Simply generating public interest alone does not guarantee that an issue will be placed on the public agenda. Policy makers should consider that the issue is within the purview of government action and deserving of public attention before they will accept it being placed on the public agenda. Many policy issues that have only long-term consequences or only minor consequences for an individual are unlikely to become health-care policy concerns. Unfortunately, many public health issues fall into this category.

Many different approaches are used to place an issue at the forefront of the public policy agenda. One method is to use 'Inside access' to try to influence policy making. This is the aspect which in western countries especially USA, is delegated to lobbyists. Another method is to influence public opinion. This can be done through the media, personal appeals by public officials and celebrities, advertising to raise public awareness and many other approaches including to interest groups and political parties. Public opinion has its greatest impact on government decision-making when people feel strongly about clear-cut preferences. Impact of public opinion is also highest during the period close to elections in democracies. Although government policy usually tends to coincide with public opinion, however if well-organized interest groups intervene, this may not be the case, particularly when public apathy is evident. Special interests can have a particularly important role in technical issues or issues that involve only a few people.

In health care, there is an unequal distribution of information; doctors and other health professionals have specialized knowledge. As a result, individuals must often place their trust in health-care professionals. These health-care professionals who hold and control information have considerable leverage over public opinion.

The media can have a strong influence on public opinion and a short well orchestrated media campaign can provide exceedingly successful results. Interest groups, politicians and others are all trying to influence how the media frame issues and report the news. Favourable media reporting has had very significant impact on decision making. Political leaders and media persons often share a symbiotic relationship. Politicians rely on the media to provide them with information (feedback from their constituency) and to convey their messages to the public. The media, in turn, rely heavily on politicians and public officials for information they use as the basis for their reporting.

Political parties serve as linkages or intermediaries between the citizens and their government. Officially and unofficially political parties have a major role in agenda setting. Party leaders have major roles in determining the agenda of the party in advance of an election and then balancing the conflicting priorities of various interest groups between elections.

Policy formulation : Once it is widely recognized that a problem requires government attention, policy makers must develop a broad policy agenda into specific policy options. Policy formulation involves developing alternative proposals and then collecting, analyzing and communicating the information necessary to assess the alternatives and begin to persuade people to support one proposal or another. The analysis process may involve cost-benefit or cost-effectiveness studies in case the proposals require substantial financial support. Policy formulation involves compromising and bargaining in order to satisfy various interests and build a coalition of support and ideally a consensus among the opposing interests.

Next step involves adoption of specific policies. Known by political scientists as legitimization, government policy must conform to the public's perception of the proper way to do things to enable its wide acceptance. Frequently, previous policies of the government are good predictors of future policies,

since people tend to prefer incremental changes over major or revolutionary changes.

In policy formulation, information is gathered, arguments developed and alternatives shaped towards winning the approval of policy makers. Sometimes this is accomplished through rational analyses of the advantages and disadvantages of various alternatives. At other times, policy formulation is a more flexible process that is likely to be influenced by which specific policy maker is involved at specific times and unexpected opportunities to affect change that arise suddenly.

Once the policy has been formulated, statements of government policies and programmes are promulgated. These can be laws, regulations, decisions on resource allocation, court decisions, etc. Equally important, the government can decide that the best alternative is in action.

Policy content : Policies are typically promulgated through official written documents. Policy documents often come with the endorsement or signature of the executive powers within an organization to legitimize the policy and demonstrate that it is considered in force. Such documents often have standard formats that are particular to the organization issuing the policy. While such formats differ in form, policy documents usually contain certain standard components including :

- A purpose statement, outlining the reasons for issuing the policy and what its desired effect or outcome of the policy should be.
- Applicability and scope statement, describing who the policy affects and which actions are impacted by the policy.
- An effective date which indicates when the policy comes into force. Policies with retrospective effect are rare.
- A responsibilities section, indicating which parties and organizations are responsible for carrying out individual policy statements.

Policy statements indicating the specific regulations, requirements, or modifications to organizational behavior that the policy is creating.

Policy Implementation : Few government policies are self-implementing. Once a policy has been formulated and promulgated, it must be implemented. Even the most brilliantly crafted law, executive order, or court decision will fail to meet the planned goals if it is poorly implemented. Implementation involves three activities directed towards putting a policy into effect. The three activities required for implementation are interpretation, organization and application

Interpretation : It requires the translation of the program language into acceptable and feasible administrative directives. Administrators need to understand the policy-makers intent and fill in the details about how the goals will be accomplished. In many instances, legislation or court decisions are purposefully left somewhat vague to allow administrators wide latitude to respond to changing conditions and conflicting demands.

Organization : This requires the establishment of administrative units and methods necessary to put a program into effect. Resources (money, buildings, staff and equipment) are required to implement a program. Implementers may choose

to organize a new policy through an existing agency, or create a new agency to administer the policy.

Application : Application requires the services to be routinely administered.

The entire process of interpreting policy and designing the organization to implement it is sometimes referred to as 'strategic planning'. This refers to setting out the broad approaches and methods for achieving the policy goals in practice. It must then be followed by 'operational planning' and management in the application phase of implementation.

Policy Evaluation : The last step in Policy formulation is evaluation. The policy is evaluated with the view to assess how well it was implemented including whether the goals and objectives were achieved and what impact was achieved. The results can determine whether the program is to be maintained, expanded, changed, or even terminated. Inputs are provided by the general public, providers and special interest groups. The inputs may range from anecdotal to formal evaluation surveys. The results of the evaluation process will lead to actions similar to that of policy making with the formulation of a revised policy based on the results of the evaluation.

Successful Public Health Policy Formulation

Public health evidence and a population based perspective do not adequately influence public policy in many cases, particularly in sectors other than health. Public health professionals are therefore often frustrated at their apparent failure. Such lack of success should only serve as a motivating factor to generate more support needed from all stakeholders and interest groups to exert a successful influence on the policy makers. Policy making is rarely an event, or even an explicit set of decisions. Policy tends to evolve, subject to continuous review and incremental change. Policy making as it impacts on a large population, is an inherently 'political process' and the timing of decisions is usually dictated as much by political considerations as the evidence. As such, policy making requires appraisal of aspects that are scientifically plausible and acceptable besides being possible to implement practically,

Potential pitfalls : A public health practitioner wishing to succeed in ensuring policy formulation must be wary of certain known pitfalls which have been mentioned earlier and take appropriate proactive actions which are reiterated for emphasis as follows :

- Prevent failure to understand the intense political nature of the policy making.
- Be realistic about the possible contribution of their evidences.
- Look for rare windows of opportunities for the uptake of evidence into policy which may occur when policy maker's interest and the social climate coincide to support public health evidence in policy making. These need to be recognized early and successfully exploited.
- Be in possession of appropriate advocacy and communication skills.
- Build relationships with civil servants and policy makers.
- Engaging with media.

Summary

A Policy is a deliberate plan of action to guide decisions & achieve rational outcomes, which can be applied to Govt. , private sector organizations & groups, & individuals. Policies are therefore political, management, financial & administrative mechanisms arranged to reach explicit goals. It differs from rules or law in that law can compel or prohibit behaviors while policy merely guides actions.

Public policy-making is accepted to be political & seldom driven by public health evidence. To achieve healthy public policy, timing & relevance of evidence are crucial. Good policy is designed for successful implementation & one approach to focus attention on progress of policy implementation is to set targets followed by local action. Framing of issues in the media is critical to how they are dealt with, influencing policy & politicians. Actions at the local level are essential, although, international developments are increasingly gaining importance. Globally, public opinion & the media can be critical in getting public health issues onto the policy agenda.

Policies are generally instituted to avoid some negative effect noticed in the organization, or to seek some positive benefit. Policies frequently have unintended consequences or counter-intuitive results. The Policy formulation process typically includes an attempt to assess as many areas of potential policy impact as possible.

Policy cycle is a tool used for analyzing the development of a policy item, having the following stages :

- Agenda setting (Problem identification)
- Policy formulation
- Decision making – Regarding Implementation & Policy content
- Policy implementation (Requires Interpretation, Organisation & Application)

- Policy analysis & evaluation (to continue or terminate)
- Successful public health policy requires appraisal of aspects that are scientifically plausible & acceptable, being possible to implement practically, besides being wary of certain potential pitfalls & take appropriate proactive actions.

Study Exercises

MCQs and Exercises

1. A deliberate plan of action to guide decisions & achieve rational outcomes, which can be applied to govt. , private sector organizations & groups, & individuals is referred to as _____.
2. Policies are political, management, financial & administrative mechanisms arranged to reach explicit goals : True/False
3. Policies are same as rules or law : True/False
4. Public policy-making is accepted to be political & is always driven by public health evidence : True/False
5. The tool used in Political Science for analyzing the development of a policy item is referred to as _____.
6. The steps in implementation of a Policy are : (a) Interpretation (b) Organization (c) Application (d) All of the above
7. The entire process of interpreting policy & designing the organization to implement it is referred to as _____.

Answers : (1) Policy; (2) True; (3) False; (4) False; (5) Policy cycle; (6) d; (7) Strategic Planning.

What is “Strategy”?

Strategies are plans or methods that are relatively broad in scope, are usually long term in nature and often involve a significant expenditure of resources. Strategy is about where we want to be in say 5 years from now. It can be considered to be a process as well as a product which enunciates the methodological framework for achieving a vision. The changes or steps which are necessary to be undertaken to enable achievement of this vision should be part of the strategy.

Planning without consideration of strategy is unlikely to be successful. Roughly speaking, strategies are likely to be used in attaining goals, whereas tactics are likely to be used in attaining objectives. Strategies can also be considered to be like other tools used in management for the purpose of helping us achieve the designated task better. Strategies provide us the framework for executing tasks needed for achieving stated goals laid down in the plan.

Health care strategy once enunciated as a statement, helps the wide range of like minded partners to understand, appreciate and address the ways of achieving health care goals by ensuring that they share common priorities which are similarly clearly elucidated. Devising strategies in public health have been recommended as public health projects involve expenditure of large amount of resources for the benefit of large population

groups. Involvement of public health practitioners in devising health strategy also adequately addresses concerns regarding needs, equity, effectiveness, etc of the health interventions. The strategy process is dynamic and has been likened to a 'journey' rather than a static single point statement of intent or purpose.

The planning process is guided by strategy. Good strategies are based on the principles inherent in the relevant policy. However, the strategies proposed to be adopted to achieve the policy goals inform the policy planners of the practicability of putting the policy into action. Strategy thus provides the practical road map, based on practical considerations of opportunities and obstacles, which will be needed to make the vision of the policy achievable. Planning concerns the day-to-day details of how the key steps of strategy are achieved over months and years. The linkage between policy, strategy and planning can be understood better with an example – The Indian government while developing national highways may consider it necessary to state a policy that trauma victims of accidents on the highways must be provided care at a fully functional trauma care centre as soon as possible on occurrence of an accident to save life and limb. The state governments, who are responsible for provision of health services, will then need to develop strategy that within a period of five years trauma care centres are provided in such a manner that the maximum distance from any site of accident on the highway is not more than 30 minutes driving distance to ensure observance of the 'golden hour' concept in trauma management. Detailed plans will therefore need to be developed of how the trauma care centres will be developed including upgrading of existing primary health centres and even seeking assistance of private hospitals.

The factors associated in general with successful strategy development have been understood with experience. Any strategy needs to incorporate the values and vision of the people who will actually implement it. The strategy must provide an impetus for forward movement towards achieving goals and the key issues clearly identifiable by planners who will need to address these issues. The uncertainties in the initial stages need to be overcome by ensuring that all participants are focused in their thinking without any constraining lateral thinking. Involvement of dedicated and correctly selected persons, right from inception stage, who will acknowledge the policy context and the needs of planners are essential to successful strategy development. Clarity of purpose, engaging of the right people and right policy context, continued evaluation and appropriate implementation are needed to avoid floundering of strategies which may have sounded grand initially. Similarly, the strategy development needs to avoid becoming too complex by attempting to keep the strategy simple and practical as far as possible without constraining thought.

Health Care Planning

Planning is the future oriented, systematic process of determining a direction, setting a goal and taking actions to reach that goal. Planning is considered a basic management function essential to the functioning of all levels of an organization. While planning can be described in terms of techniques and tools, it is also a very complicated social

process that must be mastered by the successful manager and any thriving organization. While every manager must realize the need to plan, there are few prescriptions available for effective planning. Gaps that exist between public expectations and how an institution, sector of government or the society actually functions may point to inadequate planning or lack of planning, rather than poor leadership and implementation.

Planning is as much a social and political process as a technical process. It is essential to recognize that all participatory planning takes place in the context of an organizational culture and a history of relationships between the planning parties (both organizations and individuals). Complications and conflicts often arise over disagreements on the scope of planning strategies and specific actions necessary to achieve goals. Unfortunately, policies sometimes set out grand principles and the courses of action suggested are frequently with scant details and occasionally with little apparent thought as to how they will be implemented.

In the field of public health, even in the present developed world, planning was not common until the 1920s. The increase in funds allotted to public health over the years has created a need to plan for and be accountable for the expenditure of the funds. The planning process was developed especially in countries with socialistic forms of government. India started its development program after independence and adopted the Soviet model of a command economy. The planning structure was enshrined in the Planning Commission which prepared plans for development, recommended funding mechanism through government allocation and monitored the implementation in a "top down" approach. The health sector was also included in the planning process and public health facilities were all funded through governmental sources. Since the execution of the 1st five year plan, India is now into the 11th five year plan. The funding situation till today has not seen much change as regards the public health sector is concerned.

Planning is a form of rational decision making and can be considered to be executed in a step wise manner as follows :

Step 1 : Decide on goals and objectives.

Step 2 : Determine the constraints on the planning process and the likely changes in the environment that may affect how easy the goals and objectives are to achieve.

Step 3 : Figure out what actions, policies and programs to implement.

The details of planning process are discussed in an exclusive chapter in the section on health management.

The term 'strategic planning' derives from military jargon. It implies a planning process of significance, usually done by high- level decision makers, that will result in setting the organization's overall direction. It is often coupled with the term 'long term' or 'long range' to create an important sounding term 'long range strategic planning' which implies a systematic periodic process that sets the overall business strategy of the organization for the years ahead.

Steps in Strategic Planning

Strategic planning is planning directed at the achievement of the planned goals, which are the significant or even ultimate

ends. As such, it is an extremely important task and falls largely on the shoulders of the leadership. The steps are :

Step 1 : “Planning for plan” stage – the reasons for choosing strategic planning, needs to be clear and communicated to potential stakeholders to lay the groundwork for a shared vision. It can however be an expensive process and funds will be needed for conducting it.

Step 2 : This involves the clarification of organizational mandates.

Step 3 : Agency leaders begin to investigate the values that will govern the agency and the agency’s community relationship. It may include conduct of a stakeholder analysis.

Step 4 : Assessment of the internal and external environments in order to identify the opportunities and the challenges arising from the change process, called the SWOT analysis. The internal assessment looks at the agency’s resources, the process of carrying out the agency activities and the performance outputs.

Step 5 : Identification of the issues to be addressed by the plan. Identify the critical issues and why they are critical and the consequences of not addressing these issues.

Step 6 : Development of strategies to address the issues delineated in step 5.

Step 7 : Stakeholders review, modify and adopt the strategic plan developed in step 6.

Step 8 : Creation or revision of the organizational vision. Strategic planning may lead to changes that impact the vision and thus visioning is tied to each step.

Step 9 : Implementation of the plan.

Step 10 : Monitoring the implementation and making necessary mid-course corrections.

Operational planning : This is the most common type of planning is engaged in by managers, supervisors and every member of an organization in routine yet essential, day-to-day activities. Besides being most common, it is crucial to providing the services and products in health and human service organisations. When objectives are clearly defined and resources known, operational planning is straight forward. The presently available tools like office automation, computerized scheduling systems, spread sheets, voice mail and electronic mail all provide for better planning and implementation.

Tactical planning : Its an another term having military origins, is “how to” or implementation planning. ‘Program planning’ and ‘project planning’ are other planning types that deal with implementation. Tactical planning implies a broader scope and somewhat longer time horizon than operational planning. Projects can be as massive as a new hospital or a nationwide immunization campaign or as limited as implementing a re-engineered care process or new computer software system. Numerous management tools and techniques, such as a decision support and project planning software, exist to aid in monitoring progress and optimizing project implementation. Planning process can be formal or informal. Formal planning leaves a paper trail with all critical decisions being documented. Informal planning is less organized and more guided by social interactions.

Methods and Tools for Planning

Planning information and the scientific method : Information is at the core of all planning and a variety of collection techniques may be useful. Gathering and transforming data that is useful in making decisions is at the core of any systematic planning process. Information may come from formal or informal sources or systems.

Mathematical modelling and quality planning : In recent years, various methods / models for improving the quality of products and services have become popular in health care settings. In many situations, organisations and communities must make decisions for the future with little information. Statistical modeling is among the useful techniques in such situations. Mathematical models are often essential because we may be unable to wait for even preliminary empirical data that could aid our decisions.

Integrated planning, budgeting and improvement approaches : Over the years management science, industrial engineering and organizational development specialists have developed systems designed to integrate and improve various management functions including planning. Management By Objectives (MBO) swept businesses in the 1970s with the promise of quantitatively linking the performance of every member of the organization with the organization’s goals by using a system of quantifiable objectives. Large organisations developed their own approaches including zero-based budgeting, which America tried to introduce to the public sector. Many management systems have proved to be short term fads. However, other systems and management tools have been successful and worthy of long term adoption.

Role of Public Health Practitioner in Health Care Planning

As a public health practitioner it is likely that he will need to work with the following in the field of health planning :

- Managers and clinicians in organizations who are involved in purchasing and providing health care services.
- Patients and users who will have experienced most of the good and bad aspects of any system. In western countries, citizens panels can be a good way to do this, but are time-consuming and expensive. In India the role of members of the ‘panchayati samiti’ or ‘rogi kalayan samitis’ serve a similar purpose.
- There are likely to be existing planning groups and one will need to work with these to be effective, but to be useful these planning groups need to be part of the power structure, with authority over budgets.

