alzheimer's disease). The National Alliance on Mental Illness (NAMI) provides information on a wide variety of medications used in the treatment of mental illness. The role of population health nurses with respect to pharmacotherapy for mental disorders lies primarily in monitoring and motivating medication adherence, monitoring therapeutic effects, assisting with side effects, and identifying adverse effects. Population health nurses may also need to advocate for access to therapeutic drugs for clients without health insurance or those whose insurance does not cover prescription medications. For example, one population health nurse was able to convince the County Medical Services (CMS) division to cover psychiatric medications for a low-income client even though CMS services were usually reserved for addressing physical health needs rather than psychiatric illness. At the population level, population health nurses can advocate for changes to assistance programs to achieve parity for mental health conditions in comparison to physical health needs.

Population health nurses, as well as other providers who deal with clients with mental health problems, need an awareness of ethnopsychopharmacology. **Ethnopsychopharmacology** is the study of ethnic and cultural alterations in response to medication. These alterations reflect genetic differences in drug metabolism as well as cultural practices related to medication adherence, placebo effect, diet and its effects on medication absorption and effect, and the concomitant use of traditional therapies. Members of many ethnic groups have slowed drug metabolism compared to Caucasians, which may result in higher blood levels with typical dosages, leading to adverse effects (Wong & Edmond, 2012). Members of ethnic groups and others may also use herbal remedies for a variety of conditions that interfere with prescription medications or have other adverse effects. For example, St. John's Wort is an herb frequently used for depression that has been found to affect metabolic pathways used by medications to treat conditions such as heart disease, cancer, and seizures and may interfere with treatment for these conditions (NIMH, 2011a). Population health nurses can educate clients, other health care providers, and the general public regarding ethnopsychopharmacologic implications and the potential for adverse drug effects. They can also engage in research to evaluate the effectiveness of ethnopsychopharmacologic approaches to mental health therapy.

Monitoring clients on psychotropic medications for side effects is an important role for population health nurses. Population health nurses educate clients about the intended effects and potential side effects and adverse effects of medications used to treat specific mental illnesses. The nurse also monitors the client closely for signs of toxicity. Population health nurses may need to advocate for coverage of psychotropic medications for individual clients. They may also be involved in political advocacy to promote coverage of psychiatric services, including medication, as a mandated health insurance benefit on par with coverage for physical illnesses.

Psychotherapy may be used with individual clients or with groups of people. The intent of psychotherapy is to develop an understanding of one's problems and ways of dealing with them (NIMH, 2012a). Psychotherapy may be used alone or in conjunction with medication. Several different approaches to psychotherapy are used, including cognitive behavioral therapy, dialectical behavior therapy, interpersonal therapy, family-focused therapy, psychodynamic therapy, and light therapy (NIMH, 2012b), which is used primarily for SAD.

Some other newer therapies have been found to be effective in assisting people with schizophrenia to deal with symptoms that are not eliminated by medication. One such therapy is metacognitive training, which is intended to help clients be aware of cognitive biases that lead to symptoms, and to critically analyze them and the problem-solving behaviors used to address them. Metacognitive training improves one's ability to examine one's own mental processes, identify reasoning or memory errors, and modify their behavioral responses (Favrod, Maire, Bardy, Pernier, & Bonsack, 2010). The University Medical Center Hamburg-Eppendorf (2014) has developed a metacognitive training program to assist people in identifying inappropriate thinking and modify their responses. For further information about the training modules, see the *External Resources* section of the student resources site.

Psychotherapy may not be effective with clients from some cultural groups because it is incongruent with cultural norms of not dwelling on or thinking about problems. A description of key features of several psychotherapeutic approaches is presented in Table 28-6●.

One other approach to treatment of bipolar disorder is electroconvulsive therapy (ECT), or the use of low-level electric shock to stimulate the brain. Although previously discounted as a treatment for depression, newer technologies that deliver more focused stimulation that is not even consciously perceived by the client have been shown to be highly effective for severe depressive, manic, or mixed episodes of bipolar disorder. ECT is also useful in conditions, such as pregnancy, when medications may not be safe (NIMH, n.d.b).

Additional types of therapy might be warranted for some population groups. For example, directly observed therapy has been effective in promoting medication adherence in homeless and marginally housed HIV-infected individuals with depression (Tsai et al., 2013). Similarly, people with schizophrenia may benefit from specialized education programs to promote

TABLE 28-6 Characteristic Features of Selected Psychotherapies

Psychotherapeutic Approach	Characteristic Features
Cognitive behavioral therapy (CBT)	A mix of cognitive and behavioral therapy that focuses on changing one's thoughts and beliefs to be more adaptive and promote changes in unhealthy behaviors.
Dialectical behavioral therapy	A form of CBT in which the provider points out unhealthy behaviors and teaches more effective strategies for dealing with underlying needs.
Interpersonal therapy (IPT)	Focuses on improving communication patterns and relationships with others, identifying emotional triggers to behavior and promoting healthy expression of emotions.
Interpersonal and social rhythm therapy	Combines IPT with regular routines.
Family-focused therapy	Addresses family conflict that may be making the mental health problem worse. Helps with family caretaker stress.
Psychodynamic therapy	Focuses on self-awareness, unconscious emotions, and motivations influencing behavior.
Light therapy	Exposure to bring light. Used with low dose melatonin for seasonal affective disorder.
Metacognitive therapy	Focuses on making clients aware of cognitive biases and faulty thinking. Assists them to critique their own thought processes, identify errors, and change behavioral responses.

Data from: Favrod, J., Maire, A., Bardy, S., Pernier, S., & Bonsack, C. (2010). Improving insight into delusions: A pilot study of metacognitive training for patients with schizophrenia. *Journal of Advanced Nursing*, 67, 401–407. doi: 10.1111/j.1365-2648.2010.05470.x; National Institute of Mental Health. social skills, as well as vocational, speech, and language therapies (Wexner Medical Center, n.d.). A horticulture program has also resulted in decreased rumination and increased attention in people with depression (Gonzalez, Hartig, Patil, Martinsen, & Kirkevold, 2010). Integration of a psychiatric liaison into the ED at night has also been shown to improve integration of care (Waghorn, 2010). Other programs have focused on family education and support of people with eating disorders (Gísladóttir & Svavarsdóttir, 2011) and people caring for family members experiencing a first psychotic episode (Lowenstein et al., 2010). Finally, a web-based information center for people with severe mental health problems was found to be acceptable and helpful by patients once nurses had supported them in learning to use

the computer and Internet (Kuosmanen, Jakobsson, Hyttinen, Koivunen, & Valimäki, 2010).

Population health nurses also need to be conversant with the kinds of services available to the individual client and within the population. When appropriate services are not available, population health nursing intervention may focus on advocacy and assurance of access to needed services. For example, nurses may campaign for legislation to include mental health treatment as a mandatory health insurance benefit in their state or to eliminate time limits and other constraints on existing coverage. Foci and related population health nursing strategies for resolving existing mental health problems are summarized in Table 28-7.

TABLE 28-7 Foci and Strategies for Resolving Mental Health Problems

Focus	Strategies
Promoting early identification of mental health problems	<ul style="list-style-type: none"> • Advocate for availability of screening for mental health problems for populations at risk. • Assist in developing and implementing screening programs. • Assess need and motivation for screening. • Refer for screening as needed. • Assist in interpreting screening results and refer for diagnosis and treatment as needed. • Educate clients and the public on signs and symptoms of mental health problems. • Assure that screening tools are age- and culture-appropriate.
Providing effective evidence-based treatment for mental health problems	<ul style="list-style-type: none"> • Advocate for the availability of diagnostic and treatment services. • Refer clients for diagnosis and treatment. • Educate clients and the public on treatment options. • Advocate for insurance coverage for mental health services and medications. • Monitor treatment adherence and effects. • Monitor clients for treatment side effects. • Identify ethnopharmacologic influences on treatment. • Educate providers, clients, and the public on aspects of ethnopharmacology.

HEALTH RESTORATION. In the context of mental illness, health restoration is usually thought of in terms of recovery. **Recovery** involves restoration of a meaningful life rather than symptom relief, which is the emphasis in the medical model of care. In many cases, recovery does not imply a return to full function or the ability to discontinue medication use in chronic mental illnesses. Self-help groups usually focus on recovery. Self-help groups will be discussed in more detail in the context of substance abuse disorders in Chapter 29, but population health nurses may be actively involved in initiating and supporting self-help groups for clients with mental health conditions.

Health restoration, in the context of mental illness, also includes maintenance. As was the case with the chronic physical health problems discussed in Chapter 27, there is a need to focus on disease management rather than crisis-oriented care for chronic mental health problems. Maintenance involves long-term management of chronic mental illness and focuses on rehabilitating the client and preventing relapse. The goal of maintenance in chronic mental illness is to maintain the client's level of function and to prevent recidivism or frequent rehospitalization. Maintenance may include medications and a variety of other interventions. Population health nurses may be asked to follow clients with diagnoses of chronic mental illness to provide support, encourage treatment adherence, and monitor the effects of treatment. Population health nurses can assist clients to plan regular lifestyles and to minimize sources of stress in their lives. For example, the nurse might help clients with bipolar disorder to reduce stress and to maintain regular sleeping and waking cycles to prevent relapses.

Clients using pharmacologic agents should also be cautioned about potential interactions of medications and alcohol. The nurse can also help clients and their families to identify symptoms that signal a symptomatic relapse and to seek professional assistance when these symptoms are noted. Population health nurses can educate clients and family members regarding signs of relapse and assist them to seek help when relapses occur.

Client and family involvement is an important aspect of maintenance in the control of chronic mental health problems. Population health nurses can promote client and family participation in clinical decision making as well as provide them with information on which to base decisions regarding treatment interventions. In addition, they can regularly monitor clients for medication side effects and offer suggestions for ameliorating them. If side effects cannot be effectively managed or threaten to undermine adherence with treatment, population health nurses can advocate with mental health providers for a change in the treatment regimen to minimize side effects.

It is important that population health nurses learn to assess levels of depression and suicide risk and refer clients at risk to a mental health provider immediately if they are not already involved in ongoing therapy. Population health nurses are also using approaches such as diary writing and physical exercise

to help individuals deal more effectively with depressive symptoms. For example, journaling may allow the client to identify triggers for depressive episodes or to recognize initial symptoms of depression so that medical assistance can be sought. Journaling may serve a similar function for clients with schizophrenia, allowing clients or family members to identify early signs of relapse and seek assistance. Open lines of communication are imperative among nurse, mental health provider, family, and client, particularly at times when the client is deeply depressed or actively suicidal.

Persons with chronic mental illness often have a high incidence of physical health problems and sometimes lack the capacity to seek health care in today's complex delivery systems. The population health nurse may be in the situation of following a person for a physical health problem who suddenly begins to show signs of mental illness. The nurse's role in this case is to refer the client for further diagnosis and treatment, as well as to assist in addressing the physical health problem. The population health nurse also refers clients who are exhibiting signs of exacerbation of their disorders.

Respite is another aspect of maintenance in the care of chronic mental illness. Respite has been shown to benefit both clients with serious mental illness and family caregivers. Population health nurses can refer clients and family members to existing respite services, which may be provided in the home or in specialized residential facilities. They may also be actively involved in advocating for the availability of respite for these families. Families and clients with mental illness may also benefit from participation in mutual support groups, and population health nurses can either make referrals to existing groups or work with clients and family members to establish such groups. Table 28-8 summarizes foci and strategies for health restoration related to mental health problems.

Evaluating Interventions for Mental Health and Illness

Evaluation of mental health interventions occurs at the individual and family level as well as the population level. Evidence of effective intervention for the individual client may lie in improved mental health, diminished mental distress, or a decrease in symptoms of a specific mental disorder. Similarly, effective family care may result in improved family dynamics or decreased disruption of family life by a mentally ill family member.

At the population level, evidence of effective health promotion and prevention activities would lie in improved mental health in the population and decreased incidence and prevalence of mental disorders as well as decreased reports of mental distress in the population. National health objectives for 2020 may also be used as guidelines for evaluating mental health care, particularly care related to resolution of existing problems and health restoration. Baseline data and 2020 targets for selected objectives are provided on the next page.

TABLE 28-8 Foci and Strategies for Health Restoration Related to Mental Health Problems

Focus	Strategies
Promoting disease self-management	<ul style="list-style-type: none"> • Educate clients on long-term management of chronic mental health conditions. • Promote development of and refer to mental illness support groups. • Encourage regular schedules and healthy lifestyles. • Promote physical activity. • Assist clients/families to minimize sources of stress. • Advocate for services to support self-management.
Promoting adherence to therapeutic regimens	<ul style="list-style-type: none"> • Advocate for client involvement in decision making. • Educate clients regarding the need for continued adherence. • Educate clients/families about drug/alcohol interactions. • Monitor treatment adherence and effects. • Assist clients to deal with treatment side effects.
Preventing relapse or recognizing early symptoms of relapse	<ul style="list-style-type: none"> • Assist clients and families to identify and modify risk factors for relapse. • Educate clients and families regarding early signs and symptoms of relapse. • Encourage seeking mental health care for early signs of relapse. • Assess for depression and signs of suicidal ideation and refer as needed.
Promoting quality of life	<ul style="list-style-type: none"> • Assist clients with economic issues, job training, and so on. • Educate clients and families for health interpersonal interactions. • Teach or refer for assistance in development of life skills.
Providing caregiver support	<ul style="list-style-type: none"> • Educate families about mental illness and ways to help affected family members. • Advocate for availability of respite services. • Refer to respite services as needed.
Preventing stigma and discrimination	<ul style="list-style-type: none"> • Educate the public about mental health and illness. • Advocate for antidiscrimination laws. • Support antidiscrimination policies in social and health care institutions. • Develop and implement programs to decrease stigma associated with mental illness. • Assist client and families to deal with stigma and discrimination.

Healthy People 2020

Selected Healthy People 2020 Objectives Related to Mental Health and Mental Illness

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
MHMD-3. Reduce the proportion of adolescents engage in eating disordered behavior	14.3% (2009)	12.0%	16.3% (2011)	Youth Risk Behavior Surveillance System (YRBSS), CDC/NCHHSTP
MHMD-4.1. Reduce the proportion of adolescents who experience major depressive episodes	8.3% (2008)	7.4%	8.2% (2011)	National Survey on Drug Use and Health (NSDUH), SAMHSA
MHMD-4.2. Reduce the proportion of adults who experience major depressive episodes	6.4% (2008)	5.8%	6.6% (2011)	NSDUH, SAMHSA
MHMD-5. Increase the proportion of primary care providers that provide mental health care on site or by paid referral	79% (2006)	87%	NDA	Uniform Data System, HRSA/BPHC
MHMD-8. Increase the proportion of persons with serious mental illness who are employed	58.6% (2008)	64.4%	53.4% (2011)	NSDUH, SAMHSA

Healthy People 2020 (Continued)

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
MHMD-9.1. Increase the proportion of adults with serious mental illness who receive treatment	58.7% (2008)	64.6%	59.6% (2011)	NSDUH, SAMHSA
MHMD-9.2. Increase the proportion of adults with major depressive episodes who receive treatment	71.1% (2008)	78.2%	68.1% (2011)	NSDUH, SAMHSA
MHMD-11.1. Increase the proportion of primary care physicians who screen adults for depression	2.2% (2007)	2.4%	2.4%* (2010)	National Ambulatory Medical Care Survey (NAMCS), CDC/NCHS
MHMD-12. Increase the proportion of homeless adults with mental health problems who receive mental health services	37% (2006)	41%	NDA	Projects for Assistance in Transitioning from Homelessness

NDA = No data available

*Objective has met target.

Internationally, MiNDbank, an international data base of resources launched by WHO in 2013, will assist in evaluating the state of mental health and mental illness throughout the world. The intent of MiNDbank is to allow resource

and best practice sharing and promote integration of mental and physical health, substance abuse, disability, and human rights initiatives to promote a holistic approach to health (WHO, 2013).

Global Perspectives

WHO QualityRights Project

WHO has established a QualityRights project that is designed to improve the quality and human rights conditions in mental health and social care facilities. The project will also empower organizations to advocate for the rights of people with mental and psychosocial disabilities. Major foci of the project include:

- Improving service quality and human rights conditions in mental health and social care facilities.
- Promoting human rights, recovery, and independent living in the community.
- Developing a movement of people with mental disabilities to provide mutual support, conduct advocacy, and influence policy making.
- Reforming national policies and legislation (WHO, 2014b).

MiNDbank is an international database of resources launched by WHO as part of the QualityRights campaign. The intent of

MiNDbank is to allow resource and best practice sharing and promote integration of mental and physical health, substance abuse, disability, and human rights initiatives to promote a holistic approach to health. MiNDbank will also help to reduce the fragmentation and duplication of efforts across sectors of society. Areas of focus within MiNDbank include mental health and substance abuse policies and legislation, disability-related policies and legislation, human rights of persons with mental illness, and mental health services standards. Other resources will include international and regional human rights conventions and treaties, United Nations (UN) special reports, and UN and WHO resolutions (WHO, 2013). For further information about the database, see the *External Resources* section of the student resources site.

CHAPTER RECAP

Population health nurses are actively involved in the development and implementation of programs to promote mental health for clients and populations at all age levels. In addition, because of their presence in the community and familiarity with many community members experiencing adverse life situations, population health nurses are in a position to identify clients at risk for mental health problems. Nurses can engage in activities designed to ameliorate these risks and to promote resilience and coping. Population health nurses are also able

to recognize clients with symptomatic mental illness and refer them for mental health services. Assisting clients with chronic mental illness to adjust to their conditions and live as normally as possible is another significant role for population health nurses. Finally, population health nurses may be actively involved in advocacy to assure that culturally appropriate health promotion and illness preventive, diagnostic, and treatment services are available to those in need of them.

CASE STUDY

Caring for a Client with Depression

You are the population health nurse assigned to see Donna for a well-baby visit several weeks after she delivered a healthy son. Donna is 39 and has been married to Jack, 48, for a year. Stephen is their first child. When you arrive at Donna's house, you note that she and her family live in a comfortable home in an upper-middle-class neighborhood. Donna answers the door, and you see that her eyes and nose are red as though she has been crying. You explain the purpose of your visit and examine the baby, who is in a freshly painted nursery with a bright mobile over the crib and plenty of stuffed animals and toys around. Stephen is neat, clean, and appears to be well fed, happy, and healthy.

When you finish with the baby, you ask how Donna is doing. Donna bursts into tears. She tells you that she has been feeling desperately unhappy since her pregnancy began. She has been feeling so depressed, she reports that she is not sure she will be able to get out of bed anymore to take care of her son. You say, "Tell me about this past year." Donna tells you that this is a first marriage for her and for Jack, and neither of them has children from previous relationships. In their discussions prior to marriage, she and Jack had never resolved their differences about having children. Donna was ambivalent about having a child; her husband was sure he did not want one. Because they are devout Roman Catholics, they used the rhythm method of birth control. When Donna told Jack she was pregnant after 2 months of marriage, he became very angry and blamed Donna for tricking him into having a baby. Although she had not tricked him, Donna felt guilty and blamed herself for becoming pregnant. Terrified that Jack would leave her if she told him how she felt, she kept all her own feelings of sadness, anger, and depression inside. She did not want to be a single parent. Abortion was never considered because of their religious beliefs.

During the pregnancy, Jack was emotionally withdrawn, depressed, and refused to take part in any activity related to the upcoming birth. Donna's sister attended Lamaze classes with

her and coached her during the birth because Jack would not attend. Donna felt jealous of the women whose husbands were so attentive during these classes. Ever since her son's birth, Donna says that she has had "postpartum depression." She has told no one how depressed she feels because she is afraid she will have to be hospitalized as she was several times in her late twenties and early thirties for episodes of clinical depression.

When you do a genogram with her, you discover a family history of depression. Both her grandmother and mother suffered bouts of deep depression, and her grandmother had been hospitalized for a year in a psychiatric institution following menopause. Donna's father is an emotionally withdrawn man whose only sister committed suicide when she was 40. Donna's sister has an eating disorder; she is bulimic.

Now that Donna has been home for 3 weeks with her son, she sees her sister twice a week. Jack is pleased that they have a son, and he is beginning to spend time after he comes home from work playing with Stephen. Donna cannot understand why it makes her angry instead of happy that Jack is becoming involved with their child. Because Jack has refused to support them in a manner that would allow Donna to stay home with Stephen, Donna must return to work after her 6-week maternity leave. She is afraid she will be unable to function at work and has yet to arrange child care for Stephen. Donna worries about these things and has difficulty both falling asleep and getting up during the night to feed her son. She says she cries "at the drop of a hat" and has lost weight. She weighs less now than before she was pregnant. She has little interest in anything, including her baby, and she says that life does not really seem worth living anymore.

1. Does Donna have any typical signs of depression? If so, describe them.
2. How would you assess her potential for suicide?

3. Do you think Donna's depression is "normal" postpartum depression or clinical depression requiring psychiatric assessment and treatment? Why?
4. Based on your assessment, will you follow Donna yourself or refer her to a psychiatrist or mental health worker?
5. How will you involve Donna's husband and sister in the plan of care?
6. What other interventions might be warranted with this family?

29 Substance Abuse

Learning Outcomes

After reading this chapter, you should be able to:

1. Identify signs and symptoms of psychoactive substance dependence.
2. Distinguish between psychoactive substance dependence and abuse.
3. Identify substances that lead to dependence and abuse.
4. Analyze personal, family, and societal effects of substance abuse.
5. Analyze biological, psychological, environmental, sociocultural, behavioral, and health system factors that influence substance abuse.
6. Discuss aspects of population health nursing assessment in relation to substance abuse.
7. Identify major approaches to prevention of substance abuse and analyze the role of the population health nurse with respect to each.
8. Discuss harm reduction as a preventive measure for substance abusers.
9. Describe the components of the intervention process in resolving problems of substance abuse.
10. Identify general principles in the treatment of substance abuse.
11. Describe treatment modalities in substance abuse control and analyze the role of the population health nurse in their implementation.
12. Analyze the role of the population health nurse in health restoration with regard to substance abuse.

Key Terms

addiction	drug use	physical dependence	substance-related disorders
ARV diversion	epigenetics	polydrug use	supervised injection facilities (SIFs)
brief intervention	exposome	psychoactive substance misuse	teratogenic substances
codependence	freebasing	psychoactive substances	tolerance
corporate social responsibility	harm reduction	relapse	withdrawal
crack	intoxication	relapse prevention therapy (RPT)	
designer drugs	market segmentation	relapse risk maps	

Drug Addiction Prevention at the Local Level

Charles E. Terry, MD, became city health officer of Jacksonville, Florida, in 1910. In addition to promoting strict enforcement of sanitary laws and medical examinations for school children, Terry began a concerted campaign against drug addiction while advocating for humane treatment of “drug addicts,” the term most often used at the time. He established a system to identify opiate and cocaine users and received legal authority for the health department to provide addicts with drugs if necessary (Fee, 2011).

In 1912, Terry was instrumental in the passage of a city ordinance regulating the sale of drugs containing opium and other addictive drugs, such as cocaine. Sale of these drugs required a written prescription from a physician, prohibited prescription refills, and required that records of sales be kept with copies sent to the health department. The law also provided for the health officer to provide free prescriptions to users if deemed appropriate. These provisions curtailed illegal sales of drugs and brought habitual users into contact with the health officer who obtained histories of use and identified major contributing factors for addiction. The primary contributing factor in more than half of cases was physician prescription or administration of the drugs. Other factors included the encouragement of acquaintances, “dissipation and evil companions,” and the presence of chronic and incurable disease. Terry emphasized the need for community level data on the extent of abuse and free publically funded treatment for abusers, noting that merely cutting off the supply of drugs would be “inhumane” (Terry, 1914/2011).

Promoting Effective Drug Policies

The Drug Policy Alliance (DPA) is an advocacy organization that contends current U.S. drug policies do more harm than good and seeks to foster more effective policies that recognize individual rights and minimize the personal and societal harm related to drug abuse (DPA, 2014a, para 2). DPA uses legislative avenues to promote sensible drug policy reform.

DPA was formed in 2000 with the merger of the Lindesmith Center, an activist drug policy think-tank and the Drug Policy Foundation, a drug policy reform organization. DPA is a nonprofit organization that advocates for policy reform as it relates to substance use and abuse (DPA, 2014b). DPA's mission is to promote policies that minimize the harm resulting from both drug abuse and prohibition of use and foster individual choice in the matter of drug use (DPA, 2014c). DPA members include a wide array of disciplines, including legislators, health care professionals, members of the legal profession, and others (DPA, 2014a).

The DPA-supported initiatives have led to legalization of marijuana use in Colorado and Washington state, as well as in Uruguay, decriminalization of marijuana use in Rhode Island, and legalization of medical marijuana use in several states. Other initiatives have focused on criminal justice reforms, such as modification of California's “three strikes law” such that life imprisonment is no longer imposed on people convicted of repeated minor nonviolent drug law offenses. DPA has also contributed to the passage of legislation in New Jersey that protects persons who report a drug overdose from prosecution for drug possession and expands access to naloxone to prevent drug overdose deaths. Improving access to clean syringes in New Jersey was another DPA initiative. DPA has also been involved in legislation to promote drug diversion programs and is currently advocating establishment of safe injection facilities in the United States that have been shown to be effective in reducing harm among injection drug users (DPA, 2014d, 2014e, 2014f). Several of these policy initiatives are discussed in more detail later in this chapter.

Most drugs are used appropriately for medicinal purposes. Even when used appropriately, however, drugs may result in substance-related disorders. Substance-related and addictive disorders is one of the diagnostic categories included in the fifth edition of the *Diagnostic and Statistical Manual of Mental Disorders (DSM-5)* of the American Psychiatric Association (2013a). This diagnostic category combined the prior separate diagnoses of substance abuse and substance dependence and conceptualizes the occurrence of substance-related disorders on a continuum from mild to severe. Addictive disorders are also included in the diagnostic category and, at present, encompass only gambling disorder (American Psychiatric Association, 2013b). **Substance-related disorders** are defined as maladaptive patterns of substance use resulting in impairment or distress and manifested in specific criteria over a period of time (National Alliance on Mental Illness, n.d.). In this chapter, we are concerned with substance-related disorders resulting from inappropriate use of psychoactive substances. **Psychoactive substances** are drugs or chemicals that alter brain and nervous system function (Hartney, 2011). In the International Classification of Diseases (ICD-10), the World Health Organization (WHO, 2014c) defined psychoactive substance use disorders as mental and behavioral disorders resulting from psychoactive substance abuse and including acute intoxication, harmful use, dependence, and withdrawal.

Substance abuse is a growing world problem. The illegal drug trade is big business, and the fact that many substances with the potential for abuse also have legitimate uses has made control of substance abuse difficult. **Drug use** is the taking of a drug in the correct amount, frequency, and strength for its medically intended purpose. **Psychoactive substance misuse**, or drug abuse, on the other hand, is the deliberate use of a substance for a purpose not consistent with its intended legal or medical purpose. The term misuse is preferred by many experts as being less judgmental than abuse (WHO, 2014b).

Other terms that are important in an understanding of substance abuse include addiction, physical dependence, tolerance, withdrawal, and polydrug abuse. **Addiction** is a “chronic relapsing disease, characterized by compulsive drug seeking and use, despite serious adverse consequences, and by long-lasting changes in the brain” (National Institute on Drug Abuse [NIDA], 2011, p. 1). Dependence or **physical dependence** is “an adaptive physiological state that occurs with regular drug use and results in withdrawal symptoms when the drug is stopped” (NIDA, 2011, p. 1). Dependence can also occur with appropriate use of many medications and does not, by itself, constitute addiction. Signs of psychoactive substance dependence include the following:

- Increasing amounts of substance used, or use extending over a longer period than intended
- Persistent desire for the substance or one or more unsuccessful attempts to control its use

- Increased time spent in obtaining, using, or recovering from the effects of the substance
- Frequent symptoms of intoxication or withdrawal interfering with obligations
- Elimination or reduction of important occupational, social, or recreational activities as a result of substance use
- Continued use of the substance despite recurrent problems caused
- Increased tolerance to the substance
- Experience of characteristic withdrawal symptoms
- Increased substance use to decrease withdrawal symptoms

Tolerance occurs when higher doses of a drug are required to produce the same effect achieved with its initial use; tolerance is often associated with dependence. **Withdrawal** involves the development of a complex set of symptoms that occur when drug use is abruptly stopped or reduced, usually characterized by severe discomfort, pain, nausea, vomiting, and possibly convulsions (NIDA, n.d.). The severity of withdrawal may vary with the abusive substance and the degree of dependence experienced by the client.

In the United States, the abuse of alcohol and other drugs and the use of tobacco products are of particular concern. For example, more than 1.1 million people in the United States sought substance abuse treatment in 2010 (U.S. Census Bureau, 2013a). The magnitude of concern for problems of substance use and abuse is also seen in the development of more than 100 national health promotion and disease prevention objectives and sub-objectives for the year 2020 related to tobacco use and the abuse of alcohol and other drugs (U.S. Department of Health and Human Services [USDHHS], 2014). These objectives can be reviewed on the *Healthy People 2020* website. Baseline data, targets, and current data for selected objectives are provided at the end of this chapter.

In this chapter, effects of and trends in substance use and abuse are examined. Risk factors contributing to all forms of substance abuse, signs and symptoms of specific types of abuse, and population health nursing interventions in the control of substance abuse are addressed.

Individual, Family, and Societal Effects of Substance Abuse

Substance abuse contributes to adverse effects for the abusing individual, for his or her family, and for society at large.

Individual Effects

The effects of substance abuse on the individual are physical, psychological, and social. Physical effects include increased morbidity directly related to the effects of the drug or drugs abused, as well as increased risk of a variety of diseases and conditions. Some physiologic effects may be immediate and some may constitute long-term effects. For

example, marijuana users have an estimated risk of heart attack 4.8 times that of nonusers in the first hour after use. *Cannabis* species of plants are the source of marijuana and hashish. The primary psychoactive substance in these drugs is delta-9-tetrahydrocannabinol (THC). THC may be inhaled by smoking marijuana or hashish or ingested and produces relaxation, euphoria, and occasionally altered perceptions of time and space. Marijuana use also results in a productive cough and increased risk for acute respiratory illnesses and infections (NIDA, 2014a). Synthetic cannabinoids, synthetic designer drugs used as a marijuana alternative, have been associated with severe illness resulting from hyperglycemia, hypokalemia, acidosis, and tachycardia. Other effects include nausea and vomiting, seizures, pneumonia, and myocardial infarction. Another serious adverse effect of these drugs is rhabdomyolysis (Drenzek et al., 2013). Rhabdomyolysis is the breakdown of muscle fiber and release of contents into the bloodstream resulting in severe kidney damage (National Center for Biotechnology Information, 2013).

Methamphetamine use is associated with hyperthermia; cardiovascular problems, such as tachycardia, arrhythmias, and increased blood pressure; severe dental problems referred to a “meth mouth,” weight loss, and skin lesions from scratching to relieve feelings of “bugs under the skin.” Some of these effects are reversible with long-term abstinence, but others are permanent (Gruenewald et al., 2013; NIDA, 2013, 2014b).

Alcohol misuse also contributes to a variety of physical health problems as well, including cirrhosis and liver cancer. Medical emergencies related to drug abuse resulted in 2.5 million emergency department visits in 2011 for an incidence rate of 790 visits for every 100,000 people in the United States. More than half of those visits (51%) involved use of illicit drugs; 51% involved nonmedical use of prescription medications (some in combination with illicit drugs); and 25% involved drugs combined with alcohol (Substance Abuse and Mental Health Services Administration [SAMHSA], 2013a). Methamphetamine use accounted for 103,000 emergency department visits in 2011, the fourth most frequent cause after cocaine, marijuana, and heroin. This figure, however, represents a decrease in methamphetamine-related emergency visits from 132,576 in 2004. Substance abuse treatment admissions were also down from just over 8% of admissions in 2005 to 5.6% in 2011 (NIDA, 2013).

Alcohol use during pregnancy can result in fetal alcohol syndrome, preterm labor, and a variety of fetal abnormalities as indicated in Chapter 16. Fetal exposure to nicotine adversely affects brain development, and smoking during pregnancy may result in preterm delivery and stillbirth, and has been associated with attention deficit hyperactivity disorder (ADHD) and disruptive behavioral disorders, although there is insufficient evidence at present to support a causal link between smoking and these neurobehavioral disorders (Office of the Surgeon General, 2014). Other

substances of abuse result in equally serious physical health problems.

Substance misuse also increases the potential for exposure to diseases such as HIV/AIDS and hepatitis when abuse involves use of contaminated needles or results in sexual promiscuity as a means of financing a drug habit or because of lowered inhibitions. For example, approximately one in ten new HIV infections worldwide result from injection drug use (IDU), and as much as 80% of all HIV infections in parts of Eastern Europe and Central Asia are due to drug use (WHO, 2014a). In the United States, 6% of new HIV infections in men in 2010 occurred in IDUs, and 4% of HIV infections among men in 2011 were associated with combined IDU and sexual intercourse with other men (Harris et al., 2013). Injection drug users are also at high risk for hepatitis B and C and for resulting liver cancer, cirrhosis, and death (Frimpong, 2013; Masson et al., 2013).

Smoking during pregnancy contributes to a variety of problems for mother and baby. (Jasmin Merdan/Fotolia)

Injection drug users are at high risk for bloodborne diseases.

(terekhov igor/Shutterstock)

Other physical effects of substance abuse include unintentional injury and unintended pregnancy. Substance use also contributes to a wide variety of other unintended injuries. Smoking and alcohol use are often contributing factors in house fires and burn injuries. In one study of persons burned in mobile home fires, for example, 74% of those injured were smokers and 64% reported alcohol abuse (Mullins et al., 2009). Alcohol is widely known to contribute to motor vehicle accidents (MVA), but other substances contribute to MVA injuries as well. For example, in one study cannabis use resulting in blood levels of 2 ng/mL THC (the psychoactive substance in marijuana) increased the risk of accidents four times that of the lowest levels of THC, and stimulants combined with sedatives posed the highest risk for MVAs (Kim, Kuypers, Legrand, Ramaekers, & Verstraete, 2012). Alcohol and drug use also contribute to other forms of injury. For example, in one study of unnatural deaths involving high alcohol concentrations, nearly 15% of the deaths were the result of accidental injury, 11% resulted from suicide, and nearly 7% involved homicide (Darke, Duflo, Torok, & Prolov, 2013).

Some drugs, such as alcohol, nicotine, opiates, and barbiturates, also result in withdrawal symptoms when the drug is removed from the client's system. Some drugs also produce chromosomal changes that cause congenital malformations in children as well as increased potential for spontaneous abortion. Death is the ultimate adverse effect of drug use and may result from a drug overdose, from withdrawal, or from the long-term effects of drug use such as cirrhosis, cancer, cardiovascular disease, and stroke. Assessment for both short-term and long-term physical effects of specific substances is discussed later in this chapter.

In addition to the desired effects that promote drug use and abuse, psychological effects of drug abuse can include personality disturbances, anxiety, and depression. Organic mental disorders characterized by hallucinations, delusions, dementia, delirium, and disorders of mood or perception may also be caused by substance abuse. Aggressive behavior may also result

from the use of some drugs (e.g., phencyclidine [PCP], anabolic steroids). In addition, substance abuse may trigger exacerbations of existing mental disorders, such as schizophrenia, depression, and anxiety (NIDA, 2012b).

Preoccupation with the abused substance can lead to a variety of social problems for the substance abuser. Relationships with family and friends may be impaired, or abusers may become incapable of or disinterested in performing their jobs and may be fired. Substance abuse may also lead to poor educational outcomes, limiting the abuser's employability. Initiation of substance use at a young age has been linked to lower income and lower occupational and educational attainment at midlife (Sloan & Grossman, 2011). Unemployment can lead to difficulties in obtaining housing and can contribute to homelessness. Furthermore, the need to obtain money to support a drug habit or to obtain necessities may lead to criminal activity.

Family Effects

The effects of substance abuse on the family of the abuser can be many and severe. These families are characterized by frequent conflict, anger, ambivalence, fear, guilt, confusion, mistrust, and violence as a mode of conflict resolution. The family frequently becomes socially isolated in efforts to cover up the problem of abuse and so may not be able to make use of sources of assistance that might be available to them.

Substance abuse may also be a factor in poor parental role execution, leading to neglect and abuse of children. Children of substance-abusing parents are three to four times more likely to abuse substances themselves than children whose parents do not abuse alcohol or drugs. In addition, they are more likely to exhibit depression, eating disorders, conduct disorders, emotional problems, and poor school performance (American Academy of Experts in Traumatic Stress, 2012).

Direct exposure of children to psychoactive substances within the family and home setting has a variety of adverse physical and psychological effects. Children with perinatal exposure to alcohol, nicotine, or other drugs may be lower in birth weight, be particularly irritable and difficult to comfort, and experience poor school performance later in life. Drug use during pregnancy may also contribute to premature labor. Home exposure to tobacco smoke also affects the health status of children and may contribute to a variety of respiratory conditions as well as childhood cancers. The health effects of drug exposures for infants and children are discussed in more detail later in this chapter.

Other familial effects of substance abuse may include increased illness among nonabusers, poor psychological and interpersonal function, social adjustment difficulties, and lack of family cohesion (American Psychological Association, 2014). These families may also experience interpersonal conflict; divorce is seven times more common among families with substance-abusing members than other families. Family violence is also six times more common in families experiencing substance abuse than in other families (Academy of Experts in Traumatic Stress, 2012). Legal and

financial difficulties are also common, and health care utilization rates by family members may be as much as four times higher than those of the average American family (American Psychological Association, 2014)

Family members may exhibit the phenomenon of codependence. **Codependence** is a dysfunctional relationship in which one or more family members attempt to deny the existence of a substance abuse, mental health, or other problem (e.g., compulsive gambling) in a family member and sacrifice their own needs to care for the abuser and try to “fix” his or her problems. Codependence is sometimes referred to as “relationship addiction” because the codependent person tends to form relationships that are one-sided and emotionally destructive in order to meet their own need to be needed. Codependents practice maladaptive behaviors to cope with the problem of abuse. Characteristics of codependents center on patterns of denial of feelings, emotional repression, conflict avoidance, and low self-esteem (Mental Health America, n.d.). Codependents may also engage in enabling behaviors in which they ignore the behavior of the substance abuser or make excuses for that behavior, thereby enabling the behavior to continue without challenge (Schimelpfening, 2011).

Co-dependents Anonymous (CoDA), a support group to foster healthy interpersonal relationships, has developed a set of characteristics and behavior patterns that can help people determine if they are codependent (CoDA, 2013). The patterns focus on behaviors demonstrating characteristics of denial, low self-esteem, compliance with the wishes of others, control, and avoidance typical of codependents (CoDA, 2010). In addition, the organization has developed tools for recovery that may assist people in overcoming their codependence (CoDA, 2013). For more information about these behavior patterns, characteristics, and tools, see the *External Resources* section of the student resources site.

Societal Effects

Societal effects of substance abuse include increased morbidity and mortality, economic costs, and increased crime. Physical morbidity related to psychoactive substance abuse was addressed in relation to the personal effects of substance abuse. At the societal level, abuse leads to increased incidence and prevalence of these conditions.

MORTALITY. As noted earlier, substance abuse leads to increased mortality, either directly as a result of drug overdose or withdrawal or indirectly due to other conditions related to abuse. The contribution of smoking to increased mortality was discussed in Chapter 27∞. Alcohol accounts for 2.5 million deaths per year and is the third most common cause of premature mortality worldwide (Pridemore, Chamlin, & Andreev, 2013). Most of these deaths are the result of chronic alcohol-related diseases, such as cirrhosis, liver cancer, and cardiovascular disease (World Health Organization [WHO], 2011). In the region of the Americas, alcohol is the most frequent cause of disease and disability with more than 9% of the total

disease burden in the region related to alcohol (Stockwell et al., 2013).

In the United States, excessive alcohol use resulted in approximately 79,000 deaths and 2.3 million years of productive life lost (YPLL) each year from 2001–2005. Half of those deaths and two thirds of YPLL were the result of binge drinking (Kanny, Liu, Brewer, Garvin, & Balluz, 2010). From 2006 to 2010, an average of 88,000 deaths per year occurred as a result of alcohol use (McKnight-Eily et al., 2014). In 2010, alcohol was directly related to 25,692 deaths, excluding deaths resulting from indirect effects related to MVAs, suicide, and homicide. The mortality rate for alcohol-induced deaths was 8.3 per 100,000 population (Murphy, Xu, & Kochanek, 2013a, 2013b). Globally, the World Health Organization considers alcohol use a leading factor for death and disability. Worldwide alcohol consumption contributes to 3.8% of all deaths and 4.6% of disability-adjusted life years (DALYs) (Babor & Robaina, 2013).

Accidental mortality related to alcohol abuse is of particular concern. In spite of decreases in the number of alcohol-related motor vehicle fatalities, 37% of motor vehicle fatalities among people 16 to 20 years of age in 2012 involved alcohol, a decrease from 60% in the mid-1970s (National Institutes of Health [NIH], 2013). Alcohol use is also implicated in other injury fatalities, including falls, drowning, and burns. In addition to accident fatalities, alcohol is a factor in other deaths, including homicide; suicide; deaths due to cancers of the lip, oral cavity, pharynx, esophagus, stomach, liver, and larynx; cardiovascular deaths; and deaths due to respiratory diseases, digestive diseases, and diabetes mellitus. A meta-analysis of

Alcohol misuse is a leading cause of death and disability worldwide. (kmiragaya/Fotolia)

relevant studies concluded that alcohol consumption led to an estimated 18,200 to 21,300 cancer deaths in the United States. This amounts to 3.2% to 3.7% of all cancer deaths. People who consumed more than one-and-a-half drinks per day accounted for 26% to 35% of cancer deaths, and each death resulted in 17 to 19.1 years of productive life lost (Nelson et al., 2013).

Other addictive substances also contribute to significant mortality. In 2010, for example, 40,393 drug-induced deaths occurred in the United States, for a mortality rate of 13.1 per 100,000 population. Again, these figures exclude indirect contributions of drug abuse to accidental deaths, suicides, and homicide (Murphy et al., 2013a, 2013b). Drug overdose is the leading cause of accidental death in the United States, outpacing even MVAs. Based on data from the Centers for Disease Control and Prevention (CDC), overdose rates have increased approximately 500% since 1990 (Harm Reduction Coalition, n.d.a), and in 2007, 100 drug overdose deaths occurred daily in the United States (Paulozzi, Jones, Mack, & Rudd, 2011).

Most of these deaths are due to opioid analgesics. From 2002 to 2006, deaths due to prescription opioid pain relievers increased by 98% (Momper, Delva, Tauiliili, Muehler-Williams, & Goral, 2013) exceeding combined mortality rates for heroin and cocaine (Cerdá et al., 2013). In 2010, the U.S. opioid poisoning mortality rate was 5.4 per 100,000 population (National Center for Health Statistics [NCHS], 2014).

COST. Substance abuse also affects society in terms of its economic costs. Estimates of the total economic cost for alcohol and drug abuse in the United States are more than \$600 billion per year. Approximately \$193 billion is spent each year in relation to abuse of illicit drugs, and another \$193 billion is spent in addressing problems caused by tobacco use. Alcohol abuse costs another \$235 billion per year (NIDA, 2012b). These costs include health care costs related to substance-related accidents and chronic health problems, property damage related to accidents, and substance abuse treatment costs. In addition, substance abuse poses costs for employers in terms of increased absences, tardiness, accidents, workers' compensation claims, and employee turnover and training costs (NIDA, 2014a). In addition, the estimated lifetime cost of caring for a child with fetal alcohol syndrome (FAS) is \$2 million, and the estimated annual cost of FAS in the United States is \$4 billion (Division of Birth Defects and Developmental Disabilities, 2012).

Without doubt, drug and alcohol abuse are costly public health problems that the nation can ill afford. Prevention and treatment of substance abuse, on the other hand, are cost-effective. NIDA (2012d) estimated that every dollar invested in substance abuse treatment, for example, saves \$4 to \$7 in reduced crime, criminal justice, costs, and theft. For example, the average per person cost of 1 year of methadone maintenance treatment is \$4,700, compared to the cost of 1 year of incarceration at \$24,000 per person. When reduced health care costs are included, savings exceed costs by about 12 to 1. These

figures do not even consider the reduction in costs due to lost productivity and drug-related accidents (NIDA, 2012d).

CRIME. One final social effect associated with the abuse of many substances (excluding nicotine) is increased crime. According to data from the Arrestee Drug Abuse Monitoring Program (ADAM-II) across selected major cities, arrests for drug-related crimes ranged from 19% in Denver to 43% in Chicago. Drug use is also implicated in crimes that are not drug-related, and 62% to 86% of all arrestees across sites tested positive for one or more drugs, and 12% to 34% in different jurisdictions were positive for multiple drugs. The most commonly used drug was marijuana (Office of National Drug Control Policy, 2013).

Alcohol use is also implicated in criminal activity. Alcohol use is a factor in 40% of violent crimes, and 36% of people under correctional supervision were drinking at the time of their criminal offense (National Council on Alcoholism and Drug Dependence [NCADD], n.d.b). With the exception of robberies, alcohol use is more common among perpetrators of violent crimes than other drug use (NCADD, n.d.a), and alcohol was a contributing factor in 40% of murder convictions of prisoners in jails or state prisons (NCADD, n.d.b).

Crimes may be committed as a result of the lowering of inhibitions caused by alcohol and other drugs. In other cases, crimes such as theft may be a means of supporting a drug or alcohol habit.

Trends in Substance Use and Abuse

Psychoactive substances are abused because of their desirable initial effects. Some of these effects and the drugs associated with them are presented in Table 29-1 •. Rates of psychoactive substance use in general are relatively high in the United States. The most current statistics indicate that the percentage of people over 12 years of age who reported ever using any illicit drug increased from 46.4% in 2003 to 47% in 2008. The percentage of people who reported current illicit drug use declined slightly over the same period from 8.2% to 8% (U.S. Census Bureau, 2013b), but increased to 9.2% in 2012 (NCHS, 2014). Psychoactive substances commonly involved in either dependence or abuse include tobacco, alcohol, prescription drugs, illicit drugs, and other drugs. Each category is briefly discussed below and selected characteristics are summarized in Table 29-1.

Tobacco may be consumed either by smoking or in smokeless forms. As noted in Chapter 27 ∞, approximately 19% of the U.S. adult population smokes cigarettes. In 2008, nearly 24% of the population 12 years of age and older smoked cigarettes, 5% smoked cigars, and 0.8% smoked pipes. Overall, 3.5% of people reported current use of smokeless forms of tobacco (U.S. Census Bureau, 2013b).

Although the use of smokable forms of tobacco has declined over the last several years, use of smokeless tobacco

TABLE 29-1 Selected Psychoactive Substances, Street Names, Typical Routes of Administration, and Effects Promoting Abuse

Substance	Street Names	Typical Route of Administration	Effects Promoting Abuse
Alcohol	Beer, wine, spirits, booze, various brand names	Orally ingested	Relaxation, decreased inhibitions, increased confidence, euphoria
Sedatives, hypnotics, and anxiolytics		Orally ingested, injected	Calming effect, decreased nervousness and anxiety, improved sleep, relaxation, mild intoxication, loss of inhibition
Barbiturates Amytal Nembutal Phenobarbital Seconal Tuinal Quaalude	Blues, downers Yellows, yellow jackets Phennie, purple hearts Reds, F-40s, Redbirds Rainbows, tooies Ludes, 714s, Q's, Quay, Quad, mandrex		
Tranquilizers (minor) Dalmane Equanil/Miltown Librium Valium Serax	Tranks, downs, downers, goof balls, sleeping pills, candy Muscle relaxants, sleeping pills		
Opioids Codeine Demerol Dilaudid Heroin Methadone Morphine Opium Percodan Cocaine	Schoolboy Demies, dolls, dollies, Amidone Little D, Lords Smack, junk, downtown, H, black tar, horse, stuff Meth, dollies M, Miss Emma, morph, morpho, tab, white stuff, monkey Blue velvet, black stuff, Dover's powder, paregoric Perkies Coke, snow, uptown, flake, crack, bump, toot, c, candy	Orally ingested Injected Injected Injected, smoked, sniffed Injected Injected Orally ingested, smoked, injected Orally ingested Snorted, injected, Smoked	Pain relief, euphoria Increased alertness, confidence, euphoria, reduced fatigue
Amphetamines Benzedrine Biphetamine Desoxyn Dexedrine Methedrine MDMA	Bennies, pep pills, uppers, truck drivers Black beauties Co-pilots Dex, speed, dexies Meth, crank, speed, crystal, go fast Ecstasy	Orally ingested	Increased alertness, confidence, decreased fatigue, euphoria
Hallucinogens Phencyclidine LSD MDA Mescaline Peyote Psilocybin	Angel dust, krystal, DOA, hog, PCP, peace pill Acid, microdot, cubes The love drug Cactus, mesc Buttons Magic mushrooms, shrooms, sacred mushrooms	Orally ingested, smoked, injected Smoked, orally ingested, injected	Altered perceptions, mystical experience Dreamlike state producing hallucinations
Cannabis Hashish Hashish oil	Kif, herb, hash Honey, hash oil	Smoked, orally ingested	Relaxation, euphoria, altered perceptions

(Continued)

TABLE 29-1 (Continued)

Substance	Street Names	Typical Route of Administration	Effects Promoting Abuse
Marijuana	Grass, ganja, weed, dope, reefer, Thai sticks, pot, Acapulco gold, roach, loco weed, Maui wowie, joint, Mary Jane		
Inhalants Amyl nitrate Butyl nitrate Nitrous oxide	Poppers Locker room, rush Laughing gas	Inhaled	Relaxation, euphoria, intoxication
Nicotine	Various brand names of tobacco products	Smoked, chewed	Relaxation, mild stimulation

has increased. Snus (pronounced “snoose”) or “Swedish tobacco” is a spit-free moist fermented tobacco product packaged in tea-bag-like pouches that are placed between the upper lip and gums to allow absorption of its psychoactive components (Tobacco Control Legal Consortium, 2013). In 2009, just over 5% of U.S. adults reported use of snus in their lifetimes and nearly 2% reported current use. Electronic cigarettes or e-cigarettes provide aerosolized nicotine, flavoring, and other chemicals via a battery-powered electronic device. The resultant vapors are then inhaled by the user (U.S. Food and Drug Administration [FDA], 2014). Lifetime use of e-cigarettes quadrupled from 0.6% in 2009 to 2.7% in 2010, with current use reported by 1.2% of the U.S. population over age 12. Snus and other dissolvable tobacco products and e-cigarettes provide an alternative in smoke-free environments, promote dual use of smoked and smokeless tobacco, and are considered gateways to smoking initiation by youth (Popova & Ling, 2013). These products are generally free from regulatory control except that e-cigarettes used therapeutically to assist with smoking cessation are regulated (FDA, 2014).

E-cigarettes may be used in the mistaken belief they are less harmful than regular cigarettes. (Diego cervo/Fotolia)

Although moderate alcohol intake has been suggested to have possible positive health effects, alcohol abuse remains a serious problem in the United States and elsewhere in the world. The alcohol contained in alcoholic beverages is ethyl alcohol created by the fermentation of grain mixtures or the juice of fruits and berries. After ingestion, alcohol is rapidly absorbed into the bloodstream through the gastrointestinal tract and functions as a central nervous system (CNS) depressant.

In 2012, more than half of the U.S. (52.1%) population over age 12 reported using alcohol. Almost a fourth of the population (23%) reported binge drinking, and 6.5% reported heavy drinking (NCHS, 2014). Binge drinking is defined as five or more alcoholic drinks in one session for men and four or more drinks for women. Heavy drinking is defined as more than two drinks per day for men and more than one drink per day for women (Li et al., 2011). Some authors note that the figures reported here are probably an underrepresentation of binge drinking and heavy drinking because heavy alcohol consumers are likely to underrepresent the extent of their drinking (Heath, 2012).

A variety of prescription drugs are misused, but abuse of opioid pain relievers (OPRs) is the most common occurrence. In terms of overall drug abuse, misuse of OPRs is second only to marijuana abuse (Cerdá et al., 2013). CDC and the Office of National Drug Control Policy have declared prescription drug misuse epidemic (Spath et al., 2013). OPR sales quadrupled between 1999 and 2010 to a level estimated to be sufficient to medicate every U.S. adult with a standard dose every 4 hours for a month (Paulozzi et al., 2011). In 2010, reported misuse of a prescription drug at least once in a lifetime was reported by 22% of 12- to 18-year-olds and 26% of those 18 to 25 years of age (Spath et al., 2013). In 2008, 2.5% of the U.S. population over 12 years of age engaged in current use of any psychotropic drug, and pain relievers were routinely used by nearly 20% of the population (U.S. Census Bureau, 2013b).

OPRs and other prescription drugs such as sedatives, hypnotics, and anxiolytics are frequently routinely prescribed in primary care and mental health settings to relieve pain or reduce

anxiety and tension and promote sleep. Unfortunately, their prescription for legitimate use often creates dependence. In low doses, these drugs produce a mild state of euphoria, reduce inhibitions, and create feelings of relaxation and decreased tension. Their major pharmacologic action is CNS depression. Because of their widespread use for both legitimate and illegitimate reasons and their easy availability, precise figures on the abuse of these drugs are difficult to obtain. However, in 2008, 0.7% of the population reported current use of tranquilizers and 0.1% reported use of sedatives (U.S. Census Bureau, 2013b).

Illicit drug use involves substances such as marijuana, cocaine, heroin, methamphetamine, hallucinogens such as LSD and ecstasy, inhalants, and steroids. Marijuana is the most commonly used illegal drug in the United States (NIDA, 2014a) even though its possession and use are legal in some jurisdictions and for some purposes. In 2008, more than 6% of the U.S. population over 12 years of age reported current use of marijuana; 0.1% of the population engaged in current heroin use (U.S. Census Bureau, 2013b).

Current cocaine use was reported by 0.7% of the population (U.S. Census Bureau, 2013b). Use of cocaine may be accompanied by the practice of “freebasing.” Normally, to maintain its stability, cocaine is combined with a hydrochloride base, creating a substance that is usually only about 25% cocaine. **Freebasing** involves the use of heat and ammonia or sodium bicarbonate and water to free the cocaine from its hydrochloride base, thus creating a purer product that produces a more intense effect. Because of the combination of heat and the highly volatile and explosive ether, freebasing is an extremely dangerous practice. To eliminate the need for freebasing, drug dealers created **crack**, a stable form of cocaine without the hydrochloride base that can be smoked rather than inhaled, for a more rapid and more intense effect (NIDA, 2010).

Methamphetamine use is a growing problem in the United States, particularly in the western states. The 2012 National Survey on Drug Use and Health (NSHUR) indicated that 1.2 million people (0.4% of the U.S. population) had used methamphetamine in the prior year, and 440,000 (0.2%) had used it in the prior month. This latter figure is a decrease from 0.3% in 2006. In 2012, 133,000 people over 12 years of age initiated methamphetamine use for the first time (NIDA, 2013). In California, methamphetamine abuse increased by 17% per year from 1999 through 2008. This growth occurred in three distinct phases, interrupted by laws limiting access to ingredients needed for methamphetamine production and resuming when production processes were modified to incorporate unregulated ingredients (Gruenewald et al., 2013).

Amphetamines in general lend themselves to chemical modifications to create “designer” or “club” drugs. **Designer drugs** are chemical modifications of drugs whose use in their original form is restricted (Bellum, 2011). Club drugs are used at night clubs, bars, concerts, and parties, and include 3,4-methylenedionymethamphetamine (MDMA), better known as “ecstasy”; ketamine; gamma-hydroxybutyrate (GHB); and Rohypnol (a tranquilizer). Reports of club drugs use by 12th graders in 2013

ranged from 0.9% for Rohypnol to 1.4% for ketamine (NIDA, 2012a). Club drugs may cause brain damage and coma as well as long-term effects on memory and learning abilities, seizures, malignant hyperthermia, paranoia, and hostility. Rohypnol is also known as the “date rape” drug because of its strong hypnotic properties.

Hallucinogens distort the distinction between self and the environment, making the user extremely vulnerable to environmental stimuli. Common effects of these drugs include changes in mood (euphoria or terror and despair), heightened sensation or synesthesia (merging of the senses so colors, for example, are experienced as odors or vice versa), changes in perceptions of time and objects, and changes in relationships, leading to depersonalization and feelings of merging with other people and objects.

Inhalants are abused by sniffing products such as airplane model glue, nail polish remover, gasoline, aerosols, and anesthetics such as nitrous oxide. They usually produce a sense of euphoria, loss of inhibition, and excitement. Inhalants are often used by people who do not have the financial resources to support more expensive drug habits. In addition to a variety of adverse physical effects such as kidney and heart damage, there is the potential for suffocation while inhaling these substances from a plastic bag. Because of their volatile nature, explosion is another hazard presented by inhalants. Hallucinogens and inhalants are used by relatively small numbers of people. In 2008, for example, only 0.4% of persons aged 12 years and older reported current use of hallucinogens, and 0.3% reported inhalant use.

Most steroid use occurs under medical direction for treatment of a variety of conditions in which immunosuppression is a desired outcome (e.g., severe arthritis and other inflammatory conditions). Steroids are abused by a small segment of the population, however, particularly adolescents. Anabolic steroids, more properly called anabolic-androgenic steroids due to their dual effects on muscle building and male sex characteristics, are increasing in use, particularly among youth. Anabolic steroids may be used by adolescents and athletes because of their potential to increase strength and weight and to improve body image and athletic performance. In 2013, for example, 2.1% of 12th graders reported lifetime use of steroids, 1.5% reported use in the past year, and 1% reported past month use. Among eighth-grade users, lifetime, past year, and past month use rates were 1.1%, 0.6%, and 0.3%, respectively (NIDA, 2012f).

Prolonged use of anabolic steroids leads to acne, diminished breast size, ovulatory and menstrual difficulties, deepened voice, clitoral enlargement, and male-pattern baldness in women. In men, effects of prolonged use include continuing erections (priapism), difficult urination, gynecomastia, and impotence. Both men and women may experience liver impairment, urinary calculi, anemia, gastrointestinal problems (e.g., anorexia, nausea), and insomnia.

Over-the-counter (OTC) substances are also subject to misuse. Energy drinks, for example, contain caffeine levels equivalent to one to three cups of coffee or cans of caffeinated soda. An estimated 6% of adolescents and young adults consume energy

drinks daily. At present their use is unregulated. Extensive use may result in caffeine intoxication or overdose, withdrawal, interactions with alcohol, sleep difficulties, daytime drowsiness, and potential for diminished performance and accidents. As noted in Chapter 23, excessive energy drink use is common among military personnel deployed in combat areas (Toblin, Clark-Walper, Kok, Sipos, & Thomas, 2012).

OTC laxatives and diet pills may also be abused for weight control, primarily by youth with eating disorders, particularly bulimia nervosa. An estimated 6% of adolescent girls and 4% of boys use diet products without a health professional's advice. Chronic use of laxatives and diet pills can lead to acute and chronic gastrointestinal and cardiovascular impairments, dehydration, chronic diarrhea or constipation, metabolic acidosis, hypokalemia, and other fluid and electrolyte imbalances. In a meta-analysis of 70 studies, the lifetime prevalence of laxative abuse for weight control was 4% of the general population and 15% to 62% of people with bulimia or other unspecified eating disorders. In 2007, the FDA approved the first OTC diet drug (orlistat or *alli*). Since its OTC designation, approximately 6% of persons with eating disorders have misused the drug (Pomeranz, Taylor, & Austin, 2013).

Global Perspectives

Betel Quid Abuse and Oral Cancers

In addition to substances of abuse common in the Western world, much of Asia is faced with an epidemic of betel quid abuse. Betel quid is an addictive combination of areca nut, betel leaf, slaked lime, and regional flavoring ingredients that is widely chewed throughout Asia. Its use is socially accepted in all levels of society for both men and women and for young children. This is true even in societies where tobacco use is considered objectionable. Regular chewers develop tolerance and experience withdrawal symptoms when not using betel quid. Betel quid abuse has been linked to oral premalignant disorders and cancers of the oral cavity, pharynx, esophagus, and larynx. When tobacco is added, abuse rates increase. In one study rates of abuse varied from 0.8% to 46.3% across six Asian populations. Among current chewers abuse rates were over 40%. Factors associated with abuse include lower education level, younger age at initiation, and familial history of use (Lee et al., 2012).

The combination of betel quid with other addictive substances increases the risk of oral cancer. For example, in studies in India and Taiwan, the risk of oral cancer for users of betel quid alone was 7.9 times that of nonusers; more than double the increased risk for those who only smoked tobacco and three times that for people who only drank alcohol. Combining betel quid and smoking increased the risk to 16 times that of nonusers, and the combination of tobacco smoking, betel quid, and alcohol increased the risk of oral cancer to 40 times higher than that for people who used none of the three substances (Petti, Massood, & Scully, 2013).

Population Health Nursing and Substance Abuse

Population health nurses use the nursing process in the context of the population health nursing model to identify problems related to substance use and abuse and to design, implement, and evaluate control strategies for substance abuse.

Assessing Risks for and Effects of Substance Abuse

The epidemiology of substance abuse indicates that there are contributing factors in each of the six categories of determinants of health (biological, psychological, environmental, sociocultural, behavioral, and health system determinants). Population health nurses should keep in mind that the interplay among factors in each of the six areas that leads to substance abuse is unique to each individual and to each population group. For this reason, nurses should assess the factors contributing to abuse in a given situation prior to developing interventions to address substance abuse in an individual or a population group. Assessment in the control of substance abuse problems occurs at two levels: the population or community level and the level of the individual client.

BIOLOGICAL DETERMINANTS. Human biological factors influencing substance abuse and its effects include age, gender, and race/ethnicity, genetic inheritance, and physiologic function.

Age, gender, and race/ethnicity. Age influences one's risk of exposure to tobacco, alcohol, and other drugs through social factors. For example, young people are more likely to be exposed to peer pressure supporting drug use or smoking than are older people. Adolescents and preadolescents are particularly vulnerable to this type of influence because of their developmental need to conform to peer expectations and to be part of a group. Often, being part of the group depends on engaging in behaviors that place the individual at risk, such as sexual activity, smoking, and drug and alcohol use. In addition, youth are at particular risk for substance use and abuse because areas of the brain that deal with decision making, judgment, and self-control are poorly developed in adolescence, leading to engagement in risk-taking behaviors (NIDA, 2012b).

Younger age at onset of substance use has been linked to greater risk of progression to serious abuse (NIDA, 2012b). For example, approximately 9% of marijuana users become addicted, but the rate of addiction prevalence increases to 17% for those who initiate marijuana use at a young age. Similarly, daily marijuana use increases the risk of addiction to 25% to 50% (NIDA, 2014a).

Alcohol is the substance most commonly misused by youth. Data from the Behavioral Risk Factor Surveillance System

(BRFSS) in 2009 indicated that nearly 42% of high school students reported current alcohol use, and 60% of those were binge drinkers (Kanny et al., 2010). From 2001 to 2005, excessive alcohol use accounted for 4,700 deaths and 280,000 years of productive life lost among people less than 20 years of age in the United States (Jernigan, Ross, Ostroff, McKnight-Eily, & Brewer, 2013).

Other drugs are also misused by youth. For example, the 2012 *Monitoring the Future* survey of adolescent drug use indicated that approximately 1% of 8th, 10th, and 12th graders had used methamphetamine in the prior year (NIDA, 2013). Similarly, a 2009 survey of 400 Native American tribes in the Midwest indicated that nonmedical use of OxyContin was highest in people 18 to 25 years of age (Momper et al., 2013). Population health nurses working with young people should assess their level of maturity and their ability to resist pressure to conform.

Perinatal exposures to drugs and alcohol have a variety of adverse effects on the fetus. Some psychoactive substances, such as alcohol, amphetamines, and cocaine, have teratogenic effects when taken during pregnancy. **Teratogenic substances** are those that cause physical defects in the developing embryo. Other drugs do not affect fetal development per se, but have other adverse health effects for the neonate or long-term effects for the child. For example, fetal alcohol exposure may result in prenatal and postnatal growth deficits, CNS abnormality, and delayed psychomotor development. Fetal, neonatal, and

developmental effects of selected psychoactive substances are presented in Table 29-2.

The true incidence of fetal alcohol syndrome (FAS) and fetal alcohol spectrum disorders (FASD) is not known. An estimated 0.2 to 1.5 cases of FAS occur for every 1,000 live births in the United States, and experts speculate that there may be as many as three times as many cases of FASD (Division of Birth Defects and Developmental Disabilities, 2012). From 2006 to 2010, 76% of pregnant women reported some alcohol use during pregnancy, and 1.4% engaged in binge drinking (Marchetta et al., 2012).

Use of other drugs during pregnancy can also harm the fetus. For example, methamphetamine use by pregnant women may result in prematurity, placental abruption, small gestational size, lethargy, and heart and brain abnormalities. Long-term effects may include attention deficits and increased stress (NIDA, 2013).

Population health nurses are often involved in assisting either biological or foster parents to care for infants and children exposed to alcohol in utero. As noted in Chapter 16, FAS is a condition resulting from maternal alcohol consumption during pregnancy and is characterized by growth retardation, facial malformations, and CNS dysfunctions that may include mental retardation. Long-term effects of FAS include inability to hold down a job, impulsivity, social withdrawal, poor judgment, and mental retardation. In working with newborns and young children, the population health nurse should be alert to

TABLE 29-2 Fetal, Neonatal, and Developmental Effects of Perinatal Psychoactive Substance Exposure

Substance	Fetal Effects	Neonatal Effects	Developmental Effects
Alcohol	Growth deficiency, microcephaly, stillbirth, low birth weight (LBW), joint and facial anomalies, cardiac and kidney anomalies	Acute withdrawal with sedation, seizures, poor feeding	Developmental delay, low IQ, hyperactivity
Sedatives, hypnotics	Sedation at delivery	Tremors, hypertonicity, poor suck, high-pitched cry	Unknown
Opioids	Intrauterine growth retardation, microcephaly, prematurity, hyperactivity	Withdrawal with tremors, hypertonicity, poor feeding, diarrhea, seizures, irritability	Increased rate of sudden infant death syndrome (SIDS)
Cocaine	Spontaneous abortion	Tremors, hypertonicity, muscle weakness, seizures	Developmental delay, increased rate of SIDS
Amphetamines	Intrauterine growth retardation, biliary atresia, transposition of great vessels	Stillbirth, LBW, cardiac anomalies, withdrawal	Poor school performance
Hallucinogens	Agitation at delivery, microcephaly	Irritability, poor fine-motor coordination, sensory input problems	Unknown
Cannabis	Bleeding problems in delivery	Sedation, tremors, excessive response to light	Unknown
Inhalants	Unknown	Unknown	Unknown
Nicotine	Intrauterine growth retardation, microcephaly	Jitteriness, poor feeding	Poor school performance, increased rate of SIDS

signs of perinatal drug exposure. He or she also assesses for risk factors that would make children and youth particularly vulnerable to substance abuse and its effects.

Lower rates of binge drinking are found among the elderly at only 3.8% of the population over 65 years of age. Binge drinking occurs with greater frequency in this age group but at lower levels of intensity (number of drinks per episode) (Kanny, Liu, & Brewer, 2011). Although generally less likely to abuse alcohol and drugs than their younger counterparts, older people may experience more severe consequences because of their diminished ability to detoxify toxic substances. In addition, substance abuse problems in older clients may not be diagnosed because health care providers are not alert to signs and symptoms of abuse in this age group.

Gender differences in substance use and abuse are also common. For example, 2009 BRFSS data indicated twice as many men as women engaged in binge drinking. Men also engaged in binge drinking more often and consumed a greater number of drinks per episode than women (Kanny et al., 2011). Similarly, men are slightly more likely to be admitted to a hospital for methamphetamine-related problems than women (NIDA, 2013). In addition, age-adjusted alcohol-induced mortality among men was three times that for women in 2010 (11.7 and 3.9 per 100,000 population respectively), and drug induced mortality was 59% higher for men than for women (15.9 vs. 10 per 100,000 population) (Murphy et al., 2013b).