The public health practitioner may need to help develop specific options for implementing policy, including new ‘models of health care’, involving changes to inputs or processes. The role will involve presenting to health sector civil servants or politicians and other health care professionals, research evidence on the effectiveness of relevant health interventions.

They may be tasked to also provide information for planning. This includes quantifying how the new models of health care will affect health services - patterns of provision, activity, budgets and outcomes. Based on the output from the above mentioned three tasks, usually an implementation plan for a

strategy or project proposal is developed using an agreed work plan.

The public health practitioner will also be called upon for dissemination and supporting decision-making. It is necessary to analyze thoroughly the implications of the policy options produced in earlier tasks. The planning cycle then begins again with the monitoring and evaluation tasks, to determine what effect the implemented changes are having on the existing health system.

Potential Pitfalls and Fallacies in Health Planning

Completing the implementation of planning decisions may usually take several years. Often there will be inadequate time but based on the suggested framework, it should be possible to reap the most benefit in the time available for health planning.

It must be appreciated that Planning rarely goes 'according to plan' as circumstances and personnel change. The intended objectives in planning are usually only partially attained and there are often unintended consequences. Therefore, monitoring the effects of planning and making adjustment are crucial. The public health practitioner should therefore be ready to accept only partial implementation of the planned intervention on the basis of changed circumstances, be ready with the evaluation process to assess the needs for changes in the plan which can be then presented to the decision makers and not become emotionally attached with the original plan.

Success in the planning process is usually not absolute. Although there should be specific objectives and measurement of their attainment, however, success, like the planning process, usually comes little by-little. That implies that monitoring and evaluation are essential to successful planning. Similarly, discussions with colleagues and formal evaluations, including workshops, are important.

It is clear that the terms policy, strategy and planning are linked and seen as being part of hierarchy of time-scale, but definitely not a hierarchy of challenge or importance in achieving aims. It is therefore important for public health practitioners to possess a clear understanding of the procedures involved in devising health care strategy and health care planning to meet the stipulated goals in public health.

Summary

Strategies are plans or methods that are relatively broad in scope, long term & often involve a significant expenditure of resources. It is a process as well as a product. Strategies are likely to be used in attaining goals, whereas tactics are likely to be used in attaining objectives. Devising strategies in Public health have been recommended. Planning without strategy is unlikely to be successful.

Planning needs to be compared to the process of strategy development as both the processes have distinct entities although they are linked. Good strategies are based on the principles inherent in the relevant policy. Strategy thus provides the practical road map, based on practical considerations of opportunities & obstacles, which will be needed to make the vision of the policy achievable. It must provide an impetus for forward movement towards achieving goals & the key issues

clearly identifiable by planners who need to address them.

Planning is the future oriented, systematic process of determining a direction, setting a goal and taking actions to reach that goal. It is as much a social & political process as a technical process. This process was developed especially in countries with socialistic form of government.

Planning is a form of rational decision making & can be considered to be executed in a stepwise manner as follows :

- Decide on goals & objectives.
- Determine the constraints on the planning process.
- Figure out what actions, policies & programs to implement.

Roher describes three planning models that are typically used in public health - Rational planning model, Community development model and Activist model. The 'Strategic planning model' applies to both organizational reform & community health planning & Bryson developed a ten step procedure for it. 'Operational Planning' is the most common type & is crucial to providing services & products in health. 'Tactical Planning', 'Program Planning' & 'Project Planning' are other planning types that deal with implementation.

The methods & tools for planning include the following :

- Planning information & the scientific method.
- Mathematical modeling & quality planning.
- Integrated planning, budgeting & improvement approaches.
- Funding of plan.

A Public health worker needs to work with managers, clinicians, patients, users & existing planning groups to be effective. Besides he is also required to help develop specific options for implementing policy, provide information for planning & disseminate & support decision making.

Planning rarely goes 'according to plan', as circumstances & personnel change. Therefore monitoring the effects of planning & making adjustments are crucial. It is a continuous process & evolves as it unravels. Success in the process is usually not absolute. Policy, strategy & planning are linked & seen as being part of hierarchy of time-scale, but definitely not a hierarchy of challenge in achieving aims.

Study Exercises

MCQS & Exercises

1. Plans or methods that are relatively broad in scope, long term & often involve a significant expenditure of resources are referred to as _____.
2. _____ are likely to be used in attaining goals, whereas _____ are likely to be used in attaining objectives.
3. The planning process is guided by strategy : True/False.
4. Strategy development ensures progression in small incremental but predictable steps : True/False.
5. Health care priorities need not be examined & debated, but can be hidden or accidental : True/False.
6. India adopted the _____ model of a command economy after starting its development program.
7. The planning which is empowerment oriented & promotes local citizen partnership in planning activities is : (a) Rational planning model (b) Community development model (c) Activist model (d) Strategic planning model.

8. The model that has the advantage that it applies to both organizational reform & community health planning is the: (a) Rational planning model (b) Community development model (c) Activist model (d) Strategic planning model.
9. The ten step procedure for strategic planning was given by _____.
10. The form of planning which is a type of implementation planning is : (a) Tactical Planning (b) Program Planning (c) Project Planning (d) All of the above.

Answers : (1) Strategies; (2) Strategies, tactics; (3) True; (4) False; (5) False; (6) Soviet; (7) b; (8) d; (9) Bryson; (10) d.

Bringing about Equality in Health Care

Amitava Datta

Concepts of Equity

The concept of equity dates back to early human civilization and is linked to disadvantaged, impoverished, deprived human beings. Equity has been discussed by politicians and statesmen from ancient times when comparing the 'haves' with the 'have nots'. The central dogma of the socialist pattern of politics is "To each as per his need" and "from each as per his ability". Equity includes the concepts of fairness, justice and equality which have been the central theme of modern day democracies. In the health sector, it is assessed by comparing levels of health of individuals or a community, or the ability of individuals and communities to obtain health care.

There are two forms of health equity. "Horizontal" equity refers to equal treatment for equal needs, for example, the devotion of equal resources to patients with similar conditions, or equal access to care for people with equal needs. The components of horizontal equity in health are described as providing equal resources for people with equal needs, providing equal access to health care for people with equal needs, providing equal utilization of health care by those with equal need and providing equal health aimed at reducing inequalities in health status between populations.

"Vertical equity" refers to unequal treatment for unequal needs; that is treating individuals who are unequal in society in different ways in order to overcome the effects of differences in their social or clinical situation. Vertical equity can be achieved by ensuring that individuals with more need should have more treatment to bring them upto the same level as others with less need. This might include devoting more resources to patients with serious conditions than to those with trivial conditions or financing health care according to the ability to pay. The alternative perspective points out that equal use for equal need does not necessarily always result in unequal use

of unequal need. If mildly diabetic persons are treated in the same way regardless of gender, age or ethnicity, but severely diabetic men are more likely to receive treatment than severely diabetic women, then equal use for equal need (- the concept of horizontal equity) occurs for mild diabetes but not for severe diabetes (where there is vertical inequity). The central theme of "need" therefore determines equity.

It must be recognized that differences in health care use are not biased if they are due to differences in need. Such differences demonstrate equal but fair care. The fair distribution of health care should be considered from two related perspectives. The first is that people with equal needs should be treated the same (equal use for equal needs). This is referred to as the achievement of horizontal equity. For example, if we consider differences in clinical need, such as differences in disease severity or presence of co-morbidity, then patients with similar levels of disease severity should be equally likely to receive an effective intervention regardless. The alternative perspective is that people with greater clinical needs should have more treatment than those with lesser needs (unequal use for unequal need). This is referred to as the achievement of vertical equity. Thus, patients with severe disease should be more likely to receive an effective intervention compared with patients with a milder form of the same disease, regardless of age or gender.

Theories of Equity

Although defining equity is relatively easy, however it becomes difficult to decide what is fair or just. Most of the health and health care issues related to equity come under the broad category of "distributive justice" – that is, how benefits, resources and burdens of society are distributed to each individual. The manner in which members of the society cooperate and the value system in the society determine its theory of equity. Theories of distributive justice differ in different political systems and societies. Some of these known theories of distributive justice can be broadly divided into libertarian, liberal and collectivist.

Libertarian theory : The 'Libertarians' believe in the protection of individual freedom, namely, political liberty, freedom of speech

and economic freedom. People are considered to be entitled to what they have, provided it was acquired justly. It has been propagated that for the state to raise taxes from individuals in order to provide services for the least advantaged class is a form of theft by the state against the private citizen. One obvious limitation to libertarian theory is that biological and genetic influences mean that the distribution of health cannot be described as fair. This has implications for the allocation of health care under a libertarian system.

Liberal theory : It also emphasizes individual liberty, but also includes the concept of “need” in its definition. Liberal theory also relies on the free market to allocate resources, but also recognizes the unequal distribution of assets among individuals. State intervention is therefore deemed appropriate when the market fails to safeguard the needs of all the members of society. Public health interventions such as universal immunization for measles or polio are based on utilitarianism principles.

Collectivist theory : This theory is based on 3 main rules—equality, freedom and fraternity, though the dominant concern is equality. Collectivist theories are therefore egalitarian and are in favour of positive, equalizing measures to re-distribute rights and wealth.

The Concern for Removal of Health Inequalities

In the recent years, interest in equality, equity and health of the poor has begun to assume a more important place in international agenda. The 1970s ended in the declaration for “Health for All” movement. The Alma-Ata conference in 1978, led to a strong focus on community orientation with governments supporting or encouraging the development of free health care services. The ‘primary health care’ approach was advocated by WHO to achieve provision by all countries of basic health care services to all their citizens.

Pragmatic examination of the various facets of primary health care approach created doubts whether this approach was capable of providing the dramatic improvements ascribed to it. “Health sector reform” became the new buzzword. The focus shifted to sustainability and efficiency rather than only concern for the health of the poor people living in developing countries. Importance was also given to health, nutrition and population by WHO during the late 1990s. The focus still remained on the poor – World Health Report for 1999 laid stress on reducing the burden of excess of mortality and morbidity of the poor. Overall, the situation in the recent times has become encouraging for those concerned with health equity and the health of the poor. However, it is uncertain whether it will be enough to guarantee significant improvements in health equity in a sustainable manner. The dispute ridden areas in Africa and Asia, which are taking their toll in terms of worsening human misery, are a major source of health inequity today in the world.

The Problem of Poverty and Health

Poverty and ill-health are interlinked. It is known that poor countries tend to have worse health outcomes than better-off countries. Within individual countries, poor people have worse health outcomes than better off people. The association between poverty and ill-health reflects causality running in both directions. Illness or excessively high fertility may have a

substantial impact on household income and may even make the difference between being above and being below the poverty line. Furthermore, ill-health is often associated with substantial health care costs. But poverty and low income also cause ill-health. Poor countries and poor people within countries, suffer from a multiplicity of deprivations that translate into high levels of ill-health. Poor people are thus caught in a vicious circle—poverty breeds ill health, ill-health maintains poverty.

Latin America appears to have higher inequalities in child health between poor and non-poor than other parts of the developing world, whatever health indicator is used. By contrast, inequalities in child mortality and malnutrition are less pronounced in sub-Saharan Africa than in North Africa, Asia and the Near East, but the opposite is true of inequalities concerning diarrhoea and acute respiratory infections. Socioeconomic inequalities in health seem to be widening rather than narrowing. This is true of both the developing and developed world. Three points are worth highlighting.

First, the world today knows a good deal about the extent of health inequalities between poor and non-poor in developing countries and a reasonable amount about inequalities in health determinants. Most striking in this connection is the failure of publicly financed health care to reach the poor in almost all developing countries.

Second, too little is known about the relative importance of inequalities in the determinants of health and health service utilization. Present knowledge suggests that inequalities in health and most probably in service utilization, largely reflect inequalities in variables at the individual and household levels, such as education, income, location and housing characteristics. Policies aimed at combating health sector inequalities should therefore aim to reduce both inequalities in the quality and availability of health services and inequalities in income, knowledge (especially health-specific knowledge), accessibility of health services, availability of safe drinking-water and sanitation, etc.

Third, too little is known about the impact of programmes and policies on health sector inequalities. There is undoubtedly a large gap in our knowledge on how best to reach the poor in the health sector. In order to fill this gap, more work is needed along the lines of the above studies related to health sector inequalities and public policy.

Action to Overcome Health Inequity

Having accepted that poverty is linked to almost all health inequity, it is necessary to attempt to overcome health inequity. The different approaches which may be considered are measures to improve the health of the poor, reducing poor-rich health inequalities or redressing health inequities. The approaches may be individually different. Those who approach health from a poverty viewpoint are typically concerned with improving the health of the poor alone rather than with reducing the poor-rich health differences. To improve the poverty status, the concept of ‘poverty line’ is used. While the concern for lessening poverty and improving the health of the poor is widespread, it is not necessarily the most preferred way. Many focus on inequalities in general and with respect to health in particular. Health inequalities have played a more central role than the

health of the poor alone in European concern. There appears to be different views on the most appropriate strategies for the reduction of inequalities. The aspects which must be borne in mind while considering the strategies are – how is the inequality to be measured, what aspects of inequality are most important and whether the focus should be local or global.

The concern for attaining of health equity is no longer the domain of health professionals only. It has been well appreciated that reduction in health inequity can be attained by the world through comprehensive multi-disciplinary action involving diverse resources. The adoption of the Millennium Development Goals by World Assembly in 2000, is the latest international initiative to attempt at equity including health equity. This aspect has been discussed in detail in an earlier chapter on health for all, primary health care and MDGs and the readers are advised to refer to the same. It is considered necessary to clearly highlight the appreciation by the world community of the prevalent causes of inequity and health inequity not only between countries but also within countries and the proposed means to reduce this inequity. The salient features of MDGs in relation to health equity are as follows :

Goal 1 - Eradicate extreme poverty and hunger : The fundamental problem affecting equity among mankind being poverty and its related fact, hunger, it is extremely apt that this fact has been stressed by United Nations in stating it as the first goal of all nations. It has been proposed to reduce by the year 2015, the number of people who earn less than \$ 1 per day by 50% in low and middle income countries and also reduce by 50% the persons who suffer from hunger.

Goal 2 - Achieve universal primary education : Illiteracy has rightly been considered as a major impediment to attainment of equity by all people. Hence the stress to at least attain primary education by all children of the world. To reach the education goal, countries must first enroll all school-age children. Then they must keep them in school. Although not officially included as one of the MDG indicators, primary completion rate is increasingly used as a core indicator of an education system's performance.

Goal 3 - Promote gender equality and empower women : Women have an enormous impact on the well-being of their families and societies – yet their potential is not realized because of discriminatory social norms, incentives and legal institutions. And while their status has improved in recent decades, gender inequalities remain pervasive. Gender inequality starts early and keeps women at a disadvantage throughout their lives. Educating women and giving them equal rights is important for many reasons- It increases their productivity, raising output and reducing poverty; it promotes gender equality, within households and removes constraints on women's decision making thus reducing fertility rates and improving maternal health; and educated women do a better job caring for children, increasing children's chances of surviving to become healthier and better educated.

Goal 4 - Reduce child mortality : The target is to reduce by two-thirds the under- 5 years mortality rate by 2015. Immunization is an essential component of activities to reduce child mortality. Child mortality is also closely linked to poverty. In 2002, the average under-five mortality rate was 121 deaths

per 1,000 live births in low-income countries, 40 in lower-middle-income countries and 7 in high-income countries.

Goal 5 - Improve maternal health : The target is reduce by three-quarters the maternal mortality ratio. Women in high-fertility countries in Sub-Saharan Africa have a 1-in-16 lifetime risk of dying from maternal causes, compared with women in low-fertility countries in Europe, who have a 1-in-2, 000 risk and in North America, who have a 1-in-3, 500 risk of dying. Greater access to family planning, providing rapid access to emergency obstetrical care, including treatment of hemorrhages, infections, hypertension and obstructed labor and supported by the right environment are suggested interventions.

Goal 6 - Combat HIV/AIDS, malaria and other diseases : The economic burden of epidemics such as tuberculosis, malaria and HIV/AIDS on families and communities is enormous. Estimates suggest that tuberculosis costs the average patient three or four months of lost earnings, which can represent up to 30 percent of annual household income; Malaria slows economic growth in Africa by about 1.3 percent a year; and when the prevalence of HIV/AIDS reaches 8 percent the cost in growth is estimated at about 1 percent a year. The targets are that by 2015, halt and start reversing the spread of HIV/AIDS and the incidence of malaria and other diseases.

Goal 7 - Ensure environmental sustainability : Improved water and sanitation reduce child mortality and better drainage reduces malaria. It also reduces the risk of disaster from floods. Managing and protecting the environment thus contributes to reaching the other Millennium Development Goals. Fortunately, good policies and economic growth, which work to improve people's lives, can also work to improve the environment. The targets are to halve by 2015 the proportion of people without sustainable access to safe drinking water and basic sanitation, besides achieving by 2020 a significant improvement in the lives of at least 100 million slum dwellers. The interventions suggested include reversing the denudation of forests, reduce the existing pressures on biodiversity by declaring protected areas and species, change in use of energy sources away from fossil fuels and reducing carbon dioxide emission by use of better technology

Goal 8 - Build a global partnership for development : It is advocated to have an open, rule-based trading and financial system, more generous aid to countries committed to poverty reduction and relief for the debt problems of developing countries. It draws attention to the problems of the least developed countries, which have greater difficulty competing in the global economy. It also calls for cooperation with the private sector to address youth unemployment, ensure access to affordable, essential drugs and make available the benefits of new technologies. In March 2002 leaders from developing and high-income countries came together in Monterrey, Mexico, to discuss new strategies for attacking global poverty. Rich countries made new commitments that would increase official development assistance in real terms by about \$16 billion a year by 2006.