There is also variability among racial and ethnic groups in terms of substance abuse and its effects. For example, in 2010, the age adjusted rate for alcohol-induced deaths for the American Indian/Alaska Native (AI/AN) population was 25.4 per 100,000 population, more than three times that of the next highest group—Whites at 8 per 100,000. The lowest alcohol-induced mortality was experienced by the Asian/Pacific Islander (API) population at 1.6 deaths per 100,000 population (Murphy et al., 2013b).

Drug-induced mortality in 2010 was highest for the White population (14.6/100,000 population), followed by the AI/AN population (11.4/100,000), and lowest in the API population. People of Hispanic origin had higher alcohol-induced mortality than non-Hispanics (9.1 vs. 7.4 per 100,000 population), but the Hispanic drug-induced mortality rate was less than half of that for non-Hispanics (6.1 and 14.2 per 100,000 population, respectively) (Murphy et al., 2013b). Population health nurses can initiate public education campaigns targeted at and relevant to high-risk groups. For example, prevention campaigns among Native American groups should be culturally relevant and address the myriad social factors that may contribute to abuse as well as the physiologic differences in drug metabolism that influence development of substance-related problems. Programs may also need to be modified for targeted subpopulations within racial or ethnic groups. For example, U.S.-born African Americans have been shown to have higher rates of alcohol dependence and drug abuse than Caribbean Blacks (Gibbs et al., 2013).

Genetic inheritance. A growing body of evidence suggests that substance abuse is associated with some form of genetic predisposition. Studies of adopted children, for example, indicate

that alcohol abuse by one or both of the biological parents is associated with alcohol and drug abuse by the child, but no increased risk has been noted when adoptive parents drink. The National Institute on Drug Abuse estimates that genetic factors, in combination with environmental influences, account for about half of population vulnerability to addiction. In addition, gene-environment interactions that occur at particularly critical periods of development add to the risk of substance abuse (NIDA, 2012b).

In assessing individuals and families for the level of risk for substance abuse, the population health nurse prepares a detailed genogram that includes information about the family history of substance abuse as well as the presence of physical and emotional illnesses with a genetic component. Population health nurses can also educate the public about the potential heritability of substance abuse risks and advocate for prevention among people who are at risk due to a family history of abuse.

Physiologic function. The relationship between substance abuse and physiologic function is bidirectional. Persons with chronic physical health problems or disability may abuse drugs or alcohol as an escape from pain, depression, or stress related to the disability. Substance abuse may stem from a desire for gratification when other avenues are denied or as a method of regaining control over one's choices and actions. Data from the 2009 BRFSS indicated that binge drinking prevalence, for example, was slightly lower among disabled individuals than in the non-disabled population (14.3% vs. 16%), but that frequency and intensity of binge drinking were higher in the disabled population (Kanny et al., 2011). In working with disabled clients, population health nurses assess clients' responses to disability and their vulnerability to substance abuse as a means of coping with disability.

Rates of substance abuse are also high among HIV-infected individuals. IDU, of course, is a mode of transmission for HIV infection, but even among non-IDUs, rates of substance use and abuse are high. In one national sample, for example, 40% of HIV-positive individuals reported illicit drug use other than marijuana in the prior year, and 12% screened positive for substance dependence. In another eight-city study, 40% of HIV-infected individuals reported heavy alcohol or crack cocaine use in the prior year; 38% reported marijuana use; 14% used heroin or stimulants; and 25% were polydrug users (Mimiaga et al., 2013). **Polydrug use** is the use of more than one psychoactive substance (NIDA, 2010). HIV-infected substance abusers have also been known to divert their antiretroviral (ARV) medications, selling them on the street to support their drug habits. **ARV diversion** is movement of legal regulated drugs to illegal markets (Surratt, Kurtz, Cicero, O'Grady, & Levi-Minzi, 2013). In one study, diverters were significantly less likely than non-diverters to maintain the 95% adherence to treatment required to suppress viral load and prevent HIV transmission (Surratt et al., 2013).

Substance use and abuse may result in physiologic changes. The trajectory of substance abuse usually begins with occasional use and may progress to regular use. In some people, changes in brain metabolism and activity lead to the compulsive, uncontrollable use that characterizes abuse and dependence. These

TABLE 29-3 Signs of Intoxication with Selected Psychoactive Substances

Substance	Typical Indications of Intoxication
Alcohol	Decreased alertness, impaired judgment, slurred speech, nausea, double vision, vertigo, staggering, unpredictable emotional changes, stupor, unconsciousness, increased reaction time
Sedatives, hypnotics, anxiolytics	Slurred speech; slow, shallow respiration; cold and clammy skin; nystagmus; weak and rapid pulse; drowsiness, blurred vision, unconsciousness; disorientation; depression; poor judgment; motor impairment
Opioids	Sedation, hypertension, respiratory depression, impaired intellectual function, constipation, pupillary constriction, watery eyes, increased pulse and blood pressure
Cocaine	Irritability, anxiety, slow weak pulse, slow shallow breathing, sweating, dilated pupils, increased blood pressure, insomnia, seizures, disinhibition, impulsivity, compulsive actions, hypersexuality, hypervigilance, hyperactivity
Amphetamines	Sweating, dilated pupils, increased blood pressure, agitation, fever, irritability, headache, chills, insomnia, agitation, tremors, seizures, wakefulness, hyperactivity, confusion, paranoia
Hallucinogens	Dilated pupils, mood swings, elevated blood pressure, paranoia, bizarre behavior, nausea and vomiting, tremors, panic, flushing, fever, sweating, agitation, aggression, nystagmus (PCP)
Cannabis	Reddened eyes; increased pulse, respirations, and blood pressure; laughter; confusion; panic; drowsiness
Inhalants	Giddiness, drowsiness, increased vital signs, headache, nausea, fainting, stupor, fatigue, slurred speech, disorientation, delirium
Nicotine	Headache; loss of appetite; nausea; increased pulse, blood pressure, and muscle tone

changes occur through two mechanisms: imitation of the brain's normal neurotransmitters or overstimulating the brain's "reward circuits" (NIDA, 2012b). Unfortunately, many psychoactive drugs with potential for abuse have rebound effects that are usually the opposite of their initial effects and lead to repeated use to eliminate the undesirable symptoms created by the rebound. These adverse effects are discussed later in this chapter. Because of the phenomenon of tolerance defined earlier, the user requires larger and larger doses of many drugs to combat rebound effects and to achieve the desired pleasurable effect.

Population health nurses assess individual clients for signs of intoxication with psychoactive substances, as well as for signs of withdrawal from psychoactive substance use. **Intoxication** is a state of diminished physical or mental control that occurs as

a result of the current use of psychoactive drugs. Intoxication with different drugs may be reflected in differing symptoms. For example, cocaine intoxication is characterized by disinhibition, impaired judgment and impulsivity, grandiosity, and compulsively repeated actions. Other common symptoms include hypersexuality, hypervigilance, and hyperactivity. Nicotine intoxication, on the other hand, is characterized by increased blood pressure, heart rate, and muscle tone. Table 29-3• summarizes individual signs of intoxication with selected psychoactive substances, while Table 29-4• provides indicators of withdrawal from specific substances. The nurse also assesses the incidence and prevalence of intoxication and withdrawal in the population.

Substance abuse disorders increase the risks of death and disability due to cirrhosis, heart disease, hepatocellular carcinoma,

TABLE 29-4 Indications of Withdrawal from Selected Psychoactive Substances

Substance	Indications of Withdrawal
Alcohol	Anxiety, insomnia, tremors, delirium, convulsions
Sedatives, hypnotics, anxiolytics	Anxiety, insomnia, tremors, delirium, convulsions (may occur up to 2 weeks after stopping use of anxiolytics)
Opioids	Restlessness, irritability, tremors, loss of appetite, panic, chills, sweating, cramps, watery eyes, runny nose, nausea, vomiting, muscle spasms, impaired coordination, depressed reflexes, dilated pupils, yawning
Cocaine	<i>Early crash:</i> agitation, depression, anorexia, high level of craving, suicidal ideation
	<i>Middle crash:</i> fatigue, depression, no craving, insomnia
	<i>Late crash:</i> exhaustion, hypersomnolence, hyperphagia, no craving
	<i>Early withdrawal:</i> normal sleep and mood, low craving, low anxiety
	<i>Middle and late withdrawal:</i> anhedonia, anxiety, anergy, high level of craving exacerbated by conditioned cues
	<i>Extinction:</i> normal hedonic response and mood, episodic craving triggered by conditioned cues
Amphetamines	Fatigue, hunger, long periods of sleep, disorientation, severe depression
Hallucinogens	Slight irritability, restlessness, insomnia, reduced energy level, depression
Cannabis	Insomnia, hyperactivity, decreased appetite
Inhalants	None reported
Nicotine	Nervousness, increased appetite, sleep disturbances, anxiety, irritability

and stroke. IDUs also have a high risk of impairment due to drug impurities and infection. As we saw in Chapter 26, injection drug use is associated with high incidence of HIV infection and hepatitis B, C, and D. Drug use is also associated with unprotected sexual activity and an increased number of sexual partners, increasing the risk for sexually transmitted infections (STIs) (Mimiaga et al., 2013). Tetanus and abscesses at the injection site also occur with IDU. Substance abuse also increases the risk for other communicable diseases such as tuberculosis and influenza. In addition, substance abuse acts as a barrier to effective TB treatment, control, and prevention. For example, examination of a cluster of TB patients in one county indicated that 88% were engaged in methamphetamine use, and use was reported by 67% of their contacts, with 25% of contacts screening positive for TB infection (Pevzner et al., 2010). As noted earlier, substance use and abuse may also contribute to long-term physical consequences related to accidental injury.

According to the U.S. Surgeon General's 2014 report on the health consequences of smoking and nicotine, the primary psychoactive substance in tobacco, is acutely toxic in high doses. In addition, tobacco use affects multiple biological pathways contributing to elevated risk for diseases such as lung, liver, colorectal, and breast cancers and chronic obstructive pulmonary disease. In addition, smoking increases the risk of tuberculosis disease and related mortality, and both smoking and second-hand smoke exposure increase the risk of stroke. Other effects of smoking include contributions to age-related macular degeneration, erectile dysfunction, diabetes, immune system compromise, and rheumatoid arthritis. Evidence also suggests causal relationships between smoking and asthma incidence and exacerbation, dental caries, and inflammatory bowel disease (Office of the Surgeon General, 2014).

In addition to assessing clients for signs and symptoms of intoxication and withdrawal, population health nurses also assess individual clients for symptoms of long-term effects of substance abuse. These effects can be physical or psychological

and vary with the psychoactive substance. For example, long-term effects of alcohol abuse include malnutrition, cirrhosis, and liver cancer, and typical effects of phencyclidine abuse are psychoses and insomnia. Long-term effects of selected psychoactive substances for individuals are summarized in Table 29-5. The population health nurse would assess individual clients for long-term effects of substance abuse. He or she would also determine the incidence and prevalence of these effects in the population. Biological factors contributing to or resulting from substance abuse can be identified using the *Focused Assessment* questions provided on the next page.

PSYCHOLOGICAL DETERMINANTS. Both personality traits and the presence of psychopathology may contribute to problems of substance abuse. There seem to be some commonalities in the personalities of substance abusers regardless of the type of substance abused. Personality traits that may place one at risk for substance abuse include rebelliousness and nonconformity that may lead to substance abuse as an expression of defiance or as an escape from the constraints and expectations of the adult world. Other common traits in abusers are a greater tolerance of deviant behavior, a poor self-concept, and passive surrender to belief in their own inevitable failure in life. Abusers of psychoactive substances also tend to be impulsive, be unable to value themselves, and have poor tolerance for frustration and anxiety. They may also have difficulty in acknowledging their feelings and in developing interests and deriving pleasure from them. In addition, people who abuse psychoactive substances frequently feel alienated from those around them and are socially isolated. They may also feel powerless, and they usually have poor coping skills.

Substance abusers also tend to display a common set of defense mechanisms that include denial, projection, rationalization, and conflict minimization and avoidance. Abusers frequently deny that they have a problem with substance abuse and assert that they can change their behavior. They may

TABLE 29-5 Long-Term Effects Associated with Abuse of Selected Psychoactive Substances

Substance	Long-Term Effects of Abuse
Alcohol	Malnutrition; impotence; ulcers; cirrhosis; esophageal, stomach, and liver cancers; organic brain syndrome; deafness
Sedatives, hypnotics, anxiolytics	Potential for death due to overdose from increasing doses due to tolerance, impaired sexual function
Opioids	Lethargy, weight loss, sexual disinterest and dysfunction, increased susceptibility to infection and accidents, constipation
Cocaine	Damage to nasal tissue, high blood pressure, weight loss, muscle twitching, paranoia, hallucinations, disrupted sleeping and eating patterns, irritability, liver damage
Amphetamines	Depression, paranoia, hallucinations, weight loss, impotence
Hallucinogens	Memory loss, inability to concentrate, insomnia, chronic or recurrent psychosis, flashbacks
Cannabis	Chromosome changes, reduced sperm count, impaired concentration, poor memory, reduced alertness, inability to perform complex tasks
Inhalants	Organic brain syndrome, liver and kidney damage, bone marrow damage, anemia, hearing loss, nerve damage
Nicotine	Cardiovascular disease, lung cancer, bladder cancer, chronic disease, diabetic complications

FOCUSED ASSESSMENT**Assessing Biological Determinants
Influencing Substance Abuse**

- Are there existing physical health problems contributing to substance abuse? What effects does substance abuse have on efforts to control existing physical health problems (e.g., diabetes) at individual or population levels?
- Is there a family history of substance abuse?
- Does the individual client exhibit signs of intoxication or withdrawal? Does the client exhibit long-term effects of substance use or abuse? What are the incidence and prevalence of intoxication, withdrawal, and long-term effects of substance abuse in the population?
- What influence, if any, does age have on the development of substance abuse in the individual or population? What is the extent of substance use by among various age groups in the population?
- Is the individual client pregnant? What effects will substance abuse have on the fetus? What is the extent of drug or alcohol use during pregnancy in the population?
- What physiological effects has substance use or abuse had for the individual client?
- What are the incidence and prevalence of substance-related morbidity and mortality in the population?

exhibit inability to accept responsibility for their own behavior in other areas as well, and they frequently project or transfer the blame for their own behavior onto others. They also rationalize their behavior without developing true insights into the reason for that behavior. They tend to try to avoid conflict, and may turn to substance abuse as a means of escaping from the stress generated by conflict rather than engaging in positive modes of conflict resolution.

The relationship between substance abuse and other mental illness is often a reciprocal one. For example, the presence of other mental disorders increases the risk for substance abuse. Psychological stress contributes to substance abuse as well (NIDA, 2012b). Similarly, the presence of ADHD has been linked to increased tobacco use, higher rates of hazardous alcohol use, and greater impairment with the use of drugs such as marijuana and other illicit drugs (Rooney, Chronis-Tuscano, & Yoon, 2014). In addition, ADHD has been associated with younger initiation of use of tobacco and other addictive substances, more severe abuse, and a shorter time period from initiation to dependence or abuse (Kousha, Shahrivar, & Alaghband-rad, 2014).

Conversely, substance use and abuse may contribute to or worsen mental illness. For example, marijuana use has been found to worsen schizophrenia and is associated with depression, anxiety, and other personality disorders (NIDA, 2014a). Similarly, methamphetamine use is associated with affective psychoses, schizophrenia, and depression (Gruenewald et al., 2013). Substance use and abuse is also linked to suicide. For example, alcohol use has been associated with suicide, but somewhat differently depending on age, ethnicity, and the method of suicide chosen. Among young and middle adults, alcohol use frequently accompanies suicide by firearms or hanging. For older people, alcohol use is more often associated with suicide by poisoning. Asian/Pacific Islanders often combine alcohol with poisoning as a method of suicide, whereas Blacks combine alcohol with hanging. Overall, in one study, alcohol was associated with 35% of suicides using firearms, 26.8% of hanging suicides, and 32.7% of suicides by poisoning (Conner et al., 2014). In all probability, the use of alcohol lessens inhibitions against suicide. Questions to help identify psychological determinants influencing substance abuse in the population are included in the *Focused Assessment* below.

FOCUSED ASSESSMENT**Assessing Psychological Determinants
Influencing Substance Abuse**

- Does the individual client have a poor self-image?
- What are the client's life goals? Are they realistic?
- Does the client exhibit poor impulse control? What is the client's level of frustration tolerance?
- What life stresses is the client experiencing? What is the extent of the client's coping abilities? What defense mechanisms does the client display?
- What sources of stress in the population may contribute to substance abuse?
- Is there underlying psychopathology contributing to substance abuse? What is the extent of mental illness in the population and what are the associations with substance abuse?
- To what extent is substance use or abuse associated with suicide or suicide attempts in the population?

ENVIRONMENTAL DETERMINANTS. Recent research is confirming the view of substance abuse or addiction as being a product of gene–environment interactions. The interaction between genetic inheritance and environmental factors to result in disease is referred to as **epigenetics**. The environmental component of this interaction is termed the **exposome**, which is defined as critical environmental factors that interact with genetic and psychological variables to result in addiction (Stahler, Mennis, & Baron, 2013). Based on the findings of relevant research, it is believed that memories of physical, social, and community environmental stimuli and contexts associated with prior drug use are stored in the brain. These memories then act as triggers for subsequent use resulting eventually in addiction (Stahler et al., 2013).

It has been proposed that geospatial technology pinpointing the environments in which drug use occurs can help to understand how place and environment influence behavior. It has even been suggested that tracking movement and activities of abusers over time through GPS technology might lead to real-time interventions via mobile devices to prevent drug use (Stahler et al., 2013). For example, one’s phone might locate one in an area with ready access to alcohol. If someone is at risk for alcohol abuse, an immediate automatic text message or telephone call might be generated to help him or her refrain from alcohol use in that environment. Part of the community environment may include local attitudes to drug use and tolerance of the use of specific drugs in that locale. Abuse of specific drugs is known to vary widely by geographic region within the United States. For example, methamphetamine use is more common in western states than elsewhere in the country, with the highest rates of treatment admissions for methamphetamine dependence occurring in Hawaii, followed by San Diego, San Francisco, Denver, and Phoenix (NIDA, 2013). Similarly, adolescent prescription drug misuse has been found to be more common in rural than urban areas (Spath et al., 2013).

Other elements of the environment that may contribute to substance use and abuse include the ease of access to drugs of choice. For example, the density of alcohol outlets has been found to be associated with rates of binge drinking, with 13% of people in areas with 130 alcohol outlets per square mile engaged in binge drinking compared to 8% in areas with only 20

outlets per square mile. Research has also linked alcohol outlet density to arrests for driving under the influence, MVA, injuries, suicide, violence, mean per person alcohol consumption, and alcohol-related disorders (Ahern, Margerison-Ziko, Hubbard, & Galea, 2013), as well as alcohol-related hospital admissions (Stockwell et al., 2013). Another environmental factor linked to increased rates of substance abuse is the extent of abandoned housing in the area (Stahler et al., 2013). This link may be a product of low socioeconomic status and increased stress in neighborhoods or an easy venue for drug exchanges and use.

Environmental exposure to drug-related advertising is another factor in substance use, particularly among youth. For example, one study in Boston found that public school students in grades 5 through 12 were routinely exposed to advertising in subway stations and the exposure to such advertising was 4.5 times more likely in stations in high poverty areas than in more affluent neighborhoods. The authors concluded that the equivalent of every adult and every 5th to 12th grade public school student in the region received daily exposure to alcohol advertising (Gentry et al., 2011).

The environment in which drugs are used may also contribute to adverse effects on health beyond triggers for subsequent use. For instance, many smoke-free workplace regulations provide exemptions for indoor hookah lounges, where tobacco is smoked through water or “bubble” pipes. A study of air quality in indoor hookah lounges found that air quality ranged from unhealthy to distinctly hazardous (Fiala, Morris, & Pawlak, 2012).

Finally, substance use and abuse may contribute to safety hazards in the environment. Earlier we discussed the effects of drug and alcohol use in terms of MVA, but substance use and abuse also contribute to a variety of accidents in occupational and other settings. In addition, the environment involved in methamphetamine production may result in fires or explosions. Furthermore, methamphetamine production includes a variety of toxic chemicals that may affect people living in the surrounding area (NIDA, 2014b). The *Focused Assessment* below provides questions that can assist the population health nurse in assessing environmental determinants influencing substance use and abuse in the population.

FOCUSED ASSESSMENT

Assessing Environmental Determinants Influencing Substance Abuse

- Do the incidence and prevalence of abuse of specific drugs vary by geographic region or neighborhood?
- What is the density of alcohol outlets in the area?
- How accessible are drugs of abuse in the area?
- What is the extent of abandoned housing in the area?
- Where do drugs tend to be used within the area?
- What environmental factors are associated with drug use and may trigger subsequent use?
- To what extent are members of the population exposed to advertising for alcohol and other substances?
- What are the contributions of substance use and abuse to safety and other health hazards in the environment?

SOCIOCULTURAL DETERMINANTS. Sociocultural factors may also contribute to problems of substance abuse. Sociocultural factors addressed here include cultural influences; interpersonal interactions; factors related to socioeconomic status, employment, and occupation; social policies related to substance use and abuse; and addictive substance marketing.

Cultural influences. Family attitudes derive from cultural perceptions of substance use and abuse. Different cultures may have different perceptions of the acceptability of substance use. For example, there is a growing cultural acceptance of recreational or medical use of marijuana in the United States. These changing perceptions are exemplified by the fact that two states to date have legalized recreational use of marijuana by adults and 20 states have legislation permitting medical marijuana use (NIDA, 2014a).

Different cultural groups also have different norms regarding the use of legitimate substances such as alcohol and tobacco. For example, cultural groups vary with respect to norms regarding who should drink alcohol (e.g., men, women, or both), the appropriate age for initiating alcohol use, and what beverages are appropriate (e.g., beer or hard liquor). Norms may also specify when alcohol should be consumed. For example, alcohol may be used primarily for celebratory reasons or at holidays in some cultures and on any occasion in others. Similarly, there may be restrictions on the time of day one should consume alcohol (e.g., never before noon) or specific forms of alcohol (e.g., champagne at a fancy brunch or mimosas in the morning). Other norms may involve the “etiquette” of drinking; for example, should one drink a beer from the bottle or from a glass? Whether or not to sip one’s drink or belt it down may also be dictated by cultural norms (Heath, 2012). Knowledge of cultural norms for the use of alcohol and other legitimate substances, such as tobacco and prescription medications, can assist population health nurses in identifying factors that may contribute to the risk for misuse and abuse in different segments of the population.

Interpersonal interactions. Day-to-day interpersonal interactions also influence initiation of substance use and risk for abuse. Family interactions and relationships with peers are two common elements influencing substance abuse in populations.

Families with low cohesion, high levels of conflict, few shared interests and activities, poor coping strategies, and marital dissatisfaction increase the risk of substance abuse in their members. Families who encounter multiple stressors and have inadequate resources are also at risk. Episodes of violence within the family can also lead family members to abuse substances as a means of escape from family tensions. Good parent–child communication, maternal use of reasoning with children, and adequate supervision of children, on the other hand, may have a protective effect on initiation and use of substances with the potential for abuse. Family attitudes toward and use of alcohol, tobacco, and other substances of abuse also influence substance use by family members. Population health

nurses should assess families for conditions that may contribute to substance abuse by family members.

Peer influence is another interaction factor in the social environment that may contribute to substance abuse. In adolescents and preadolescents, in particular, pressure from peers to smoke, drink, or use other psychoactive drugs is a powerful motivator for initiating these behaviors (NIDA, 2012b). In working with young people, in particular, the nurse carefully assesses peer attitudes toward substance use and abuse as well as the degree to which the individual feels a need to conform to peer-dictated norms.

Modes of social interaction may also contribute to access to and misuse of psychoactive substances. For example, the Internet makes it much easier to obtain controlled substances. Similarly, cellular telephones and social networking sites can facilitate drug distribution (Stahler et al., 2013).

Socioeconomic status, employment, and occupation. Social factors related to one’s socioeconomic status, employment, and occupation may also contribute to substance use and abuse. For example, *community level income inequality*, or the magnitude of differences between the richest and poorest members of a population, has been associated with both light and heavy drinking, with these associations found to be stronger for Blacks and Hispanics than for Whites (Karriker-Jaffe, Roberts, & Bond, 2013). Binge drinking is more common among people with annual incomes over \$75,000 than among those with incomes under \$25,000. Persons with cellular telephones also have higher rates of binge drinking at both high and low socioeconomic levels than those with landline telephones only (Kanny et al., 2010), perhaps reflecting the availability of disposable income. Heavy drinking is more prevalent at higher-income levels than among people with lower annual incomes; however, lower-income levels are associated with greater frequency and intensity of heavy drinking (Kanny et al., 2011).

Social factors such as poverty, unemployment, and discrimination may create a sense of hopelessness and powerlessness that leads to substance abuse as an escape or to enhance one’s own feelings of competence. In addition, income levels may affect the extent and severity of substance-related health problems. For example, in one study in New York City, analgesic overdose fatalities were less common in higher-income neighborhoods than in lower-income area. Neighborhoods with high rates of analgesic overdose fatalities were characterized by fragmentation, increased levels of divorce, low employment and education levels, lack of health care resources, and neighborhood deprivation (Cerdá et al., 2013).

Substance abuse disorders are prevalent among homeless individuals, but the direction of the relationship may be unclear. In many cases, individuals become homeless as a result of substance abuse disorders and inability to maintain suitable housing. In others, homeless people may turn to alcohol or drug abuse as a means of coping with their homelessness. Substance abuse has been found to be the strongest predictor of returning to homelessness (Zur & Mojtabai, 2013).

Occupation is another sociocultural determinant that may contribute to substance abuse. Some occupational groups may be at increased risk for substance abuse, particularly those who are expected to entertain clients who drink. Similarly, substance abuse may occur among health care providers because of easy access to controlled drugs. An estimated 10% to 15% of nurses, for example, may be impaired by or recovering from substance abuse disorders. The legal obligation of coworkers to report an impaired nurse varies among jurisdictions, but nurses have an ethical obligation to clients, colleagues, the profession, and the public to assure that impaired nurses do not compromise patient safety (Thomas & Siela, 2011).

Employer attitudes toward and sanctions for alcohol, drug, and tobacco use also influence the extent of use among employees. As we saw in Chapters 23 and 27, smoke-free workplaces lead to reduced smoking among employees as well as decreased exposure to second-hand smoke for nonsmoking employees. Some businesses and industries also perform drug testing at the time of employment or periodically throughout employment. Unemployment and attendant stress and hopelessness may contribute to substance abuse. The effects of unemployment are also seen in the aftermath of substance abuse among recovering substance abusers who experience difficulty obtaining work.

Social policy issues. Societal attitudes and policies related to drug use and abuse also influence the extent of substance abuse in the population. Legal jurisdiction for policies related to substance use and abuse occurs at multiple levels. For example, states and municipalities have jurisdiction over laws that govern tobacco and alcohol use and, increasingly, use of marijuana for recreational or medicinal purposes. The multiplicity of jurisdiction leads to differences in access to addictive substances, substance control spending, smoke-free air laws, advertising regulations, and excise taxes. Increased excise taxes on tobacco and alcohol have been shown to affect per capita consumption. For example, in one study of state tobacco excise taxes, every ten-cent increase in taxes on a pack of cigarettes reduced cigarette consumption by nearly three fourths of a pack per person per month (Sanders & Slade, 2013). Similarly, a 10% increase in the minimum price per unit of alcohol was associated with an almost 9% decrease in acute alcohol-related hospital admissions and a slightly greater decrease in admissions for chronic problems related to alcohol use (Stockwell et al., 2013).

States and municipalities also vary with respect to the extent and strength of tobacco-free legislation. Throughout the nation, coverage under such legislation differentially affects certain groups. For example, one national study indicated better coverage and more comprehensive laws in areas with high Asian and Hispanic populations, and less coverage in primarily White or Black populations, suggesting a need for regionally tailored policy interventions to equalize disparities in coverage (Gonzalez, Sanders-Jackson, Song, Chen, & Glantz, 2013).

Tobacco control in the military falls under federal jurisdiction. Some authors have noted that Congressional

opposition has impeded tobacco control in military settings. This opposition may even be abetted by the views of civilian public health leaders. In one study of national public health leaders, several were opposed to banning tobacco use on military installations as a violation of smokers' rights (Smith & Malone, 2013).

In Russia, alcohol control policy is federally mandated and regulates the production and sale of alcohol-containing products. Legislation requires registration of production and distribution facilities at relatively high fees. This has resulted in fewer producers because many producers were forced to close when they could not afford the registration fees. Fewer producers has increased the price of alcohol and decreased consumption. As a result, Russia experienced a drastic decline in alcohol-related transportation fatalities, male alcohol-poisoning deaths, male and female cirrhosis deaths, and suicide rates. The policy change, initiated in 2006, has been credited with saving more than 4,000 lives per year (Pridemore et al., 2013).

In the United States, *internal possession laws* enacted in several states have been associated with decreased probability of past month drinking among youth. Internal possession laws prohibit minors from possessing alcohol within their bodies and permit arrests based on behavioral assessment or blood or urine alcohol levels rather than being caught with alcohol in one's possession (Disney, Lavalley, & Yi, 2013).

Policy initiatives such as internal possession laws can contribute to substance control, but may also have unanticipated consequences. For example, implementation of age-related restrictions on the purchase, possession, and consumption of alcohol among youth have resulted in decreased hospital admissions for alcohol-related conditions among youth under the legal drinking age. Among youth just over the legal age, however, hospitalization rates for alcohol use disorders, self-inflicted injury, and alcohol-related MVA increased. Increased rates were also noted for emergency department visits, assaults, and alcohol-related suicide in the group just over the legal drinking age (Callaghan, Sanches, Gatley, & Cunningham, 2013). These figures suggest that youth who are freed from age-related restrictions on alcohol use may tend to engage in over-use in celebration of that freedom.

Other policies also influence control of substance abuse, some more successfully than others. For example, California has made several attempts to control methamphetamine production, use, and abuse by restricting purchase of chemicals needed for production. Such legislation has resulted in transient decreases in methamphetamine arrests and hospitalizations, but has inevitably been followed by changes in production and distribution processes and subsequent increases in abuse (Gruenewald et al., 2013).

As noted earlier, recent policy changes in some jurisdictions reflect changing societal attitudes to marijuana use and decreased perception of the associated risks. As of early 2014, two states had legalized recreational use of marijuana by adults and 20 states had enacted medical marijuana use laws (NIDA,

2014a). Medical marijuana use laws typically include four main provisions. Users must possess a state issued registry or identification card authorizing marijuana possession and use. The laws also address specific conditions for which marijuana may be used and include provisions prohibiting disciplinary action against physicians who prescribe marijuana for these conditions. Additional provisions regulate access to and possession and cultivation of marijuana. Finally, the legislation provides protection from prosecution for the medical marijuana user. Despite concerns that legalization of marijuana for medical purposes might lead to increased use by adolescents, research has indicated that has not occurred (Lynne-Landsman, Livingston, & Wagenaar, 2013).

Recreational use of marijuana is proving a bit more difficult to control, however. In Colorado, recreational use was approved in 2014 making it legal for persons over 21 years of age to possess up to one ounce of marijuana for any purpose. Unlike medicinal marijuana, recreational marijuana is being sold in a variety of food and beverage items that require child-proof packaging. Like regulation of tobacco sales, prevention of purchase of these items by minors is difficult with retailers not engaging in mandated age verification procedures. In addition, these products contain less than 10 mg of tetrahydrocannabinol (THC), the main psychoactive ingredient in cannabis preparations, resulting in a slower high and temptations to use larger amounts (James, 2014).

Attitudes that promote incarceration rather than treatment are another example of societal policy issues that influence substance abuse and its effects. As noted in Chapter 24, many jurisdictions are opting for drug courts and mandatory treatment rather than incarceration for first-time offenders. Goals of drug court programs include reducing substance abuse and criminal justice recidivism among abusers and increasing the likelihood of drug offenders' successful rehabilitation. Drug courts provide access to substance abuse treatment and minimize use of incarceration as a control strategy (Judicial Council of California, 2014). The National Association of Drug Court Professionals (NADCP) has developed a set of key principles for court-directed treatment programs. These principles include the following:

- Integration of substance abuse treatment with justice system case processing
- Use of a non-adversarial approach by prosecution and defense lawyers, focusing on public safety while protecting offenders' right to due process
- Early identification of eligible offenders
- Assured access to substance abuse treatment and other rehabilitative services
- Objective monitoring of continued substance use by testing
- A coordinated response to noncompliance
- Ongoing interaction between offenders and the court
- Evaluation of program outcomes
- Continuing interdisciplinary education of program officials and providers

- Development of partnerships between courts and public and community-based agencies for program support
- Ongoing case management and support for social reintegration
- Appropriate program flexibility to address the needs of special populations (e.g., women, ethnic minorities)
- Provision of post-treatment and aftercare services and support (NADCP, n.d.).

In addition, NADCP (2013) has developed a set of best practice standards for drug courts. For further information about the standards, see the *External Resources* section of the student resources site.

Other jurisdictions are choosing to reduce sentences for nonserious, nonviolent crimes, including possession and use of drugs. For example, California voters passed the Three Strikes Reform Act of 2012 (proposition 36), which shortens the sentences for prisoners convicted of nonserious, nonviolent crimes, including substance abuse-related crimes. As of August, 2013 only 1,000 eligible inmates had been released, and less than 2% of them had been rearrested, a recidivism rate far below state and national averages. Unfortunately, those released are not eligible for state or county employment, housing, or substance abuse treatment assistance putting them at a disadvantage in successfully reorienting their lives. In the first year of implementation, the early release program saved the state \$10 to \$13 million (Stanford Law School Three Strikes Project & NAACP Legal Defense and Education Fund (n.d.).

Addictive substances marketing. In today's world, cultural attitudes toward specific behaviors may be strongly influenced by media messages. For example, media portrayals of drinking and smoking as desirable behaviors influence use of alcohol and tobacco. Media are also being used to send messages to discourage inappropriate use of drugs and alcohol. Some of these media messages are being generated by firms that produce alcoholic beverages in an attempt to convey an image of corporate social responsibility. **Corporate social responsibility** has been defined as business practices that assist companies to maintain a positive public image and exert favorable influence on policy makers (Babor & Robaina, 2013).

Typical health-related corporate social responsibility activities of the alcohol industry center on research sponsorship, efforts to mold public perceptions of alcohol policy research, sponsorship of scientific documents and conferences, and efforts to influence public health policy. Independent scientific evidence generally supports reducing alcohol consumption through regulatory measures, but industry-supported researchers frequently criticize the methodology and findings of independent research. As a result, the alcohol industry has engaged in research and policy related activities that fall under the guise of corporate social responsibility, but are primarily intended to further the industry's own interests and policy agenda (Babor & Robaina, 2013).

Evidence-Based Practice

Understanding Attempts to Derail Evidence-based Policy

A significant body of research is available that underscores the effects of addictive substances and behaviors, such as alcohol, tobacco, drug use, and uncontrolled gambling, on personal and population health. Unfortunately, this evidence base is rarely used in developing control policies. Adams (2013) contended that another body of evidence is needed regarding what he referred to as “addiction studies research” to understand the influence exerted by addiction product industries (e.g., tobacco and alcohol producers and advertisers, casinos, etc.). Such research could inform strategies to counteract industry attempts to derail or modify legislative policies that might reduce industry profits. Adams described three approaches to addiction industries research, all of which will be needed to develop a sufficient evidence base to counteract addiction industry influence in policy making.

The first area of research involves understanding the pathways by which industry influence occurs. Examples found in recent literature include the expected advertising, targeted marketing, and lobbying strategies, but other forms of influence include research and event sponsorship and charitable giving. The second focus of addiction industries research should be on determining and making public the amount of money spent by addiction industries on influencing policy and public opinion. Finally, research is needed on effective strategies to minimize industry influences (Adams, 2013). Some of this research is already being conducted, but more is needed. Armed with this three-pronged evidence base, public health organizations would be better equipped to promote effective policies for addiction prevention and control.

The value of underage drinking is estimated at \$22.5 billion per year, while excessive drinking among adults accounts for another \$48.3 billion in revenues the alcohol industry is reluctant to give up. To forestall regulatory initiatives, the alcohol industry tends to support research that emphasizes the positive effects of moderate drinking to offset data on the burden of illness derived from independent studies. Although moderate drinking has been shown to have some positive effects at the individual consumer level, these effects have not held up in aggregate level studies. The alcohol industry provides research support for grant-making organizations that often have industry representatives on boards that award funds and target studies that are likely to be favorable to the industry. For this reason, some scientists have called for a moratorium on accepting alcohol (and tobacco) industry funding for research because of the potential for conflicts of interest.

The alcohol industry has also attempted to sway public perceptions of alcohol-related research. For example, a report on alcohol policies generated for the British government with the assistance of the Portman Group, a major alcohol producer, has been criticized for opposing, minimizing, or ignoring evidence-based alcohol control policies in favor of approaches such as school-based alcohol education, which have proven less effective, but are less detrimental to industry interests. In addition, the industry has also paid academics to write letters to editors of professional journals criticizing and discrediting the findings of independent research. Similarly, industry-sponsored publications and conferences have been criticized for ignoring dissenting findings and being overly enthusiastic about the positive effects of alcohol use. Finally, the industry consistently supports policy initiatives that do not conflict with industry interests, such as drunken driving legislation, responsible drinking initiatives, and industry self-regulation (Babor & Robaina, 2013). The Smirnoff company, for example, has

engaged in a campaign to convince policy makers of its commitment to preventing underage drinking and reducing harmful effects of alcohol use. Company efforts have emphasized funding prevention programs focused on education, public awareness, and responsible retail practices, which have been shown to be ineffective, broadcasting “responsibility” ads, establishing partnerships with government and public health agencies, and establishing a self-regulatory structure to regulate advertising (Mosher, 2012).

Industry self-regulation typically focuses on industry pledges not to market addictive substances to youth. For example, the alcohol industry voluntarily agreed not to advertise alcohol on television when more than 30% of the audience is expected to be less than 21 years of age. The National Research Council of the Institute of Medicine proposed lowering the standard to times when more than 15% of viewers would be expected to be youth. A study of advertisements in 25 market areas indicated that nearly 24% of the ads violated the industry standard and 35% would violate the more stringent IOM standard (Jernigan et al., 2013). Similarly, the beer industry has developed a self-imposed advertising code that addresses types of content and exposure markets to be avoided. A study of beer advertising during NCAA basketball tournaments from 1999 to 2008 indicated that 35% to 74% of the ads had code violations, primarily related to the association of beer drinking with social success and use of content that would appeal to people under 21 years of age (Babor, Xuan, Damon, & Noel, 2013).

Media marketing for addictive substances such as tobacco and alcohol often relies on **market segmentation**, which involves the development of tailored marketing plans for specific segments of the population. The intent of segmentation is to identify groups of potential consumers who share certain characteristics and can be anticipated to respond in similar ways to particular marketing strategies. Segmentation requires a

substantial population segment that is measurable in terms of its size and purchasing power, is accessible, and is “actionable,” meaning that specific marketing strategies can be designed to influence its members (Iglesias-Rios & Parascandola, 2013).

Segmented marketing approaches are typically based on sophisticated analyses of the target population’s characteristics. As an example, the R. J. Reynolds Tobacco Company identified young Hispanics as an undersold market and developed a sophisticated surveillance system to track tobacco use in this population. Their research identified five key population segments, those who were concerned with being ruggedly masculine, the “cool” group, those focused on being stylish, those who believed in moderation, and those concerned with savings. Acknowledging the heterogeneity of the Hispanic market, the company then developed marketing strategies to address each of these market segments. They also focused on personality traits characteristic of the population. For example, to address the cultural trait of sociability, ads stressed that tobacco products were “for sharing and savoring.” In addition, because certain segments of the market valued attending Hispanic functions, the company sponsored major events (Iglesias-Rios & Parascandola, 2013). Similar tactics were used in marketing tobacco to White and African American men, focusing on the image of the masculine, independent loner (the “Marlboro Man”) in marketing to White males and the “Kool” connected and influential man among African Americans (White, Olliffe, & Bottorff, 2013).

Diageo, the company that produces the Smirnoff brand of vodka, used a marketing approach to undo the effects of prohibition on attitudes to distilled spirits or hard liquor. Control policies at the end of the prohibition era in the United States were focused on high alcohol content beverages with prior links to organized crime and bootlegging operations. At the time, beer and wine were viewed as “beverages of moderation” and control strategies promoted a shift to beer and wine through higher taxes on distilled spirits, limitation of outlets where hard liquor could be sold, and allowing beer and wine to be advertised on electronic media. As a result, from 1970 to 1997, hard liquor was associated with older generations, and beer was the beverage of choice for younger consumers. In an effort to increase sales of its Smirnoff vodka brand to a younger market, the company created beverages with vodka that tasted like soft drinks; marketed the products as malt beverages to compete with beer in regard to pricing, availability, and advertising restrictions on hard liquor; and posed their products as a young people’s drink using fruit flavors and other marketing strategies. Such strategies were effective in increasing vodka consumption among younger people (Mosher, 2012). Marketing and other sociocultural factors influencing substance abuse in the population can be assessed using the questions provided in the *Focused Assessment* on the next page.

BEHAVIORAL DETERMINANTS. Recreational activities can contribute to the use of psychoactive substances in that alcohol and tobacco use is a frequent adjunct to such activities.

Tobacco companies target their marketing strategies to attract specific segments of the population. (Dominique VERNIER /Fotolia)

People tend to drink and smoke when they socialize with others. Friday or Saturday night binges are a relatively common phenomenon, when people can “let go” and drink because they know they will have time to recover before returning to work on Monday. Next to alcohol, marijuana is the most widely used recreational drug, but cocaine is also used recreationally and has the connotation of high status, glamour, and excitement. PCP and the club drugs are also used for recreational purposes.

Alcohol use and frequenting bars are also associated with higher rates of tobacco use and with binge drinking. In addition, alcohol use and bar attendance also make smoking cessation more difficult. Alcohol use has been negatively associated with attempts to quit smoking among light smokers, but has a positive association with successful quitting among heavy smokers (Jiang & Ling, 2013). Smoking in hookah lounges contributes to inhalation of 40 times the volume of smoke as cigarette smoking, exacerbating the negative effects of smoking (Fiala et al., 2012). Drug use is also often combined with smoking (Hunt, Gajewski, Jiang, Cupertino, & Richter, 2013), and early marijuana use has been linked to use of other addictive substances (NIDA, 2014a).

Drug and alcohol use and abuse may also contribute to unsafe sexual activity, particularly among members of sexual minority groups. Substance abuse is more prevalent among sexual minorities, probably as a result of exposure to chronic socially based stressors (Newcomb, Birkett, Corliss, & Mustanski, 2014). Sexual minority youth, in particular, are more likely than their heterosexual counterparts to report lifetime and past month use of alcohol, heavy episodic drinking, and early initiation of alcohol use (Talley, Hughes, Aranda, Birkett, & Marshall, 2014).

Specific behaviors related to actual abuse of drugs also contribute to physical and mental health problems. Injection drug use, for example, increases the risk of HIV infection and related behaviors. For example, in one study of IDUs in 20 cities, 69% engaged in unprotected sexual activity, 34% shared injection equipment, and 23% engaged in unprotected heterosexual

FOCUSED ASSESSMENT**Assessing Sociocultural Determinants
Influencing Substance Abuse**

- To what extent do cultural attitudes and social mores contribute to substance abuse?
- What effect does legislative activity have on substance abuse? What other policy issues influence the incidence and prevalence of substance in the population? How do policies support or impede control of substance misuse and abuse in the population?
- Do peer networks support substance use and abuse? Is substance use a regular part of social interaction in the population?
- Does the individual client's family exhibit characteristics of codependence?
- What cultural or religious values or practices influence substance abuse among individuals and in the population?
- Has the individual client been a victim or perpetrator of family violence? To what extent does victimization contribute to substance abuse in the population?
- What social factors (e.g., unemployment, poverty) contribute to substance abuse?
- How readily available are abused substances?
- What contribution, if any, does occupation make to substance abuse? What is the effect of substance abuse on the individual client's ability to work?
- What is the contribution of substance abuse to criminal activity? To homelessness?
- What is the extent of substance abuse among homeless individuals? How does homelessness influence substance abuse treatment?
- To what extent do alcohol and tobacco producers influence health policy and control of substance abuse? How is this influence exerted?
- Does alcohol and tobacco advertising employ market segmentation approaches?

anal sex. In 2009, 9% of all new HIV infections occurred among men who had sex with men (Wejnert et al., 2012). Methamphetamine use also contributes to sexual transmission of HIV, HBV, and HCV infections due to drug-related short-term increases in libido. Long-term methamphetamine use, however, leads to decreased sexual function (NIDA, 2013, 2014a).

One other surprising behavioral factor that has been linked to substance misuse and abuse is participation in high school athletics. High school sports result in a high incidence of injuries for which Vicodin and OxyContin are increasingly prescribed for pain relief. In fact, the number of prescriptions for controlled pain medications for adolescents nearly doubled from 6.4% in 1994 to 11.2% in 2007. Prescription of these drugs often leads to sharing among friends and teammates (Veliz,

Boyd, & McCabe, 2013). Assistance for assessment of behavioral determinants influencing substance abuse is provided in the *Focused Assessment* below.

HEALTH SYSTEM DETERMINANTS. Many of the psychoactive substances with abuse potential originated within the health care system. Opioids were widely used for pain control even during the American Civil War and are still the drug of choice for relief of severe pain. Cocaine and PCP were first used as surgical anesthetics, and marijuana has some legitimate medical use in the treatment of glaucoma and chronic pain. Sedatives and hypnotics are widely used for controlling anxiety, and amphetamines were originally developed as diet aids, although they no longer have any accepted medical use.

FOCUSED ASSESSMENT**Assessing Behavioral Determinants
Influencing Substance Abuse**

- What substances are abused by members of the population?
- What is the extent of substance use and abuse in various segments of the population (e.g., among sexual minority group members, members of particular ethnic groups)?
- Are abused substances used recreationally? Is substance use associated with leisure activities?
- To what extent do substance abusers engage in other high-risk behaviors (e.g., driving while intoxicated, high-risk sexual activity)? What are the health effects of these behaviors in the population?
- What is the extent of injection drug use in the population?
- To what extent do members of the population combine alcohol and other substance use? What is the extent of polydrug use in the population?

Several aspects of the U.S. health care system have contributed to the growing problem of substance abuse. Lack of attention to educating clients and the public about the hazards of substance abuse and failure to identify clients with substance abuse problems have impeded efforts to control abuse. In one study, primary care physicians failed to document conducting screening or intervention in 62% of encounters with patients with risky alcohol use and 59% of encounters with patients engaged in risky drug use even when patients had been screened by health educators prior to the encounter (Kim et al., 2013). Similarly, 2011 BRFSS results from 44 states and the District of Columbia indicated that not quite 16% of U.S. adults had ever discussed alcohol use with a health care provider and only slightly higher percentages of drinkers (17.4%) and binge drinkers (25.4%) had ever had a health care provider discuss the dangers of excessive alcohol intake (McKnight-Eily et al., 2014). At the same time, some health care providers have actively fostered drug abuse by prescribing psychoactive drugs inappropriately or by not monitoring the extent of clients' use of these drugs.

In the past, the health care system has impeded control of substance abuse by failing to provide adequate insurance coverage for substance abuse treatment. In 2009, spending on substance abuse treatment accounted for only 1% of all health care spending in the United States (SAMHSA, 2013a). In a 2008 report, only 65% of substance abuse treatment facilities accepted private insurance reimbursement for services, whereas 96% accepted self-payment (Center for Behavioral Health Statistics and Quality, 2011). In addition, coverage for services may be constrained by a variety of regulations. For example, Medicare Part A only covers inpatient care for substance abuse with out-of-pocket expenditures similar to those for hospitalization for physical illnesses. Coverage in a psychiatric hospital extends to a total of 190 days over an entire lifetime. Some additional care for substance abuse services in general hospitals may also be covered. As of 2014, Medicare Part B covered 80% of outpatient substance abuse services from a clinic or hospital outpatient department. Methadone maintenance, however, is only covered if provided in an inpatient setting. Medicare Part D drug plans can cover medically necessary drugs to treat substance abuse under a formulary list, but do not cover methadone maintenance treatment. Medicare will also reimburse providers for assessment and brief intervention services for drug abuse or dependence and screening and counseling for persons who exhibit substance misuse but are not dependent (Medicare Rights Center, 2011). Medicaid coverage for substance abuse treatment services varies widely from state to state, although all states provide some form of substance abuse treatment under their Medicaid programs.

Under the provisions of the Affordable Care Act (ACA), insurance purchased through state or federal insurance exchanges is required to cover substance abuse services as an essential benefit. In addition, any limitations on services, copayments and out-of-pocket expenditure limits, and requirements for prior authorization of services will have to be

comparable to those for medical and surgical services (Centers for Medicare and Medicaid Services, n.d.). These provisions will undoubtedly increase access to treatment services for some substance abusers. As an example, Medicaid eligibility expansion in Massachusetts resulted in a 21% increase in treatment admissions for substance abuse (Zur & Mojtabai, 2013).

Coverage for smoking cessation treatment has also been lacking for some groups. Medicare, for example, covers medications and counseling for a maximum of two treatment attempts per year for people over 65 years of age. Under the provisions of ACA, the Medicare Part D "donut hole" for medication coverage is being reduced, resulting in more affordable medications. Medicaid has covered cessation services for pregnant women since 2010, but will expand coverage to all low-income adults in 2014 under ACA. Coverage of comprehensive tobacco cessation treatment under state health insurance exchanges has not yet been delineated, and all new employer-sponsored insurance plans will need to cover tobacco cessation (American Lung Association, 2014).

In addition, an estimated 77% to 90% of drug abusers also smoke, yet few drug treatment centers provide access to tobacco cessation treatment. In one study of 405 drug treatment facilities, only 14% provided nicotine replacement therapy for smoking cessation, while only one third had protocols, procedures, or curricula for smoking cessation and only 20% reported having the financial resources to support tobacco counseling (Hunt et al., 2013).

Another health system factor that impedes control of substance abuse is failure to refer clients to appropriate sources of treatment. For example, in 2011, approximately 250,000 emergency department visits were made by patients seeking detoxification or substance abuse treatment. Unfortunately, only about 60% of those patients received any follow-up care. About 30% of them were hospitalized, 20% were referred to detoxification or treatment facilities, and 7% were transferred to other facilities (SAMHSA, 2013a).

Provision of adequate treatment of substance abuse may be further impeded by negative feelings on the part of health care providers toward those who abuse psychoactive substances. For example, despite knowledge of the effectiveness of harm-reduction strategies and the prevalence of periodic relapse during substance abuse treatment, many programs expel clients who revert to drug use during treatment. In addition, many clients in need may not have access to supportive services. For example, many shelters for the homeless refuse abusers despite the fact that a large proportion of homeless individuals abuse alcohol and other drugs. It may also be difficult for pregnant abusers or women with children to find appropriate treatment programs.

The health care system may pose additional barriers to care that are particularly burdensome for some population groups. For instance, most treatment programs are geared toward the needs of younger people and may not recognize the unique needs of the elderly substance abuser. In addition, because older people are often considered nonproductive

FOCUSED ASSESSMENT

Assessing Health System Determinants Influencing Substance Abuse

- What are the attitudes of health care providers toward clients with substance abuse problems?
- Are health care providers alert to signs and symptoms of substance abuse? To what extent do health care providers screen for substance misuse and abuse?
- To what extent do health care providers educate clients about substance abuse?
- What health system factors contribute to substance abuse (e.g., inappropriate prescription of psychoactive drugs)?
- What treatment facilities are available to substance abusers? To special populations of substance abusers (e.g., pregnant women, adolescents)?
- How is substance abuse treatment financed?

members of society, priority for placement in overburdened treatment facilities may be given to younger people. Tips for assessing health system factors influencing substance abuse in individuals and in the population are included in the *Focused Assessment* above. A Substance Abuse Risk Factor Inventory is provided on the student resources site.

Diagnostic Reasoning and Control of Substance Abuse

Population health nurses make nursing diagnoses related to substance abuse at two levels. The first level involves diagnoses related to individuals who have problems of substance abuse and their families. For example, the nurse might make a diagnosis for the individual client of “increased risk of substance abuse due to family history of alcohol abuse” or “abuse of sedatives due to increased life stress and poor coping skills.” Nursing diagnoses related to the family of a substance abuser might include “codependency due to family feelings of guilt related to daughter’s cocaine abuse” and “school behavior problems due to children’s anxiety over mother’s alcoholism.”

At the second level, the population health nurse might make diagnoses of community problems related to substance abuse. For example, the nurse might diagnose an “increased incidence of motor vehicle fatalities due to driving under the influence of psychoactive drugs,” or “increased prevalence of drug abuse among minority group members due to discrimination and feelings of powerlessness.” Another example of a population-based diagnosis is “increased prevalence of fetal alcohol syndrome due to alcohol use by pregnant women.”

Planning and Implementing Control Strategies for Substance Abuse

Strategies for controlling problems of substance abuse can involve health promotion, prevention of substance abuse and its consequences, resolution of existing substance-related problems, and health restoration.

HEALTH PROMOTION AND PREVENTION. Health promotion with respect to substance abuse primarily reflects

efforts to improve coping skills and promote sound decision making related to initiation of substance use. Teaching effective coping skills and providing opportunities for their implementation may assist individual clients to decrease stress that might otherwise lead to substance abuse. Similarly, providing people, particularly youth with effective problem-solving and decision-making strategies may lead to healthier decisions regarding initiation of psychoactive substance use and subsequent abuse.

Specific prevention strategies may have one of four foci: preventing initiation of substance use, preventing progression from experimental use to regular use, preventing substance dependence, and preventing adverse consequences of substance use and abuse.

Preventing or delaying initiation of tobacco and alcohol use are major emphases in the *Healthy People 2020* objectives. Specific substance abuse objectives reflect efforts to modify attitudes toward and perceptions of risk involved in substance use and abuse. In addition, tobacco-related objective TU-3 addresses initiation of tobacco use among children, adolescents, and young adults. More information on these and other substance abuse-related objectives is presented at the end of this chapter. Similarly, prevention of drug abuse and excessive alcohol use is one of the priority areas in the National Prevention Strategy put forth by the U.S. Surgeon General’s Office (National Prevention Council, 2011).

Universal prevention interventions targeted to overall prevention of risk behaviors among youth have been shown to be effective in preventing prescription opioid and overall prescription drug misuse in adolescents and young adults, particularly among youth at greatest risk for misuse (Spath et al., 2013). Universal preventive interventions frequently involve school-based programs designed to target multiple risk behaviors including those related to substance abuse. For example, the *All Stars* program addresses substance abuse, fighting, and bullying. Program foci include identifying positive goals and aspirations, establishing positive norms in the school population, developing personal commitments to avoid high-risk behaviors, promoting bonding to the school or peer group, and fostering positive parental attention (Tanglewood Research, 2013). Other similar programs focus on life skills training related to

personal self-management skills, social interaction skills, and drug resistance skills (National Health Promotion Associates, n.d.). For further information on three such programs, see the *External Resources* section of the student resources site.

Prevention of substance use initiation and escalation may involve modification of risk factors for use and abuse. Risk factor modification can occur with individuals, families, or society at large. Population health nurses may assist individuals to modify factors that put them at increased risk for substance abuse. For example, the nurse might assist clients experiencing stress to eliminate or modify sources of stress in their lives, or the nurse can assist clients and families to develop more effective coping skills.

In addition, the nurse may make referrals for social services to eliminate financial difficulties and other sources of stress. Or, the nurse might assist a harried single parent to obtain respite care. Nurses can also assist families to enhance family communication and cohesion to minimize the risk of substance abuse among children. Preventing alcohol use and/or promoting contraceptive use among childbearing women can help to reduce the incidence of FAS.

At the societal level, population health nurses can engage in political activity to control access to and limit the availability of psychoactive substances as well as to modify societal factors that contribute to abuse. For example, the nurse might advocate enforcement of laws restricting the sale of alcohol and tobacco to minors, or the nurse might work to reduce discrimination against members of minority groups or to ensure a minimal income for all families. Systematic research reviews have indicated that control of alcohol outlet density is an effective control measure for alcohol abuse (Ahern et al., 2013), and nurses may advocate for legislative control of outlet availability. Similarly, nurses may advocate for legislative and regulatory controls on the availability of laxatives and diet drugs and access by youth. Other control measures for these drugs that have been recommended include specific package labeling with the intended purposes of the medications, appropriate duration of use, warnings regarding possible organ damage and other adverse effects, and age verification for consumers (Pomeranz et al., 2013). Preventing adverse effects of substance use and abuse involves harm reduction. **Harm reduction** involves actions to minimize the harmful effects of drug use rather than preventing drug use *per se* (Harm Reduction Coalition, n.d.b). Harm reduction has also been described as a social justice movement based on respect for the rights of those who use drugs. The following principles underlie a harm reduction philosophy:

- Use of illicit substances is a fact of modern life, so control strategies should focus on addressing the adverse effects of use rather than on its control.
- Drug use is a complex phenomenon and some approaches to use are more harmful than others and should be discouraged in favor of safer approaches.
- The quality of individual and community life should be the focus of intervention, not cessation of use.
- Services provided to drug users should be nonjudgmental and noncoercive.
- Drug users should be involved in harm-reduction program design.
- A harm-reduction approach emphasizes reduction of harm as the primary responsibility of users and promotes mutual sharing of information and support among users.
- Harm reduction recognizes the contribution of societal and personal factors such as poverty, discrimination, social isolation, past trauma, and social inequalities to substance use.
- Harm reduction does not attempt to minimize or ignore the dangers of substance abuse, but seeks to reduce its potential effects (Harm Reduction Coalition, n.d.b).

The initial focus of harm reduction was on preventing infection-related harm from injection drug use, but has since been expanded to encompass other risks of substance abuse. Harm reduction may include prevention of overdose fatalities, a variety of infections, family disruption, social marginalization, and legal risks entailed in substance use (Jauffret-Roustide, 2009). For example, harm-reduction strategies may not only address the provision of clean injection equipment for IDU, but also prohibition of prosecution of people who make use of syringe exchange programs. In fact, the World Health Organization (WHO) supports a wide array of harm-reduction strategies for injection drug users, including needle and syringe exchange programs; drug abuse treatment; HIV testing, counseling, treatment, and care; condom distribution and STI treatment; and tuberculosis and hepatitis management (WHO, 2014a).

The emphasis in harm reduction is on meeting people where they are and reducing the harm of substance use while simultaneously addressing other issues and contributing factors (e.g., homelessness, mental illness, unemployment). Harm reduction focuses on identification of personal goals, not necessarily discontinuation of use, as the criteria for success and may result in a range of outcomes from controlled use, to non-harmful use, to abstinence (Lucas, 2012).

Access to clean needles and syringes is critical to harm reduction from IDU and prevention of HIV, hepatitis, and soft tissue infections. Research has consistently demonstrated the effectiveness of exchange programs in preventing these consequences. Exchange programs also provide opportunities to link drug users with drug treatment and other health services and housing assistance, and to provide overdose prevention education (Harm Reduction Coalition, n.d.c). Exchange programs have also been shown to decrease inappropriate disposal of used syringes and needles, thereby minimizing the potential for needlestick injuries and infection in the general population as well as among IDUs (Wenger et al., 2011).

Other infection prevention strategies include incorporating hepatitis immunization and care coordination into methadone maintenance programs (Masson et al., 2013). Similarly, antiviral prophylactic treatment for IDUs has been suggested as a mechanism for preventing HIV infection, particularly in areas with high HIV prevalence resulting from IDU (Alistar, Owens, & Brandeau, 2014). Another approach to HIV prevention among drug abusers in treatment is a culturally adapted “Real Men are Safe” program, which focuses on safe sexual practices. In one study, 87% of

participants completed the program and demonstrated reduced incidence of unprotected sexual encounters (Calsyn et al., 2013).

Overdose prevention is another important aspect of harm reduction. Prevention efforts include education on prevention, recognition, and response to drug overdoses for users, their family members, and service providers (Harm Reduction Coalition, n.d.a). The Substance Abuse and Mental Health Services Administration (SAMHSA) has developed an overdose prevention toolkit that addresses strategies and information for community members; essential steps for first responders; information for prescribers, clients, and family members; and information and resources related to recovery from an overdose (SAMHSA, 2013b). For further information about the toolkit, see the *External Resources* section of the student resources site.

Another approach to harm reduction for persons who abuse alcohol is the installation of ignition interlocks in their cars. Ignition interlocks are connected to a vehicle's ignition system. They are capable of analyzing alcohol on one's breath. If the alcohol level is above the set limit, the lock prevents the vehicle from starting. Some form of ignition interlock legislation exists in all 50 states and the District of Columbia, and several states require all persons convicted of drunken driving offenses to install the locks in their vehicles (Teigen, 2013). Such devices have been estimated to reduce rearrest for driving under the influence of alcohol by a median of 67% across states (National Center for Injury Prevention and Control, 2013).

Supervised injection facilities are another harm-reduction strategy that is gaining acceptance throughout the world, but is not yet approved in the United States. **Supervised injection facilities (SIFs)** are legally sanctioned venues in which

IDUs can inject pre-obtained drugs under medical supervision (DPA, 2014e). SIFs may also be referred to as safer injection sites, drug consumption rooms, or supervised injecting centers. In early 2014, 98 SIFs were in operation in 66 cities in ten countries. One of the most widely studied sites is the Canadian *Insite* program in Vancouver. The *Insite* program is funded by the British Columbia Ministry of Health through Vancouver Coastal Health and the Portland Hotel Society. The program is based on a harm-reduction philosophy, focusing on reducing the harm related to IDU without requiring abstinence (Vancouver Coastal Health, n.d.).

Research has consistently demonstrated that SIFs, including *Insite*, increase admissions to drug treatment facilities, reduce public injection and increase public safety, serve a population at high risk for infection and overdose, and reduce HIV and hepatitis risk behaviors related to syringe sharing and unsafe sexual practices. In addition, SIFs have saved hundreds of lives through overdose management and resulted in health care cost savings (DPA, 2014f; Kerr & Montaner, 2013). No evidence has been found that SIFs increase rates of drug use, initiate drug use, or promote drug-related crime (DPA, 2014f). Finally, a ruling by the Supreme Court of Canada in 2011 indicated that “*Insite* saves lives. Its benefits have been proven. There has been no discernable negative impact on the public safety and health objectives of Canada in its eight years of operation” (quoted in Drug Policy Alliance, 2014f, para 10). The Drug Policy Alliance has developed a toolkit advocating for legislation to promote supervised injection facilities in the United States. For further information about the toolkit, see the *External Resources* section of the student resources site. Table 29-6 • summarizes major emphases

TABLE 29-6 Health Promotion and Prevention Strategies in the Control of Substance Abuse

Health Promotion Foci	Related Strategies
Development of effective coping strategies	<ul style="list-style-type: none"> • Teach coping strategies to individual clients/families. • Advocate for incorporation of coping skills into school curricula. • Develop and implement programs to foster effective coping skills.
Development of effective problem-solving skills	<ul style="list-style-type: none"> • Teach problem-solving skills to individual clients/families. • Advocate for, develop, and implement programs to foster effective problem solving.
Development of strong self-image	<ul style="list-style-type: none"> • Foster and reinforce strong self-image in individual clients. • Promote societal attitudes and conditions that foster development of healthy self-images in the public. • Work to change social attitudes to stigmatized groups that might foster substance abuse.
Prevention Foci	Related Strategies
Prevention or delayed initiation of substance use	<ul style="list-style-type: none"> • Educate individual clients regarding substance use risks. • Advocate for, develop, and implement substance risk education programs in schools. • Advocate for, develop, and implement public substance risk-education campaigns.
Control of access to substances of abuse	<ul style="list-style-type: none"> • Advocate for strong control policies regarding access to alcohol, tobacco, and prescription drugs.
Modification of substance abuse risk factors	<ul style="list-style-type: none"> • Advocate for social and policy changes to modify or eliminate factors contributing to substance abuse (e.g., poverty, unemployment).
Harm reduction	<ul style="list-style-type: none"> • Advocate for harm-reduction programs for substance abusers (e.g., syringe exchanges, SIFs, immunizations). • Educate substance abusers and the public regarding harm-reduction strategies. • Educate abusers, family and friends, and service providers for overdose prevention, recognition, and response • Develop and implement harm-reduction programs.

and related population health nursing strategies for health promotion and prevention related to substance abuse.

RESOLVING EXISTING SUBSTANCE ABUSE PROBLEMS. Resolution of existing problems related to substance abuse among individuals and population groups involves screening, brief intervention, and treatment.

Screening. Problem resolution with respect to substance abuse begins with screening for excessive or inappropriate use of psychoactive substances. The U.S. Preventive Services Task Force (USPSTF) has recommended that health care providers ask all adults and pregnant women about tobacco use and provide tobacco cessation interventions for those who use tobacco products, with interventions specially tailored for pregnant women who smoke (USPSTF, 2009). This recommendation is in the process of being updated. USPSTF also recommended universal screening for alcohol misuse for all adults 18 years of age and older, followed by brief behavioral intervention for those engaged in high-risk drinking behaviors (USPSTF, 2013). However, there is insufficient evidence to date to warrant recommending routine screening of adults, adolescents, or pregnant women for illicit drug use (USPSTF, 2008).

In addition, the Community Preventive Services Task Force (CPSTF) has recommended routing electronic screening for excessive alcohol consumption in the general public, with brief intervention for those engaged in high level consumption. This recommendation was based on strong evidence of the effectiveness of electronic screening and intervention in decreasing binge drinking and drinking intensity (CPSTF, 2013). Similarly, the SAMHSA-HRSA Center for Integrated Health Solutions (SAMHSA-HRSA CISH) has recommended screening, brief intervention, and referral to treatment (SBIRT) to identify persons with substance use problems and link them to appropriate services. SBIRT components include screening for risky substance use in any health care setting, brief intervention, and referral to treatment for those needing additional services (SAMHSA-HRSA CISH, n.d.b). Screening for substance misuse usually involves use of a brief initial screening questionnaire such as the National Institute on Alcohol Abuse and Alcoholism's (NIAAA) three-item screening tool or NIDA's quick screen tool. A positive screening result is followed by more in-depth assessment using tools such as WHO's Alcohol, Smoking, and Substance Involvement Screening Test (ASSIST) or Alcohol Use Disorders Identification Test (AUDIT) for those whose initial screening result is positive (SAMHSA-HRSA CISH, n.d.c). For further information about a variety of screening tools, see the *External Resources* section of the student resources site.

Brief intervention. Brief intervention is a 5- to 30-minute interaction between a health care provider who is not a substance abuse expert and substance users who are not drug dependent to motivate changes in high-risk behaviors. Brief intervention is designed to assist people at risk for substance abuse to reduce or eliminate substance use by assisting them to fully understand

potential consequences of use and abuse. Brief intervention frequently employs cognitive behavioral therapy (CBT) or motivational interviewing techniques (SAMHSA-HRSA CISH, n.d.a).

Key components of brief interventions for high-risk alcohol use have been identified by the National Institute on Alcohol Abuse and Alcoholism (NIAAA, 2014). These components and their characteristic features are summarized in Table 29-7•. For further information about brief intervention, see the *External Resources* section of the student resources site. Brief interventions have been shown to result in significant reductions in risk scores for cannabis, opioid, cocaine, and amphetamine-type stimulant use and overall illicit drug involvement in several countries (Humeniuk et al., 2012). Population health nurses may provide brief interventions to clients perceived to engage in risky substance use behaviors incorporating the key components included in Table 29-7.