Health inequity has come to the forefront of international concern in recent years. With globalization, boom in information technology and communication, besides relative affluence and overall development in many parts of the

world, there is greater awareness of the existing disparity in health equity in different parts of the world. This awareness exists at the individual, governmental and institutional levels. Philanthropic institutions and professional bodies are investing their own resources in developing and implementing strategies to overcome many of the identified inequities. It can be reasonably anticipated that the pace of reduction of health inequities will proceed in a sustained manner as planned by the international agencies like United Nations with the full participation of national governments and assisted by like minded donor agencies.

Summary

Equity includes the concepts of fairness, justice & equality, which in the health sector is assessed by comparing levels of health of individuals or a community or their ability to obtain health care. The two forms of health equity are 'Horizontal equity' which refers to equal treatment for equal needs & 'Vertical equity' which refers to unequal treatment for unequal needs. The central theme of "need" therefore determines equity.

Differences in health care use are not biased if they are due to differences in need. Such differences demonstrate equal but fair care. It is essential to take account of different levels of clinical need in order to measure the fair use of health care.

Most of the health & health care issues related to equity come under the broad category of "distributive justice". Theories of "distributive justice" can broadly be divided into : Libertarian theory, Liberal theory and Collectivist theory

Poverty has long been associated with health inequities. Also poverty & ill-health are interlinked. The international community has an increasing concern over health inequities in recent times. The different approaches which may be considered to overcome this are to improve the health of the poor, reducing poor-rich health inequities or redressing them. The priority need at present is to begin applying what is already known to obtain political commitment & develop effective intervention strategies, besides redefining health goals.

The adoption of Millennium Development Goals by World Assembly in 2000, is the latest international initiative to attempt at equity including health equity. It may be expected that the pace of reduction of health inequities will proceed in a sustained manner as by the international agencies with participation of national Govts. & assistance by like minded donor agencies.

Study Exercises

MCQs and Exercises

1. The equity which refers to equal treatment for equal needs is referred to as _____
2. 'Vertical equity' refers to equal treatment for unequal needs : True/False
3. The central theme of "need" determines equity. True/False
4. The theory of equity which emphasizes individual liberty with the concept of need is : (a) Libertarian (b) Freedom (c) Liberal (d) Collectivist
5. The theory of equity which is based on 3 main rules of equality, freedom & fraternity is : (a) Libertarian (b) Freedom (c) Liberal (d) Collectivist
6. The adoption of Millennium Development Goals by World Assembly took place in the year : (a) 1999 (b) 2000 (c) 2001 (d) 2002
7. As per the MDGs, the target of Goal 4 is to reduce under - 5 mortality by _____ by the year _____.
8. As per the MDGs, the target of Goal 5 is to reduce maternal mortality ratio by one-fourth : True/False

Answers : (1) Horizontal equity; (2) False; (3) True; (4) c; (5) d; (6) b; (7) Two-thirds, 2015; (8) False.

75 Health Care Quality

Amitava Datta

The word "quality" can convey different meanings. It can convey a high degree of excellence, e.g. "a quality product", or a degree of excellence or the lack of it e.g. "work of average quality", or a property of something, e.g. "the addictive quality of alcohol". Usually however the word is used in the world of business where it is subjective term for which each person has

his or her own definition. In technical usage, quality can have two meanings – first, the characteristics of a product or service that bear on its ability to satisfy stated or implied needs and second, a product or service free of deficiencies. It has been opined that "Quality in a product or service is not what the supplier puts in. It is what the customer gets out and is willing to pay for." Quality thus has no specific meaning unless related to a specific function and/or object. Quality is a perceptual, conditional and somewhat subjective attribute.

Health care Quality also has many facets which are needed to be understood as the health care manager, usually a public

health specialist is expected to assess the quality of health care in given community. According to the United States Institute of Medicine, 'Quality of health care' is the degree to which health services for individuals and populations increase the likelihood of desired health outcomes and are consistent with current professional knowledge. This definition explicitly acknowledges that 'Quality' is measured as a scale or degree, encompasses all aspects of care and can be observed from an individual as well as a population perspective. The quality 'outcomes' do not specify for whom, thus allowing differing perspectives on which aspects of quality are most important (professional, patient, public, political, etc). There is rarely a causal link between the quality of care and outcome. The phrase 'consistency with current professional knowledge' indicates that the quality of care can only be judged relative to what is known at that moment in time.

Defining and Measuring the Quality of Health Care

Although it is apparent that quality often being perceived as difficult to define, however the quality of a service is the degree to which it conforms to certain preset standards of good care. An important dimension of measuring quality is to make the standards against which one is assessing quality absolutely explicit and preset. It has been expounded that there are six dimensions of quality which can be considered while measuring the quality of a product or practice – effectiveness, efficiency, acceptability, access, equity and relevance which are explained as follows :

Effectiveness : measures the desired effect.

Efficiency : measures the cost of the input as compared with the cost elsewhere for the same requirement (treatment) / service.

Acceptability : measures how humanely and considerately the treatment/service is delivered. What does the patient think of it? What does an observant third party like his attendant think? To what extent does the treatment /service conform to patient/public expectations and how much are they utilizing it.

Access : measures whether people get this treatment/service when they need it. Identifiable barriers like large distances to travel, inability to pay and waiting times also influence the access.

Equity : measures whether all groups of patients are being fairly treated compared to others or is there discrimination in who gets the service / treatment.

Relevance : compares the treatment / service with the best that could be achieved, taking account the needs and wants of the population.

Measurement of 'Quality'

The quality of health care can be assessed by measuring the structure, process, or outcomes. "Structure" (often also referred to as "inputs" in certain managerial parlances) refers to the components of the health-care system like number of health centres, the number of beds in the health centre, the ratio of the number of nurses and doctors to the number of beds in a centre, the presence of laboratory, x-ray machine, etc.

Although the absence of adequate health structure has strong negative influence on health, however, mere presence of health care structure cannot necessarily improve the health of the population.

The "processes" of health care are those things which are delivered to individual patients in specific clinical circumstances, such as prescription of certain medications, conduct of diagnostic tests and therapeutic procedures, etc.

"Outcomes" refer to health states such as recovery, death, disability, improvements in functional status, etc. Measuring outcomes appears logically to be the best measure of the quality of health care but there are serious limitations because of the following reasons :

Many determinants of outcome are poorly understood or not under the control of the health-care system. For example the recovery of a patient treated with angioplasty after a heart attack cannot be clearly measured. His functional state may not be an indication of the competence of the cardiologist or the hospital as various other factors like the severity of the disease process, socio-economic support system of the patient and his age, occupation, etc may play a major role on his complete physical, social, mental and economic rehabilitation

For many chronic conditions, the time between the key processes of care and the outcomes may be very long. For example, untreated diabetes may be asymptomatic for years before leading to retinal damage or kidney failure.

Therefore, use of outcome measures of quality is usually restricted to areas where the above problems are not present, for example in measuring mortality following major surgical procedures in a hospital.

By assessing the health processes as indicators of health care quality, we measure what is delivered to patients under specific circumstances and they must be strongly linked to subsequent outcomes, preferably by good evidence from epidemiological studies like randomized clinical trials, or professional consensus. A good example to study the effect of a "process" is an immunization campaign as a means of reducing morbidity and mortality due to an infectious disease like measles.

For all of these reasons, measures of health-care quality are dominated by "process" measures rather than "outcome" measures.

Measuring Quality of Care

In order to assess and improve the quality of health care provided to a community, it first must be measured. For example, let us examine an operational statement about a specific health-care process – "if a patient has diabetes and is over the age of 55 and is at increased risk for cardiovascular disease then he should be offered treatment with an ACE inhibitor". To be a quality measure it will need to be applied to a specific population and data sources and spell out precisely how patients with diabetes are to be identified, what factors (and how they are measured) are considered to be evidence of increased cardiovascular risk and what efforts count in terms of offering ACE inhibitor therapy.

Criticisms of the use of quality indicators or measures include that the selected items aren't necessarily related to improved

health outcomes and that focusing attention on certain measures will lead to decreasing attention on other aspects of health care, which may be as much or more important. Therefore, development of measures should aim to be as rigorous as possible and cover a broad array of aspects of health care, to better represent care and minimize the ability to distort or game the measurement system.

The Appropriateness of Clinical Interventions

The 'appropriateness' of health-care interventions have been defined as the degree to which benefit of care exceeds the expected negative consequences. Through this concept it is possible to establish a set of rules or standards of care based on identifying appropriate interventions which should be used (or not used) in a specific clinical situation.

The 'appropriateness method' was developed as a pragmatic solution to the problem of trying to assess for which patients certain surgical and medical procedures are 'appropriate'. For example, it may be stated that in the case of middle aged male patients detected to have single or double vessel blockage on coronary angiography, they be offered angioplasty. However for triple vessel blockage in similar age group of patients, coronary bypass graft surgery be offered. Attempts are made to determine 'appropriateness' with a thorough literature review, but this may prove insufficient for developing comprehensive, clinically detailed measures of appropriateness in some cases. Several fundamental concepts assist in developing the 'appropriateness'. Some of these are :

- Clinical judgment is required to supplement findings published in medical literature which on its own is insufficient.
- All relevant clinical disciplines must be involved
- Indicators must be specific and described in sufficient clinical details specially with respect to risks and benefits of the procedure.
- The definitions of appropriate care should be comprehensive and applicable to a very large number of the possible clinical situations relevant to the procedure.
- Applying the method must be feasible in terms of resources.

The key elements of the appropriateness method are somewhat arbitrary and hence the method has been criticized because there is potential for variability in the process due to the composition of the panel or the actual panel members themselves as well as the role of the moderator. There is a possibility of misclassification bias of individual scenarios and the process lacks specificity about what outcomes are being considered for individual scenarios. The ratings may reflect nothing more than codifying existing clinical dogma. A substantial amount of methodological research has been done to try and assess these criticisms which have determined that clinicians who perform the procedure are more enthusiastic about its use. Favourable predictive validity for appropriateness ratings have been reported for several procedures, including coronary angiography and coronary revascularization. The sensitivity and specificity of the method for identifying inappropriate over use has been estimated at varying between 68% and 99% and under use 94% and 97% respectively.

Comparative Quality Standards

In contrast to the 'appropriateness method' for specific patients and interventions a variety of standards have been set by comparing performance of different clinicians or services. Take the example of normal delivery by gynecologists. It may be that after an uneventful period of recovery in hospital and discharge in the case of 100 such primi-gravida cases, there are unplanned readmission rate for post delivery reproductive tract infection which varies from 1% to 5% in different hospitals. What rate of unplanned readmission should we adopt as an indicator of high-quality care? If we adopt the lowest, we may be ignoring avoidable problems even in the best units. On the other hand, we may be setting impossible targets that cannot be achieved.

The different levels of standards usually used are

- Excellent standards- these are typically standards achieved by the 'best' services, such standards can identify what's possible and challenging excuses.
- Minimal acceptable standards- are those below which no service should fall; this may arbitrarily be what 90% of hospitals are achieving.

In practice, the standards must be such that it is clear what individuals need to do to achieve them and they must be attainable. i.e. a balance needs to be struck between standards of excellence and achievable standards. These standards must be agreed to, implemented and achieved preferably locally. Standards developed in one country may not necessarily be applied in another. Most standards applied in medicine are based on achievements in western countries like USA. However adaptation for local conditions may be needed before its acceptance. The standards may also vary. For example, exacting standard of sterility will be required in a cardiology OT or orthopedic OT. However it may not be necessary or cost effective to insist on same standards in a general surgery OT. Not only do different people value different dimensions differently but the same individual may value different dimensions over time or depending on the condition that needs attention.

Perspectives on Improving Quality

Assessing quality through mechanisms such as monitoring, audit and evaluation is essential. However, there are different philosophical and practical approaches to how a system's quality is maintained and improved. Comparison in medical care giving will invariably identify bad doctors or bad procedures. It is difficult to identify the other end of the spectrum – good doctors or good procedures which can be the standard which is aimed to be achieved. After assessment, if a 'punitive' attitude is taken, it need not necessarily lead to improvement in standards. In the 'system improvement' approach, emphasis is laid on learning from mistakes but some mistakes will have to be permitted although all efforts made to lessen their chance of occurrence.

Highlights of Measurement of Health Quality

The issues which must be considered when measuring quality of health care are :

- The need to measure quality
- Definition of the aspects which have been planned to be measured

- Choice of investigators involved in the assessment process. Care to consult all those with a stake in the issue and their perspective on quality understood.
- Aspect of quality planned to be assessed may need to have been analysed before deciding on which ones will be measured.
- Perspective of quality which will be considered needs to be decided based on rational understanding of advantages and limitations of each.
- Aspects of Population appropriateness and Individual appropriateness
- Approach planned to be used
- Dimension planned to be assessed - structure, process or outcome

Taking Action to Improve Quality

After conducting an assessment of quality of health care, the logical sequelae must be to improve the quality of health care. By definition, a quality improvement project is a clearly articulated plan to improve the quality of health care. Commonly, the quality improvement will be attempted to incorporate one or more aspects and include Safety, Timeliness, Effectiveness, Efficiency, Equity and Patient-centeredness.

To implement a successful improvement project it is necessary to develop 'will' (that is support of senior leaders and clinicians), have good ideas and have a carefully thought out strategy for execution. The 'ideas', or 'change package', may be a strategy for implementing clinical practice guidelines that has already been tested and is ready for local adoption and adaptation, or may require innovation if no one has achieved quality improvement in a similar setting before.

Obtaining the Support of Senior Leaders and Clinicians

Senior leaders and clinicians may not be directly involved in the day-to-day work of improvement, but their support is crucial to success. 'Not all change is improvement, but all improvement is change' and organizations tend to resist change. By getting the leaders to agree to the changes will help remove obstacles to change. This can be achieved by use data to demonstrate the opportunities for improvement, build a business case for improvement, periodically get reports on safety and quality for consideration of leaders and if available use stories of real patients to reinforce the suggested change.

The Business Case for Improvement

To project a business case for improvement it will be necessary to use data to show how the projected changes will improve results either directly or indirectly besides reduction of wastage in the system or other business parameters which either increase efficiency or reduce losses.

Forming Quality Improvement Team

The team should to implement the quality improvement must include representatives from all disciplines and departments involved in the improvement work, who are preferably enthusiastic about the changes which have been demonstrated to them. The important stakeholders must be incorporated and not necessarily all senior persons. The team must be encouraged to study the existing process and help identify opportunities

for improvement. They must collaborate and share ideas with institutions with similar problems or where similar problems have been solved to arrive at an appropriate improvement strategy. While implementing the improvement project, it is necessary to set clear measurable goals, like, 'to reduce hospital acquired infections among newborn by 50 percent over a six months period of time'. The measures of the outcome must be specified so that the improvement can be measured, documented and communicated in the form of graphs, charts, etc. The team must be motivated and prepared for hard work and provided required commitment and support from the leadership in order to be able to succeed in implementing the desired changes.

Summary

The term 'quality' refers to perceptual, conditional and a subjective attribute of a product or service, to satisfy stated or implied needs. According to United States Institute of Medicine, 'Quality of health care' is the degree to which health services for individuals and population increase the likelihood of desired health outcomes and are consistent with current professional knowledge. In order to assess, improve and compare the quality of health care provided to the community, it must first be measured against defined standards, to assess the quality. There are six dimensions to measure the quality of health care services viz- effectiveness, efficiency, acceptability, access, equity and relevance. The quality of health care can be assessed by measuring the structure, process or outcomes. The appropriateness method of health care interventions is the degree to which benefits of care exceed the expected negative consequences. This method has been criticized because of potential for variability, besides lacking specificity. Comparative method utilizes comparing performance of different clinicians and services either by using established excellent standards or minimal acceptable standards. Assessing quality through mechanisms such as monitoring, audit and evaluation is the heart of system improvement approach. Quality improvement has to incorporate aspects of safety, timeliness, effectiveness, efficiency, equity and patient centeredness.

Study Exercises

MCQs

1. Which dimension of Health Care Quality measure, assesses the cost of input compared with cost elsewhere for the same reqmt : (a) Effectiveness (b) Efficiency (c) Relevance (d) Acceptability.
2. The quality of health care can be assessed by measuring : (a) Structure (b) Process (c) Outcome (d) All.
3. Measures of health care quality are dominated by "process" measures rather than "outcome" measures : True/False

Answers : 1. (b); 2. (d); 3. True.

Anuj Bhatnagar

Social marketing can be described as the process of motivating people (through application of marketing techniques) to voluntarily adopt behaviour which is beneficial to them, over other 'potentially' harmful behaviour. It can be defined as 'the design, implementation and control of programs seeking to increase acceptability of a beneficial social idea or practice in target group(s) (Philip Kotler 1975). Social marketing is a means to assist in gaining acceptance and willingness on the part of the concerned individuals to adopt a particular behaviour. For example, for a new vaccine to be successful, it should first be developed and produced, then social marketing should be used to create acceptance of need for the vaccine among physicians and public, so that it is used by the target groups. The term 'Social Marketing' gained popularity when the Journal of Marketing brought out an issue on the topic in July 1971 (Kotler 1971). Around the same time, it was being increasingly felt that health professionals should assume more responsibility for health education in community.

The objective of social marketing is to promote public health with the overall aim of improving health for all. It therefore relies heavily on preventive medicine. Moreover, social marketing should not be confused with marketing of new commercial health & hospital establishments since these promote curative services for profit of shares holders and the resultant benefits may not always be beneficial to public health. Social Marketing offers a unique opportunity for public health specialists to bridge the gap between the health care delivery systems and those who are unaware or unwilling to use it.

Principles & Techniques of Social Marketing

As a health planner, one must be aware that like commercial marketing, Social Marketing also consists of four marketing elements (marketing mix) of Product, Place, Price and Promotion.