Treatment. Treatment for substance abuse is based on several general principles that have been identified by the National Institute on Drug Abuse (NIDA, 2012c). A similar set of treatment principles has been developed for substance abuse treatment in correctional facilities (NIDA, 2012e). Table 29-8• summarizes these two sets of principles.

Treatment for substance abuse employs many of the same psychotherapeutic modalities used for mental illness and discussed in Chapter 28∞. Evidence-based treatment modalities include medications, behavioral therapies, or some combination of both. The type of treatment modality used is frequently based on client and provider preference and comfort and the type of drug involved. Medications such as methadone, buprenorphine, and naltrexone are often used for opioid addiction, while nicotine patches and other forms of nicotine may assist with tobacco cessation. Disulfiram, acamprosate, and naltrexone may also be used for alcohol dependence (NIDA, 2012a). Currently no medication is available to assist with methamphetamine abuse, although there is some promise for drugs that target glial cell activity or anti-methamphetamine vaccines or antibodies that are currently being studied in human beings (NIDA, 2013). Medications may also be used to help clients deal with the symptoms of withdrawal.

Although smokeless tobacco products have been touted as promoting tobacco use cessation, they are themselves addictive and have not been shown to be of much help in cessation. In some studies, use of such products has been associated with attempts to quit, but not with successful cessation (Popova & Ling, 2013). In fact, in one study of military recruits, initiation of smokeless tobacco use actually led to harm escalation rather than reduction (Klesges, Sherruk-Mittleman, Ebbert, Talcott, & DeBon, 2010).

Behavioral therapies are often used in conjunction with medication to assist substance abusers to identify and address underlying reasons for their substance misuse and to help develop strategies that will promote abstinence and/or harm reduction. Treatment for dual diagnosis of substance abuse and other psychiatric disorders often requires integrated treatment approaches addressing both conditions at once.

TABLE 29-7 Key Components and Characteristic Features of Brief Interventions

Key Components	Characteristic Features
Feedback related to personal risk	Provision of information on users' personal risks for adverse effects of substance use based on current use patterns, problem indicators (e.g., abnormal lab values), and existing medical problems due to use
Emphasis on client responsibility	Emphasis on personal control and choice to reduce risk behaviors
Advice for changing behaviors	Provision of suggestions on ways to reduce or eliminate risky substance use
Options for reducing use	Provision of several strategies to reduce substance risk (e.g., setting specific limits on use, recognizing and counteracting antecedents to excessive use)
Empathetic counseling style	Use of a concerned and reflective style for delivering the intervention rather than a confrontational or coercive style
Focus on self-efficacy	Emphasis on client strengths and resources, optimistic focus on client ability to change behavior
Goal setting	Development of a specific negotiated goal for behavior change, written as a contract or prescription
Incorporation of follow-up	Periodic follow-up and monitoring of client's success in changing behavior
Timing	Assessment of readiness to change and implementation of strategies to promote readiness

TABLE 29-8 General Evidence-Based Principles of Drug Abuse Treatment and Evidence-Based Principles of Drug Abuse Treatment in Correctional Settings

General Evidence-Based Principles of Drug Abuse Treatment	Evidence-Based Principles of Drug Abuse Treatment in Correctional Settings
Addiction is a complex but treatable disease that affects brain function and behavior.	Drug addiction is a brain disease that affects behavior.
No single treatment approach works for everyone.	Recovery from addiction requires effective treatment followed by long-term management.
Treatment services need to be readily available.	Treatment must last long enough to result in stable behavioral changes.
Effective treatment addresses multiple needs of the individual, not just his or her drug abuse.	Assessment is the first step in treatment.
Retention in treatment for sufficient time is critical.	Services need to be tailored to fit the needs of the individual.
Behavioral therapies are the most commonly used forms of drug abuse treatment.	Drugs used in treatment should be carefully monitored.
Medications are an important element of treatment for many abusers, especially in conjunction with behavioral therapies and counseling.	Treatment should target factors associated with criminal activity.
The client's treatment and services plan must be assessed and modified as needed.	Criminal justice supervision should include treatment planning for drug-abusing offenders, and treatment providers should be aware of correctional supervision requirements.
Drug abuse often co-occurs with other mental disorders.	Continuity of care is essential on reentry into the community.
Detoxification is only the first step in substance abuse treatment.	A balance of rewards and sanctions encourages prosocial behavior and treatment participation.
Treatment does not need to be voluntary to be effective.	Persons with co-occurring substance abuse and mental health problems often require integrated treatment.
Drug misuse during treatment must be monitored because lapses frequently occur.	Medications are an important part of treatment.
Treatment programs should incorporate HIV, hepatitis, tuberculosis, and other infection disease testing as well as providing risk-reduction education and treatment for existing health problems as needed.	Treatment planning for community reentry should include treatment of other medical conditions as well.

(2012e). *Principles of drug abuse treatment for criminal justice populations: A research-based guide*. Retrieved from http://atforum.com/addiction-resources/documents/podat_cj_2012.pdf

In today's electronic environment, delivery of treatment modalities might encompass electronic approaches. For example, in one study, face-to-face and telephone treatment strategies were equally effective in treating tobacco addiction. Results varied somewhat based on client characteristics. For example, telephone intervention was more effective among people of higher socioeconomic status than lower status. Whichever modality was used, long-term abstinence was associated with exposure to more content (Sheffer, Stitzer, Landes, Brackman, & Munn, 2013). As we saw earlier, there is increasing potential for delivery of interventions in real time at critical points through geospatial technology.

Some complementary therapies have also been used for treating substance abuse. For example, hypnosis has been used successfully to assist some clients with smoking cessation and alcohol abuse. A novel approach to treatment for families of alcohol abusers using a systemic reflecting intervention has been effective in changing both drinking behavior on the part of the abuser and family behaviors. In this approach, families meet with a therapist and their interaction is watched by a team of observers through one-way mirrors. When the family and therapist agree that they are ready to receive feedback, team members provide reflections and observations on family interactions providing the family with outside perspectives on their behavior and its influence on drinking. Three studies using this technique demonstrated a decrease in drinking behavior, improved family problem-solving abilities, better communication, and retention in treatment (Flynn, 2010).

Population health nurses may be involved in treatment for substance abuse in a number of ways. First, nurses might identify cases of substance abuse and plan to refer clients and their families to treatment resources in the community. Nurses may also educate the general public on the signs and symptoms of substance abuse as well as the availability of treatment facilities. In addition, population health nurses can monitor the use of medications during withdrawal (if this is done on an outpatient basis) or on a long-term basis (e.g., methadone maintenance).

Population health nurses might also be involved in psychosocial therapies by referring clients to sources of group, individual, or family therapy, or the nurse might reinforce contracts made for reducing the use of substances. This is particularly true in

measures to help clients stop smoking. In this instance, population health nurses may initiate behavioral contracts with clients to enable them to gradually cut down on tobacco consumption or quit smoking for gradually lengthened periods of time.

At the population level, nursing efforts to control substance abuse might include political activity to support the development of adequate treatment facilities, especially those geared to the needs of currently underserved population groups such as pregnant women, the homeless, and the elderly. Population health nurses might also be involved in political activity and advocacy to encourage insurance coverage of treatment for substance abuse. Major foci and related population health nursing strategies for resolving substance abuse–related health problems are summarized in Table 29-9.

HEALTH RESTORATION. Health restoration in the context of substance abuse is often referred to as recovery. SAMHSA developed a working definition of substance abuse–related recovery as “a process of change through which individuals improve their health and wellness, live a self-directed life, and strive to reach their full potential” (SAMHSA, 2012, p. 3). The agency has also identified four dimensions that support recovery: health, home, purpose, and community. The health dimension focuses on managing related diseases or symptoms of addiction (e.g., cravings) and making decisions that support physical and mental health. The home dimension reflects the need for a safe and stable residence. The purpose dimension emphasizes the importance of carrying out meaningful daily activities such as work, school, and family responsibilities and having the resources needed to do so effectively. Finally, the community dimension focuses on interpersonal relationships and social networks that provide support and promote abstinence (SAMHSA, 2012).

In addition, SAMHSA has identified ten guiding principles of recovery. These principles include the following:

- Recovery derives from hope and a belief that recovery is possible and will lead to a better future.
- Recovery is person-driven and requires self-determination and self-direction in defining and achieving individually defined goals.

TABLE 29-9 Major Foci and Strategies Related to Resolution of Existing Substance Abuse–Related Problems

Focus	Related Strategies
Early identification of persons with substance use and abuse problems	<ul style="list-style-type: none"> • Screen individual clients for risk for substance abuse. • Screen individual clients for evidence of excessive substance use, misuse, or dependence. • Educate clients, families, and the public regarding signs of substance use problems. • Promote substance abuse screening in multiple health care venues.
Brief intervention for persons engaged in risky substance use	<ul style="list-style-type: none"> • Provide brief intervention for clients engaged in high-risk substance use.
Treatment of substance abuse	<ul style="list-style-type: none"> • Refer substance-abusing clients to treatment services. • Monitor clients during treatment. • Advocate for the availability of substance abuse treatment. • Advocate for insurance coverage of substance abuse treatment.

- There are many pathways to recovery and the recovery needs, goals, and strengths of each individual are unique and dependent on cultural background, life experiences, and other factors.
- Recovery is holistic and addresses all of an individual's needs, not just the substance-abusing behaviors.
- Effective recovery is supported by peers and allies including the support of mutual support and mutual aid groups.
- Recovery is supported through interpersonal relationships and social networks of people who believe in the person's ability to recover.
- Recovery is culturally based and influenced by cultural factors, and recovery services need to be culturally sensitive and congruent with client's cultural values, attitudes, and beliefs.
- Recovery is supported by addressing prior experiences of trauma.
- Recovery involves individual, family, and community strengths and resources; individuals have personal responsibility for their own self-care but may need assistance with self-advocacy. Families have responsibilities in supporting recovering members, and communities have a responsibility to provide resources that support recovery, promote inclusion, and minimize discrimination.
- Recovery is based on respect for the rights of those affected with mental health and substance abuse problems. Self-respect is also essential for successful recovery (SAMHSA, 2012).

Recovery or health restoration is aimed at preventing a relapse into prior substance-abusing behaviors by the individual or into enabling behaviors by family members and significant others. Additional foci in health restoration include dealing with the consequences of substance abuse, and building a foundation for recovery.

Relapse prevention. Relapse has been defined as a return to substance use behaviors after a prolonged period of abstinence. Relapse is a common phenomenon among substance abusers, and the emphasis in relapse prevention is elimination of personal triggers for substance use and abuse. Relapse frequently results in response to one of three types of triggers: a small amount of the abused substance, exposure to environmental cues or contexts associated with use and abuse, and stress. Research has indicated that abusers tend to be more susceptible to the action of such cues than nonabusers (Becker, n.d.).

Relapse Prevention Therapy (RPT) is a treatment approach that emphasizes self-control and assists abusers to anticipate and cope with factors that may contribute to relapse (SAMHSA's National Registry of Evidence-based Programs, 2014). Relapse prevention is based on the perspective that drug use behavior is reinforced by external cues that have become linked with rewards (e.g., the positive effects of drugs) and that these cues must be avoided to promote abstinence. Such cues may include people, places, drug use paraphernalia, or sensations previously associated with drug use. Other factors that

may contribute to relapse include inadequate skill in dealing with pressures to return to substance use, poor conflict management skills, and a desire to test one's personal control over behavior.

Development of coping skills is central to relapse prevention. RPT focuses on understanding relapse as a process and on identifying and coping with high-risk situations that may precipitate relapse. RPT also emphasizes coping with urges and cravings, minimizing negative consequences of relapse, continued engagement in treatment despite relapse, and creation of a more balanced lifestyle. RPT has been found to be effective in promoting smoking abstinence, treatment for cocaine use and drinking behavior, and in marital adjustment (SAMHSA's National Registry of Evidence-based Programs, 2014).

Relapse prevention may be facilitated by the use of relapse risk maps. **Relapse risk maps** are graphic representations of the factors that contribute to relapse into substance-abusing behaviors drawn by the client with the assistance of a nurse or counselor. For example, the relapse prevention map of a college student with an alcohol problem might include a drawing of the university to represent the stress of making good grades; an endless circle among classrooms, the library, and work representing stressful demands on the student; and the bar where the student stops to relax every night on the way home from class. Other elements of the map might include a demanding employer or girlfriend or friends who encourage drinking. Relapse prevention maps can help clients with substance abuse problems identify factors that contribute to relapse and suggest strategies for dealing with them (e.g., making new friends, cutting back on work, or going to school part-time) (Weegmann, 2008). Similar maps can also be used during the early recovery stage to help identify factors that contribute to substance abuse behaviors.

Mutual-support and self-help groups are another strategy to aid in health restoration and relapse prevention related to substance abuse. Mutual-help groups consist of people who are abusers of the same substance and who provide for each other understanding and support in conquering their substance abuse habit. For example, Alcoholics Anonymous (AA) is a mutual-help group for alcohol abusers, and Pot smokers Anonymous is a mutual-help group for marijuana abusers.

In 2010, AA, the first organized mutual support group, celebrated its 75th anniversary. At that time, the organization included more than 2 million members (1.2 million in the United States alone) in 160 countries. AA originated out of the tenets of the Oxford Group, a Christian sect, but includes no specific religious doctrine. It is better described as a spiritual, rather than a religious program. AA support services are usually used in conjunction with professional care, and there is extensive evidence of its success in helping members maintain sobriety. The emphasis in this and other mutual support groups is voluntary service by recovering substance users helping other users (Gross, 2010). AA, in particular, does not rely on external monetary support, and its funding comes from voluntary contributions of members (AA, 2014).

Self-help therapies usually involve use of publications and educational materials that help people identify underlying reasons and triggers for substance use and suggest specific strategies for curtailing use. *SMART Recovery* is a self-help program that combines self-help education and literature and group interaction to implement its four-point recovery program that includes tools and techniques to help people: (a) build and maintain motivation to stop addictive behaviors, (b) cope with urges to engage in the behavior, (c) manage their thoughts, feelings, and behaviors, and (d) live a balanced life. Unlike AA, which is focused on alcohol addiction, *SMART Recovery* addresses multiple forms of addictive behavior. Group interaction is accompanied by manuals that provide practical tools and strategies for addressing each of the four points (*SMART Recovery*, n.d.). Recently a tailored manual was developed specifically for use by health care professionals with addictions (*SMART Recovery*, 2014).

The concepts of self-help or mutual support are predicated on perceptions that “the needs of patients are not adequately taken into account by institutions and professionals” and the concept that substance users are “lay experts” (Jauffret-Roustide, 2009, p. 159). Support groups for substance abusers may be of two types: therapeutic peer support groups, such as AA and *SMART Recovery*, and interest groups. Interest groups are groups of substance abusers focused on empowerment of group members to advocate for public policies that “change society and make it more tolerant of differences” including drug use (Jauffret-Roustide, 2009, p. 159). The intent of such groups is to advocate for the rights of drug users to choose drug use. These groups are less focused on day-to-day support for abstinence than on advocacy for alternatives based on the concept of harm reduction discussed earlier. The activities of such groups have led to changes in perceptions of users as irresponsible persons with an illness to responsible persons able to adopt behaviors that reduce the personal and societal harm due to substance abuse (Jauffret-Roustide, 2009).

Population health nurses can assist clients with substance abuse problems to identify triggers for relapse and to develop strategies for dealing with them. They can also assist in the development of relapse prevention groups that provide clients with the support of others in dealing with their relapse issues. They may also help to motivate family members and significant others to participate in relapse prevention, educating both clients and significant others about relapse, its causes, and prevention strategies. Population health nurses’ involvement with self-help and mutual-help groups usually occurs in the form of referrals for these types of services. In some instances, however, population health nurses are actively involved in initiating support groups. Population health nurses may also be involved in empowerment-focused groups advocating for the rights of substance abusers.

Population health nurses can also contribute to health restoration efforts by providing emotional support to recovering abusers and their families and by linking them with other sources of support. Other health restoration measures might include efforts to eliminate or modify stressors that contribute to relapse.

For example, assisting the recovering abuser to find work can alleviate the stress of unemployment and financial worries.

The nurse can also reinforce the individual’s motivation to abstain from drug use or engage in harm-reduction strategies by commending and highlighting successes. Development of positive coping skills may also prevent relapse. Other health restoration needs may involve providing information on resources, providing respite from onerous burdens of care, or helping individuals plan time for themselves.

At the population level, population health nurses may be involved in planning and implementing services for people with substance abuse problems (e.g., initiating a mutual-help group or a relapse prevention group). They may also need to participate in political advocacy to assure the availability of health restoration services or to mandate their coverage as a routine health insurance benefit.

Dealing with consequences of abuse. Substance abuse may lead to a variety of physical, psychological, and social consequences with which population health nurses need to assist clients. Population health nurses may provide treatment for physical consequences of substance abuse and assist clients to deal with psychological and social consequences. For example, they may treat abscesses due to injection drug use or refer clients for treatment if necessary. Other examples include assisting clients in recovery to deal with the feelings of guilt engendered by their behavior and its effects on loved ones, or helping them to regain custody of children placed in foster care.

Population health nurses may also need to help family members deal with the consequences of substance abuse in the family. For example, group interventions for schoolchildren whose parents have substance abuse disorders have been shown to reduce feelings of isolation and to improve problem solving, conflict resolution, and social skills as well as enhance academic skills. In addition, such programs provide a sense of personal safety and belonging, and program staff can engage in advocacy for appropriate care of these children. Population health nurses can be actively involved in developing these and similar programs. They can also engage in political activity to assure access to and funding for these types of programs. Political advocacy may also be needed to assure insurance coverage for health services to deal with the physical and emotional consequences of abuse for substance abusers and their family members.

Building a foundation for recovery. Treatment for substance abuse is more than a matter of detoxification and modification of cravings for the drug in question. It is usually a total program of modification that results in changes in modes of thinking and acting. This may be achieved through professional therapy as discussed above, participation in mutual-help groups, changes in environment and lifestyle, self-image enhancement, and development of new coping skills and new patterns of family interaction.

Nurses can also assist clients to plan changes in their environment to minimize stresses that may contribute to substance

abuse. For example, the nurse can refer a client for help with financial difficulties or for respite from the care of a handicapped child or elderly parent. Socially isolated older persons who abuse substances can be linked to sources of social support, and unemployed persons can be assisted to find employment or to learn skills that enhance their employability. The provision of housing for homeless substance abusers has been shown to reduce emergency department use, detoxification center use, hospital admission, and jail bookings. One such program cost approximately \$18,600 per person, but resulted in per capita savings of \$36,579 (Srebnik, Connor, & Sylla, 2013). Similarly, the *Pathways Housing First* program focuses on housing and community-based treatment services for homeless individuals, many of whom have substance abuse disorders. In one study, the program resulted in an 84% rate of retention in treatment after 2 years, reductions in psychiatric symptoms, improvements in alcohol dependence, and declines in community services use (Tsemberis, Kent, & Respress, 2012).

Population health nurses can also help individual clients develop stronger self-images by reinforcing their successes and helping them realistically examine their expectations for themselves. In addition, nurses can help clients who abuse psychoactive substances to develop alternative ways of coping with stress by taking action to modify stressors or changing their perceptions of and responses to stressors.

Treatment efforts are also needed for members of the abuser's family to enable them to recover from codependence. Goals in the care of families of substance abusers include stabilizing the family system, making changes in family interactions, and developing mechanisms for maintaining those changes.

Family stabilization may be achieved by linking families to needed support services and engaging in the crisis intervention strategies described in Chapter 14. The nurse can also make referrals for marital or family therapy as needed and can assist families to identify their use of defense mechanisms similar to those used by the substance abuser.

The population health nurse might also provide families with anticipatory guidance about the negative effects of life change events and help them deal with these events without resorting to substance abuse. Family members may also need help in working through resentment related to substance abuse and subsequent behaviors by the abuser.

Building positive experiences in the life of the family also fosters cohesion and helps to stabilize the family. The population health nurse can assist the family to plan activities in which all members can participate. It is particularly important to integrate the substance-abusing member into these occasions, if possible, to prevent further alienation.

The population health nurse can also assist families to develop new patterns of interaction. For example, the nurse might help the family realign members into the more usual husband-wife coalition rather than parent-child coalitions by improving family communication and developing joint problem-solving skills. The nurse can also assist family members to identify and express feelings and learn negotiating strategies. The systemic reflecting strategy discussed earlier is one approach to assisting families to develop new patterns of interaction. Even children can be incorporated into such an approach if desired (Flynn, 2010). Areas of focus and strategies for health restoration with respect to substance abuse are summarized in Table 29-10.

TABLE 29-10 Health Restoration Strategies in the Control of Substance Abuse

Focus	Strategies
Support for abusers	<ul style="list-style-type: none"> • Provide emotional support and encouragement to individual clients and their families. • Assist with abuser reintegration into the family. • Refer for emotional or material support services as needed. • Advocate for development of and access to support services for abusers and their families.
Relapse prevention	<ul style="list-style-type: none"> • Educate individual clients and families regarding the process of relapse and relapse prevention. • Assist abusers to identify relapse triggers. • Assist with the development of relapse risk maps and relapse prevention plans. • Assist in minimizing effects when relapse occurs. • Initiate or refer clients to mutual support groups or self-help groups.
Modification or elimination of factors contributing to relapse	<ul style="list-style-type: none"> • Assist with employment, housing, etc. • Refer for financial assistance as needed. • Refer for respite services to address caregiver burden. • Advocate for societal changes that eliminate stressors that contribute to substance abuse. • Advocate for changes in societal attitudes toward substance abusers.
Dealing with the consequences of abuse	<ul style="list-style-type: none"> • Provide care to individual clients or refer for services to address physical and psychological consequences of substance abuse. • Advocate for availability of and access to treatment services to address consequences of substance abuse. • Assist family members to deal with the effects of substance abuse on the family or refer for needed services. • Advocate for available services for family members of substance abusers.
Building a foundation for recovery	<ul style="list-style-type: none"> • Assist substance abusers and family members to develop effective coping strategies. • Promote new family interaction patterns. • Promote family cohesion and reintegration of the substance abuser.

Evaluating Control Strategies for Substance Abuse

Evaluating interventions with individual substance abusers and their families focuses on the extent to which problems of substance abuse have been resolved. Has the abuser been able to abstain from substance use or to engage in harm-reduction strategies? Have stresses contributing to substance abuse been modified? Have personal and family consequences of substance abuse been addressed as far as possible?

At the population level, the nurse could evaluate the effects of intervention programs on the incidence and prevalence of substance abuse as well as indicators of morbidity and mortality related to abuse. The nurse evaluating the effects of programs directed at substance abuse might examine the extent to which national health promotion and disease prevention objectives have been met in the population. The current status of selected *Healthy People 2020* objectives related to substance use and abuse is presented below. As can be seen, very few of the objectives have already reached the targets, but other objectives (e.g.,

exposure of young people to tobacco marketing on the Internet) are moving away from their targets. For others, the movement toward the target has been slow, suggesting the need for more concerted efforts to control substance use and abuse.

Another source of evaluative information on the overall effectiveness of criminal justice approaches to the control of substance abuse lies in the Office of Management and Budget (OMB) assessment of federal agencies. In its most recent assessment of the Drug Enforcement Administration (DEA) in 2003, the OMB rated the agency's performance as "adequate." In its report, the OMB noted that "the Drug Enforcement Administration is unable to demonstrate its impact on the availability of drugs in the U.S. but has shown sustained progress in disrupting and dismantling high priority drug trafficking organizations" (OMB, 2003, para 2). Based on this assessment and the continued problem of substance abuse, it would seem clear that drug enforcement activities are not having a significant effect on the problem of substance abuse in the United States, and that other strategies are needed.

Healthy People 2020

Selected Objectives Related to Substance Use and Abuse

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
SA-2. Increased the proportion of high school seniors who have never used				
2.3. alcoholic beverages	27.7% (2009)	30.5%	NDA	Monitoring the Future Study (MTF), NIH/NIDA
2.4. illicit drugs	53.3% (2009)	58.6%	NDA	
SA-4. Increase the proportion of adolescents who perceive great risk associated with				
4.1. Binge drinking	40% (2008)	44%	40.7% (2011)	National Survey on Drug Use and Health (NSDUH) SAMHSA
4.2. Marijuana use	33.4% (2008)	36.7%	27.6% (2011)	
4.3. Cocaine use	49.4% (2006)	54.3%	48.1% (2011)	
SA-6. Increase the number of states with mandatory ignition lock laws for first and repeat impaired driving offenders	13 (2009)	50 states and DC	NDA	Mothers Against Drunk Driving
SA-7. Increase the number of admissions to treatment for injection drug use (per year)	254,278 (2006)	279,706	NDA	Treatment Episode Data Set (TEDS), SAMHSA
SA-11 Reduce cirrhosis deaths (per 100,000 population)	9.1 (2007)	8.2	9.4 (2010)	National Vital Statistics System-Mortality (NVSS-M), CDC/NCHS
SA-12. Reduce drug-induced deaths (per 100,000 population)	12.6 (2007)	11.3	12.9 (2010)	NSDUH, SAMHSA

Continued on next page

Healthy People 2020 (Continued)

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
SA-14 Reduce the proportion of people engaged in binge drinking in the last month				
14.3. Adults	21.7% (2008)	24.4%	26.7% (2011)	NSDUH, SAMHSA
14.4 Adolescents 12–17 years of age	9.5% (2008)	8.6%	7.9% (2011)	
SA-16. Reduce average annual alcohol consumption (gallons per person)	2.3 gal (2007)	2.1 gal	NDA	Alcohol Epidemiologic Data System (AEDS)
SA-17. Reduce the rate of alcohol impaired driving (per million vehicle miles driven)	0.4 (2008)	0.38	NDA	Fatality Analysis Reporting System (FARS), DOT/NHTSA
SA-18.3 Reduce steroid use by 12th graders (similar objective for 8th and 10th graders)	2.2% (2009)	NT	NDA	MTF, NIH/NIDA
SA-19 Reduce nonmedical use of any psychotherapeutic drug (in past year)	6.1% (2008)	5.5%	5.7% (2011)	NSDUH, SAMHSA
SA-20. Reduce the number of deaths attributable to alcohol	79,646 (Avg 2001–2005)	71,681	NDA	Alcohol Related Disease Impact System (ARDI), CDC
SA-21. Reduce the proportion of adolescents who use inhalants	4% (2008)	NT	3.3% (2011)	NSDUH, SAMHSA
TU-1.1. Reduce cigarette smoking by adults	20.6% (2008)	12%	19% (2011)	National Health Interview Survey (NHIS), CDC/NCHS
TU-2.1. Reduce past month tobacco use by adolescents	26% (2009)	21%	23.4% (2011)	Youth Risk Behavior Surveillance System (YRBSS), CDC/NCHHSTP
TU-3. Reduce initiation of tobacco product use				
3.1 by adolescents (12–17 years)	7.7% (2008)	5.7%	6.9% (2011)	NSDUH, SAMHSA
3.5. by young adults (18–25 years)	10.8% (2008)	8.8%	10.4% (2011)	
TU-5.1. Increase smoking cessation success by adults	6% (2008)	8%	6.7% (2011)	NHIS, CDC/NCHS
TU-6. Increase smoking cessation during pregnancy	11.3% (2005)	30%	18.9% (2010)	NHIS, CDC/NCHS
TU-8. Increase states with Medicaid coverage of treatment for nicotine dependence	6 states (2007)	50 states and DC	5 states (2009)	State Medicaid Coverage for Tobacco Treatment
TU-11. Reduce the proportion of children 3–11 years of age exposed to environmental tobacco smoke (similar objectives for adolescents and adults)	52.2% (2005–2008)	47%	NDA	National Health and Nutrition Examination Survey (NHANES), CDC/NCHS

Healthy People 2020 (Continued)

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
TU-12. Increase the proportion of people covered by indoor worksite policies that prohibit smoking	75.3% (2006–2007)	100%	NDA	Current Population Survey (CPS), Census & DOL, BLS
TU-15.1. Increase tobacco-free environments in junior high schools (similar objectives for middle schools, high schools, and Head Start programs)	65.4% (2006)	100%	NDA	School Health Policies and Practices Study (SHPPS), CDC/NCHHSTP
TU-18.1 Reduce the proportion of adolescents and young adults exposed to tobacco marketing on the Internet (similar objectives for other media)	36.8% (2009)	33.1%	40.6% (2011)	National Youth Tobacco Survey (NYTS), CDC/NCCDPHP/OSH

NT = No target set yet, informational data only

NDA = No data available

CHAPTER RECAP

Factors related to each of the six categories of determinants of health influence psychoactive substance use and abuse. Population health nurses engage in a variety of strategies at each level of health to address the problems of substance use and abuse. Health promotion strategies, for example, include development of effective coping and problem-solving strategies and strong individual self-images. Prevention activities focus on preventing substance use initiation, controlling access to drugs and alcohol, modifying substance use and abuse risk factors, and engaging in harm reduction to prevent harmful consequences

of substance use and abuse. Strategies designed to resolve existing problems of abuse include screening for excessive use and abuse, brief intervention, and substance abuse treatment. Finally, health restoration involves support for the abuser and his or her family, relapse prevention, modification of factors that promote relapse, dealing with the physical and psychological consequences of abuse, and building a foundation for recovery. Evaluation of control efforts occurs at both the individual client and population levels.

CASE STUDY

Alcohol on Campus

Members of the senior class of the baccalaureate nursing program at a state university have noticed that alcohol use is prevalent on their campus. Several friends have been arrested for driving under the influence and one student's boyfriend was killed in a drunk-driving accident. The students have also noted a significant amount of binge drinking at weekend parties when people "let down their hair." The university has a no-drinking-on-campus policy, but enforcement is lax, and alcohol is frequently smuggled into the dorms. The student health center does not really address the problem of excessive alcohol intake and few students use the campus counseling center.

1. What factors related to biological, psychological, environmental, sociocultural, behavioral, and health system determinants of health are operating in this situation?
2. What additional information related to determinants of health might the nursing students need to collect? Where might they obtain that information?
3. What actions by the nursing students might help to address the problem of alcohol use in the campus population? Would these actions primarily reflect health promotion, prevention, resolution of existing problems, or health restoration?
4. How might the students evaluate the effects of their efforts?

30 Societal Violence

Learning Outcomes

After reading this chapter, you should be able to:

1. Compare types of societal violence.
2. Analyze the influence of biological, psychological, environmental, sociocultural, behavioral, and health system determinants on societal violence.
3. Identify major foci in health promotion and prevention related to societal violence.
4. Describe approaches to resolving existing problems of societal violence.
5. Discuss considerations in health restoration related to societal violence.
6. Analyze the role of population health nurses with respect to control of societal violence.

Key Terms

aggravated assault

alcohol-facilitated sexual abuse

assault

code of the street

collective violence

community violence

dating violence

domestic violence

domestic violence restraining order

family/partner violence

female genital mutilation (FGM)

homicide

interpersonal violence

intimate partner violence (IPV)

psychological violence

self-directed violence

sexual violence

shaken baby syndrome

stalking

street efficacy

suicidal ideation

suicide

suicide attempt

trafficking

violence

Protecting Children from Abuse

Until the late 1800s, there was no systematic protection of children from abuse, although isolated instances of criminal prosecution for egregious abuse occurred periodically. Arguments against intervention included parental rights to raise their children as they saw fit. In 1869, however, the Illinois Supreme Court ruled that punitive action could legally be taken against parents who failed to exercise their parental authority “within the bounds of reason and humanity” (Myers, 2008). Similarly, as early as 1642, Massachusetts enacted legislation that enabled magistrates to remove children from parents who did not care for them properly, but such actions were rare.

In 1866, the American Society for the Prevention of Cruelty to Animals (ASPCA) was formed and provided the foundation for similar protective organizations for children. The first such organization in the world was the New York Society for the Prevention of Cruelty to Children (NYSPCC) established in 1875. The impetus for the society’s establishment was the case of a young girl named Mary Ellen, who was routinely abused by her guardian. Mary Ellen’s plight was reported by a neighbor to a church worker who sought the aid of Henry Berg, founder of the ASPCA. Berg enlisted the aid of the organization’s attorney, Elbridge Gerry. Gerry employed an obscure section of the rule of habeas corpus to file a complaint, initiating the child’s removal from the home and criminal proceedings against the guardian.

As a result of the case, Berg and Gerry enlisted the aid of philanthropist John D. Wright in establishing the NYSPCC. The organization’s purpose was to

Rescue little children from the cruelty and demoralization which neglect, abandonment and improper treatment engender; to aid by all lawful means in the enforcement of the laws intended for their protection and benefit; to secure by like means the prompt conviction and punishment of all persons violating such laws and especially such persons as cruelly ill-treat and shamefully neglect such little children of whom they claim the care, custody or control. (NYSPCC, 2000, p. 7)

Through links established with local police, the society was notified of all cases of abuse of children, and the New York State Attorney General and the county district attorney authorized the society to act on their behalf in court proceedings. During its first 8 months, the society rescued 72 children and prosecuted 68 criminal cases. In addition, the society was active in promoting legislation to protect children and is credited with being the impetus for most of the body of modern child protective law (NYSPCC, 2000). It was not until 1962 that child protective services were identified as part of public responsibility with amendments to the Social Security Act (Myers, 2008).

Establishing a Women’s Shelter

Rates of domestic violence against American Indian women are higher than in the general population. In one small town on the Navajo Indian Reservation, community members collaborated to establish a shelter for abused women. For most of the community and residents of surrounding rural homes or sheep camps, domestic violence was not considered a problem, or was not one that outweighed the daily struggle for survival. However, churches and agencies serving abused women were amenable to taking action and provided volunteers to help with establishing the shelter. Other organizations, including members of the tribal police force, also became allies and were kept apprised of progress (Begay, 2011).

Considerable initial resistance to the project was encountered in the community based on denial of a problem or beliefs that domestic violence was a family issue that should be addressed within the confines of the family. Other sources of resistance included beliefs that the problem of domestic violence stemmed from excessive alcohol use, which should be the focus of community efforts (Begay, 2011).

Efforts began with a campaign to educate tribal elders and convince them of the problem within cultural constraints of respect for authority. These efforts were followed by presentations and discussion in multiple community venues, including the weekly flea market, WIC program office, police departments, and schools. The planning group also sponsored an educational float in the high school home coming parade (Begay, 2011).

Barriers to shelter development included difficulties raising funds and finding a site for the shelter. The latter was complicated by community members' reluctance to have the shelter located in their neighborhoods. The initial shelter site was in a mobile home. Due to funding inadequacies, the shelter was forced to close periodically. Development of policies and procedures was another aspect to be considered, and the community group adopted and adapted policies and procedures from another shelter. Assuring the safety of residents from the local community was difficult because the shelter's location was well known, so women from the local area were transferred to another shelter as soon as possible (Begay, 2011).

Lessons learned from the project included the need for clarity in the mission and commitment from the working group and from other supporters, particularly elders and tribal leaders. Developing community awareness of domestic violence was an early issue that needed to be overcome. Continuous outreach to other individuals and groups and flexibility were also essential as was maintaining the enthusiasm and commitment of those involved. Despite the obstacles encountered, the shelter was established and continues to meet the needs of women in the surrounding area (Begay, 2011).

Violence is a pervasive phenomenon in our society. In part, this is a function of the American heritage and the actions required to carve a nation from a wild and uncivilized land. Violence has historically been seen as a mode of resolving conflict and even of ensuring support of law and order. The vigilante approach to justice on the Western frontier is one example of the use of violence to protect society. Excessive attention to "national security" issues may also be used to justify societal violence and is an outcome that population health nurses can help to guard against by advocating the protection of civil liberties. The World Health Organization (WHO) defined **violence** as the purposeful use of actual or threatened force against another individual or a group that results in, or could result in, harm (Violence Prevention Alliance [VPA], 2014).

In societies in which survival is subjected to physical threats that must be countered by physical force, violent behavior may be more or less of a necessity. Some authorities, however, contend that humankind has failed to adapt to changes in survival needs and has continued to exercise proclivities to violence that are not warranted in today's society. Societal violence has become a global as well as national concern.

Violence may occur in one of three forms: self-directed violence, interpersonal violence, and collective violence. **Self-directed violence** is deliberate behavior directed at oneself that results in or has the potential for injury (Haegerich & Dahlberg, 2011). Self-directed violence encompasses self-abuse and neglect and suicide (VPA, 2014). **Interpersonal violence** involves violence between individuals and includes violence within families or intimate partner relationships and community violence. Family/partner violence includes child maltreatment, intimate partner violence (IPV), and elder abuse. **Community violence** occurs outside of family or intimate partner relationships and may involve acquaintances or strangers; examples include youth violence, assault by strangers, violence in the commission of a crime, workplace violence, and so on. **Homicide**, which is the intentional killing of one person by another, overlaps all of the family/partner and community violence categories. **Collective violence** is violence perpetrated by a group of individuals on another group (VPA, 2014). War, genocide, and political or economic repression are examples of collective violence. Figure 30-1 • presents an overview of

Global Perspectives

Violence Prevention at a Global Level

Violence is a growing global problem. Violence results in 1.4 million deaths per year, or 3,800 deaths per day. More than half (58%) of these deaths are self-inflicted; 36% are caused by others, and 6% resulted from war or other forms of collective violence. Deaths due to violence are particularly prevalent among men aged 15 to 44 years. For every person killed by violence perpetrated by others, another 20 to 40 people receive injuries severe enough to require hospitalization. Similarly for every suicide among people under age 25, another 100 people attempt suicide (World Health Organization [WHO], 2014a).

In 2002, WHO initiated its *Global Campaign for Violence Prevention*. In 2012, the Violence Prevention Alliance established its plan of action for 2012 to 2020. The plan of action is directed toward the achievement of six global goals for violence prevention throughout the world. The first two goals focus on prioritizing violence prevention within the global public health agenda. Goals 3, 4, and 5 address the construction of a foundation for ongoing-violence prevention efforts. The final goal emphasizes the use of evidence-based strategies to prevent multiple forms of violence. The six goals are as follows:

1. Intensify global communication and advocacy for allocation of resources to prevention programs and support for clear violence prevention policy agendas.
2. Enhance integration of violence prevention in global agendas.
3. Strengthen national violence prevention action plans.
4. Increase individual and institutional capacity for violence prevention and provision of services to victims and perpetrators.
5. Promote research and data collection related to violence and its prevention.
6. Implement evidence-based violence prevention strategies, including
 - a. Parenting support strategies
 - b. Life and social skills training
 - c. Initiatives to change social and cultural norms that support violence and to promote nonviolent norms
 - d. Reducing access to excessive use of alcohol as a contributing factor in social violence
 - e. Programs to reduce firearms-related deaths and injuries
 - f. Services to address the consequences of violence and prevent recurrence (Violence Prevention Alliance, 2012)

the types of societal violence. The focus of this chapter is on self-directed and interpersonal violence.

Societal violence seems to be escalating throughout the world and in the United States in particular. In part, the increasing frequency with which violence is reported may be a

result of greater recognition of violent behaviors, but the following figures serve to highlight the magnitude of the problem of violence in the United States.

- The U.S. homicide rate is three to five times that of any other Western democracy.
- A violent crime occurs every 23 minutes.
- Someone is murdered every 33 minutes.
- Someone is raped every 6 minutes.
- A child is abused or neglected every 13 to 35 seconds.
- An incident of elder victimization occurs every 3 minutes.
- IPV against a woman occurs every 1.3 minutes and every 6.7 minutes against a man.
- Someone attempts suicide every 39 seconds.
- Someone successfully ends their own life every 16 minutes. (Gellert, 2010)

These factors may actually underrepresent the extent of violence in America. In fact, the Department of Justice estimates that only 37% to half of violent crimes are reported (Gellert, 2010).

Worldwide, violence results in an estimated 1.6 million deaths each year (Centers for Disease Control and Prevention [CDC], 2013). Approximately 55,000 of those deaths occur in the United States (Parks, Johnson, McDaniel, & Gladden, 2014). Violence is one of the top ten causes of death for all age groups from birth to 64 years of age and results in 1.5 million years of productive life lost before age 65 each year (Haegerich & Dahlberg, 2011). In addition, violence results in significant injury as well as fatality. For example, from 2005 to 2010, violence contributed to approximately 388,000 emergency department visits (National Center for Health Statistics [NCHS], 2013b). Dealing with the problem of violence by promoting “injury and violence free living” is one of the national priorities identified in the National Prevention Council’s (2011) *National Prevention Strategy*.

Trends in Societal Violence

We will briefly describe features of and trends in the different forms of violence encountered in society. Areas to be addressed include self-directed violence and suicide, family/partner violence, community violence, and homicide.

Self-Directed Violence

Self-directed violence includes both suicidal and nonsuicidal behavior (Haegerich & Dahlberg, 2011). Nonsuicidal self-injury involves deliberately causing physical harm to oneself without the intention to cause death. Self-injurious behavior was discussed in Chapter 24∞. Cutting and burning are two examples of self-injury that may be employed by young people as a means of coping with emotional pain, anger, or frustration. Self-injury may build to more serious self-aggressive action (Mayo Clinic Staff, 2012). As we saw in Chapter 19∞, self-injury may also include self-neglect which may be seen among

FIGURE 30-1 Categories of Societal Violence

the elderly who fail to address their own physical, emotional, or social needs through inadequate nutrition, shelter, clothing, medication use, or administration of finances (National Center for Injury Prevention and Control [NCIPC], 2014d). Although self-injury is not intended to result in death, those who engage in these behaviors may die as a result of miscalculating the potential effects of their actions.

Suicide, on the other hand, is a “death caused by self-directed injurious behavior with the intent to die as a result” (NCIPC, 2013a, para. 1). A **suicide attempt** is “a nonfatal self-directed potentially injurious behavior with an intent to die as a result” (NCIPC, 2013a, para. 2). **Suicidal ideation** involves thinking about or planning to end one’s own life (NCIPC, 2013a).

Suicide rates increased by about 60% in the last 50 years (Demirçin, Akkoyun, Yilmaz, & Gökdoğan, 2011) to the point that suicide has become the tenth leading cause of death in the United States (NCIPC, 2013f). In 2009, suicide surpassed motor vehicle accidents as the leading cause of injury deaths (Rockett et al., 2012). The age-adjusted suicide rate for 2010 was 12.1 per 100,000 population (NCHS, 2014), resulting in 38,000 deaths. Another 1 million people attempted suicide, and 2 million engaged in suicidal ideation (NCIPC, 2013f). On average, 31,000 suicide deaths occur each year in the United States (Degutis, 2013). Suicide is also one of the top ten causes of death throughout the world, with an estimated 10 to 20 suicide attempts for every completed suicide (Demirçin et al., 2011).

U.S. costs for suicide are estimated at \$34.6 billion per year. When the costs of lost productivity for lives cut short are calculated, the average cost of suicide is more than \$1 million per

person. In addition, suicide has long-term psychological costs for survivors of suicide victims. Approximately 7% of the U.S. population knows someone who committed suicide in the last year, and suicide by a family member increases the risk of suicide in survivors (NCIPC, 2013f).

Interpersonal Violence

Forms of interpersonal violence include family or intimate partner violence and community violence. Both will be briefly addressed here.

FAMILY/PARTNER VIOLENCE. Family violence has been defined by Canada’s Department of Justice (2013) as “any form of abuse, mistreatment, or neglect that a child or adult experiences from a family member, or from someone with whom they have an intimate relationship” (para. 1). Similarly, Family Law Courts (n.d.) of Australia defined family violence as “violent, threatening or other behavior by a person that coerces or controls a member of the person’s family . . . or causes the family member to be fearful” (para. 1). In the United States, the term **domestic violence** is more often used and is defined as a “pattern of abusive behavior in any relationship that is used by one partner to gain or maintain power or control over another intimate partner (U.S. Department of Justice, 2013, para. 1). The definition of **family/partner violence** used here is any form of violence or coercion perpetrated by one family member or partner against another.

Family/partner violence encompasses child maltreatment, elder abuse, and intimate partner violence. In many families, these forms of abuse are intertwined, creating an intergenerational pattern of violence in which children who are subjected

Children exposed to violence in the home experience a wide variety of negative consequences. (Pixel Memoirs/Fotolia)

to or witness violence in the family internalize violence as a mode of family interaction. These children may then become abusive or enter abusive relationships in adulthood (Spivak et al., 2014). These abusive relationships may also carry over into care of aging parents, particularly if the parents were abusive themselves.

Child maltreatment. Child maltreatment or abuse was defined in Chapter 16 and involves intentional physical or mental harm to a child by someone responsible for the child's welfare including parents, caregivers, or other persons in a custodial role (e.g., a coach, teacher, or clergy person) (NCIPC, 2014b). Child maltreatment includes both acts of commission and omission. Acts of commission are intentional and deliberate actions or words that cause or threaten harm to a child or have the potential to cause harm. Acts of commission include physical, sexual, and psychological abuse (NCIPC, 2014a). Physical violence involves nonaccidental physical injury to a child by a parent or other person responsible for the child's welfare. Sexual

abuse encompasses a wide array of sexual activities, such as genital fondling, penetration, incest, rape, sodomy, or exploitation through prostitution or production of pornographic materials. Emotional or psychological abuse involves actions that undermine a child's emotional development or sense of self-worth. These actions may be positive actions, such as engaging in constant criticism, or negative actions, as in withholding love and support (Child Welfare Information Gateway, 2013).

Acts of omission or neglect involve "failure to provide for a child's basic physical, emotional, or educational needs or to protect a child from harm or potential harm" (NCIPC, 2014a, p. 2). In physical neglect, caretakers fail to provide the child with the material requirements for healthy growth. Physical neglect may include failure to feed or clothe a child appropriately. Emotional neglect involves failure to provide a child with the love and affection needed for optimal emotional development. Educational neglect is failure to educate the child or to provide for special education needs. Medical neglect is another aspect of neglect in which caretakers fail to provide needed medical, dental, or mental health treatment (Child Welfare Information Gateway, 2013; NCIPC, 2014a). Abandonment is another form of neglect and occurs when caretakers leave children alone in circumstances that may cause harm or fail to maintain contact with children (Child Welfare Information Gateway, 2013). Finally, failure to provide adequate supervision for children or exposing children to dangerous environments (including drug use) is considered an act of omission constituting child maltreatment (NCIPC, 2014a).

In 2012, more than 3.2 million reports of maltreatment affecting more than 6.3 million children were made to child protective service (CPS) agencies in the United States. Of these, 62% or 2.1 million reports involving 3.2 million children were investigated, and more than 686,000 children were found to be victims of maltreatment. The majority of cases (78%) involved neglect, but more than 18% involved physical abuse, and 9% involved sexual abuse, 7% involved emotional abuse, and 2.2% involved medical neglect. Child maltreatment resulted in 1,649 deaths among children as a result of abuse for a national fatality rate of 2.2 per 100,000 children. Slightly more than 70% of fatalities occurred in children under 3 years of age (Administration for Children and Families, 2012).

Perpetrators of child abuse tend to be family members, typically parents. Other perpetrators include mothers' boyfriends, babysitters, and stepfathers. In 2012, just over 80% of child maltreatment was perpetrated by parents, most of whom were biological parents (Administration for Children and Families, 2012).

Societal costs for child maltreatment are extensive. For example, the lifetime cost for 1 year's worth of confirmed child maltreatment cases was estimated at \$124 billion. When lost productivity costs are considered, each death due to child maltreatment costs approximately \$1.3 million, and lifetime costs for children who survive are estimated at \$210,012 per child, a figure higher than or similar to the lifetime cost of conditions such as stroke and diabetes (Division of Violence Prevention, 2014).

Intimate partner violence. **Intimate partner violence (IPV)** is defined as violence between two people of the same or opposite sex who are current or past intimate partners (Degutis, 2013). An estimated 1.3 million women and more than 834,000 men experience IPV. In addition 7.7% of women and 0.3% of men report being raped by an intimate partner at some point in their lives (Haegerich & Dahlberg, 2011). Like child maltreatment, there are several forms of IPV: physical violence, sexual violence, threats of physical or sexual violence, and psychological or emotional violence. Physical violence is the intentional use of force with the potential to cause harm and may involve the use of a weapon, restraints, or one's body size or strength to cause damage (NCIPC, 2013c). Physical violence may also be referred to as "battering" (Women against Domestic Violence, n.d.).

Sexual violence involves the use of force to compel sexual activity against one's will. It also includes attempted or completed sex acts against a person who cannot understand the nature of the act (e.g., a cognitively disabled person) or one who cannot communicate their unwillingness. Sexual violence also includes coercion to engage in sexual activity and noncontact sexual acts, such as verbal sexual harassment, being flashed, or being forced to look at sexually graphic materials.

In some parts of the world, sexual violence against women also includes female genital mutilation (Basile & Smith, 2011). **Female genital mutilation (FGM)** includes any procedure involving partial or total removal of external female genitalia or other nonmedical injury to female genital organs. Approaches to FGM may include clitoridectomy (removal of the clitoris), excision (removal of the clitoris and labia minora, with or without removal of the labia majora), or *infibulation* (narrowing of the vaginal opening). FGM may be motivated by social or cultural conventions, efforts to prevent illicit sexual activity, or conceptions of femininity and modesty. FGM is most often performed in African and Middle Eastern countries, but population health nurses may encounter immigrant women who have been subjected to FGM. Although most FGM is performed by unlicensed personnel, WHO has reported that more than 18% of FGM is carried out by health care providers. Consequences of FGM include infection, hemorrhage, urinary retention and infection, cysts, infertility, and increased risk of complications in childbirth. More than 125 million girls and women have been affected in the countries where FGM is most commonly practiced (WHO, 2014b).

Threatening physical or sexual violence also constitutes IPV. **Psychological violence** or "psychological battering" includes

Evidence-Based Practice

Combining Efforts to Address Sexual Violence and HIV/AIDS

International literature suggests that HIV/AIDS and gender violence are twin epidemics resulting from gender inequities in many regions of the world. This underlying cause suggests that approaches to resolving gender inequities can assist in preventing both HIV/AIDS and violence. Two evidence-based approaches have been suggested to address the problem of gender inequity: one focused on empowerment of women and the other focused on changing attitudes and behaviors among men (Dworkin, Dunbar, Krishnan, Hatcher, & Sawires, 2011).

Strategies to empower women focus on changing social and cultural conceptualizations of gender that constrain women in much of the world (Dworkin et al., 2011). Examples of such strategies include the *Intervention for Microfinance and Gender Equity* (IMAGE) program in South Africa and *Shaping the Health of Adolescents in Zimbabwe* (SHAZ). IMAGE combines education for women on gender equity, violence prevention, and HIV prevention with microfinance of women's businesses. The program also includes training on community mobilization for change. The program has been shown to increase participant use of counseling and HIV testing, improved communication with partners and families, and individual and community action related to IPV resulting in a 55% reduction in IPV (Dworkin et al., 2011).

The SHAZ program includes vocational training and microgrants for small businesses, skill development related to HIV

prevention and interpersonal communication, development of peer social support networks and counseling, and reproductive health and HIV services. Program results included improved economic status and "relationship power" as well as a 50% reduction in physical and sexual violence (Dworkin et al., 2011).

Because women's ability to even participate in empowerment programs is often constrained by domination by their partners, other programs have focused on masculinity and its effects on the health of men and women. In these programs men are assisted to reflect on conceptualizations of masculinity and their potential to lead to behaviors that put both men and women at risk for poor health outcomes. Viewing current conceptualizations of masculinity as harmful to themselves can lead men to adopt new gender identities that are more conducive to health and may also lead to reduced gender discrimination. For example, the *Men as Partners* program focuses on getting men to question patriarchal attitudes and their effects on family health resulting in more equitable views of gender, particularly with respect to gender-based violence. A similar program, *Stepping Stones*, led to decreases in herpes simplex virus (HSV) infection rates and IPV incidence (Dworkin et al., 2011). Perhaps the most effective response to the problem of gender-based violence would be to combine approaches to address both men and women.

Sexual violence often results from highly traditional gender roles.

(BlueSkyImages/Fotolia)

denigrating the victim, diminishing their sense of self-worth, or socially isolating him or her from others (NCIPC, 2013c; Women against Domestic Violence, n.d.).

IPV is believed to occur in a predictable cycle that includes a period of growing tension in the batterer, culminating in a specific incident of battering followed by a period of remorse and forgiveness (Strengthen Our Sisters, n.d.).

Approximately 24 people per minute experience IPV. This figure is most likely an underrepresentation of the true magnitude of the problem, because many incidents of IPV go unreported. In 2010, IPV accounted for 10% of all homicides in the United States (Spivak et al., 2014). Approximately one in four women will experience some form of domestic violence or IPV in their lifetimes, and IPV is a significant contributor to homelessness among women (National Coalition for the Homeless, 2012).

Stalking is another form of IPV. **Stalking** involves “a pattern of harassing or threatening tactics used by a perpetrator that is both unwanted and causes fear or safety concerns in the victim” (Division of Violence Prevention, 2011, p. 29). Stalking may include following someone, appearing at their home or work place, making harassing telephone calls, leaving threatening messages, or vandalizing their property. Stalking may also employ technological approaches such as text messages, surveillance, and global positioning systems to track victims (Division of Violence Prevention, 2011). An estimated 6.6 million people or 1 in 6 women and 1 in 19 men are subjected to stalking each year. Nearly half (46%) are stalked at least weekly, and 11% have been stalked for 5 years or longer (Stalking Resource Center, 2012).

Stalking may lead to violence, and one in five stalkers uses a weapon to threaten his or her victim. More than three fourths (76%) of women killed by an intimate partner had been stalked beforehand. More than half of these women had reported being stalked prior to being killed (Stalking Resource Center, 2012).

When IPV involves violence that occurs in a dating relationship, it is often referred to as **dating violence**. Nearly one third of high school and college women report dating

violence, and dating violence accounts for half of the sexual assaults experienced by women aged 12 to 24 years. Women who have a history of childhood sexual abuse are at higher risk for dating violence than women who were not abused as children (Degutis, 2013). Dating violence may involve physical, sexual, and emotional abuse and stalking (NCIPC, 2012).

The estimated annual direct and indirect cost of IPV is \$8.3 billion (NCIPC, 2013b). Mental and physical health care costs may be as high as \$4.1 million per year (National Coalition for the Homeless, 2012). Stalking also results in lost worktime and productivity. For example, one in eight stalking victims loses worktime (Stalking Resource Center, 2012). Severe IPV results in the loss of nearly 8 million days of work productivity for employed women and 5.6 million days of lost household productivity (NCIPC, 2013b).

In addition to its economic costs, IPV also has significant health effects for victims as well as for family members who witness the abuse. Health effects are both physical and emotional and include injury, sexually transmitted infections, depression, anxiety, and post-traumatic stress disorder (PTSD). These effects will be discussed in more detail in the section on psychological determinants. Pregnancy is another effect of sexual violence, and pregnancy in the context of IPV may lead to abortion. In a study in one abortion clinic, for example, almost 10% of patients reported a history of physical abuse and 2.5% reported sexual abuse. Most often the violence in these cases was perpetrated by former, rather than current, intimate partners (Safilis et al., 2010). In another study, IPV was associated with male involvement in a pregnancy ending in abortion and with conflict related to abortion decisions. The authors noted that policies requiring partner consent for an abortion may put women at risk for IPV (Silverman et al., 2010).

IPV occurs throughout the world in all nations and in all social, economic, religious, and cultural groups. IPV is often referred to as *gender-based violence* because in many cultures it arises in part from women’s subordinate social status.

Although most people think of IPV as occurring in heterosexual relationships, there is evidence to suggest that IPV also occurs in same-sex relationships (Spivak et al., 2014). IPV in same-sex relationships was discussed in Chapter 20∞.

Elder abuse. As we saw in Chapter 19∞, elder abuse or maltreatment is purposeful physical or psychological harm or exploitation of elderly persons. Elder abuse can occur within families or in institutional settings such as nursing homes and other residential facilities for the elderly. The focus of this chapter, however, is on abuse of older persons within community, rather than institutional, settings.

Excluding financial exploitation, approximately one in ten elderly individuals in the United States experiences maltreatment. This figure probably represents only about a fourth of the actual incidence of elder abuse. In one study in New York State, there are an estimated 24 unknown cases of elder abuse for every known case (National Center on Elder Abuse, n.d.). There are few national studies of the incidence of elder abuse,

but in another state study, the average annual rate of elder victimization from 2005 to 2009 was 204.5 per 100,000 population. Half of these incidents involved serious violence against older individuals (National Center for Victims of Crime, 2013).

Several forms of elder abuse occur, many of them similar to the types of abuse found among children and intimate partners. Types of abuse that may be encountered by population health nurses working with elderly clients include physical and sexual abuse, neglect, emotional abuse, abandonment, and financial or material exploitation (NCIPC, 2013h). Physical abuse of the elderly may include injury, inappropriate restraint, or overmedication. Neglect may involve failure to meet physical or emotional needs, failure to attend to medical needs, or self-neglect by the older person himself or herself. Emotional abuse may consist of verbal abuse or disrespect or social isolation. Older clients may also be financially exploited when their funds or material goods are appropriated by others rather than used to meet their needs. Older clients' personal rights may be violated if they are not allowed to participate in decisions regarding their lives when they are capable of making such decisions. Some older clients may be abandoned or deserted by those responsible for their care. In addition, there is an increasing incidence of Internet crime focused on the elderly. For example, people over 60 years of age make 14% of fraud reports to the Federal Trade Commission and as many as 14% may be subjected to identity theft (National Center for Victims of Crime, 2013). Community violence and political violence disproportionately affect the elderly as well as children.

Perpetrators of elder maltreatment are usually family members or acquaintances. In fact, up to 90% of elder abuse is perpetrated by family members, most often spouses (Acierno, Hernandez-Tejeda, Muzzy, & Steve, 2009; National Center on Elder Abuse, n.d.).

In a 2009 national epidemiologic study funded by a National Institute of Justice grant, emotional mistreatment was the form of elder abuse most frequently reported, affecting 4.6% of the respondents. Only 8% of the mistreatment was reported, and more than half was perpetrated by family members—25% by spouses and 19% by children or grandchildren. Physical abuse was reported by 1.6% of the elders in the study. Elders were more likely to report physical abuse to police (31%), and more than three-fourths of the perpetrators were family members. Less than 1% of the elders (0.6%) reported experiencing sexual abuse, but only 16% of those reported it to the authorities. Again, half of sexual abuse against elders was perpetrated by family members, typically a partner or spouse. Slightly more than 5% of the elders were experiencing current potential neglect (defined as at least one essential need not being met, although no one in particular may have been designated responsibility for meeting that need). A total of 11% of the elderly respondents had experienced any of these forms of abuse (Acierno et al., 2009).

In the same study, financial exploitation by family members was reported by 5.2% of the elders. Exploitation was more common among elders who were functionally impaired or those receiving social services whose providers should have been alert

to the potential for financial abuse. An additional 6.5% of the elderly reported lifetime experience of financial exploitation by strangers, usually involving fraud (Acierno et al., 2009).

COMMUNITY VIOLENCE. Interpersonal violence also occurs outside of family or partner relationships. Forms of community violence to be addressed here include assault and sexual assault, hate crimes, and trafficking.

Assault and sexual assault. Multiple forms of physical assault take place each day in the United States, with the most extreme form of assault resulting in homicide. **Assault** is defined as “an unlawful physical attack or threat of attack” (Bureau of Justice Statistics, 2013, para. 1). Assault may be classified as either simple or aggravated. An **aggravated assault** is one in which a weapon is used or in which serious injury is inflicted without use of a weapon (e.g., a severe beating). In a simple assault, no weapon is used and no injury or minimal injury results (Bureau of Justice Statistics, 2013). Incidents of rape, attempted rape, and sexual assault are excluded from assault figures. In 2012, more than 1 million aggravated assaults occurred in the United States. These assaults involved more than 1.2 million victims and nearly 1.2 million offenders (Criminal Justice Information Systems Division, 2013b). During the first 6 months of 2013, the number of aggravated assaults decreased by 6.6% from the same period in 2012 (Federal Bureau of Investigation [FBI], 2013).

As we saw earlier, sexual assault not only occurs frequently within family or intimate partner relationships, but also occurs as a form of community violence. In 2012, 73,132 forcible sexual offenses and 6,493 nonforcible offenses were reported to the FBI (Criminal Justice Information Systems Division, 2013b). In the first 6 months of 2013, reports of forcible rape declined by 10.6% (FBI, 2013). Approximately 18.3% of U.S. women and 1.4% of men will be raped at some point in their lives. As we noted earlier, the majority of rape of women in the United States occurs within the context of an intimate partner relationship, but just over 40% of women report being raped by an acquaintance rather than a partner. More than half of men are raped by an acquaintance and 15% by strangers.

Most incidents of sexual violence are perpetrated by single offenders, but sexual violence is often used in civil conflicts, such as war and insurrection, as a systematic tactic to destabilize and demoralize whole populations. For example, over several years of civil war in the Democratic Republic of Congo, an estimated 1 million women and girls have been subjected to sexual violence (Peterman, Palermo, & Bredenkamp, 2011).

Hate crimes. As we saw in Chapter 20, hate crimes are motivated by a bias against a particular group of people. In 2012, 1,730 law enforcement agencies reported 5,796 incidents of hate crimes to the Federal Bureau of Investigation. Nearly half of the single-bias incidents (these motivated by a single source of bias) were racially motivated, and nearly 20% were motivated by sexual orientation. Another 17.4% of incidents were based on religious bias, 11.5% on the victim's ethnicity or national ori-

gin, and 1.6% on disability bias. Two thirds of racially motivated incidents were directed at Blacks and 22% at Whites. Smaller proportions of incidents were the result of bias against Asians/Pacific Islanders, American Indian/Alaska Native, or people of mixed race (4.1%, 3.3%, and 4.1%, respectively) (Criminal Justice Information Systems Division, 2013a).

Nearly two thirds (59.7%) of religiously motivated hate crimes were directed at Jews, 12.8% toward members of Islam, and 6.8% at Catholics. More than half of hate crimes based on sexual orientation were directed at gay men, and only 12.3% involved lesbian victims. An additional 2% of hate crimes in this category involved anti-heterosexual bias. Nearly 60% of hate crimes based on ethnic bias were directed at Hispanics and the remainder at members of other ethnic groups. Finally, a large majority (82%) of disability bias-motivated incidents involved victims who were mentally ill; only 20% involved bias against physical disability (Criminal Justice Information Systems Division, 2013a).

Trafficking. Trafficking is another form of community violence. **Trafficking** is defined as:

All acts involved in the recruitment, abduction, transport, harboring, transfer, sale or receipt of persons, within national or across international borders, through force, coercion, fraud or deception, to place persons in situations of slavery or slavery-like conditions, forced labor or services, such as forced prostitution or sexual services, domestic servitude, bonded sweatshop labor, or other debt bondage. (California Department of Justice, n.d., para. 5).

The International Labor Organization has estimated that 12.3 million people, half of them girls and women, are held in situations of forced or bonded labor (Hossain, Zimmerman, Abas, Light, & Watts, 2010). Although there are many forms of trafficking, the most common are forced labor and sex trafficking, and as many as 1.3 million persons may be involved in sexual servitude, 56% of whom are women. Trafficking is a crime in the United States and in many other countries. The Trafficking Victims Protection Act of 2000 makes provision for prosecution of persons engaged in human trafficking and promotes rescue and long-term assistance for trafficking victims (Moynihan & Gaboury, 2013).

Victims of trafficking may be prevented from escape by a number of means, including being illegally confined. Other traffickers use debt bondage, social isolation, confiscation of legal documents, and threats of violence to prevent victims from leaving the situation. Other controlling tactics include threats of shaming, threat of imprisonment or deportation, and control of money (Office of Refugee Resettlement, 2012). Trafficking results in a variety of health and social consequences for victims, including PTSD, depression, anxiety, injury, sexually transmitted infections, pregnancy and abortion, and substance abuse (Hossain et al., 2010; Moynihan & Gaboury, 2013).

A report from the National Academies of Science identified risk factors for trafficking at several levels: individual, relationship, community, and societal. Individual level risk factors

include a history of childhood maltreatment, being homeless or a runaway or thrown-away youth, being a member of a sexual minority, and criminal justice or foster care involvement. Relationship factors reflect family conflict or dysfunctional family dynamics. Community level factors include social norms that create a demand for trafficked labor or sexual partners; social isolation; gang involvement; and under-resourced schools, communities, and neighborhoods. Societal level risk factors include lack of awareness of commercial sexual exploitation, sexualization of children, and lack of resources (Clayton, Krugman, & Simon, 2013). For example, in some parts of the world, poverty-stricken families may sell young children into forced labor or prostitution as a means of supporting other family members.

HOMICIDE. As noted earlier, homicide is a form of societal violence that cuts across the family/intimate partner and community categories of violence. For that reason, it is addressed separately. Approximately 37% of intentional injury deaths are the result of homicide (Degutis, 2013). The 2010 age-adjusted homicide rate in the United States was 5.3 deaths per 100,000 population. This figure represents a decline from 5.9 per 100,000 population in 2000 to 5.5 per 100,000 in 2009 (NCHS, 2014). In 2012, 3,943 homicides were reported to the FBI (Criminal Justice Information Systems Division, 2013b). The number of homicides reported from January to June of 2013 decreased by 6.9% from the number of cases reported during the same period in 2012.

Population Health Nursing and Societal Violence

Violence contributes to a variety of physical, psychological, and social problems that can be prevented by population health nursing efforts to modify factors that contribute to violence against self or others. Population health nurses play an active role in responding to societal violence. This role may be enacted in services to individual clients and families or in planning and implementing interventions to control the problem of violence at the community or population level. Control involves use of the nursing process to assess factors contributing to and impeding violence, planning and implementing evidence-based control strategies, and evaluating their effectiveness.

Assessing Risks for and Effects of Societal Violence

The National Academies Panel on the Understanding and Control of Violent Behavior (Gellert, 2010) identified four levels of risk factors for societal violence. These included biological, psychological, microsocial, and macrosocial level factors. Biological factors include hormonal and chemical influences on violence, genetics, and the effects of drug use and traumatic brain injury on cognitive ability and impulse control. Psychological factors include temperament, coping skills,

learned responses, and negative emotions. Microsocial factors reflect the influence of encounters and relationships between people. Finally, macrosocial factors include societal characteristics at community or population levels that promote or deter violence. As we will see, these categories of risk factors are encompassed within the discussion of determinants of health as they affect societal violence.

BIOLOGICAL DETERMINANTS. Biological considerations related to violence include both factors that contribute to or protect against violence and those that arise as a consequence of violence. Areas to be addressed include age, gender, race/ethnicity, and physiologic function.

Age. Age influences both one's potential for exposure to violence and the severity of its effects. During 2009–2010, homicide was the 15th leading cause of death for the overall population, but was the 2nd most common cause of death for people 10 to 19 years of age (Kegler & Mercy, 2013). U.S. homicide rates in 2010 were highest among people 20 to 24 years of age at 13.2 per 100,000 population and second highest for those 15 to 19 years old (8.3/100,000). When these two groups are combined, the overall homicide mortality rate was 10.7 per 100,000 people. A shocking 7.9 per 100,000 infants under 1 year of age were victims of homicide, but the rate decreased dramatically to 1.1 for children from 1 to 14 years of age and to 2 per 100,000 for people over 65 years of age (NCHS, 2014).

Infants and toddlers are also at increased risk for injury from abuse. For example, 12% to 20% of fractures in very young children are due to abuse, and premature infants are at greater risk for abuse than infants born at term, possibly due to their greater neediness (Harrison & Vega, 2014). In addition, an estimated 1,300 children experience shaken baby syndrome each year, and death occurs in about 20% of victims (National Center on Shaken Baby Syndrome, n.d.). **Shaken baby syndrome** is a traumatic brain injury that results from violently shaking an infant. Effects include visual, motor, and cognitive impairment (National Institute of Neurological Disorders and Stroke, 2014).