The Product : In health care setting, the product may be a tangible material (such as a therapeutic drug or an educational pamphlet) or an intangible/non-standardised service (such as a training course on HIV counselling or nursing care in ICU). Social marketing of health products also involves issues like product/service branding, packaging, positioning, form, life cycle and product development. For example, if the packaging and quality of a condom is poor, there is bound to be poor response and low acceptability of such condoms. Thus, pretesting and obtaining feedback from users can reduce some obstacles in social marketing.

The Place : It is important for success of social marketing that the product/service should be located where users are most likely to find them without any stigma. Marketing of STD clinics as a separate entity has largely been a failure because of stigma attached to such clinics, hence poor utilisation of such services. On the other hand, some countries have very successfully increased utilisation of condoms by making them

available in areas where the potential users can find them easily, such as in 'red light' areas, on bus stands, on highways etc. Similarly, a public health specialist should realise that the best place to undertake social marketing of immunisation and breast feeding would perhaps be an antenatal clinic of a hospital which is visited by expecting mothers.

The Price : In ordinary curative or promotive health care scenario, the demand for health care is dependent on the price and personal income, in comparison with life threatening situations, where an individual seeks the required surgical/medical care at whatever cost it is available, irrespective of his personal income. For promotive/preventive health care, demand is more if the price is low and personal income is high. In addition, the 'perceived value' of the health service/behaviour also determines the demand. For example, use of helmets among two-wheeler users would be higher if cost of good quality helmets is affordable and also if driver perceives the benefit of using a helmet, which may be as a safety measure or even as a fashion statement.

In addition, a public health specialist should realise that social marketing is also associated with 'convenience costs' (cost of loss of work, pay or travel if the individual has to visit a clinic) and 'response costs' (embarrassment in case of purchase of condoms in market place or exposure of a particular personal problem in case of visit to a STD clinic in the neighbourhood). Such costs are often intangible since they are personal to the individual and thus are difficult to accurately quantify.

Promotion (Visibility & Timing) : High visibility constantly reminds the user of the existence of a product/service. Timing, on the other hand, pertains to presenting the reminder when the user is most likely to accept the idea, product or the service. People at different times vary in their readiness to receive information and accept new ideas. A new message should thus be promoted to people when they are most likely to accept it and it should be in a form and from a source most acceptable. For example, social marketing of Oral Rehydration Solution (ORS) is best undertaken by doctors in a paediatric OPD or by Village Health Guides during home visits, especially when a child is suffering from diarrhoea. Educating a woman about ORS when she is about to go into labour would be of no consequence since the felt-need is not present at that time and the woman is thus not receptive to the idea.

Designing the message : A message for any social marketing endeavour depends on local sensitivities rather than on any strict rules. Social marketing messages should be able to educate the target group about the existence of the health problem and its understanding, empower the group to undertake action/behaviour recommended and explain to the target group about benefits of a particular recommended behaviour. The social message must also overcome any cultural, social and traditional practices, which resist change. Repeated message for Pulse Polio Immunisation on mass media by leading film stars in India is an excellent example of an effectively designed and presented social message. A social message needs to be short, correct and delivered to target audience at most opportune moment when they are most likely to accept and adopt new behaviour, by overcoming existing resistance.

A Step-Wise Approach to Social Marketing

Step 1 - Identification of health problem & establishing methods for social marketing : Effective social marketing needs an in-depth identification of the health problem. In addition, rigid customs and opinions of community have to be considered. Consensus building among public (to minimise conflicting opinions) through operational and political cooperation with community is essential. The decision makers in government and community should be identified at the earliest since their cooperation is essential for success of social marketing. In addition, social marketing for healthy behaviour will require identification of traditional health measures, demographic & population studies including mortality/ morbidity patterns and economic impact etc. The causes of the problem have to be established clearly and the required & available resources like mass media, marketing & design expertise should also be identified.

Step 2 - Identification of priorities and implementation of affordable efforts : Organising priorities saves time, energy and money for a social marketer. The health problem and desired objectives should be assessed from the viewpoint of the consumer and should ideally be quantified. Cost estimates for media, material & delivery, personnel and other resources should be assessed in advance. It is essential to project realistic and achievable goals & objectives and prepare realistic budgets.

Step 3 - Analysis of marketing activities, including social message : The strategy of social marketing needs to be evaluated regularly. There may be a need to adopt different messages and message styles for effectively communicating the message for a particular target group. For example, messages and their style of delivery for HIV prevention would be different for college students, commercial sex workers, MSM groups, truck drivers and housewives.

Step 4 - Identification of target audience for each marketing component : 'Market segmentation' involves accurate identification of the group or individual who is not doing what they should be doing, in terms of health related behaviour (for example, identification of clients of CSWs who are not using condoms when they should be using). Accurate market segmentation will result in better and effective social marketing & better message delivery since a health message needs to be designed and delivered differently for different socio-economic and demographic groups.

Step 5 - Analysing each marketing strategy to determine attitudes and potential resistance among target groups : A public health specialist should identify all possible cultural, social and religious resistance points, which will differ in strength within each target group. Attitude testing techniques are used to isolate beliefs and values which offer resistance to healthy behaviour. Instead of countering such beliefs head-on (which will result in rejection of the social message), it is more appropriate to build consensus and strategy to overcome the resistance.

Step 6 - Identification of objectives for each target group : The proposed behaviour change in each target group should be accurately identified and preferably quantified. For example, we may define our objective as "raising condom use among

clients of CSWs in a geographical area from 40% to 90% in next one year" or "increasing household use of iodised salt in a given district from 60% to 95% in next 2 years". All necessary and relevant information should be provided according to understanding abilities of the target group and effect of each message should be evaluated periodically to assess if it has been understood properly or not.

Step 7 - Designing and testing the social message : The social message should be pretested on samples of target audience for acceptability, comprehension, believability and conviction. Even the best designed social message is of no utility if it is not understood or believed by the target audience. After pre testing, messages should be revised and retested as necessary.

Step 8 - Selection of marketing/distribution system : Media and distribution system for the message should be in a manner which ensures maximum coverage among target audience. Introduction of statutory warnings on tobacco products is one such way to ensure that the anti-smoking message reaches all target audience.

Step 9 - Evaluate the impact of social messages : Quantifiable variables should be identified which indicate impact of the social messages over a certain period of time. These should be assessed periodically to evaluate the impact of social marketing and mid-term corrections should be made wherever required. For example, incidence of sexually transmitted diseases as ascertained from a busy STD clinic or hospital in a district is a good indicator of the impact of social marketing for condoms in that district.

Limitations of Social Marketing

A public health specialist should realise that social marketing techniques are only appropriate in certain circumstances and have certain limitations. It is most often focussed on change in individual behaviour whereas other health education techniques aim intervention at families, villages and communities. Social marketing may lead people to believe that a particular marketed behaviour is better than other health promoting behaviours, which are not being marketed intensively. For example, use of condoms for multi partner sex may be perceived by some as better than abstinence and avoidance of multi partner sex due to intensive social marketing for promoting condom use. Social marketing often proves ineffective where major barriers (such as poverty, lack of health facilities, social discrimination and lack of political will) resist change in individual behaviour. It is also ineffective where individual efforts are inadequate to achieve the desired behaviour. Social marketing must ideally involve the consumer in decision making as there are often ethical and social difficulties in determining who must make the decisions or what behaviour must be promoted. For example, the decision to promote condoms in India still faces resistance from some sections, who favour promotion of single-partner sex and avoidance of sex outside marriage. Social marketing is often a labour and time intensive activity and obtaining adequate funds may be a problem. Actual social marketing programs are very few due to high demand of manpower & resources. Since the target population of social marketing is traditionally devoid of cash, the process of behaviour change is culturally, socially and psychologically different from commercial marketing. As a result, progress is slow and results are difficult to achieve,

making social marketing efforts low priority activities even within government channels. Mass media too is mostly aimed at an audience capable of paying, thus social marketing efforts by mass media are often poor in quality & ineffective. In addition, social marketing faces greater challenges as compared to commercial marketing as highlighted under :

(a) Accurate market analysis is most often not possible. Primary data collection, besides being expensive and time consuming, is also inaccurate due to incorrect or socially desirable responses of subjects. Secondary data is inaccurate, simplistic and not easily available, since social behaviour is complex and can not be objectively measured.

(b) Market segmentation, which is essential for targeting efforts towards the target audience, may itself be detrimental to efforts because of discrimination & stigma attached to such segmented behaviour. For example, clients of commercial sex workers for targeted intervention for promoting condoms or patients of sexually transmitted diseases (STDs) when they visit designated & well advertised STD clinics may be discriminated against due to their high visibility & stigma. Such kind of stigma and discrimination is contrary to audience response in conventional commercial marketing scenario.

(c) Product strategy in the form of developing complex behaviour which is acceptable to target audience and which meets their felt needs is difficult in social marketing.

(d) Pricing strategy in social marketing is also a challenge since a social marketer aims to reduce monetary barriers which prevent consumers from adopting healthy behaviour, rather than maximising the tangible financial gains for the consumer. Social marketing often has no control over (and cannot address) issues of intangible consumer costs such as cost of personal embarrassment (as in case of examination by a male doctor for cervical cancer) or fear (as in voluntary testing for HIV).

(e) Strategy for selecting channels for dissemination of social messages is a challenge since incentives & financial returns for the medium of distribution (such as a doctor or a hospital) are minimal, intangible and often non- financial. In addition, indirect dissemination of social message is often associated with misinformation.

(f) Communication options in social marketing are limited because paid advertising is often not possible and large amount of information needs to be conveyed to target audience before behaviour can be changed.

(g) Social marketing programs often face failure due to limited knowledge of marketing principles among health planners. Such programs also often face opposition from competing groups (such as tobacco companies in anti-smoking campaigns and baby food manufactures in breast feeding campaigns).

(h) Evaluation of impact is especially difficult in case of social marketing because change in social & individual behaviour & attitude is complex and intangible with very few objective variables.

Summary

Social marketing involves the research, product design, distribution, information, communication & often introduction of a new product / concept /service, with the aim of changing

behaviour. The basic differences between commercial and social marketing are summarised as under :

Commercial marketing : (1) Meets identified needs & wants of target market segment. (2) Aims to make a profit by serving the interests of target market. (3) Marketing of products/services mostly through ideas.

Social marketing : (1) Aims to change attitudes & behaviour to a healthier behaviour. (2) Serves interests of target market without personal profit. (3) Mostly marketing of ideas and concepts rather than tangible products.

A social marketer primarily acts in the benefit of targets group. Social marketing aims to broadly bring about social changes as under :

(a) **Cognitive changes** : are relatively easy to market where groups which need information are identified through market research, their media habits are identified and messages are carried to the target audience through appropriate channels.

(b) **Action changes** : involves that the target audience should understand the social message and take specific action based on it. Action change may be hampered by factors such as distance & non-availability of product/service hence the social marketer has to often facilitate action for target group by making the products/services easily available, accessible & acceptable.

(c) **Behaviour change** : is still more difficult than action change as it requires careful segmentation of target audience and specifically tailored 'solutions' for each segment; to enable them to alter their behaviour consistently.

(d) **Value change** : attempts to alter the deeply held beliefs of an individual & thus is most difficult. A prolonged and intense indoctrination program is required to change an individual from one basic value - orientation to another.

Social marketing uses scientific evidence on health and creates education and action programs for healthier habits & behaviour through methods of marketing. Social marketing can be used to help combat many major fatal diseases, especially in children in developing countries, that can be prevented by vaccination, nutrition or hygiene. Even in developed societies, social marketing finds place in diet education programs to lower cholesterol levels or anti-smoking campaigns.

Study Exercises

Long Questions : (1) You are posted as a Medical Officer in a PHC. Plan a step-wise approach for "Social marketing of new Oral Rehydration Solution (ORS)" in a particular Village. (2) What is Social Marketing? What are the principles, techniques and Limitations of Social Marketing?

Short Notes : (1) Differentiate Social marketing from Commercial marketing. (2) Principles of Social marketing (3) Enumerate Steps for Social marketing (4) Limitations of Social Marketing.

MCQs

- Which of the following is true about Social marketing?
 - Meets identified needs & wants of target market segment.
 - Aims to make a profit by serving the interests of target market.
 - Marketing of products/services mostly through ideas.
 - Marketing of ideas and concepts rather than tangible products.

2. Social marketing aims to broadly bring about the following changes except (a) Cognitive Changes among people (b) Behaviour changes among people (c) Price value changes of that particular product (d) changes in false beliefs of an individual.
3. All of the following are the elements of commercial marketing which are also used in social Marketing except (a) Product (b) Place (c) Price (d) None of the above.
4. The accurate identification of the group or individual who is not doing what they should be doing, in terms of health

related behaviour is known as (a) Marketing Analysis (b) Market segmentation (c) Commercial marketing (d) None of the above.

5. Social Marketing can be used for (a) Health education (b) Behaviour change (c) Combating many major fatal diseases, especially in children, that can be prevented by vaccination and nutrition (d) All of the above.

Answers : (1) d; (2) c; (3) d; (4) b; (5) d.

77

Public Health Aspects of Disaster Management

Ashok K. Jindal & Puja Dudeja

It is the people who matter most and without the people we have no disasters.

Disasters have existed ever since the existence of mankind and no community is immune to the emergence caused by natural and man-made disasters. Worldwide, natural disasters have been known to be one of the major problems in terms of mortality, number of people adversely affected and economic losses. The spectrum of occurrence of disasters indicates that the Asian region is one of the most disaster prone regions as 60% of the major natural disasters reported in the world occur in this region. India is amongst the most disaster prone countries in the world due to high vulnerability to natural disasters like floods, earthquakes, cyclones and droughts. In India, flood affects over 9 million hectares area annually, 56% of landmass is vulnerable to seismic activity of varying degree and 5700 kms long coastline is prone to severe cyclones with very severe loss of life and economic damage. Besides the natural disasters, India is also vulnerable to man-made disasters like transportation accidents, chemical and technological disasters and other such events.

It is evident from the spectrum of occurrence that adequate procedures to deal with disaster situations are necessary. Disaster management requires well-coordinated public policy for disaster prevention, mitigation, preparedness, emergency response and reconstruction. Health care in disaster is one of the critical elements (1). The issue becomes even more relevant since proper foresight and planning is of considerable importance for disaster management. Often, in disaster situations, a lot of resources have been wasted due to improper planning and impulsive actions (2).

Definition

Commonly disasters are defined as an 'overwhelming ecological disruption which exceeds the capacity of a community to adjust

and consequently requires assistance from outside'. W Nick Carter defined it as 'an event, natural or man-made, sudden or progressive, which impacts with such severity that the affected community has to respond by taking exceptional measures'(3). As per the Disaster Management Act 2005, 'Disaster means a catastrophe, mishap, calamity or grave occurrence in any area, arising from natural or man-made causes, or by accident or negligence which in substantial loss of life of human suffering or damage to and destruction of property, or damage to, or degradation of environment and is such a nature or magnitude as to be beyond the coping capacity of the community of the affected area (4).

Classification of Disasters

(i) Natural Disasters

(a) Meteorological Disasters : Storms, cyclones, hailstorms, hurricanes, tornados, typhoons, snow storms, cold spells, heat waves and droughts.

(b) Topological Disasters : Earthquake, avalanches, landslides and floods

(c) Biological Disasters : Epidemics of communicable diseases and insect swarms (e.g. locust swarms)

(ii) Man-made Disasters

(a) Accidents : Transportation accidents (Land, air and sea), collapse of buildings, dams and other structures, mine disasters and technological failures such as mishap at a nuclear power station or leak at a chemical plant causing pollution of atmosphere (5).

(b) Civil disturbances : Riots and demonstrations.

(c) Warfare : Conventional warfare (Bombardment, blockage or siege); Non - conventional warfare (Nuclear, Biological and Chemical warfare, guerrilla warfare including terrorism).

(d) Refugees : Forced movements of large number of people usually across the frontiers.

Elements of Disaster Management

The spectrum of disaster management involves disaster prevention, mitigation, preparedness, response and recovery (Fig. - 1).

Fig. - 1 : Elements in the disaster management

(a) Disaster Prevention : It covers those measures, which are aimed at impeding the occurrence of a disaster event and/or preventing such an occurrence having harmful effects on communities. It is concerned with the formulations and implementation of long-range policies and programs.

(b) Disaster Mitigation : Measures aimed at reducing the impact of a natural or man-made disaster on a nation or community.

(c) Disaster Preparedness : Measures, which enable governments, organizations, communities and individuals to respond rapidly and effectively to disaster situations. Preparedness measures include the formulation of viable disaster plans, the maintenance of resources and the training of personnel. Organizing, planning coordinating, resources planning and training are its major concerns.

(d) Disaster Response : Response measures are those, which are taken immediately, prior to and following disasters. Such measures are directed towards saving life and protecting property and dealing with the immediate damage caused by the disaster. Its success depends vitally on good preparedness.

(e) Disaster Recovery : Recovery is the process by which communities and the nations are assisted in returning to their proper level of functioning following a disaster. Disaster

situation has been conceptualized as a process with differing phases. In each different phase, the information needed, the action required, the problem encountered and people involved may be quite different.

Principles of Disaster Planning

Disaster Management means a planned and systematic approach towards understanding and solving problems in the wake of disasters. Disaster planning cannot prevent disasters but its effect could be minimized by appropriate plans and preparedness. The key issues in disaster management are communication, coordination and control. Important issues in pre-disaster management are prediction, prevention, planning and preparedness. The critical issues when disaster event occurs are the immediate response, rescue, relief and rehabilitation. Fig. 1 shows elements in the management of a disaster.

Effects of Disaster

These are summarised in Table - 1.