In 2009, 762,940 children were victims of abuse. Three fourths of them (76%) were subjected to neglect, 16.4% experienced physical abuse, 8.8% experienced sexual abuse, and 7% were subjected to emotional abuse. In addition, 2.2% of child maltreatment involved medical neglect. Overall incidence of child maltreatment is highest in 2- to 5-year-olds (25.9% of abuse), followed by 6- to 9-year-olds at 21.5% (U.S. Census Bureau, 2013b). Among the elderly, “younger” elders (those under 70 years of age) are less likely to be subjected to emotional abuse than “older” persons (those over age 70) (Acierno et al., 2009).

The first incident of IPV is also more likely to occur at younger than older ages. For example, 22% of women victims encountered IPV between 11 and 17 years of age, and another 47% before the age of 25 years. The first experience of IPV occurred between the ages of 11 and 17 for 15% of abused men, while 39% experienced IPV for the first time between 18 and 24 years of age. In addition, 21% of women and 31% of men reported their

first experience of IPV victimization between 25 and 34 years of age. Overall, 90% of women and 85% of men experience their first episode of IPV before 35 years of age (Spivak et al., 2014). Similarly, most (71%) victims of rape are under 18 years of age and half of those are under age 12 (Basile & Smith, 2011).

The age distribution for suicide mortality shows somewhat different patterns. In one study, people under 30 years of age were significantly more likely than those over age 30 to engage in thoughts of suicide, formulate a plan, and attempt suicide (Crosby, Han, Ortega, Parks, & Gfroerer, 2011). Despite these findings, the highest rate of completed suicide in 2010 was among people 45 to 64 years of age (18.6/100,000 population), then decreased for older ages, to rise again to 17.6 among people 85 years of age and older. In contrast, the 2010 suicide rate for people aged 15 to 24 years was 10.5 (American Foundation for Suicide Prevention, 2014), and for youth 10 to 19 years of age, the rate was 4.5 per 100,000 population (Perou et al., 2013).

Gender. Gender also influences risk of violence. For example, men are approximately three times more likely than women to be victims of homicide (U.S. Census Bureau, 2013a). In 2010, the age-adjusted homicide rate was 8.4 per 100,000 men compared to 2.3 for women (NCHS, 2014). Only among people over 65 years of age are women more likely to be victims of homicide than men (National Center for Victims of Crime, 2013).

With respect to suicide, some research has indicated that women have more suicidal thoughts than men (Crosby et al., 2011), but men have higher rates of completed suicide than women, primarily because men choose more lethal methods for suicide (Haegerich & Dahlberg, 2011). In 2010, the suicide mortality rate for men was 19.8 per 100,000 population, compared to 5 per 100,000 women (NCHS, 2014).

On the other hand, women are more likely than men to experience severe physical and sexual violence related to IPV and are more likely than men to be injured. Women are also twice as likely as men to be killed as a result of IPV. Approximately 24% of women are subjected to physical and/or sexual IPV, whereas only 13.8% of men experience violence from an intimate partner (Spivak et al., 2014). Similarly, women are at higher risk for sexual violence in general (Basile & Smith, 2011), whereas men are nearly always the perpetrators of sexual violence (Black et al., 2011).

Race and ethnicity. Racial and ethnic disparities are also noted in the incidence of particular forms of societal violence. For example, in 2010 suicide rates were highest for non-Hispanic White men at 24.2 per 100,000 men; followed by American Indian/Native Alaskan (AI/AN) men (15.5 per 100,000); and Hispanic, Asian Pacific/Islander, and Black men (at 9.9, 9.5, and 9.1 deaths per 100,000 population, respectively). A similar distribution, but lower rates are noted for suicide among women. Overall, from 1999 to 2010, suicide rates were twice as high for Whites as for Blacks (NCHS, 2013a), with increases of more than 65% in suicide rates among AI/AN populations and 40% among Whites (Sullivan, Annet, Luo, Simon, & Dahlberg, 2013).

Although both men and women perpetrate intimate partner violence, women are more likely to sustain serious injuries.

(Amyinlondon/Fotolia)

Conversely, homicide rates were highest among Black or African American men (31.5 per 100,000), with rates nearly four times higher than any other racial or ethnic group. The second highest rate was noted for AI/AN men (8.8/100,000), followed by Hispanic men at 8.7, and non-Hispanic Whites at 3.3 per 100,000 population. The lowest homicide rates were noted among API men (2.6/100,000). The distribution of homicide rates by race or ethnicity among women was similar, with the highest rates for Black or African American women, followed by AI/AN women, non-Hispanic White women, Hispanic women, and API women (NCHS, 2014). From 1999 to 2010, age-adjusted homicide rates were four times higher for Blacks than Whites (NCHS, 2013a).

With respect to IPV and sexual violence, Hispanic and AI/AN women have been found in some studies to be at greater risk for rape than other women (Basile & Smith, 2011). IPV has been found to occur in AI/AN women at rates 80% above those of other women, and as many as 65% of urban AI/AN women may be subject to IPV (Begay, 2011). In other studies, approximately 22% of Black women, 27% of AI/AN women, 19% of

non-Hispanic White women, and 15% of Hispanic women have been raped at some point in their lives. Among men, 45% of AI/AN men and 40% of Black and multiracial men have been subjected to sexual violence by an intimate partner in their lifetimes (Black et al., 2011). Although racial and ethnic variations in violence occur, studies have found that disparities are explained by a variety of socioeconomic factors, including marital and immigration status and neighborhood social context. These findings suggest that general interventions to improve social and economic factors affecting populations will help to reduce racial and ethnic disparities in the incidence and prevalence of violence. For instance, among immigrant populations, the stresses arising from acculturation and language and economic barriers may contribute to abuse and could also be resolved by improvement in social conditions. Population health nurses can be actively involved in advocacy to improve living conditions for both immigrant and nonimmigrant populations.

Physiologic function. Physiologic status may influence one's risk for violence victimization. Conversely, violence may result in a variety of physiologic effects. Physical illness and disability may increase one's risk of abuse. For example, older persons who need assistance with activities of daily living have been found to be at twice the risk of emotional abuse as those without functional limitations (Acierno et al., 2009). Similarly, poor overall health among the elderly has been associated with greater risk of abuse (National Center for Victims of Crime, 2013) and institutionalized women with disabilities were more likely to report a history of IPV, including sexual and physical abuse, than nondisabled women (National Center on Elder Abuse, n.d.). Physical health problems and disability are also risk factors for suicide (NCIPC, 2013g; Parks et al., 2014).

Violence victimization also leads to a variety of physical health effects. For example, sexual violence may lead to injuries, genital tearing (experienced by 50% to 90% of rape victims), sexually transmitted diseases (4% to 30% of victims), and pregnancy (5%). In addition, IPV may result in a 20% pregnancy rate. Other effects include pelvic inflammatory disease

FOCUSED ASSESSMENT

Assessing Biological Determinants Influencing Societal Violence

- What influence does age have on the incidence and prevalence of violence in the population? What is the age distribution among victims of specific types of violence? What is the age distribution among perpetrators of violence?
- Are there gender differences in victimization or perpetration of specific forms of violence in the population?
- What is the racial/ethnic distribution of violence victimization and perpetration in the population?
- Are there physical considerations that place clients at risk for family violence or suicide (e.g., disability, pregnancy)? What is the extent of these conditions in the population?
- Is there physical evidence of abuse?
- What are the physical effects of violence for the individual victim? What is the extent of physical effects of violence in the population?

and other genito-urinary problems (Basile & Smith, 2011). IPV has also been shown to affect endocrine and immune systems as a result of chronic stress, resulting in conditions like fibromyalgia, irritable bowel syndrome, gynecologic disorders, and complications of pregnancy (NCIPC, 2013b). Physical abuse also results in multiple injuries for children and older persons and population health nurses should be alert to signs and symptoms of abuse. *Focused Assessment* questions for assessing biological determinants influencing societal violence are provided on the previous page.

PSYCHOLOGICAL DETERMINANTS. As was the case with biological determinants, psychological factors serve as both contributors to and consequences of violence. For example, caregiver resentment, fatigue, family conflict, and personality traits have been found to contribute to elder abuse. The presence of psychiatric disorders also increases the potential for all forms of violence. For example, major depressive disorder, borderline personality disorder, PTSD, and nicotine dependence have been linked to suicide risk (Bolton & Robinson, 2010). Similarly, other psychological factors such as hopelessness, impulsivity, and aggressiveness may contribute to suicide. Conversely, protective factors include effective coping, problem-solving skills, and conflict resolution skills and knowledge of nonviolent ways of addressing disputes (NCIPC, 2013g). Suicide is often precipitated by mental health problems, intimate partner conflict, or a recent crisis (Parks et al., 2014).

Risk for IPV increases in the presence of low self-esteem on the part of both victims and perpetrators, a history of aggressive or delinquent behavior as a youth, depression, anger and hostility, antisocial or borderline personality disorders, emotional dependence and insecurity, and desires for power and control (NCIPC, 2013d). IPV is also associated with adverse psychological effects, such as depression, suicidal behavior, anxiety, low self-esteem, PTSD, fear of intimacy and inability to trust others, emotional detachment, and difficulties sleeping (NCIPC, 2013b). Sexual assault results in similar psychological consequences. PTSD, in particular, is common, and is more likely to occur in people who experience rape as adults, rather than in childhood, and with forcible rape. Experience of gang rape is also more likely to result in suicide than rape by a single perpetrator (Basile & Smith, 2011). Perpetration of elder abuse is associated with high levels of hostility and poor coping skills, as well as current mental illness in the perpetrator. Exposure to abuse as a child may also contribute to elder abuse (NCIPC, 2014e). Elder abuse may also be the result of caregiver strain or emotional or material dependence on the elder (NCIPC, 2013h). Older persons with dementia may be at higher risk for abuse than those with normal cognitive abilities. An estimated 47% to 50% of people with dementia are abused by their caretakers (National Center on Elder Abuse, n.d.). Psychological effects of elder abuse include fear, anxiety, and distrust (NCIPC, 2013h), as well as lower feelings of self-efficacy and greater psychological distress than in nonabused elders (NCIPC, 2013h; National Center on Elder Abuse, n.d.). Psychological effects of

violence experienced by parents may also affect the behavior of their children. For example, the occurrence of a homicide near the home increased caretaker distress and was also associated with decreased attention and impulse control in their children (Sharkey, Tirado-Strayer, Papachristos, & Raver, 2012).

The emotional climate in the family can also contribute to abuse. Families that exhibit increased emotional tension and anxiety, with little display of visible affection or emotional support, are considered emotionally impoverished and are at risk for violence. Similarly, family communication patterns that are non-nurturing, destructive, or ambiguous may also indicate risk for family violence. Couples that experience IPV have been found to have poorer communication skills and less satisfying relationships than other couples. These couples may also be characterized by poor conflict negotiation skills and poor problem-solving skills.

Child abusers may exhibit unrealistic expectations of children, particularly as sources of warmth and love. When they are disappointed in these expectations, abuse may occur. For example, children who are irritable, who cry often, or who do not care to be cuddled may be perceived as rejecting the parent. For parents with low self-esteem, this perceived rejection can set the stage for abuse. Population health nurses can assist parents to develop age-appropriate expectations of their children and engage in strategies that assist parents to recognize and foster normal child development.

Population health nurses can identify risk factors for perpetration of violence or victimization in individuals and families or in population groups. In addition, they can assist individuals and families to deal with the psychological effects of violence. They may also need to advocate for changes in societal perceptions of and attitudes toward victims of abuse to prevent feelings of guilt and diminished self-worth.

Witnessing abuse may also have psychological effects. Consequences of witnessing abuse among children include emotional and behavioral problems, anxiety, poor school performance, low self-esteem, disobedience, nightmares, physical complaints, and aggression. Depression is a particularly common effect of witnessing parental domestic violence, especially among adolescents. Witnessing violence in childhood may also contribute to perpetration of violence as an adult (Haegerich & Dahlberg, 2011). The *Focused Assessment* on the next page includes questions that the population health nurse can use to examine psychological determinants influencing violence in a specific population group or family.

ENVIRONMENTAL DETERMINANTS. Environmental factors may also influence the incidence and prevalence of societal violence. For example, schools have become a source of exposure to violence in today's society. In 2011, for example, 597,500 students 12 to 18 years of age experienced nonfatal violence victimization, with more incidents occurring within than outside of school. During the 2010–2011 school year, 31 violent deaths occurred in schools (25 homicides and 6 suicides) among children 5 to 18 years of age, and 24% of U.S. public

FOCUSED ASSESSMENT

Assessing Psychological Determinants Influencing Societal Violence

- What is the level of stress experienced by potential abusers or suicide victims? To what extent are stressors present in the population (e.g., unemployment) that might influence violence or suicide?
- What coping strategies are employed by members of the population? By family members? How effective is coping among members of the population or family?
- Is there evidence of psychiatric disorder in the family? Depression? What is the extent of psychiatric illness in the population and what effect does it have on the incidence of societal violence?
- Are members of the population with mental illnesses subjected to stigma or violence?
- Do potential victims or perpetrators of violence exhibit poor self-esteem? Poor impulse control?
- Is there a negative emotional climate in the setting that might contribute to violence? In the population (e.g., general hostility or feelings of frustration with life circumstances)?

schools reported at least one incident of violence, with 16% reporting incidents involving serious violence (Robers, Kemp, Truman, & Snyder, 2013).

A significant portion of school-related violence is directed at sexual minority youth, but the character of the school environment may have a protective effect for this population group. In one study, for example, gay, lesbian, bisexual, and transgender (GLBT) youth in states and cities with more protective school climates exhibited a decreased prevalence of suicidal ideation. Protective school climates include antibullying policies that address sexual orientation, have active gay-straight student alliances on campus, incorporate information on HIV, STI, and pregnancy prevention relevant to GLBT youth into school curricula, provide safe spaces in which youth can receive support from staff, provide staff training on supportive environments for GLBT youth, and make referrals to offsite providers to meet the needs of this vulnerable population (Hatzenbuehler, Birkett, Van Wagenen, & Meyer, 2014).

The home is another potential environment for violence. Both suicides and homicides occur more frequently in houses or apartments than in any other locale (Parks et al., 2014). Central cities also have higher rates of some forms of homicide than other areas. For example, from 2006 to 2007, two thirds of the 50 largest metropolitan statistical areas (MSAs) in the United States had firearms homicide rates that exceeded national rates, and 86% of center city areas had rates higher than the related MSAs (Kegler, Annett, Kresnow, & Mercy, 2011). Similar distributions were noted for both homicides and suicides employing firearms in 2009–2010, although suicide rates were lower than those for homicides (Kegler & Mercy, 2013). From 2007 to 2009, homicide rates were highest in large central metropolitan counties, and homicide rates for men in these areas were 76% higher than in other locales (NCHS, 2012).

Occupational environment may also contribute to violence. For example, more than 15% of women and 0.7% of men receiving care from the Veteran's Health Administration reported military sexual trauma (Kimerling et al., 2010). Risk for

violence also increases in occupational settings associated with the use of alcohol.

One other influence of environment on societal violence lies in the availability of means of suicide or homicide. For example, from 1999 to 2010, there was a more than 81% increase in suicides due to suffocation, a 24% increase in suicides due to poisoning, and a 14% increase in suicides using firearms (Sullivan et al., 2013). Suffocation may result from mixing household chemicals and inhaling the resulting fumes in an enclosed space, or exposure to exhaust fumes in a closed area (McNew et al., 2011). The extent of household gun ownership in an area has been found to be a significant predictor of firearms-related homicide rates. An estimated 1% increase in the number of guns is associated with a 0.9% increase in homicide rates (Siegel, Ross, & King, 2013).

In other locales, jumping from high places may be the preferred form of suicide. For example, falls and firearms were the two most common modes of suicide in 284 incidents in 84 national parks over a period of 7 years (Newman, Akre, Bossarte, Mack, & Crosby, 2010). Similarly, high bridges may be a common venue for suicides. Installation of a bridge barrier on a bridge in Montreal, Canada, effectively reduced suicide rates. Suicides were not found to be displaced to other places because of the iconic value of the bridge as a site for taking one's life (Perron, Burrows, Fournier, Perron, & Ouellet, 2013). Population health nurses should be alert to environmental influences on societal violence and can assess those influences using the *Focused Assessment* questions posed on the next page.

SOCIOCULTURAL DETERMINANTS. Sociocultural factors influence both perpetration of and victimization in societal violence, and risk factors for violence occur at both individual and community levels. Individual level risk factors for perpetration of violence include low educational level, low income, social isolation, association with delinquent peers, gang involvement, family disruption and poor family function, family conflict, unsupportive environments, and poor parent-child relationships

FOCUSED ASSESSMENT

Assessing Environmental Determinants
Influencing Societal Violence

- Do school environments support or impede violence?
- To what extent do schools incorporate violence prevention strategies into school curricula?
- In what settings does violence typically occur within the population?
- What methods of violence are available within the home or the population (e.g., availability of firearms, iconic suicide locations, such as famous bridges for jumping to one's death)?
- What physical environmental features, if any, deter violence in the population (e.g., bridge barriers, well-lighted streets)? What physical environmental features promote violence (e.g., secluded areas, poor lighting, prevalence of bars and retail alcohol outlets, abandoned building)?

(Haegerich & Dahlberg, 2011). Additional individual risk factors for perpetration of violence include unemployment, marital conflict or instability, and economic stress (NCIPC, 2013d). Elder abuse is associated with caregivers' assumption of responsibility for elder caregiving at a young age, exposure to abuse as a child, lack of formal support, and expectations of caregiving without assistance from others (NCIPC, 2014e).

Risk factors for violence victimization at the individual level include unemployment or retirement among older persons, low household income, and lack of social support (National Center for Victims of Crime, 2013). Having strong relationships with a variety of people and the availability of social support are protective factors against elder abuse (NCIPC, 2014e). IPV risk may be increased by being divorced or separated and by emotional or financial dependence on the abuser (Basile & Smith, 2011).

Family relationships and dynamics may increase the risk for child maltreatment or serve as protective factors. Family risk factors include social isolation, parental lack of understanding of child development, family disorganization, and lack of family cohesion. Negative parent-child interactions and parental stress levels may also contribute to family violence. Protective factors within families include supportive family relationships, nurturing parenting skills, stable family relationships, household rules, and adequate role models outside the family. Population health nurses can work with families to enhance protective factors against violence and to modify those that contribute to violence. For example, the nurse may teach parenting skills or assist with finding employment.

Community or population level sociocultural risk factors for violence include poverty and diminished economic opportunity, residential instability, overcrowding, low levels of social capital, social disorganization, and lack of institutional support. Additional population level factors include a general tolerance for violence and cultural norms that support violence, traditional gender norms and support for male dominance and sexual entitlement, weak laws and policies related to violence, and weak social sanctions against violence (Haegerich & Dahlberg, 2011; NCIPC, 2013d). Other population level factors

that influence elder abuse include negative societal beliefs and attitudes toward the elderly, the societal latitude frequently given to their caretakers, and failure to monitor the welfare of elderly community members. Conversely, the availability of support services and respite for caretakers, a strong sense of community cohesion, greater community efficacy, and the presence of effective monitoring systems for older individuals are protective factors against elder abuse (NCIPC, 2014e).

Social networks and attitudes may also contribute to increased incidence and prevalence of violence. For example, membership in social networks of co-offenders (people arrested together for the same crime) that include homicide victims has been shown to increase one's risk of homicide. The closer one's relationship to the homicide victim is within the network, the greater one's own risk of being killed. In another similar study, 85% of gunshot injuries in one community were among members of a single network (Papachristos & Wildeman, 2014).

The social context of violence in some communities reflects a so-called **code of the street**, or informal expectations for interpersonal interaction among various members of the community that both "street" people and "decent" people must adhere to (Richardson, Brown & Van Brakle, 2013). The code relies on the use of violence to acquire, defend, and maintain personal respect within the system. A series of focus groups with violent juvenile offenders in adult prisons indicated that one needed to be willing to engage in violence at any moment to protect and maintain respect leading to desensitization to the threat of violence and belief in the inevitability of violent death (Richardson et al., 2013). Street efficacy is a converse concept to the code of the street. **Street efficacy** is the ability to avoid entanglement in dangerous interpersonal interactions (Gibson, Fagan, & Antle, 2014). While the code of the street necessitates dealing with violence by becoming violent, street efficacy is associated with a decreased likelihood of violent victimization in which youth actively avoid situations where violence is likely to occur. Street efficacious youth are less likely than others to spend time with peers who engage in delinquency and violence (Gibson et al., 2014).

Population level risks for suicide include cultural and religious beliefs that suicide is an “honorable” way out of personal difficulties, easy access to lethal methods of suicide, and unwillingness to seek assistance with mental health problems due to perceived stigma. Conversely, cultural or religious proscriptions against suicide have a protective effect (NCIPC, 2013g). As noted in Chapter 25, forced migration is a risk factor for suicide. For example, suicide rates among Bhutanese refugees resettled in the United States were higher than the global suicide rate and were comparable to those of people awaiting resettlement in camps in Nepal, suggesting that resettlement resulted in stressors beyond those that caused migration from their homeland. Some of the stressors identified included language issues, lack of residential and occupational choices, and worry about family members left in Bhutan (Cochran et al., 2013).

The social response to violence also influences its occurrence. Cultural factors, for example, influence the willingness of persons outside the intimate relationship to take action when IPV is suspected. The incidence of abuse tends to be higher in cultures in which family matters are considered “private” and where community sanctions against IPV are weak (NCIPC, 2013d). Being a victim of certain forms of violence may carry with it a level of social stigma that may prevent victims from reporting the violence or taking action to escape it. For example, social stigma attached to rape is often the product of enduring myths such as perceptions that women lead men on, participate willingly in the violation, or make false accusations of rape for their own purposes. Population health nurses can be involved in educating the public to change these perceptions and foster willingness to report and take action to prevent abuse.

Legislation prohibiting violence, protecting victims, and mandating sanctions for abusive behaviors is another social response to violence, particularly family violence. While all U.S. states have legislation related to child abuse, fewer states have adequate legislation and policy addressing IPV and elder abuse. For example, *Futures Without Violence*, a domestic violence advocacy organization, has evaluated state and territorial efforts with respect to six criteria related to domestic violence. The criteria include conducting a state- or territory-wide domestic violence fatality review, mandatory reporting of domestic violence by health care providers, prohibition of insurance discrimination against victims of domestic violence, development of protocols addressing domestic violence, screening for domestic violence by health care professionals, and training of health professionals regarding domestic violence. This evaluation has been conducted three times since 2001. In the most recent edition, only three states, California, New York, and Pennsylvania, and none of the territories or the District of Columbia had effectively addressed all of the criteria. An additional eight states had met five of the six criteria, with the criterion related to screening for domestic violence the one least likely to have been addressed (Durborow, Lizdas, O’Flaherty, & Marjavi, 2013).

Social responses to violence also include the development of support services for victims of violence, particularly family violence. In many U.S. cities, for example, there are safe houses and shelters for abused women, children, and elders. Use of shelters, of course, depends upon the willingness of victims to leave an abusive situation.

Legal alternatives open to victims may also influence response to violence. For example, women may be more likely to seek a domestic violence restraining order or personal protection order (PO) against an abusive partner than to press criminal charges. A **domestic violence restraining order** is a court order that prohibits the restrained person from engaging in abusive activities directed at a family member or intimate partner. Restraining orders and processes for obtaining them vary from state to state, but in many jurisdictions they apply to married or registered domestic partners, divorced or separated individuals, dating or former dating partners, cohabiting partners, or other closely related person (parent, child, sibling, etc.). Depending on the specifications of the order, the restrained person may be prohibited from contacting the person who requested the order or others close to that person, coming to the home or place of work of the person requesting the order, or possessing a gun. The order may also mandate certain behaviors such as support payments, return of property, and so on (California Courts, n.d.).

Research funded by the National Institute of Justice (2011) indicated that restraining orders resulted in decreased abuse and fear of abuse in about 50% of cases, even when the abuser violated the order. POs were also found to save money for justice and social service systems, but ease of obtaining an order and enforcement varied among jurisdictions. Restraining orders may not be as effective among abusers with a history of other criminal activity or juvenile offenders. Similarly, threat of prosecution and the ability to drop charges if warranted provided some protection from further abuse, but mandatory intervention programs for abusers did not seem to be effective in deterring future abuse (National Institute of Justice, 2011).

Restraining orders may also be available to prevent elder abuse and abuse of children. Men subjected to IPV, particularly in same-sex couples, may have more difficulty obtaining restraining orders or other services that are designed primarily to address the needs of abused women. In some jurisdictions, abuse within same-sex couples may not even be acknowledged as IPV (Herek & Sims, 2008). Similarly, although stalking is considered a crime in most jurisdictions, less than a third of states classify stalking as a felony on the first offense, and only half consider it a felony on the second offense or when stalking involves aggravating factors, such as weapons possession or violation of a court order (Stalking Resource Center, 2012).

Another social factor that influences societal violence is media attention. Some authors contend that unbalanced media attention to some types of homicide (e.g., of children or by children) provides the public with an inaccurate view of the problem that hampers their ability to engage in effective

problem solving. Others suggest that exposure to media violence is a causal factor in homicide and suicide. The media no longer presents extensive coverage of youth suicides, for example, because of the known effect seen in cluster suicides. The contention is made that similar coverage of adolescent homicide creates inappropriate role models for vulnerable youth. Questions for exploring the sociocultural factors influencing societal violence are included in the *Focused Assessment* below.

BEHAVIORAL DETERMINANTS. Behavioral risk factors contribute to societal violence and may also be a consequence of violence. For example, data from the National Council on Alcoholism and Drug Dependence [NCADD] (n.d.b) indicate that 40% of violent crimes involve alcohol use. In addition, alcohol use is implicated in 3 million crimes each year, including 37% of rapes, 27% of aggravated assaults, and 25% of simple assaults. Approximately two thirds of violent victimizations by a known perpetrator involve alcohol use, as do 1.4 million incidents of violence among strangers. Alcohol use is also a factor in half a million incidents of IPV and 118,000 incidents of other forms of family violence. In addition, use of alcohol is a contributing factor in half of murder convictions among inmates in state prisons (NCADD, n.d.a.). Similarly, IPV and elder abuse have both been linked to heavy alcohol and other drug use and abuse (NCIPC, 2013d, 2013h).

Alcohol use also contributes to suicide, but differentially for different methods of suicide, age groups, and ethnic groups. Alcohol use in general is linked to suicide using firearms,

hanging, and poisoning. For young and middle adults, alcohol use is more likely to be associated with use of guns and hanging than among older persons. Among older age groups and members of Asian Pacific Islander groups, alcohol use is more closely associated with suicide by means of poisoning. For Blacks, however, the strongest link between alcohol and suicide method relates to hanging (Conner et al., 2014).

Drugs and alcohol may also be used by perpetrators of sexual violence to facilitate sexual abuse. **Alcohol-facilitated sexual abuse** occurs when someone who is intoxicated or incapacitated due to drugs or alcohol is subjected to sexual behavior to which he or she is unable to consent or refuse (Basile & Smith, 2011). The behavior of the perpetrator in such a situation may be either opportunistic or proactive. An opportunistic perpetrator takes advantage of the fact that a potential victim is intoxicated or incapacitated by drugs or alcohol. In proactive alcohol-facilitated sexual abuse, the perpetrator purposely introduces the drug or alcohol without the victim's knowledge. In either case, the drug or alcohol may either decrease the victim's inhibitions related to sexual activity or may actually incapacitate them rendering them vulnerable to assault. Sexual penetration has been found to be more likely when the victim has been drinking, and perpetrators may be less aggressive when victims are intoxicated. In one emergency department approximately 12% of cases of sexual assault were suspected to be alcohol- or drug-facilitated, and figures have been as high as 18% of cases in other studies. Drug and alcohol use also tend to occur in settings where exposure to sexual predators is more likely (Basile & Smith, 2011).

FOCUSED ASSESSMENT

Assessing Sociocultural Determinants Influencing Societal Violence

- Do sociocultural norms support violence?
- Is there evidence of a “street culture” that supports violence as a means of conflict resolution or achieving respect?
- What is the extent of “street efficacy” in neighborhoods with high rates of violence?
- To what extent is the welfare of vulnerable groups within the population monitored (e.g., the elderly)?
- What is the extent of latitude accorded to heads of households or caretakers to control the behavior of others without outside interference?
- What effects do expected gender roles have on violence within families? In the population?
- What is the legal and economic status of women, minors, and the elderly in the population?
- What legislative approaches have been taken to prevent violence? To support victims of violence?
- Is there intergenerational evidence of violence in the family? In the population?
- Are family social interactions positive or negative? What is the quality of social interactions between various segments of the population?
- Do societal conditions contribute to stress (e.g., unemployment, homelessness)?
- Do cultural or religious values influence the risk of violence? Is this influence protective or does it support violence?
- Are there adequate social support networks available to family members? To members of society?
- Are there occupational risks for violence? If so, what occupations are most affected? What features of these occupations increase the risk for violence?
- What is the societal response to violence? What is the media response to violence?
- Is there a perception of social stigma attached to reporting or experiencing violence?
- Is there social unrest in the population that may contribute to increased violence (e.g., war or other social conflict)?

Sexual orientation is another behavioral factor associated with the risk of violence. For example, meta-analyses indicated the lifetime risk of suicide is 2.47 greater for members of sexual minority groups than for the heterosexual population (Choi, Paul, Ayala, Boylan, & Gregorich, 2013). As we saw earlier, sexual orientation and gender identity may put people at risk for hate crime victimization. Experience of physical or sexual abuse by sexual minority youth has also been associated with increased risk of injection drug use and high-risk sexual behavior.

Exposure to violence may also contribute to risky behaviors. For example, sexually abused women have been found to be more likely to use drugs and alcohol than nonabused women (Basile & Smith, 2011). Similarly, sexual abuse of women in childhood has been linked to other negative health-related behaviors such as unprotected sexual activity, multiple sexual partners, early initiation of consensual sexual activity, and participation in sex work. A history of prior sexual abuse has also been associated with smoking, overeating, and failure to use seat belts (Basile & Smith, 2011).

IPV among adult women is also associated with high-risk sexual behaviors, multiple partners, smoking, and unhealthy eating behaviors, such as fasting, purging and vomiting, abuse of diet pills, and overeating (NCIPC, 2013b). A meta-analysis of related research has indicated that victims of IPV, particularly women, are also more likely to smoke than those who are not subjected to violence (Crane, Hawes, & Weinberger, 2013). The *Focused Assessment* below includes questions to identify behavioral determinants influencing societal violence among individuals and in population groups.

HEALTH SYSTEM DETERMINANTS. Health system factors contributing to violence relate primarily to the failure of health care providers to identify clients at risk for or experiencing violence. Providers are generally able to deal with the physical effects of IPV or attempted suicide or homicide but may be less adept at dealing with underlying causes or addressing safety issues. Only a small percentage of health care providers routinely screen clients for risk for violence.

Even when abuse is suspected or confirmed, providers may be hesitant to report findings. Barriers to reporting abuse of

older clients also exist. For example, some providers report confidentiality issues, fear regarding the response of the abuser, desires to avoid involvement in court proceedings, distrust of the effectiveness of follow-up, and doubt of their own abilities to accurately recognize abuse as reasons for not reporting abuse. Population health nurses can help to educate providers about the need to identify and report abuse and can help them develop skills in intervening in abusive situations.

Health care providers also often fail to identify clients at risk for suicide. Suicide risk is increased in people with chronic physical illness, particularly illnesses that result in significant long-term pain. This suggests that better disease management for prevalent chronic illnesses could help to reduce suicide. Similarly, better access to care for substance abuse and mental health problems could serve to decrease suicide rates among these populations (NCIPC, 2013g). In addition, victims of IPV and sexual violence have been found to overuse health care services, providing opportunities for alert health care providers to identify problems of violence victimization (Basile & Smith, 2011; NCIPC, 2013b).

In part, the lack of health care provider screening for societal violence may lie in lack of education regarding issues of violence or lack of ability to identify persons at risk for or experiencing violence. For example, health care providers have been found to misdiagnose as much as 20% of fractures related to abuse in children under 3 years of age (Harrison & Vega, 2014). Tables 30-1●, 30-2●, and 30-3● present common physical and psychological indicators of child maltreatment, IPV, and elder abuse, respectively. Even with knowledge, however, providers may be reluctant to address issues of abuse and violence for a variety of reasons (e.g., unwillingness to become involved, lack of comfort in asking about abuse, or lack of knowledge of resources for dealing with abuse).

As we have seen, numerous biological, psychological, environmental, sociocultural, behavioral, and health system factors contribute to the occurrence of violence in individual clients and families and in society at large. Tips for exploring health system factors involved in societal violence are presented in the *Focused Assessment* on p. 927. Tools for assessing individual

FOCUSED ASSESSMENT

Assessing Behavioral Determinants Influencing Societal Violence

- Is there evidence of substance abuse in the family situation? What is the extent of substance abuse in the population? How does substance abuse influence societal violence?
- What is the extent of smoking among family members? In the general population?
- Is there evidence of high-risk sexual behavior by family members? In the general population?
- To what extent does sexual orientation or gender identity contribute to risk for violence in the individual or population?
- To what extent do members of the population engage in other behaviors that might lead to violence (e.g., bullying, carrying weapons)?

FOCUSED ASSESSMENT

Assessing Health System Determinants Influencing Societal Violence

- Are health care providers alert to risk for or evidence of violence? To what extent do health care providers screen for risk for or evidence of violence perpetration or victimization?
- What is the response of health care providers to evidence of violence or potential for violence?
- To what extent does the health care system provide for support and care of victims of societal violence? For perpetrators of violence?
- To what extent do victims of violence use health care services?