Health Problems Common to all Disasters

(a) Social reactions : These could be grouped as follows :

- (i) Spontaneous behavioral reactions e.g. generalized panic or stunned waiting.
- (ii) Widespread looting

Table - 1 : Effects of Disaster

Effects	Type of Disaster			
	<i>Earth-quakes</i>	<i>High Winds (Without Flooding)</i>	<i>Tidal waves (Flash Floods)</i>	<i>Floods</i>
Death	Many	Few	Many	Few
Severe injuries requires extensive care	Overwhelming	Moderate	Few	Few
Increased communicable disease load	Potential risk following all major disaster (Probably rising with overcrowding and declining sanitary conditions)			
Food scarcity	Rare	Rare	Common	Common
Population displacements and movements	Rare	Rare	Common	Common

- (iii) Rumors regarding spread of epidemic
- (iv) Population displacements leading to excessive burden on relatives and friends, parks city squares, vacant lots and government buildings in urban areas where public services can't cope resulting in increased morbidity and mortality.

(b) Exposure to elements : The need to provide emergency shelter varies greatly with local conditions.

(c) Food and Nutrition : Food shortages in the immediate aftermath may arise in two ways. Food stock destruction within the disaster area may reduce the absolute amount of food available, or disruption of distribution system may curtail access to food even if there is no absolute shortage.

(d) Communicable Diseases : The transmission of communicable diseases after natural disasters may be influenced by following factors :

(i) Pre existing Diseases in the Population : The risk of epidemic after a disaster is related to the endemic levels of diseases in the population. Where a disease agent did not exist in a population before a disaster, there is generally no risk of an outbreak occurring. These include diarrhea and dysentery, cholera, measles, whooping cough, meningococcal meningitis, tuberculosis, malaria, intestinal parasites, scabies and other skin diseases, louse borne typhus and relapsing fever.

(ii) Ecological Changes resulting from Natural Disasters : Natural disasters may alter the potential for disease transmission by altering the ecological conditions. In this context, the most important diseases are those transmitted by mosquito vectors and by water. The breakdown in living conditions following disasters may increase the hazard of transmission of plague, louse borne typhus and relapsing fever. The incidence of dog bite and risk of rabies may increase as neglected strays come in close contact with persons living in temporary shelters.

(iii) Population Movements : Population movements may influence the transmission of diseases by increasing population density causing burden on the water supply and other services in the receiving areas and/or introducing susceptible population to a new disease or disease vector. The important diseases to occur in temporary settlements are diarrheal diseases and dysentery, viral hepatitis, measles, whooping cough, malaria, tuberculosis, scabies and other skin infections.

(iv) Damage to public Utilities : Damage to water supplies and sewage disposal systems may increase water borne and excremental diseases.

(v) Interruption in Public Health Services : The important services interrupted in this context are vector control programme, which might lead to resurgence of malaria and other vector borne diseases, routine immunization programme against measles, whooping cough, poliomyelitis, tuberculosis and diphtheria.

(vi) Altered Individual Resistance to diseases : Protein Energy Malnutrition, which affects children in poorer population of most of the developing countries, increases susceptibility to many communicable diseases including malaria and tuberculosis.

Medical Care for Disaster

The principles of mass casualty management are universal and can be applied in any mass casualty situation, natural

or man-made. The importance of triage, first aid, life saving measures, transport and evacuation for definitive care to hospital has been recognized the world over. The mass casualty management demands standard simple therapeutic procedures and standardized drugs & medical supplies. On site care demands establishment of a command post triage team, first aid team, mobile hospital (if required), evacuation team, transport and communication.

Disaster Preparedness

Disaster plan should be realistic, adaptable and harmonized at all levels. It must be clearly written and periodically tested. It should include

- (a) Resources plans for health care.
- (b) Role and responsibility of resources organization.
- (c) Logistics, equipment and supplies required.
- (d) Arrangement for communication, transportation and evacuation.
- (e) Coordination and control.
- (f) Disaster drills.

Disaster Management Plan for Natural Disasters

All disasters are unique in that they affect areas with different social, medical and economic backgrounds. The peculiar problems associated with disasters are essentially due to increased load of communicable diseases, food scarcity and mass population displacements and movements. Disaster management includes certain interventions namely good site planning, provision of basic clinical services, shelter, clean water, good sanitation, vaccination and control of disease vectors. The diseases prevented by these interventions are given in Table - 2.

Preventive measures	Impact on spread of
Site planning	Diarrhoeal diseases, acute respiratory infections
Clean water	Diarrhoeal diseases, typhoid fever, hepatitis A and E
Good Sanitation	Diarrhoeal diseases, vector-borne diseases, scabies
Adequate nutrition	Tuberculosis, measles, acute respiratory infections
Vaccination	Measles, meningitis, Japanese encephalitis, diphtheria
Vector control	Malaria, plague, dengue, Japanese encephalitis, other viral haemorrhagic fevers
Personal protection (insecticide-treated nets, clothing, shoes)	Malaria, leishmaniasis, leptospirosis
Personal hygiene	Louse-borne diseases, typhus
Health education	Diarrhoeal diseases

Organisation of Medical Setup

The State Chief Secretary should be overall incharge of Disaster Management in the State. The medical aspects will be coordinated by the State DGHS. He will ensure that adequate manpower reserves are rushed from non affected areas in the State to those which are worst affected so that medical manpower is properly augmented.

At the District Level, the District Collector will be the Chief Executive of the Disaster management cell. He will be in a position to coordinate all relief efforts with various departments including ensuring NGO participation. The medical team will be headed by the Chief Medical Officer (CMO) of the district. The various programme officers under him like the District Malaria Officer, the District Immunisation Officer, etc will ensure availability of equipment, stores and manpower required for disaster activities. The District hospital will be responsible for providing referral services for curative care as well as outreach teams to be deployed at short notice in affected remote areas. These teams should have medical officers, surgeon, anaesthetists and adequate paramedical staff. The nodal peripheral unit for providing medical relief will be the PHC of the area and the MO i/c PHC will coordinate all efforts and seek assistance of the CMO as and when required. The sub-centre staff will support him in all the activities.

Public Health Aspects

The important aspects include provisioning of appropriate shelter for displaced population, potable water supply, food and nutrition and sanitation.

Excreta Disposal : Improper excreta disposal contaminates soil and water sources. It also often serves as a breeding ground for certain species of flies and mosquitoes, giving them the opportunity to lay their eggs and multiply or to feed and transmit the infection. It also attracts domestic animals and rodents which carry fecal matter on them and with it, potential diseases. Furthermore, this situation usually creates unsightly areas and disagreeable odors. The goal of sanitary excreta disposal is to isolate excrement so the infectious agents in it cannot reach a new host. The method selected for a given area or region will depend on many factors, including local geology and hydrogeology, the communities' culture and preferences, the materials available locally and the cost.

The aim is to develop physical barriers against the transmissions of diseases, in order to protect the health of the disaster affected population. These barriers include both engineering measures and personal hygiene measures. The provision of latrine and the development of methods of waste disposal are essential elements of the programme. These measures are only fully effective, when complemented by a sanitation education programme. The efficient and safe disposal of human excreta is as important as the provision of water in its positive effect on the health of the emergency affected population. Human excreta are more likely to transmit diseases than animal waste. It contributes to the transmission of numerous diseases (particularly when combined with low levels of nutrition) and can also be a breeding ground for flies and other insects. In the acute phase of an emergency, any form of excreta disposal is better than none. The simplest and quickest methods should be

adopted; these can later be improved on and changed initially speedy action is important in averting human catastrophe.

What to do :

- a. If there are no sanitation services, latrines must be built (individual, collective, portable).
- b. Before installing a latrine, the soil at the site must be evaluated along with topographical conditions, user access and the presence of surface and ground water in the surrounding area.
- c. If the land is not appropriate for latrine construction (rocky soil or high water table) aboveground latrines with removable tanks must be built. The excreta must be transported to a pit located on appropriate ground, for immediate burial.
- d. Estimate the number of latrines to be installed, based on the number of persons in the shelter (1 waterless toilet/25 women and 1 waterless toilet and 1 urinal/35 men).
- e. Provide information and instructions to the population on throwing used toilet paper into the latrine.
 - Using the sanitation services only for defecating or urinating (do not store tools or other items in the latrine)
 - Washing their hands with soap and water after urinating or defecating.
 - Keeping the floor, walls and area surrounding the latrine clean.

Not defecating or urinating outdoors in the area around the sanitation services or near bodies of water, since this encourages the proliferation of flies and larvae and water contamination through water runoff.

What not to do :

- a. Install excreta disposal systems without first assessing the situation (existence of sanitation services, number of users and characteristics of the site, among others)
- b. Select the location of the sanitation services without taking into account the characteristics of the site (soil type, topography, accessibility, presence of bodies of water, etc.)
- c. Try to implement sophisticated excreta disposal technologies without having facilities to operate / maintain.

Accommodation : In natural disaster, the displaced population must be sheltered in temporary settlements or camps. The selections of sites must be well planned to avoid risk factors for communicable diseases transmission, such as overcrowding, poor hygiene and inadequate water supply, insanitary disposal of excreta vector, inadequate sites and lack of adequate shelter. Such conditions favour the transmission of diseases such as measles, meningitis and cholera. Critical factors to consider when planning a site are : water availability, means of transport, access to fuel and access to fertile soil. The guidelines are given in Table - 3. The surrounding environment may also pose a threat to health in the form of vectors not encountered in the population's previous place of residence. In order to reduce such risks it is essential that site selections, planning and organization be undertaken as soon as possible.

Water supply : Water and sanitation are vital elements in the transmission of communicable diseases and in the spread of diseases prone to cause epidemic. Diarrheal diseases are

Area per person for collective activities	30 m ²
Shelter space per persons	3.4 m ² (4.5 -5.5 m ² in cold climates)
Distance between shelters	2m minimum
Area for support services	7.5 m ² /persons
Number of people per water point	250
Number of people per latrine	20
Distance to water point	150 m maximum
Distance to latrine	30m
Distance between water point and latrine	100m
Firebreaks	75m every 300m

a major cause of morbidity and mortality among affected populations, most being caused by a lack of safe water, inadequate excreta disposal facilities and poor hygiene. The goal of proper water and sanitation facilities is to minimize risks to the health of a population, particularly one caught up in the difficult circumstances of an emergency with its attendant displacement and dangers. Such a programme is an integral part of preventive health activities. The main focus of such a programme is on the following :

- (a) The provision of a safe and sufficient water supply
- (b) Provision for excreta disposal and the establishment of other waste control and hygiene measures
- (c) A programme of public education of the affected population on the issue of hygiene and water use.

In a natural disaster, the affected population need immediate access to a water supply in order to maintain health and to reduce the risk of epidemics. If the emergency affected populations have to be sheltered in temporary settlements or camps, water supply is an essential consideration in choosing the site location. An adequate amount of safe drinking water must be provided for the entire displaced population. The first objective is to provide sufficient water; quality can be addressed later, sufficient water of low quality is better than very little water of high quality. During the rapid assessment of a proposed site it is essential to protect existing water sources from possible contamination. If the population has already moved into the area in question, then immediate measures should be taken to isolate and protect the water sources, if it is on or near the site. Table - 4 gives the recommended doses of Chlorine tablets that can be distributed to the affected population to prevent diarrheal diseases. Location, design and number of water distribution points are given in Table - 5.

Solid Waste : Solid waste may be refuse, manure for animal cadavers. There is a correlation between improper solid waste disposal and the incidence of vector-borne diseases. As a result, arrangements must be made to collect, store and dispose of solid waste.

What to do

- a. Assess the situation, considering the number of people in the shelter, existing services, collection service, topographic conditions, accessibility and soil type (if the waste must be disposed of on site).

- b. Estimate the quantity, type and capacity of the water storage containers, based on the number of persons and existing services. For a short time, empty food containers, plastic or water-resistant paper bags and disposable packaging can be used. The capacity of the containers should be 50-100 liters and should not exceed 20-25 kg when full.
- c. Provide three or four containers per 100 persons and distribute them so that every family has access to a container (or plastic bag).
- d. The containers should not touch the ground, for example they should be on a wooden platform. They must be emptied and washed daily.
- e. If there is regular waste collection and final disposal service :
 - Coordinate with the responsible entity to cover refuse collection from the shelter or camp.
 - Check the accessibility of the regular collection service and take the appropriate steps for the shelter or camp.
 - If the regular service does not have access to the shelter or camp, place waste pick-up sites in the surrounding area and locate storage bins or containers away from water sources.
- f. If there is no regular waste collection and final disposal service :
 - Organize collection, transport and final waste disposal service, involving the persons living in the shelter or camp.
 - For final disposal, bury the waste by building pits 1.5 meters wide, 1.5 meters long and 2 meters deep. At the end of each day, cover the refuse with 15 cm of dirt and pack it down. This pit will last 10 days for a population of 200. For larger populations, increase pit size proportionately, up to a maximum of 3 meters x 3 meters. Before the pit is full, cover it with a layer of packed dirt 40 cm thick, so that it is level with the ground. Then dig a new pit.
- g. Dead animals and excrement from domestic animals must be buried immediately, since they can be a source of contamination.
- h. Provide information and training to the population on sanitary refuse handling.

What not to do

- a. Request tools, containers, bins, plastic containers or other devices without first assessing the situation.

		Type of water source			
		<i>Clear piped water</i>	<i>Protected tube wells, ring wells, clear rain water</i>	<i>Unprotected wells and cloudy water (filtered before purifying)</i>	<i>Water known to have faecal contamination (filtered before purifying)</i>
Tablet Size	Chlorine per tablet (mg)	Volume of water treated per tablet (Litres)			
8.5mg	5	5	2.5	1	0.5
17mg	10	10	5	2	1
67 mg	39.41	39.41	19.7	7.77	3.94
340mg	200	200	10	40	20
500mg	294	294	147	58.5	29.4
Free available chlorine content after treatment (Residual)		1mg/Litre	2mg/Litre	5mg/Litre	10mg/Litre

Location	Water distribution point must be set up in suitable places around the camp. A good location is an elevated spot in the centre of a living area. If the water points are from ground sources, no sanitation facilities should be within 50 meters and definitely not closer than 30 meters. If the water point is too far away, people will not collect.
Design	When designing water points consider the following : - Traditional water carrying methods - The containers used : for example, a raised area is suitable for people who carry the bucket on their heads - Persons collecting and carrying the water (it is usually the women and children) - The availability of spare parts. - There should be enough space on the concrete slab around the water point for laundry and bathing areas. If sanitation is compromised, it may be felt necessary to locate bathing and washing areas away from collection points. However, traditional practices and habits need to be accommodated as much as possible. Animals must certainly be kept away. If they are mobile herds, watering facilities should be established some distance away and a fence erected around the water point.
Number	One tap per 200-250 people is the ration recommended by the United Nations High Commissioner for Refugees (UNHCR). The more the people per tap, the more would be wear and tear. Nobody should have to wait longer than a few minutes : if collection takes a long time, people will return to old, contaminated but quicker sources.

- b. Mix common waste with medical waste, thus endangering the population.
- c. Accept or request sophisticated technology for treating medical waste without having the facilities or trained personnel to operate it.

Vector control : The purpose of a vector control programme is to reduce disease transmission by rendering the environment unfavourable for the development and survival of the vector. Prevention is better than cure and when the planning and construction of camps is undertaken, preventing the development of vector problems should be taken into account. The vector population and its life expectancy should be kept to a minimum. Community adhesion and participation in a vector control programme is essential for its success. Early diagnosis and treatment are needed to prevent severe forms of the disease (especially for malaria) when transmission control is needed to reduce incidence. Both are complementary and

two essential components of any effective vector borne disease control programme.

Types of vectors : The major biological vectors are mosquitoes, sand flies, ticks, fleas, lice, mites. Important carrier reservoirs or intermediary hosts are synanthropic flies and rodents.

Diseases spread : The diseases most commonly spread by vectors are malaria, filariasis, dengue fever, leishmaniasis, typhus and plague. Major diseases transmitted by intermediate hosts or carriers are schistosomiasis, diarrhoeal diseases and trachoma.

Prevention : The main methods of control in emergency situations can be classified into the following groups :

- Residual spraying,
- Personal protection,
- Environmental control,
- Camp site and shelter design and layout,
- Community awareness.

Indoor Residual Spraying : This is a recommended technique for controlling mosquitoes and sandflies. It is the most common method in the post-emergency phase when the displaced population is living in more permanent dwellings such as huts or houses. IRS is very effective in almost all epidemiological settings and recommended as the first line intervention to control epidemics. *Ground space spraying*, either Ultra-Low-Volume (ULV) cold mist or thermal fogging, is not the preferred intervention for malaria vector control in emergency situations. In the context of camps, especially in crowded areas, ground space spraying can be resorted to if residual spraying is delayed or cannot be implemented. Pyrethrins or pyrethroids are the best choice for such application but organophosphate insecticides are also suitable.

Personal protection : Personal protection against the spread of disease includes a variety of methods : insecticide-treated nets, treated sheets and blankets, personal hygiene, insect repellents and clothing and dusting powder. *Insecticide-Treated Nets* (ITNs) are primarily used to protect against mosquito. Daily bathing, washing of hands after using the latrine, regular washing of clothes and good food and water storage practices can prevent the spread of fly-borne diseases. Biting by mosquitoes, flies and ticks can be reduced by wearing long-sleeved shirts and long trousers and by using insect repellents. Appropriate *dusting powders* can be used in the treatment of flea and louse infestations.

Environmental control : Environmental control strategies aim to minimize the spread of disease by reducing the number of vector breeding sites. Some of the most important measures, namely the provision of clean water, the provision and maintenance of sanitary latrines and the efficient and safe disposal of waste water are other important aspects to be looked into. Larvicides may be applied via hand-carried, vehicle-mounted or aerial equipment. The larvicide is added to water at sites that are recognized breeding grounds, such as ponds or water jars, in areas where the breeding sites are limited in number. Long-term measures, such as land drainage or filling, should be planned and implemented to avoid future spraying.

Community awareness and health education : Community participation in a vector control programme is essential for its success. It allows the implementing agency to develop an awareness of community practices that prevent or encourage the spread of disease. Both the community and the vector control team can develop strategies that can be implemented with some degree of success. Information on the spread of disease can be disseminated in a culturally sensitive manner.

Food and nutrition : Food shortages and malnutrition are common features of emergency situations. Ensuring that the food and nutritional needs of an emergency-affected population are met is often the principal component of the humanitarian response to an emergency. When the nutritional needs of a population are not met, this may result in protein-energy malnutrition and micronutrient deficiencies such as iron-deficiency anaemia, pellagra, scurvy and vitamin A deficiency. There is also a marked increase in the incidence of communicable diseases, especially among vulnerable groups such as infants and young children and these contribute further

to the deterioration of their nutritional status.

The mean daily per capita energy requirements for some population groups vary depending on the weight, age, gender and physical activity of the individual. Energy requirements increase during certain specific situations, such as the second and third trimesters of pregnancy, lactation, infection (e.g. tuberculosis) and recovery from illness (for every 1°C rise in body temperature there is a 10% increase in energy requirements), cold temperatures (an increase of 100 kcal per person for every 5 °C below 20 °C), moderate or heavy labour. The mean energy requirement is 2100Kcal per person per day, out of which 17-20% of energy should be in the form of fats or oils and 10-12% from proteins.

Food is an important source of pathogens and there is a risk of diarrhoeal disease epidemics when basic food safety principles are not followed. It is estimated that 70% of diarrhoeal episodes in children under the age of 5 years are due to the consumption of contaminated food. There are a number of routine practices that should be adhered to when preparing food, in both the household and in health facilities. To overcome this menace following actions are recommended :

- Ensure an adequate water supply.
- When preparing food or washing utensils, use a chlorinated water supply.
- Store food in sealed containers.
- Ensure that food is covered during cooking and prior to serving.
- Ensure that cooked food is consumed once prepared.
- Cover food when served, if left unattended.
- Place hand-washing facilities outside latrines, living areas and kitchens.
- Ensure that people use them.
- Ensure an adequate number of sanitary latrines and that they are maintained and used.
- All areas in a feeding centre must be cleaned daily using chlorine as a disinfectant.
- Cover water containers at all times.
- Ensure that water is taken either from a tap or from a clean container.
- Disposal of garbage safely.

Prevention & control of communicable diseases: The prevention and control measures of communicable diseases should be on the following broad principles.

(a) Setting up a Surveillance System : It is established to collect, collate and interpret the data, It will need the services of an epidemiologist/public health specialist, paramedical and health personal and clerical staff.

(b) Disease Surveillance : The objective of disease surveillance after disaster is to identify disease outbreak, in order to investigate them and to instigate appropriate disease control measures. The diseases considered for surveillance include those known to be endemic to the area, those, which represent a serious health hazard and those, which are amenable to control. A more focused, system based surveillance system should be instituted. This system complex, which might be important, include fever, fever and diarrhea, fever and cough, trauma, burns, measles etc. This data should be analyzed, interpreted and presented to the higher authorities (6, 7).

(c) **Laboratory Services** : Lab for basic diagnostic tests of stool and blood may be established by field reporting units but for specific bacteriological and virological tests, the referral labs in nearby cities or areas will have to be marked (7, 8, 9).

(d) **Vaccinations and Vaccination Programs** : Mass vaccination campaigns against Tetanus and Measles will be helpful, as well as some other vaccines for specific diseases, depending on the threat perception (7, 8, 9). However mass vaccination campaign against typhoid and cholera should be avoided because of the following reasons :

- (i) Offer low and little individual protection.
- (ii) Complete coverage of population is probably impossible
- (iii) Require large number of workers who could be better employed elsewhere.
- (iv) Could lead to reuse of inadequately sterilized needles that may transmit Hepatitis B/HIV.
- (v) May lead to false sense of security about the risk of diseases and to neglect effective control measures.

Surveillance system : The objectives of a surveillance system in a disaster are to :

- (a) Identify public health priorities.
- (b) Monitor the severity of an emergency by collecting and analyzing mortality and morbidity data.
- (c) Detect outbreaks and monitor response.
- (d) Monitor trends in incidence and case-fatality from major diseases.
- (e) Monitor the impact of specific health interventions (e.g. a reduction in malaria incidence rates after the implementation of vector control programmes).
- (f) Provide information to the Ministry of Health, agency headquarters and donors to assist in health programme planning, implementation and adaptation and resources mobilization.

Experience from many disaster situations has shown that certain diseases/syndromes must always be considered as priorities and monitored systematically. In the acute phase of an emergency, the major diseases/syndromes that should be reported are : Bloody diarrhoea; Acute watery diarrhea; Suspected cholera; Lower respiratory tract infections; Measles; and Meningitis. After the second/third week the following diseases should be added on : Malaria; Dengue/DHF; JE; Leptospirosis; and Septic dermatological complications. Lab for basic diagnostic tests of stool and blood may be established by field reporting units but for specific bacteriological and virological tests, the referral labs in nearby cities or areas will have to be marked.

Burial / Disposal of the Dead : Bodies are unlikely to cause outbreaks of diseases such as typhoid fever, cholera, if death resulted from trauma. However, they may transmit gastroenteritis or food poisoning syndrome to survivors if they contaminate water sources. Despite the negligible risk, dead bodies represent a delicate social problem. The normal local method of burial or cremation should be used although mass cremation requires large amounts of fuel. Before disposal, bodies must be identified and the identifications recorded.

Suggested Logistics Planning

The suggested (approximate) requirements of drugs, vaccines and insecticides / hygiene chemicals for a displaced population

for a period of 30 days are laid down in Table 6a, b & c. Readers may please note that these are only suggestions for logistic planning and the actual requirement should be worked out after actual on-ground assessment of the displaced population.

Vaccine	Doses
Typhoid oral	600
Cholera	400
Measles	250
Japanese Encephalitis	250
Tetanus Toxoid	300
Tetanus immunoglobulin	300
Meningococcal vaccine	300
Vaccine Carrier	15
Cold boxes	10

Thermal fogger	01
Knapsack sprayer(16L)	02
Compression sprayer(12L)	03
ULV fogger	01
Malathion EC 50% DDP WP	300 l/Kg
Temephos/Baytex EC	10L
Aquatabs (17 mg)	1,00,000
DMP oil	25L
Impregnated bed nets*	600
Bleaching powder (33# Available Chlorine)	30 Kg
Cresoli Black	150L
* alternatively, 6 ltrs of 2.5% deltamethrin solution will be required to impregnate 600 bed nets

Summary

Worldwide, natural disasters have been known to be one of the major problems. India is amongst the most disaster prone countries in the world. Adequate procedures to deal with disaster situations are necessary. Disaster management requires well-coordinated public policy for disaster prevention, mitigation, preparedness, emergency response and reconstruction. Health care in disaster is one of the critical elements. Disasters are defined as an 'overwhelming ecological disruption which exceeds the capacity of a community to adjust and consequently requires assistance from outside. Disasters can be classified into natural disasters (which would include Meteorological, Topological & Biological disasters) and Manmade disasters (that would include Accidents, Civil disturbances & Warfare). The spectrum of disaster management involves disaster prevention, mitigation, preparedness, response and recovery. Disaster Management means a planned and systematic approach towards understanding and solving problems in the wake of disasters. The key issues in disaster management are communication, coordination and control. Important issue in pre-disaster management is prediction, prevention, planning and preparedness.

There are some health problems which are common to all types of disasters. These include Social reactions (such as looting,

rumor spreading etc.), Exposure to elements - depending on local conditions and issues of Food and Nutrition. Also prominent among the health problems would be risk of spread of communicable diseases, the occurrence of which would depend on factors such as pre-existing Diseases in the Population, Ecological Changes Resulting from Natural Disasters, Population Movements, Damage to public Utilities, Interruption in Public Health Services and Altered Individual Resistance to diseases. The principles of mass casualty management during disaster include the vital elements of triage, first aid, life saving measures, transport and evacuation for definitive care to hospital has been recognized the world over. Disaster plan for preparedness should be unambiguous, well-rehearsed and must specify Resources plans for health care and Coordination and control, among other essentials. Disaster management plan should include good site planning, provision of basic clinical services, shelter, clean water, good sanitation, vaccination, healthy food and nutrition and control of disease vectors. In organization of medical set-up, the nodal point(s)/ personnel in-charge of co-ordination and execution of activities would be : State Chief Secretary & District Collector at respective levels for overall administration, State DGHS, Chief Medical Officer (CMO) of the district and MO i/c PHC at respective levels for the medical aspects. The aim of hygienic excreta disposal is to develop physical barriers against the transmissions of diseases, in order to protect the health of the disaster affected population. These barriers include both engineering measures and personal hygiene measures. The simplest and most effective measure in this context would be construction of appropriate latrines (catering to aspects such as topography, numbers) and also educating the public on relevant aspects. Temporary settlements or camps would form the best possible mode of accommodation in disaster scenario. The selection of sites must be well planned to avoid risk factors for communicable diseases transmission and keeping in mind water availability means of transport, access to fuel and access to fertile soil. The goal of proper water and sanitation facilities is to minimize risks of water-borne diseases such as diarrheal diseases to the population. In a disaster, the affected populations need immediate access to a water supply in order to maintain health and to reduce the risk of epidemics. The first objective is to provide sufficient water; quality can be addressed later. Appropriate chlorination, proper location of water distribution points and health education are inevitable steps in this regard. Necessary arrangements must be made for collection, storage and disposal of solid waste. The vital steps would be assessment of the situation, tailor-making the supplies- quantity and quality-wise; according to the need (a thumb-rule could be 03 or 04 containers per 100 persons) and proper disposal, depending on whether regular waste collection and final disposal service are available or not. Preventing the development of vector problems should be taken into account, when the planning and construction of camps is undertaken. Community adhesion and participation in a vector control programme is essential for its success The main methods of vector control in emergency situations would include residual spraying (preferably Indoor Residual spraying with pyrethrin or pyrethroids), personal protective measures [using Insecticide-Treated Nets (ITNs) and/or dusting powders], environmental

control (measures such as provision of clean water, provision and maintenance of sanitary latrines for short –term purposes and land drainage or filling for long –term), campsite and shelter design and layout and creation of community awareness. Ensuring that the food and nutritional needs of an emergency-affected population are met is often the principal component of the humanitarian response to an emergency, since protein–energy malnutrition, micronutrient deficiencies and a marked increase in the incidence of communicable diseases, especially among vulnerable groups will result if due care is not accorded to provision of adequate healthy food. The mean daily per capita energy requirements for some population groups vary depending on the weight, age, gender and physical activity of the individual. There are a number of routine practices that should be adhered to when preparing food, in both the household and in health facilities. Some useful measures in this regard would include, among other points, ensuring an adequate and safe water supply, placing hand-washing facilities outside latrines, living areas and kitchens and so on. The prevention and control measures of communicable diseases during disasters should be on the broad principles of Setting up a Surveillance System, Disease Surveillance, establishment of Lab facilities for basic diagnostic tests of stool and blood, mass vaccinations and Vaccination Programs (definitely targeting Tetanus and Measles, but never against Typhoid or Cholera). The normal local method of burial or cremation should be used, after proper identification and recording. Requirements of drugs, vaccines and insecticides / hygiene chemicals should be worked out after actual on-ground assessment of the displaced population.

Study Exercises

MCQs and Exercises

- All of the following are examples of natural disasters except (a) Meteorological Disasters (b) Topological Disasters (c) Accidents (d) Biological Disasters.
- All of the following are Elements of Disaster Management, except : (a) Disaster Treatment (b) Disaster Preparedness (c) Disaster Response (d) Disaster Recovery .
- Measures aimed at reducing the impact of a natural or man-made disaster on a nation or community, is collectively known by the term (a) Disaster Response (b) Disaster Mitigation (c) Disaster Recovery (d) Disaster Prevention.
- Relief, Rehabilitation and reconstruction are essential components of (a) Disaster Mitigation (b) Disaster Response (c) Both of the above (d) None of the above.
- Overwhelming number of Severe injuries which require extensive care, when compare to other disasters, take place in (a) Flooding (b) Tidal waves (c) High winds (d) Earthquakes.
- All of the following factors influence the transmission of communicable diseases after natural disasters, except (a) Damage to public Utilities (b) Population Movements (c) Interruption in Public Health Services (d) Social reactions.
- The nodal peripheral unit for providing medical relief in times of disasters, will be (a) Sub-centre (b) Anganwadi (c) Primary Health Centre (d) District hospital.
- At the District Level, the CMO (Chief Medical Officer) will be the Chief Executive of the Disaster management cell. Yes/ No.
- Among the following choices, the most appropriate one while constructing toilets in disaster scenario, will be (a) 1 waterless toilet/25 women (b) 1 waterless toilet/25 men (c) 1 waterless toilet/35 women (d) 1 waterless toilet/45 men.
- While considering factors for proper accommodation of homeless persons in disaster situation, the distance from the site to the water point should be not more than (a) 50 meters (b) 100 meters (c) 150 meters (d) 250 meters.
- Sufficient water of low quality is better than very little water of high quality, in disaster scenarios. Yes /No.
- While locating water points during times of disasters, if the water points are from ground sources, no sanitation facilities should be definitely not closer than a distance of (a) 50 meters (b) 100 meters (c) 10 meters (d) 30 meters.
- The ratio of taps to persons as recommended by the United Nations High Commissioner for Refugees (UNHCR), especially in setting of disasters, is (a) One tap per 100-150 people (b) One tap per 200-250 people (c) One tap per 250-300 people (d) One tap per 50-100 people.
- The maximum permissible weight of solid waste that can be collected in a single container, (i. e weight of a single container, when full), is (a) 20-25 kg (b) 30-35 kg (c) 40-45 kg (d) 50-55 kg.
- The Insecticidal method of choice for controlling mosquitoes and sandflies during disaster situations is (a) Space spraying (b) Knockdown spraying (c) Indoor residual spraying (d) Ground spraying.
- The mean energy requirement per person per day, that has to be catered for by provision of appropriate food, at times of disasters, is (a) 2500 Kcal (b) 2000 Kcal (c) 2100 Kcal (d) 2300 Kcal.
- Mass vaccination campaigns against one of the following diseases would be imperative and helpful in times of disasters (a) Typhoid (b) Cholera (c) Scrub Typhus (d) Measles.
- Match the following features in column A with that in Column B.

Column A	Column B
<i>Type of water at source</i>	<i>Recommended Free available chlorine content after treatment (Residual)</i>
(a) Clear rain water	(i) 5mg/Litre
(b) Unprotected wells	(ii) 1mg/Litre
(c) Water known to have faecal contamination	(iii) 2mg/Litre
(d) Clear piped water	(iv) 10mg/Litre

Answers : (1) c; (2) a; (3) b; (4) b; (5) d; (6) d; (7) c; (8) No; (9) a; (10) c; (11) Yes; (12) d; (13) b; (14) a; (15) Yes; (16) c ;(17) d; (18) (a) iii; (b) i; (c) iv; (d) ii.

Anuj Bhatnagar

World Health Organisation (WHO) has defined a 'hospital' as *'an integral part of a social and medical organization, the functions of which are to provide to the population, complete health care, both curative and preventive including out-patient services which reach out to the family in its own environment and also carry out training of health workers/functionaries and undertake bio-social research'*. Besides this comprehensive WHO definition, a hospital has also been described as an institution which is operated for medical, surgical and/or obstetrical care of in-patients and which is deemed to be a hospital by the government or local licensing bodies (Directory of Hospitals in India, 1988)

Hospitals are generally considered as institutions where the sick and injured are treated as indoor patients, in comparison to *dispensaries* where primarily out-door patients are treated and medicines are distributed. Thus, a hospital can be described as an organisation which provides health care services (preventive, promotive and curative) by pooling in the various skills & services of health professionals, supportive staff and ancillary staff, with the overall objective to provide health care to patients.

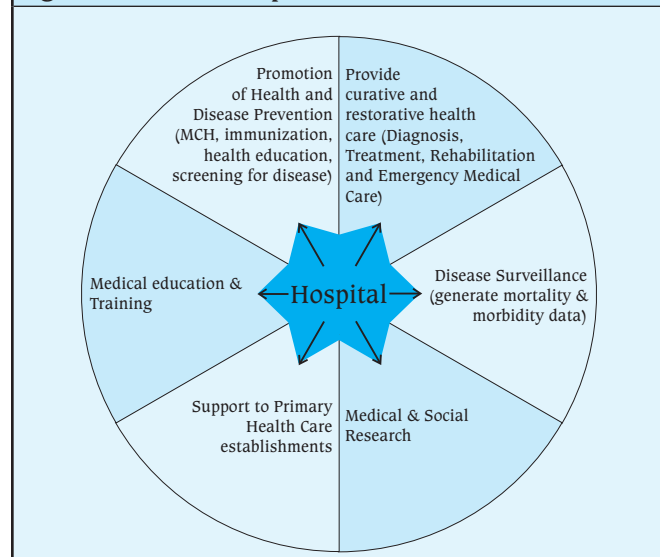

Role of a Hospital

The role of a hospital in a community can be summarized graphically as shown in Fig. - 1.

Peculiarities of a Hospital as an Organisation

As a health manager, one should be acutely aware that a hospital differs greatly from any other organisation. It is a highly complex institution which brings together highly qualified and highly technical professionals for common cause of providing comprehensive health care and medical care to patients, in the most cost-effective manner, within the limited available resources. The peculiarity of a hospital as an organisation is enhanced since the 'product' in a hospital is 'medical care',

Fig. - 1 : Role of a Hospital

which is highly personalized, professional and technical in nature and hence can not be assessed in quality by a lay person.