TABLE 30-1 Physical and Psychological Indications of Child Maltreatment

Type of Abuse	Physical Indications	Psychological Indications
Neglect	<ul style="list-style-type: none"> Persistent hunger Poor hygiene Inappropriate dress for the weather Constant fatigue Unattended physical health problems Poor growth patterns 	<ul style="list-style-type: none"> Delinquency due to lack of supervision School truancy/poor school performance Begging or stealing food Behavior problems
Physical abuse	<ul style="list-style-type: none"> Bruises or welts in unusual places or in several stages of healing; distinctive shapes Burns (especially cigarette burns; immersion burns of hands, feet, or buttocks; rope burns; or distinctively shaped burns) Fractures (multiple or in various stages of healing, inconsistent with explanations of injury) Joint swelling or limited mobility Long-bone deformities Lacerations and abrasions to the mouth, lip, gums, eye, genitalia Human bite marks Signs of intracranial trauma Deformed or displaced nasal septum Bleeding or fluid drainage from the ears or ruptured eardrums Broken, loose, or missing teeth Difficulty in respirations, tenderness or crepitus over ribs Abdominal pain or tenderness Recurrent urinary tract infection 	<ul style="list-style-type: none"> Wary of physical contact with adults Behavioral extremes of withdrawal or aggression Apprehensive when other children cry Inappropriate response to pain
Emotional abuse	<ul style="list-style-type: none"> Nothing specific 	<ul style="list-style-type: none"> Overly compliant, passive, and undemanding Extremely aggressive, demanding, or angry Behavior inappropriate for age (either overly adult or overly infantile) Developmental delay Attempted suicide
Sexual abuse	<ul style="list-style-type: none"> Torn, stained, or bloody underwear Pain or itching in genital areas Bruises or bleeding from external genitalia, vagina, rectum Sexually transmitted diseases Swollen or red cervix, vulva, or perineum Semen around the mouth or genitalia or on clothing Pregnancy 	<ul style="list-style-type: none"> Withdrawn Engages in fantasy behavior or infantile behavior Poor peer relationships Unwilling to participate in physical activities Wears long sleeves and several layers of clothes even in hot weather Delinquency or running away Inappropriate sexual behavior or mannerisms

TABLE 30-2 Physical and Psychological Indications of Intimate Partner Violence

Physical Indications	Psychological Indications
Chronic fatigue Vague complaints, aches, and pains Frequent injuries Recurrent sexually transmitted diseases Muscle tension Facial lacerations Injuries to chest, breasts, back, abdomen, or genitalia Bilateral injuries of arms or legs Symmetric injuries Obvious patterns of belt buckles, bite, fist, or hand marks Burns of hands, feet, buttocks, or with distinctive patterns Headaches Ulcers	Casual response to a serious injury or excessively emotional response to a relatively minor injury Frequent ambulatory or emergency room visits Nightmares Depression Anxiety Anorexia or other eating disorder Drug or alcohol abuse Poor self-esteem Suicide attempts

TABLE 30-3 Physical and Psychological Indications of Elder Maltreatment

Type of Abuse	Physical Indications	Psychological Indications
Neglect	Constant hunger or malnutrition Poor hygiene Inappropriate dress for the weather Chronic fatigue Unattended medical needs Poor skin integrity or decubiti Contractures Urine burns/excoriation Dehydration Fecal impaction	Listlessness Social isolation
Emotional abuse	Hypochondria	Habit disorder (biting, sucking, rocking) Destructive or antisocial conduct Neurotic traits (sleep or speech disorder, inhibition of play) Hysteria Obsessions or compulsions Phobias
Physical abuse	Bruises and welts Burns Fractures Sprains or dislocations Lacerations or abrasions Evidence of oversedation	Withdrawal Confusion Fear of caretaker or other family members Listlessness
Sexual abuse	Difficulty walking Torn, stained, or bloody underwear Pain or itching in genital area Bruises or bleeding on external genitalia or in vaginal or anal areas Sexually transmitted diseases	Withdrawal
Financial abuse	Inappropriate clothing Unmet medical needs	Failure to meet financial obligations Anxiety over expenses
Denial of rights	Nothing specific	Hesitancy in making decisions Listlessness and apathy

risk for family violence and suicide are also provided on the student resources site.

Population health nursing assessment related to societal violence may entail identification of risk factors at individual/family or population levels. For example, nurses working with families would assess them for factors in each of the six dimensions of health that increases their risk for family violence, suicide, or homicide. In addition, nurses would be alert to the signs and symptoms of actual family/partner violence presented in Tables 30-1, 30-2, and 30-3 or signs of impending suicide. At the community or population level, nurses would identify risk factors that lend themselves to high incidence and prevalence of societal violence. For example, they would identify unemployment or other causes of social stress (e.g., homelessness, racial/ethnic tension) as risk factors for social violence. Information on risk factors for and the incidence and prevalence of violence would be used to derive nursing diagnoses and to plan strategies to minimize or control societal violence.

Diagnostic Reasoning and Societal Violence

Nursing diagnoses may be derived from assessment data related to individual clients and families or population groups. An example of a nursing diagnosis for an individual client might be “potential for child abuse due to increased stress of single parenthood and care of a disabled child.” A population-based diagnosis might be “increased potential for violence due to prevalence of weapons carrying among high school students.”

Planning and Implementing Control Strategies for Societal Violence

Population health nurses are actively involved in planning control strategies for societal violence related to health promotion, prevention, resolution of existing problems, and health restoration. Some interventions at each level are discussed below.

HEALTH PROMOTION. Health promotion related to societal violence involves development of effective coping skills in individuals and adoption of nonviolent conflict resolution strategies by individuals and groups of people. Specific strategies at the population level might include teaching effective coping, conflict resolution, and anger management strategies within school curricula. Similar strategies might be used to develop healthy coping skills and aversion to violence in individuals and families.

Increasing aversion to violence may be accomplished by teaching alternative methods of conflict resolution and by imposing cultural and social sanctions against violent behavior. For example, in societies in which violence is not perceived as an acceptable approach to interpersonal conflict, less violence occurs. Similarly, strong religious convictions may deter attempted suicide. Population health nurses can be actively involved in teaching positive modes of conflict resolution,

anger management, and coping strategies and in activities designed to change societal attitudes toward the acceptability of violence.

Population health nurses can also assist clients and families at risk to develop effective parent–child and intimate partner relationships by providing anticipatory guidance, assistance with communication, and so on. For instance, the nurse can educate new parents about child behavioral cues and appropriate parental responses as well as provide reinforcement for positive responses. In addition, the nurse can suggest activities that will enhance the bond between parents and child (e.g., reading to or playing with the child), and educate parents regarding appropriate forms of discipline.

PREVENTION. A public health approach to violence prevention encompasses four major activities: monitoring the incidence and burden of violence over time, identifying contributing and protective factors, developing and testing control strategies to address those factors, and disseminating and promoting adoption and adaptation of effective strategies in families, communities, and populations (Haegerich & Dahlberg, 2011).

Several general evidence-based strategies have been developed to prevent each of the types of violence discussed in this chapter. For example, family support and parenting programs and hospital-based programs to educate new parents on crying and its management have been shown to be effective in reducing child maltreatment, particularly for young children. Similarly, school-based programs to develop social and emotional skills coupled with intensive family and community-based approaches have reduced youth violence. Street-level outreach and conflict mediation strategies among violent youth have also been found to be effective (Haegerich & Dahlberg, 2011).

Effective prevention programs for IPV have included school-based curricula focusing on healthy interpersonal relationships and social norms that inhibit violence as a mode of conflict resolution. Screening for and amelioration of risk factors for violence perpetration or victimization have also been effective in reducing IPV. Similarly, school-based programs focused on healthy relationships and changing social norms have been shown to reduce the incidence of sexual violence (Haegerich & Dahlberg, 2011). Prevention of sexual violence needs to start early with efforts to promote healthy and respectful relationships in families, foster healthy parent–child relationships, and create supportive family environments. Several effective programs have been found to decrease IPV. Examples include the “Start Strong: Building Healthy Teen Relationships Initiative” (Spivak et al., 2014) and “Safe Dates” programs designed to change social norms related to sexual violence and improve problem-solving skills in youth (NCIPC, 2012). These and similar school-based programs have been found to reduce violence among high-school students by as much as 29% and by 15% across all grade levels (NCIPC, 2013e). For further information about the Start Strong and Safe Dates programs, see the *External Resources* section of the student resources site.

Prevention of child maltreatment may employ similar strategies. For example, child–parent centers provide support to economically disadvantaged families focusing on a child-centered approach to services. Such services resulted in a 52% decline in child maltreatment in one study. Similarly, the “Durham Family Initiative” coordinates services to families at high risk for child maltreatment and has resulted in a 57% decline in incidence in the affected county compared to other counties without similar services. Comparable results in decreasing child maltreatment have been noted for other similar programs such as the “Nurse-Family Partnership” program, the “Triple P: Positive Parenting Program,” and the “Safe Environment for Every Kid” (SEEK) program (NCIPC, 2014c). For more information about these programs, see the *External Resources* section of the student resources site. Population health nurses may be involved in providing services through these and other similar programs or may refer families at risk for child maltreatment to appropriate services and programs.

Prevention strategies for elder abuse include listening to elders and their caregivers and addressing their needs. Population health nurses can also encourage both elders and caregivers to seek help and refer them to appropriate services that can minimize the stress of caregiving (NCIPC, 2013h). They may also refer elders to day care centers or assist caregivers to access respite services. Population health nurses may also need to advocate for the availability of such services.

Evidence-based prevention measures for self-directed violence include screening for risk in health care settings, suicide awareness programs in schools, reduced stigma attached to sexual minority membership and mental illness, and restriction of access to lethal means of suicide (Haegerich & Dahlberg, 2011). Programs such as the U.S. Air Force Suicide Prevention Program focus on early recognition and treatment of people at high risk for suicide. Other foci include education and reduction of stigma attached to seeking help. The program is designed to normalize feelings of distress, promote effective coping skills, and eliminate negative career consequences of help seeking and treatment (Knox et al., 2010). The Youth Suicide Prevention Program has developed suicide prevention curricula for elementary, middle, and high school students as well as community programs and initiatives targeted to particularly vulnerable populations such as sexual minority youth (Youth Suicide Prevention Program, n.d.). See the *External Resources* section of the student resources site for sources of information about these programs.

Population health nurses can also help to remove or reduce factors that contribute to stress and the potential for abuse. For example, the nurse might refer caretakers of an elderly client or a child with disabilities for respite services, assist an unemployed parent to find employment, or increase social support networks for socially isolated families. Treatment of substance abuse problems in the individual or family may also decrease the potential for violence. Crisis intervention and hotlines may also prevent suicide.

Decreasing access to weapons has also been suggested as a preventive measure for violence, but the Community Preventive Services Task Force (CPSTF, 2014) has found insufficient evidence that firearms control legislation prevents violence. The task force examined such approaches as bans on specific types of weapons, waiting periods before purchase, purchase restrictions, registration and licensing of firearms, prevention of child access to firearms, and zero tolerance policies in schools and found insufficient evidence to recommend any of them as major foci for violence prevention. Other research has indicated that weapons control is an effective measure against violence in specific circumstances. For example, easy access to firearms has been found to increase the risk of murder by perpetrators of IPV. Federal law prohibits the purchase or possession of firearms by persons convicted of IPV who are under a restraining order. Ten states require and another 20 states authorize courts to order respondents to restraining orders to surrender their firearms for the duration of the order. A California program uses a variety of data sources to identify perpetrators of IPV who own firearms, which are then confiscated under the terms of a restraining order. Such programs have been shown to decrease retaliatory homicides against family members seeking restraining orders (Wintemute, Frattaroli, Claire, Vittes, & Webster, 2014).

Environmental measures to deter suicide include placing barriers at iconic jumping locations (Perron et al., 2013). Recommendations have also been made to erect site-specific suicide barriers in National Parks with a high incidence of suicide (Newman et al., 2010).

Older clients may use several options to safeguard their funds and property from financial abuse. Some of these options include a financial representative trust, durable power of attorney, and joint tenancy. In a *financial representative trust*, the older person transfers to a trustee, selected by himself or herself, responsibility for managing his or her property. A

Easy access to lethal weapons contributes to violence-related deaths. (Oocokun/Fotolia)

durable power of attorney is a written document in which the older person grants another person the authority to handle financial matters in his or her stead. In *joint tenancy*, the older person is co-owner of the assets covered with one or more designated others. All parties involved have the use of funds or property covered under joint tenancy. In the event of the death of one party, ownership automatically devolves on other members of the joint tenancy agreement. Each of these options has advantages and disadvantages and population health nurses would be best advised to refer older clients to reputable sources of legal and financial information to assist them in selecting options to protect themselves from financial abuse. Health promotion strategies and prevention strategies related to elder abuse and other forms of societal violence are summarized in Table 30-4.

RESOLVING EXISTING PROBLEMS OF VIOLENCE.

Resolving existing problems related to family/partner violence involves identification of abuse and treatment for its immediate effects. Many victims of abuse choose not to identify themselves or report the abuse for a variety of reasons. Female victims of IPV, for example, may fear additional violence. In other cases, victims may feel stigmatized or wish to protect the abuser.

Identification requires screening for those at risk for or experiencing abuse, and routine screening for abuse has been suggested in emergency departments, women's health clinics, and primary care settings. Workplace screening programs have also been suggested, and population health nurses can be involved in designing and implementing screening programs in the work setting and other venues.

Screening for family/partner violence should be conducted when the client is alone using any of a variety of screening tools. Available tools deal with different issues depending on client characteristics (Sheridan, Nash, Hawkins, Makely, & Campbell, 2013). For example, screening tools for the elderly or disabled individual would include questions about the withholding of needed care or financial abuse in addition to asking about other forms of abuse. Tools for IPV and child maltreatment would address psychological as well as physical and sexual abuse. Child maltreatment screening tools would also explore issues of neglect.

A variety of screening tools have been developed for screening for IPV, most of them directed toward women. NCIPC has published a compendium of assessment tools for IPV screening. For further information about these tools, see the *External Resources* section of the student resources site. Information resources for elder abuse screening tools are also provided.

In 2012, the U.S. Preventive Services Task Force updated its 2004 recommendation related to IPV screening. The previous recommendation had indicated insufficient evidence that screening for IPV was effective in reducing the incidence and prevalence of abuse. The updated recommendation, however, indicates that "screening instruments accurately identify women experiencing IPV" and their use is unlikely to

result in adverse effects (Nelson, Bougatsos, & Blazina, 2012, p. 796).

Similarly, the task force found insufficient evidence for the effectiveness of screening for abuse in older clients (Moyer, 2013). Another systematic review by Caldwell, Gilden, and Mueller (2013) found a growing body of evidence that suggests that routine screening for abuse among the elderly is an effective intervention. Once evidence of family/partner violence has been detected, treatment focuses on assessing the client for immediate danger, providing appropriate care for the consequences of violence, documenting the client's condition, developing a safety plan, and making needed referrals to community services. Management of IPV should include assurances that the client is not alone, that he or she is not at fault for the abuse, and that confidentiality of information shared is dependent upon applicable state laws. Injuries must be thoroughly documented, with photographs, if possible. In addition, the victim should be educated regarding available resources and options, including resources, and should be assisted to develop a safety plan for himself or herself or other family members threatened by violence. This may include children who may be harmed by witnessing abuse even if they are not abused themselves. Elements of a safety plan should include hiding money and extra keys, establishing a secret code with friends or family members, asking neighbors to call the police in the event of an altercation, removing weapons from the home, and putting copies of important documents in a handy and secure location. Documents may include Social Security numbers (for the victim and children as well as the abuser), rent and utility receipts, birth certificates and marriage license if relevant, driver's license or other identification (e.g., a passport), bank account and insurance policy numbers, jewelry and other easily transported valuables, names and telephone numbers of important contacts, extra clothing, and essential toiletries. Population health nurses can assist clients at risk for family/partner violence in developing a safety plan and in identifying sources of assistance.

Intervention may include referring an abused family member to a shelter or removing a dependent victim from the abusive situation. Resolution at this point also includes treatment for the perpetrator of violence and for family members who witness violence. Resources may need to be developed to address the needs of male as well as female victims of violence. In addition, criminal justice systems must provide equitable treatment for victims of abuse, whether they are men or women. Population health nurses can advocate for equitable enforcement of laws prohibiting violence as well as for legislation that protects victims from abuse and assures the availability of resources to both victims and perpetrators.

Resolution of violence also involves mandatory reporting of suspected child maltreatment and, in some jurisdictions, reporting of IPV or elder abuse. Reports are generally made initially by telephone to the appropriate agency and are followed,

TABLE 30-4 Individual/Family-Oriented and Population-Oriented Health Promotion and Prevention Strategies Related to Societal Violence

Health Promotion Focus	Individual/Family-Oriented Strategies	Population-Oriented Strategies
Development of effective coping skills	<ul style="list-style-type: none"> • Teach coping and stress management skills to individuals and families. 	<ul style="list-style-type: none"> • Teach coping and stress management skills to population groups. • Advocate for inclusion of coping and stress management in school curricula.
Development of self-esteem	<ul style="list-style-type: none"> • Foster self-image. 	<ul style="list-style-type: none"> • Advocate for school programs to foster self-esteem in young people.
Development of realistic expectations of self and others	<ul style="list-style-type: none"> • Educate parents on child development. • Educate caregivers on the needs of the elderly. • Help clients recognize strengths. 	<ul style="list-style-type: none"> • Educate the public regarding developmental expectations. • Advocate for and implement parenting education programs. • Develop and implement caregiver education programs.
Development of effective parenting and interpersonal skills	<ul style="list-style-type: none"> • Teach parenting skills. • Teach and role model effective communication skills. • Refer families with communication difficulties for counseling assistance. 	<ul style="list-style-type: none"> • Advocate for communication education in school curricula. • Advocate for and implement parenting education programs. • Advocate for available counseling services to improve family communication.
Promotion of nonviolent conflict resolution	<ul style="list-style-type: none"> • Teach nonviolent conflict management strategies. 	<ul style="list-style-type: none"> • Advocate for inclusion of conflict management content in school curricula and other education programs.
Prevention Focus	Individual/Family-Oriented Strategies	Population-Oriented Strategies
Treatment of psychopathology or substance abuse	<ul style="list-style-type: none"> • Refer for treatment. 	<ul style="list-style-type: none"> • Advocate for available and accessible treatment services.
Provision of emotional and material support	<ul style="list-style-type: none"> • Refer to sources of assistance as needed. • Assist in development and expansion of social support networks. 	<ul style="list-style-type: none"> • Advocate for supportive services for persons at risk for violence perpetration or victimization. • Advocate for societal changes to minimize sources of stress contributing to violence.
Reduction of risk behaviors	<ul style="list-style-type: none"> • Encourage clients not to frequent places where violence is likely to occur. • Encourage clients not to use alcohol or drugs in circumstances in which interpersonal conflict is likely. 	<ul style="list-style-type: none"> • Educate the public on the influence of drugs and alcohol on violence. • Advocate for adequate police protection in high crime areas. • Advocate for social mores to promote early intervention to prevent escalation of conflict to violent behaviors.
Decreased availability of weapons, drugs, and alcohol	<ul style="list-style-type: none"> • Encourage removal of weapons from homes. • Encourage responsible alcohol use. 	<ul style="list-style-type: none"> • Engage in political activity to promote weapons control and limit access to drugs and alcohol.
Change in societal attitudes to violence	<ul style="list-style-type: none"> • Teach nonviolent modes of conflict resolution. • Teach problem-solving and decision-making skills. • Discuss appropriate approaches to discipline. 	<ul style="list-style-type: none"> • Develop and implement campaigns to change cultural perceptions of violence as a means of conflict resolution.
Development of policies that discourage violence and protect potential victims		<ul style="list-style-type: none"> • Engage in political activity and advocacy. • Promote positive attitudes toward the elderly and disabled. • Advocate for women's social rights.

usually within 48 hours, by a written report. In making a report, the population health nurse should be careful to focus on objective evidence that suggests violence victimization and to report exactly what he or she has seen or verbatim reports of those involved.

When IPV involves sexual assault or rape, or when such events occur outside intimate relationships, population health nurses should refer victimized clients to a local emergency department for assessment. Most emergency departments have sexual assault response teams (SART) or sexual assault nurse examiners (SANE nurses) that have extensive background in assessment and care of persons who have been sexually assaulted. Members of SART teams and SANE nurses also have expertise in the collection of forensic evidence that may be used in criminal proceedings against the abuser (International Association of Forensic Nurses & American Nurses Association, 2009). SANE nurses also provide emotional support, emergency contraception, STI or injury treatment, education regarding HIV and pregnancy risk, and practical assistance with clothing, transportation, and safety planning (Basile & Smith, 2011). Population health nurses should encourage victims of sexual abuse and other forms of IPV to report the event and to seek help in an emergency department. Clients should be particularly cautioned not to “clean themselves up” following the assault as this destroys physical evidence of the assault.

Programs to prevent violence by chronically delinquent youth have shown some success. Therapeutic foster care is one such program and is recommended by the Community Preventive Services Task Force (2014). Therapeutic foster care is an approach in which young people with emotional, behavioral, physical, or developmental needs unable to be met within their own families are placed with a foster family with special training in providing a structured environment that fosters the development of social and emotional skills (Northern Virginia Family Services, 2014; Oklahoma Department of Health Services, 2014). Foster parents receive intensive training in dealing with youth with special needs and become part of the treatment team to meet those needs. Goals of therapeutic foster care include community integration of services, meeting the health care needs of the child, eliminating inappropriate behaviors, and supporting the child’s educational needs (Friends of Youth, n.d.). Based on evaluation of the effectiveness of therapeutic foster care, the Community Preventive Services Task Force has recommended this intervention for use in preventing violence among youth (CPSTF, 2014). Such programs may be used in place of incarceration for juvenile offenders and are more effective. Similarly, research has indicated that programs developed for violent offenders in juvenile justice settings are not appropriate for juveniles held in adult correctional facilities (Richardson et al., 2013). Population health nurses may be involved in the establishment of therapeutic foster care programs or in providing support to foster parents and their young charges.

Much of the nursing research related to IPV and other forms of societal violence is directed toward identifying contributing factors and responses of and effects on victims or witnesses, with few controlled studies of the effectiveness of interventions. Recent research, however, has demonstrated the effectiveness of integrated treatment for substance abuse and IPV among substance-abusing perpetrators (Kraanen, Vedel, Scholing, & Emmelkamp, 2013). Similarly, a telephone intervention providing personalized feedback on factors contributing to IPV among substance-abusing men has demonstrated some effectiveness in reducing IPV perpetration (Mbillinyi et al., 2011).

A systematic review of interventions with victims of domestic violence suggested that brief interventions that included specific foci were effective in addressing the needs of survivors. The recommended foci included provision of information on the dynamics of IPV and safety concerns, development of cognitive reframing and survival skills, culturally competent interventions, promoting social connections, and individualization to specific survivor needs (Warshaw, Sullivan, & Rivera, 2013).

Resolution of problems related to societal violence also involves the early identification of persons who are contemplating suicide or homicide and intervention to prevent the act or limit the consequences. Health care providers, teachers, and counselors may recognize the signs of impending suicide or escalating aggression and should take immediate action. Such action might include counseling, referral, or hospitalization if the danger appears imminent. Population health nurses may also be involved in educating individuals who work with young people, the elderly, and others at risk for suicide to recognize indicators of a potential suicide attempt. Indications of suicide risk are summarized in the *Focused Assessment* on the next page. Foci and strategies for resolving existing problems of violence at individual/family and population levels are summarized in Table 30-5.

HEALTH RESTORATION IN SOCIETAL VIOLENCE.

Health restoration in the context of societal violence involves dealing with the consequences of violence and preventing its recurrence. Interventions intended for the individual or family level include providing treatment for long-term physical or psychological effects of violence. For example, victims of IPV may need a referral for treatment of PTSD, or children who witness or experience abuse can be referred for counseling. Victims of abuse may also need assistance in finding coping strategies as alternatives to subsequent alcohol and drug abuse or high-risk sexual behaviors. Similarly, the loved ones of suicide or homicide victims may need assistance in dealing with their loss. Assistance needed may range from counseling to cope with the loss of a loved one to help with concrete tasks like planning a funeral, filing claims for death benefits, settling the victim’s estate, and dealing with the criminal justice sys-

TABLE 30-5 Individual/Family-Oriented and Population-Oriented Strategies to Address Existing Problems of Societal Violence

Focus	Individual/Family-Oriented Strategies	Population-Oriented Strategies
Identification of persons at risk for or experiencing violence	<ul style="list-style-type: none"> Engage in case finding. Teach teachers and counselors to recognize signs of abuse or risk for violence. Screen for evidence of abuse or potential for violence. 	<ul style="list-style-type: none"> Educate the public regarding risks and signs of violence victimization. Develop screening programs for risk or experience of violence.
Provision of counseling for victims and perpetrators of violence	<ul style="list-style-type: none"> Refer for counseling. Provide emotional support to both victims and perpetrators. 	<ul style="list-style-type: none"> Advocate for available counseling services.
Provision of treatment for victims of violence	<ul style="list-style-type: none"> Refer for necessary services. 	<ul style="list-style-type: none"> Engage in political activity and advocacy to assure availability of adequate treatment facilities.
Identification of episodes of violence	<ul style="list-style-type: none"> Report instances of violence. 	<ul style="list-style-type: none"> Monitor trends in societal violence to identify problem areas.
Provision of safe environments	<ul style="list-style-type: none"> Remove victims of abuse to safe environments. Plan with victims to achieve a safe environment. Refer to a shelter as needed. Initiate involuntary commitment proceedings if the person is a clear danger to self or others. 	<ul style="list-style-type: none"> Advocate for available shelter or other resources for victims of violence.
Education of health care providers for effective response to incidents of violence	<ul style="list-style-type: none"> Educate individual providers for sensitive and caring response to victims of violence and family members. 	<ul style="list-style-type: none"> Advocate for effective training regarding response to violence in health professions curricula.

FOCUSED ASSESSMENT**Assessing Suicide Risk**

- Is there a family history of suicide? Of other forms of violence?
- Do family or cultural views support suicide? Do cultural beliefs lead to stigma and unwillingness to seek help for depression or other problems?
- Does the client hold religious beliefs that would protect against suicide?
- Is there a history of prior suicide attempt(s) by the client or by significant others?
- Is there a history of mental illness? Is the client exhibiting current symptoms of mental illness? Has the client experienced barriers to obtaining mental health services?
- Is there a history of substance abuse by the client or significant others?
- Does the client exhibit impulsive or aggressive behavior?
- Has the client experienced a recent serious loss (particularly in the last 6 months)?
- Does the client have a chronic illness that is severely affecting his or her quality of life?
- Does the client exhibit signs of depression?
- Does the client express feelings of hopelessness or helplessness?
- Does the client talk about wanting to die or express the wish that he or she were dead?
- Does the client express feelings of being a burden to others?
- Does the client express feelings of isolation?
- Does the client display evidence of anxiety, irritability, or panic?
- Does the client fail to refer to future goals or activities?
- Does the client express frequent or persistent thoughts of suicide?
- Has the client developed a carefully thought-out plan for suicide?
- Has the client chosen a lethal method for suicide with reduced likelihood of rescue?
- Does the client have easy access to lethal methods of suicide?
- Is suicide planned for the near future?
- Does the client exhibit behavior designed to “put one’s house in order” (e.g., making a will, giving away prized possessions)?
- Does the client engage in behavior that would be likely to result in death (e.g., provoking fights with others, hazardous driving)?
- Has there been extensive media attention to recent suicides?

tem. Another health restoration measure for suicide and homicide is control of media representations that promote copycat events.

Health restoration for family/partner violence also entails changing circumstances that promote violence. For example, the population health nurse may assist abusive parents to understand the needs and behavioral cues of their children or help caregivers of disabled children or elderly family members to find respite. Other potential health restoration strategies for elder maltreatment include providing alternatives to home care of the elderly and increasing community support services for persons who are caring for older family members.

Population health nurses may also be involved in the development of programs to assist the perpetrators of violence. For example, they may plan and implement anger management programs for people who see violence as a means of dealing with anger. They may also advocate for and assist in initiating treatment programs for abusers. Another approach involves parenting classes for abusive parents and referral to Parents Anonymous, a mutual-help group for parents who have a history of or are at risk for child abuse.

Nurses may also assist family members to improve coping and communication skills as well as to improve self-esteem. This is particularly important for victims of child abuse if the intergenerational cycle of abusive behavior is to be broken. This may involve identifying past family interaction patterns, needed changes in those patterns, and mechanisms to achieve those changes. Table 30-6• summarizes

areas of focus and related strategies in the context of societal violence.

Evaluating Control Strategies for Societal Violence

The effectiveness of control strategies for societal violence can be evaluated at the level of the individual client or family or at the population level. For example, the nurse might determine whether or not child abuse has been prevented in a family at high risk for abuse, or whether subsequent instances of abuse have been experienced by an older client or pregnant woman. At the population level, the population health nurse might look for changes in suicide or homicide rates or the frequency of reports to child protective services to evaluate the effectiveness of population-based interventions. As noted earlier, there is a great need for nursing research to examine the effectiveness of interventions to address societal violence. For example, nurses might study the effects of school curricula on culturally prescribed gender roles and their influence on IPV. Or they might contribute to the body of knowledge on the effectiveness of screening for suicide risk in decreasing the incidence of suicide in the elderly.

In assessing the effectiveness of strategies to reduce societal violence, population health nurses and others might evaluate the extent to which national objectives related to violence and suicide have been achieved. Baseline and target information for selected objectives are presented on the next page.

TABLE 30-6 Individual/Family-Oriented and Population-Oriented Foci and Strategies Related to Health Restoration in Societal Violence

Focus	Individual/Family-Oriented Strategies	Population-Oriented Strategies
Prevention of suicide clusters and copycat murders		<ul style="list-style-type: none"> • Assist in the development of community response plans. • Advocate for control of media exposure to violence.
Provision of care to families of homicide and suicide victims	<ul style="list-style-type: none"> • Assist families to work through feelings of grief, anger, and guilt. • Assist families to find positive ways to cope with loss. • Refer for assistance with legal and other tasks as needed. • Refer for counseling as needed. 	<ul style="list-style-type: none"> • Advocate for support services for families of victims.
Treatment of consequences of violence	<ul style="list-style-type: none"> • Refer for physical and psychological treatment services as needed. 	<ul style="list-style-type: none"> • Advocate for available services for victims and perpetrators of violence.
Reduction of sources of stress to prevent recurrence of violence	<ul style="list-style-type: none"> • Refer to sources of assistance. • Develop or expand social support networks. • Arrange for respite care as needed. • Assist with employment and other social needs. 	<ul style="list-style-type: none"> • Advocate for social changes to minimize sources of stress contributing to violence. • Advocate for development of respite care and other support services.

Healthy People 2020

Selected Objectives Related to Societal Violence

OBJECTIVE	BASELINE (YEAR)	TARGET	CURRENT DATA (YEAR)	DATA SOURCES
IVP-29. Reduce homicide deaths (per 100,000 population)	6.1 (2007)	5.5	5.3* (2010)	National Vital Statistics System—Mortality (NVSS-M), CDC/NCHS
IVP-33. Reduce physical assaults (per 1,000 population 12 years and older)	21.3 (2008)	19.2	19.4 (2011)	National Crime Victimization Survey (NCVS), DOJ/BJS
IVP-36. Reduce weapon carrying by adolescents on school property	5.6% (2009)	4.6%	5.4% (2011)	Youth Behavior Risk Surveillance System (YRBSS), CDC/NCHHSTP
IVP-37. Reduce child maltreatment deaths (per 100,000 children)	2.3 (2008)	2.1	2.1* (2011)	National Child Abuse and Neglect Data System (NCANDS), ACF
IVP-38. Reduce nonfatal child maltreatment (per 1,000 children)	9.4 (2008)	8.5	9.1 (2011)	NCANDS, ACF
IVP-41. Reduce nonfatal intentional self-harm requiring medical attention (ED visits per 100,000 population)	125.3 (2008)	112.8	153.0 (2010)	National Electronic Injury Surveillance System—All Injury Program (NEISS-AIP), CDC/NCIPC and CPSC
IVP-42. Reduce children's exposure to violence	58.8% (2008)	52.9%	56.5% (2011)	National Survey on Children's Exposure to Violence (NatSCEV), DOJ/OJJDP
MHMD-1. Reduce the suicide rate (per 100,000 population)	11.3 (2007)	10.2	12.1 (2011)	NVSS-M, CDC/NCHS
MHMD-2. Reduce suicide attempts by adolescents (per 100 population)	1.9 (2009)	1.7	2.4 (2011)	YRBSS, CDC/NCHHSTP

CHAPTER RECAP

Societal violence occurs in many forms including self-directed violence, family/partner violence, and community violence. Collective violence by one social group against another may

also occur, but is less amenable to intervention by population health nurses than the forms of violence presented in this chapter.

Factors related to each of the six categories of determinants of health influence the development of problems related to societal violence. In some instances factors related to some determinants of health may be protective against violence (e.g., street efficacy and family or community cohesion). Control strategies

related to societal violence may include health promotion and specific prevention strategies as well as strategies for resolving existing problems related to violence and health restoration after violence has occurred.

CASE STUDY

Preventing Dating Violence

You are a population health nurse assigned to an adolescent clinic. Part of your responsibility in the clinic is to conduct intake interviews for girls who come to the clinic requesting pregnancy tests. In the last several months, you have identified several girls who indicate that they became pregnant as result of sexual activity in which they were verbally coerced by their boyfriends despite not really wanting to engage in sex. Subsequent focus group interviews with adolescent girls at the local public high school indicated that many girls engage in sex because they are afraid they will lose their boyfriends or because boyfriends have specifically indicated they will end the relationship unless the girls “put out.” In addition, several of the girls reported incidents of parties at which girls who had had too much to drink were subjected to unwanted sexual activity. In a few cases, boys had been heard joking about purposely getting their girlfriends drunk to decrease their inhibitions. A small minority of the girls reported being subjected to physical force when their boyfriends wanted to have sex.

None of the girls in the clinic or those in the focus group had reported the sexual coercion to their parents or school officials.

In the case of parents, the girls were reluctant to admit to engaging in sexual activity. With respect to school officials, the girls felt they would not be listened to or would be perceived as bringing the problems on themselves by getting into compromising situations with their boyfriends. Most of the girls were also afraid their parents might forbid them to see their boyfriends if they knew about the situation. In addition, they reported not wanting to get their boyfriends in trouble or make them angry.

1. What biological, psychological, environmental, sociocultural, behavioral, and health system factors are contributing to the problem?
2. What interventions might be appropriate for addressing the problem?
3. Who might you collaborate with in resolving the problem?
4. How would you evaluate the effectiveness of your interventions?