This 'service' provided by a hospital can not be quantified in any economic/financial terms and can not be evaluated on any objective criteria for quality and standard. Hospital care and service differs for every patient depending on his/her condition & requirements and thus standardization of such medical care is not possible. Pre-planning at micro level is not possible in a hospital and most often, hospital management is *management by crisis* wherein each patient is unique requiring highly professional and personalized medical care, provided by the entire team rather than any one individual. A hospital also employs a wide variety of people, from highly trained professionals to unskilled individuals. It is thus a challenge for any hospital manager to manage people of such wide ranging skills as a team and to make them work together. In addition, staff in a hospital is always under dual control, with *professional control* vested with heads of respective departments and

administrative control vested with the hospital administrators, which often leads to conflict of interest among the various members of the team.

Work Areas of a Hospital

A hospital can be broadly divided into :

(a) **Clinical Areas** : A&E Dept, OPD, Operation Theatre, ICU & inpatient services

(b) **Diagnostic Areas** : Laboratory, radiological services, blood transfusion & pharmacy services

(c) **Support Services** : CSSD, medical records dept, laundry services & dietary services

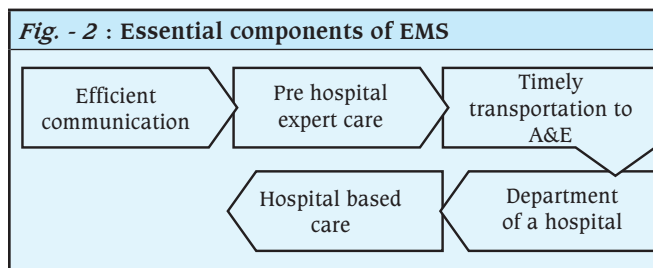

(d) **Auxiliary Services** : Basic and allied engineering services.

Clinical Areas of a Hospital

A hospital comprises of certain key clinical areas which are engaged in the primary task of providing medical care to the patients. These clinical areas are vital areas in hospitals where the actual objective of the hospital (of treating the sick and injured) is achieved through various categories of health care providers. A description of these areas is as follows :

Accident and Emergency Services (A & E Services)

The term "Accident and Emergency Department" was suggested to be used in all hospitals by Platt Committee in UK in 1960s and in India, the Central Council of Health, as early as 1963, recommended the setting up of 'emergency medical services' in all States. *Emergency Medical Services* (EMS) can be described as medical services undertaken with the aim to transport the right patient to the right hospital at the right time so that right treatment can be given, thereby preventing death & disability among such patients. The essential components of EMS are described as in Fig. - 2.

Planning considerations for A&E facilities of a hospital

(i) Patient load (ii) Morbidity pattern (iii) Time of maximum patient load (iv) Location of main roads (v) Communication facilities (vi) Similar facilities for population (vii) Architecture of hospital (viii) Industries / infrastructure in the area.

Role of A&E Services in a Hospital

1. Provisioning of prompt life/limb saving medical care (including surgeries) to patients in need, at all times.
2. Liaise with police and assist the courts in medico-legal cases, but without compromising on the primary duty of providing life saving medical care.
3. To provide ambulance services equipped with trained

manpower and adequate life saving equipment for transport of patient to & from the hospitals.

4. To function as an information centre about seriously injured patient, especially in case of large scale disasters.
5. To sensitively and maturely cater to the emotional needs of relatives of seriously ill/ injured patients brought to the hospital.
6. Continuous training of medical staff in trauma care and emergency medical care.

Planning of an A&E Dept : The basic principle while planning an A&E Dept in a hospital must be remembered that 'design should follow function' that means that various areas should be planned and designed according to their intended function, as under :

(a) **Location** : The A&E Dept should be separated from the main hospital but with access to dependent areas like ICU, OT, laboratories and mortuary etc. It should be situated on ground floor with direct access from main road and a porch for patients to alight from ambulances. There should be adequate facility for parking of ambulances and other patient vehicles. Adequate sign posting (both at day & night) should exist.

(b) **Space requirements** : The A&E Dept should have an average space of 10 square meters per patient visiting the Dept, with an additional 50% of space to avoid overcrowding. For example, if the A&E Dept of a hospital is visited every day by an average of 50 patients, the required space would be 500 square meters + 250 square meters = 750 sq m. There should be facility for expansion of A&E Dept without affecting functioning or form of any other department. Approximately 10% of all patients coming to the hospital visit A&E Dept during any given time; hence there should be 6 parking spaces for every 10, 000 annual visits. All A& E Depts should have a Trolley/Wheel chair bay (1 wheelchair & trolley per 1000 annual visits).

(c) **Planning of facilities** : The A&E Dept of a hospital should be planned to ensure availability of Reception, Registration and Waiting areas. There should also be a police and mass media room. The Dept should have a separate entrance 1.6 meter wide with two-way doors with glass panel at eye height. Triage area, separate examination and treatment areas, resuscitation cubicles, observation beds, plaster room (1 per 15, 000 annual visits), burns room, radiography unit, ECG room, isolation room and an emergency laboratory should also be catered for.

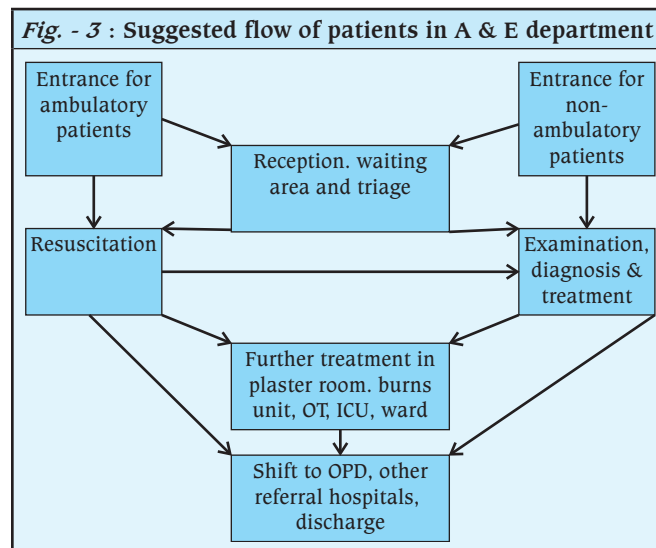

(d) **Architectural design** : While planning the architectural design of an A&E Dept, the following aspects should be kept in mind.

- (i) Entrance should be separate for ambulatory and stretcher-borne patients with two-way swinging doors 1.6 meters wide with glass at eye level. There should be no steps, only ramps with side railings should be provided at the entrance.
- (ii) Waiting area should be in form of a large lobby, including the waiting area which may also be used for triage of patients. Toilets should be located near the main entrance and every specialist cubicle or special investigation should have its own sub-waiting area.
- (iii) Reception, Registration & Records should have an office adjacent to main entrance which should be manned

24 hours. This office should be used for admissions, discharges, billing, record keeping and safe keeping of patients' valuables. There should also be an adjacent Nurses Station and work room.

- (iv) Examination & Treatment area should be in form of cubicles (7m x 13.4m) with temporary partitions which can be removed to expand the area. There should be examination beds which permit access to patients from all sides. Loose hanging wires or clutter of unwanted equipment should be avoided.
- (v) Resuscitation Room should ideally have an area of 30 square meters with all resuscitative equipment & standby emergency electricity supply system. All shelves, drawers & cabinets should be properly labeled.
- (vi) X Ray facility in A&E Dept is desirable if more than 1000 patients undergo radiological investigations in A&E Dept per month. It should have an area of 180 square feet.

Suggested flow of patients in A & E department : It is described in Fig. - 3

Out - Patient Department

An out-patient department (OPD) can be defined as that part of the hospital with allotted physical and medical facilities and staff in adequate numbers, with regularly scheduled hours, to provide care for patients who are not registered as indoor patients. The present magnitude and importance can be gauged from the fact that a hospital OPD load is around 500 patients per bed per year against an inpatient load of 25 patients per bed per year.

Out patients Departments are also called the 'show windows' of hospitals. They are the first point of contact between the patients/their relatives and the hospital staff and the facilities and the care provided in OPDs often are the true reflection and determine the image of the hospital. The important functions of an OPD in a hospital are summarized as under :

- (a) To provide day care investigative, diagnostic and treatment specialist procedures to the community.
- (b) To undertake day care surgical procedures (e.g. vasectomy) for ambulatory patients.

- (c) To conserve hospital beds (and inpatient resources) by acting as an admission filter and admitting only those patients who are actually in need of admission.
- (d) Undertake health education and thus promote health.
- (e) To carry out medical follow up and rehabilitation of patient after discharge from the hospital.
- (f) To undertake various promotive and preventive measures such as antenatal care, vaccination, well baby clinics etc.

Broadly, the OPD Services can be classified into two types. Firstly, the decentralized type in which the specialist services are located in the respective departments (specialty clinics). All specialist services are usually located in a compact area, including all diagnostic and therapeutic facilities (polyclinic).

Planning Considerations and Principles for OPD : The planning of an OPD facility in a hospital would be determined by many key factors. The range of services to be offered (investigative and therapeutic services offered) would determine the space requirement and the capacity of the OPD being planned. Other important considerations for planning an OPD are the number of medical and paramedical personnel available to the hospital for OPD, the service time for patients, type of patients expected, rate of arrival of patients, holding capacity expected & the number of admissions to the hospital. The following principles should be observed for planning an OPD :

(a) Location : The OPD of a hospital should be located near the main road and near the main entrance of the hospital with adequate space for parking of vehicles including ambulances. The OPD should ideally be separate from in-patient wards but connected to them, especially vital investigative centers like pathology laboratory and radiological services.

(b) Patient flow : It should be only in one logical direction with minimal cross traffic. This can be ensured by planning the various facilities in a logical sequence of possible utilization by the patients.

(c) Interdepartmental Resource Sharing : All OPDs should be so located that they are all able to share common and interdepartmental resources of the hospital such as pharmacy, radiological services, pathology services, hospital records, billing etc.

(d) Facility for expansion : All OPDs should be planned and laid so that they can be expanded in future without disrupting the routine functioning.

(e) Physical facilities

(i) Space provisions : The Bureau of Indian Standards (BIS) has laid down the space specifications of 2 square meters per bed for entrance zone, 10 square meters per bed for ambulatory area, 6 square meter per bed for diagnostic zone for OPD area out of a total OPD space specification of 60 square meter per bed for the entire hospital area.

(ii) Public areas in OPD : An OPD should have a wide entrance with double swinging doors with glass at eye level, ramps and steps. Reception and information desk should be located near the entrance in the public area. There should be registration counters (01 desk per 20 patients per hour) with a counter for storing files etc. The waiting area should be at the scale of 0.1 square meter per patient (minimum of 4 square meter) adjacent to Reception/Registration. Sub-waiting areas should

also be provided for specialist consulting rooms & special investigations. Public toilets should be provided separately for males and females at the rate of one toilet each for 200 patients/ visitors. Snack bar should be conveniently located in the waiting area in for large OPD.

(iii) Clinical areas of OPD : These include various specialist consulting areas such as surgical OPD, Ophthalmic OPD, Medical OPD, Dental OPD, Pediatric OPD etc. and may also include certain super specialty OPDs such as cardiology, neurology etc. These specialist and super specialist OPDs should have separate sub-waiting areas and at any given time should not have more than one thirds of the total patients of OPD in each sub-waiting area. The consultation room should have a space of 14-28 square meter, should accommodate all furniture and equipment necessary for examination of patients and each consultation room should be able to cater for examination of 100 cases per day.

(iv) Additional clinical areas : These include

- Injection room with 12-40 square meter area and waiting area for 10-20 patients, depending on the patient load.
- Dressing and Treatment Room with an area of 12-16 square meter.
- Pharmacy is generally the last point to be visited by OPD patients, by which time they are tired, hence it should have multiple dispensing windows & adequate staff to reduce waiting time, in addition to comfortable seating arrangements for the patients.

(v) Auxiliary facilities for OPD : These should be able to provide care both to inpatients and outpatients and thus should be easily approachable from OPD and various wards. The important auxiliary facilities in any hospital are :

- Pathology laboratory with separate male and female toilets (15 square meters) and bleeding room (20 sq mt).
- Radiology Services.
- Blood Bank with adequate waiting area, reception, bleeding room, laboratory, recovery room and storage facility for blood and blood components.
- Health Education Facility with adequate audiovisual aids.
- Medico-Social Service Facility with adequate number of counselors, located in OPD.
- Screening Clinic should be located near the reception with adequate equipment for examining patients where all patients would be initially screened and referred to the appropriate specialist OPD. This reduces the load on specialist OPDs, guides the patients correctly and improves the quality of OPD services.
- Preventive & Promotive Health Care facility with an area of at least 15 square meter, would be the centre for advice on preventive and promotive health aspects such as immunization, nutrition, family welfare & counseling, sanitation etc.

(vi) Administrative Areas of an OPD : These areas should consist of an administrator's office, a business office for personnel section, record keeping, requisitions etc, a janitor's closet for house keeping and adequate storage facility for general stores, drugs (including dangerous and controlled drugs) and linen etc.

(vii) Circulation Areas : These include corridors, lifts and stairs and would occupy almost 30% of the total area of an OPD complex. These areas, esp corridors and doors should be at least 1.8 mt wide to allow the passage of a stretcher with a person on either side. Adequate communication facilities, lighting, public address system and fire fighting facilities should also be provided.

Common problems faced in OPDs :

- (a) Overcrowding at screening OPDs, specialist OPDs and special investigation centres.
- (b) Timings of OPDs and auxiliary/ supportive services may not be same.
- (c) Jumping of queue by influential patients/ staff members.
- (d) Long waiting time.
- (e) Investigation results not available centrally and on time.
- (f) Lack of communication (absence of PA system and patient call system).

Operation Theatre

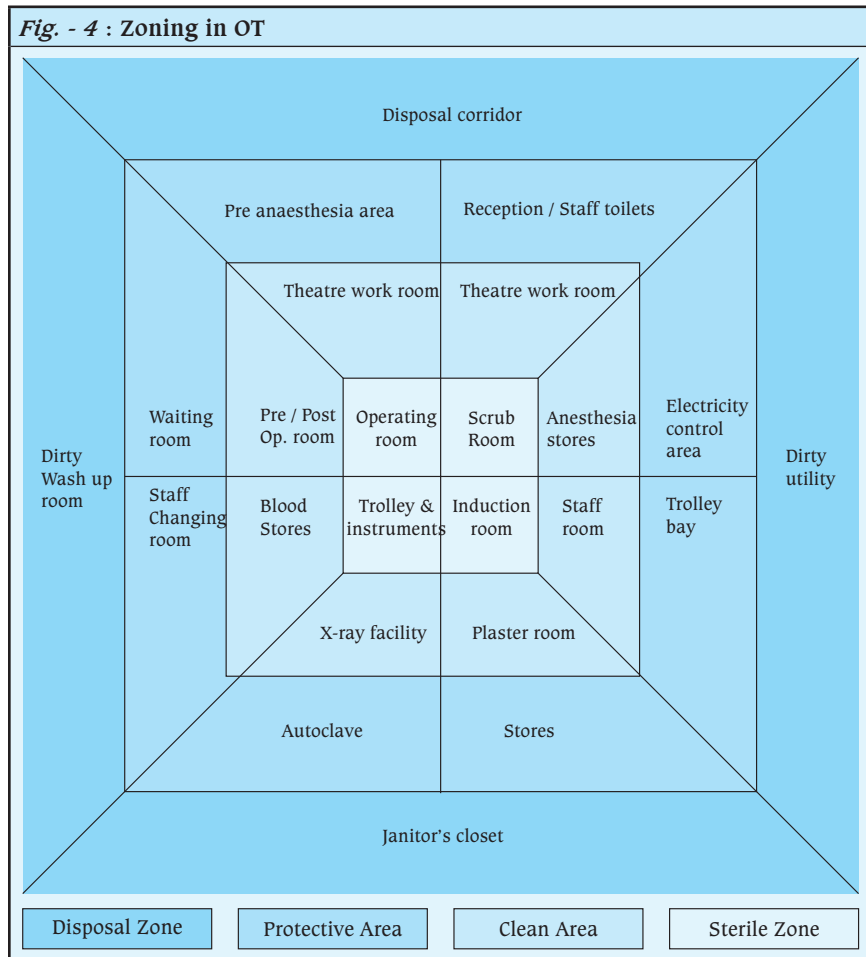

An Operation Theatre (OT) is defined as a specialized facility of the hospital where life saving / life improving procedures are carried under strict aseptic conditions in a controlled environment by specially trained personnel, to promote healing and cure with maximum safety, comfort and economy. Surgical operations have been classified broadly as emergency surgeries (which must be carried out as soon as the diagnosis has been made and patient prepared for surgery in a proper manner) and elective surgeries (undertaken some time after the diagnosis has been made and when best suited to the patient & hospital). An OT in a hospital should be planned with the following objectives in mind :

- (a) Ensure complete asepsis during surgeries.
- (b) Ensure maximum safety for patients and medical personnel from bio-medical, engineering, electrical and radiological hazards in the OT environment.
- (c) Optimal utilization of trained manpower and other resources in OT.
- (d) To optimize working condition for OT staff.
- (e) Allow for flexibility.
- (f) Minimize maintenance and regulate flow of traffic through OT.

The Concept of 'Zoning' in an OT : The OT has to be divided into four distinct zones based on bacteriological cleanliness, in order to attain maximum asepsis for surgeries. Bacteriological contamination progressively diminishes from outer zone to the core zone (100% sterile) where all surgeries are performed. The following zones are identified in an OT (Fig. 4):

- (a) *Disposal zone* with facilities like patient closet, disposal corridor for solid linen and surgical waste and dirty wash up room.
- (b) *Protective zone* includes areas in OT like Reception, waiting room, stores, trolley bay, autoclave, TSSU, control area of electricity, changing rooms for staff with toilets and pre-anesthesia room.
- (c) *Clean Zone* includes areas in OT such as theatre work room, plaster room, recovery room, surgeons'/ nurses' staff rooms, anesthesia stores, X Ray facility, blood stores, pre and post operative rooms.

Fig. - 4 : Zoning in OT

- (d) *Sterile Zone* (innermost) consists of facilities like operating room, scrub room for staff, anesthesia induction room and instruments/trolley area.

Intensive Care Unit

The intensive care unit (ICU) of a hospital is one of the most important places in a hospital. It can be defined as a specific area in a hospital where sophisticated monitoring, titrated life support, specific therapy and specialized nursing are provided for potentially salvageable, critically ill patients with life threatening illness or injuries. ICU is a place where seriously sick patients, highly skilled medical and nursing staff with knowledge and experience & sophisticated medical equipment are brought together for better health care at an optimum cost. One of the major objectives of ICU is to identify patients who require intensive medical care and close monitoring round the clock. Broadly, such patients are classified as :

- Patients expected to survive.
- Potentially recoverable patients.
- Patients with uncertain prognosis.
- Patients not likely to survive irrespective of whatever is done.
- Patients for whom death is imminent.

Classification of ICU : (based on organizational structure)

- Open unit* is available for admission to all patients by any attending physician but the triage decision and allotment

of a bed is the decision of the medical officer in charge of the intensive care unit.
 (ii) *Semi closed unit* is where the medical team in charge of the intensive care unit must review and approve all admissions into ICU. Concerned specialists recommend ICU admissions but all final decisions rest with administrators.

(iii) *Closed unit* is one where Heads of Departments and treating physicians are responsible for all admissions and discharges but after admission, the ICU team along with the treating physicians is responsible for providing health care.

Staffing requirements in ICU : Since ICU is one of the most sensitive places in a hospital, it is necessary to be staffed accordingly by medical and nursing personnel. Ideally, ICU should have a medical officer in charge who should provide continuity and direction to ICU services. The ICU should also be staffed by one Resident round the clock in addition to a junior resident who is pursuing post graduate studies. ICU has extensive nursing and paramedical requirements. The acceptable staff : patient ratio are as under :

Nurse : patient ratio - 1 : 1 during day & 1 : 2 during night

Staff : Patient ratio - 2 : 1 for a 6-8 bedded ICU

Any ICU for constant patient care requires a nurse : bed ratio of 4 : 2 allowing for leave and other absences of nursing staff.

Physical facilities and design of ICU

(a) Location : ICU should be ideally located near operation theatre and should have access from other departments. The movement areas in ICU should be spacious and corridors should be at least 2.4 m wide.

(b) Space requirement : The should have a space of 50 sq m per bed. There should be facility for removing shoes and wearing masks /gowns and entrance should have air curtains to prevent dust from entering. Every patient should have at least 15 sq ft of clear space (with minimum head wall width of 1-2 ft / bed) excluding service areas like toilets. ICU should have a nursing station equipped with patient monitoring equipment (including an alarm system and telephone to call for assistance from outside). At least one hand washing facility should also be provided for every three beds in ICU.

(c) Patient services : ICU should have piped oxygen supply and suction facility. Adequate electric sockets should be available for every bed. Each bed in ICU should be isolated by mobile partition to form a small cubicle for each bed.

(d) Nursing station in ICU : It should have adequate storage space for documents and should have adequate counter space. Since all patients in ICU need to be monitored round the clock, nursing station in ICU should be so oriented so that every

patient can be directly observed from central nursing station without being able to see other patients in ICU.

(e) Miscellaneous : ICU should be well illuminated without reflective or bright lights. It should stock all necessary routine and emergency medicines, should have refrigerator for storing medicines which require to be stored at low temperature. In addition, every ICU should have a clean supply room, clean linen store, soiled linen holding room, X-Ray viewing facility and equipment storage space. Laboratory, radiological and pharmacy services should be available to ICU round the clock.

In-Patient Services

The inpatient services of a hospital provide clinical care to non-critical patients who need to be admitted to the hospital for investigations, diagnosis and treatment. The hospital wards (which accommodate the inpatients) and their ancillary areas & services thus are the most vital areas of any hospital, occupying as much as 50% of the entire hospital area. The inpatient areas consist of various wards (including the nursing station) the patient beds and the entire necessary support services and areas. Since inpatients are required to be monitored and are mostly dependent on nursing staff, these areas also witness non-stop patient related activities. A 'ward' in a hospital can be defined as a section of a hospital, including a nursing station, bed and necessary storage service, work and public areas, where nursing care is provided to in patients.

Various types of wards : The main factor to be kept in mind while designing a ward is that nursing staff should be able to hear & see all patients and should be able to react accordingly with maximum efficiency and least stress and strain.

(a) Open ward (pavilion type) : It was first constructed in 1770 by a Frenchman and later modified by Florence Nightingale in 1850's. Such wards have patients' beds in two rows at right angles to the longitudinal walls. Bathrooms and toilets are located at one end while the nursing station and doctor's room is located at the other end. The usual length of such open ward was 96 feet, where 30-35 patients were admitted (Fig. - 5).

Sun glare in tropical countries was prevented by constructing covered verandas on either side of wards. After 1925, the nursing station was shifted to center of the ward to reduce nurse fatigue. Similarly, service areas were also shifted to a central annexe to reduce the distance traveled by each patient.

Open wards offer the advantages that all patients are directly visible to nurses on duty, adequate ventilation and natural light is available to all patients and it is economical to construct and maintain. It however suffers from certain disadvantages like lack of privacy, danger of cross infection and constant glare for all patients. Moreover, seriously ill patients requiring constant attention have to be placed in the center close to the nursing station which is also the area for maximum movement in the ward.

(b) Rig's ward : In Denmark, Rig's Hospital first adopted a design where patient beds were arranged in small cubicles along the longitudinal walls of the wards. This has the advantages that patients have privacy, cross infection can be contained to some extent, infectious patients can be partially isolated in cubicles and patients of both sexes can be accommodated in the same ward since privacy is offered by cubicles. However Rig's pattern of ward suffers the disadvantages that patients are not under direct supervision of nurse, there is difficulty in communication between patients and nurse, additional nurses are required since wards became larger and it is costly to construct and maintain (Fig. - 6).

The Committee On Plan Projects (Buildings Projects Team) of the Planning Commission (COPP) has recommended 20-30 beds per ward with 2-3 single-bed rooms for patients requiring special nursing care. In addition there may be 2-3 additional beds for patients on payment. The rest of the ward should be divided into cubicles with 6-8 hospital beds each. Outer verandas are no longer recommended. Recent studies have indicated that Nightingale pattern is more acceptable and appropriate for inpatients in India since it was easier to observe all patients at all types. The nurse fatigue is less and hence job satisfaction is higher among nurses. Open type wards offer a subtle form of group therapy for admitted patients and ambulatory patients are less likely to feel bored.

The primary area in a ward consists of patient space, with generally 7 square meter space per bed. The size of the bed is 1 meter X 2 meter and the minimum distance between centre of adjacent beds should be 2.5 meters. The distance from centre of the aisle to the foot end of bed should be 0.9 meter and distance from wall to head end of the bed should be 0.25 meter.

Ward Management : The objective of Ward Management is to provide the best possible medical & nursing care to patients by using the abilities of every member of the staff to fullest extent possible & by providing close supervision of both patient care & of the individuals who provide the health care. The common problems in ward management are summarised in Table - 1.

Table - 1 : Common problems in Ward Management

- Over crowding
- Inadequate staff
- Untrained staff
- Excessive use of student nurses
- Lack of equipment /supplies/ stores
- Multiplicity of units
- Pilferage of stores & medicines
- Undue paper work/ inventory
- Lack of discipline in staff
- Lack of supervision
- Lack of incentives for staff
- Lack of coordination

Ward management would consist of the following :

(a) Patient Management

- Admission & orientation of the patient
- Realistic assessment of patients' needs
- Observation and recording
- Monitoring the progress & reporting
- Assignment of patient care
- Planning of work schedule
- Ward rounds
- Disposal & rehabilitation of patient

(b) Management of Supplies & Equipment

- Indent, receipt & issue of supply
- Accounting of drugs & med stores
- Requisition of diets & its distribution
- Provision of linen & its exchange
- Maintenance of equipment

(c) Management of Environment

- Adequate lighting, ventilation, prevention of noise, dust control, regulation of temp & humidity, adequate privacy, control of visitors & control of infection

(d) Management of personnel

- Junior Doctors & interns, Nurses, paramedicals and ancillary staff

Diagnostic Services

The diagnostic and supportive services in any hospital broadly consist of the laboratory services, radio-diagnostic and imaging services, blood transfusion services and pharmacy services, which are described in detail subsequently.

Laboratory Services

The functions of a laboratory can be described as :

- Provision of comprehensive & accurate analytical test results
- Collective consultation with clinicians regarding most useful application of scientific procedures for patient care
- Training of professional & technical staff

- Research (e.g. types of diseases, social, genetic, nutritional, environmental etc.)
- Adaptation of Laboratory Medicine to useful advances in basic science
- Preventive (through examination of food handlers, personnel, materials for delivery rooms, nursery, OT, examination of food, water & milk)

Major considerations while planning a hospital laboratory

(a) Space : The total area of a hospital laboratory should be 10.3 to 14.4 square feet per bed depending on the load and the type of hospital. A hospital laboratory broadly consists of three areas. Primary space is the area occupied by technical & professional staff and should be ideally 3.5 Laboratory Space Unit (LSU) (1 LSU = 200 square feet). Secondary space (1.4 LSU) is the area for non-professional activities of those personnel who occupy the primary space. Circulation space (0.4 LSU) is the area for movement of personnel and goods.

(b) Staffing : The suggested staffing pattern is as summarised in Table - 2.

The average number of tests which can be performed by a technician, depending on the automation of the laboratory is as under :

- Semi automated laboratory : 1800 tests per year
- Partial automated laboratory : 25,000 tests per year
- Totally automated laboratory : 2,85,000 tests per year

Table - 2 : Staffing pattern in a laboratory			
Beds	Pathologist	Technicians	Steno
<50	1 (part time)	2-3	As needed
50-100	1 (part time)	3-5	Part time
100-200	1	5-8	Part Time
200-300	1 or more	8-10	1
300-500	3	20-30	2-3

Blood Transfusion Services

A blood bank is defined as a organisation for carrying out all or any of the operations pertaining to collection, aphaeresis, storage, processing & distribution of blood drawn from a donor &/or preparation, storage & distribution of blood components, with the aim to provide adequate quantity of safe blood & blood products or components for patients in a cost effective & coordinated manner. The role and functions of a blood bank can be summarized as under :

- Selection of donors & maintenance of donor records
- Collection of blood in an aseptic manner
- Screening for HIV, Hepatitis B & C, Malaria & Syphilis
- Component preparation
- Optimum storage of blood and blood components
- Carry out emergency matching, cross matching
- Record all Blood Bank procedures
- Training of medical & paramedical staff
- Conduct camps in community for voluntary donation of blood

Blood banks can be broadly classified into three categories based on consumption of blood :

- (a) Category I : Hosp consuming 3-7 units of blood/yr/bed (100-400 beds) (100 sq m space)
- (b) Category II : Hosp consuming 8-15 units of blood/yr/bed (400-1000 beds) (300 sq m space)
- (c) Category III : Hosp consuming >16 units of blood/yr/bed (>1000 beds) (895 sq m space)

Planning considerations for establishing blood transfusion services :

The location should be preferably on ground floor and easily accessible from Operation Theatre & A&E Dept. There should be proper signage and parking facilities for donors and ambulances. The *public access areas* should consist of donor reception office, counseling room, medical examination room, bleeding room and refreshment / rest room (including toilet & pantry). The *laboratory areas* (accessible only by professional staff consists of a transfusion lab, a component lab and facilities for disposal of biomedical waste. The *storage & issue areas* consist of storage facilities for blood and blood components and issue counter, which should be prominently marked and located near A&E Dept/OT. *Administrative areas* in a transfusion facility would include offices for medical officer & paramedical staff, rest rooms for technicians, conference room & library etc. Equipment required for blood transfusion services are described in Table - 3.

For Routine Work	For Blood Component work
<ul style="list-style-type: none"> ● Refrigerators ● Centrifuges ● Dielectric tube sealers ● Plasma separators ● Hot air oven ● Microscope ● Tube stripper / cutter/ sealer ● Blood Bags 	<ul style="list-style-type: none"> ● Refrigerated Centrifuge (5000Xg) ● Deep freezers with power back up Water baths ● Incubators ● Platelet agitators ● Cryo precipitate thawing bath ● Laminar flow ● Weighing scales

Supportive Services

Central Sterile Supply Department (CSSD)

The Central Sterile Supply Department is responsible for collecting & receiving used patient care items with the view to decontaminate, process, sterilize, store and dispose these items to all other parts of the hospital (Mayhall). Thus the Central Sterile Supply Department (CSSD) comprises of the services within the hospital which receives, stores, processes, sterilizes, distributes and controls professional supplies and equipments, both sterile and non sterile, to all departments of the hospital for the care and safety of patients. The CSSD is a central agency in a hospital which ensures quality control of sterilized material, economy of scale (since it dispenses optimum requirements of various wards) and better utilization of trained nursing manpower. CSSD is set up in hospital with the aim of providing sterilized materials from a central department where sterilizing practices is conducted under conditions which can be properly controlled (thereby reducing incidence of hospital infections)

and to take some of the work off the nursing staff so that they can devote more time to patient care. The objectives of a CSSD are thus,

- To provide sterile supplies centrally
- To provide assistance to purchasing dept in selection and pretesting of goods
- Advisory role to Hosp Infection Control Committee (HICCOM)
- Ensure quality control measures in sterilization of various items
- Impart training to hospital personnel

CSSD caters for sterilization of items such as needles & glass syringes, rubber goods, including catheters & tubings, treatment & diagnostic sets (such as lumbar puncture sets), dressings, intravenous sets and infusion fluid for renal dialysis. Normally, CSSD does NOT include sterilization of surgical instruments used in OT, bed pans & urinals, bedding of patients, diets, medicines including blood & crystalloids and laundry.

Planning considerations : CSSD must be located close to and be easily accessible to areas which it serves most frequently such as Operation Theatre, ICU, acute wards & labour room. The space requirements recommended for CSSD (based on number of beds) are as shown in Table - 4 :

Up to 100 beds	10 square feet per bed
101 - 200 beds	9-10 square feet per bed.
201 - 300 beds	8-9 square feet per bed
301 beds and above	7-8 square feet per bed

The *functional layout* of CSSD should be so planned so that sterile and contaminated items do not come in contact and are not handled in the same area. Functional areas are thus divided into Receiving area, Cleaning and washing area, Unsterile area for inspection and maintenance, Work area for assembly and packing, Work area for sterilization, Sterile storage area, Gloves and rubber goods processing area and Issue area. Broad layout of a CSSD is as shown in Fig. - 7:

The concept of 'Zoning' in CSSD : Zoning is essential to ensure that contaminated items do not mix with sterile items in CSSD. Broadly the CSSD is divided into (i) Dirty Zone (receiving area, cleaning area and repair place); (ii) Clean Zone (Assembly and packing place) and (iii) Sterile Zone (Sterilisation, storage and issue areas). Accordingly the flow of items inside CSSD should be in such a manner that dirty items and sterile items do not mix.

Distribution System : CSSDs in various hospitals may follow any one of the distribution systems in vogue, as under :

- (a) *Clean for Dirty Exchange system* in which one used item is exchanged for sterile one on an exchange basis. This method of distribution is mostly used in cases where the demand for sterile items is less, such as in chronic wards.
- (b) *Topping system* where stocks of each ward, OT, ICU etc. are topped up daily to a predetermined level by making rounds and topping up the stocks. It is recommended that 50% extra items (more than the average daily consumption) should be added when one daily round is made and 25% extra items should be added when two daily rounds are made.
- (c) *Requisition system* where the requirements of each ward, ICU, OT etc are intimated to CSSD in advance and sterile items from CSSD are supplied based on the demand from each ward.
- (d) *Exchange Trolley system* wherein entire trolley is exchanged which has a fixed number of items. Such a system is followed where demand is substantial, such as a busy OT, ICU or acute surgical wards.

Medical Records Department

A medical record is defined as a clinical, scientific, administrative and legal document related to patient care in which is recorded sufficient data in sequence of events to justify the diagnosis, warrant the treatment given to the patient and results (McGibony 1969). Medical records are thus clear, concise & accurate history of patient's life & illness, written from medical point of view (Mac Eachern 1957). They are the sequentially recorded findings, observations and prescriptions of all medical & paramedical health care providers who attend to a patient during his / her interaction with health care facility.

Types of Medical Records

- (a) *Directly related to patient care* such as admission forms, medical history sheets, medical record forms, nurses' bedside records like TPR charts, consultations, investigations ordered & their results, OT notes and discharge summaries etc.
- (b) *Indirectly related to patient care* such as budget, accounts and financial transactions during patient's stay in hospital.

Importance of medical records

- For the patient, medical records help in continuity of medical care, prevent omission / duplication of investigations, support or refute medico-legal issues, provide reliable information for health insurance and disability entitlements for the patients.
- For the treating physician, accurate medical records provide a quality check regarding the adequacy and continuity of medical care, helps in evaluation of medical care provided and protects from legal suits of medical malpractice or medical negligence.
- For the hospital, medical records serve as evidence for evaluation of medical & nursing care, helps the management in planning & allocation of resources for the future and protects in case of legal suits.
- For medical research, accurate medical records assist in deriving conclusions or investigating them, aids informal

education, forms basis for clinical research and provides reliable source for advancement of medicine.

- For public health, medical records provide reliable info regarding mortality & morbidity profile of population, assists in planning preventive & social measures and provides early warning of incidence of communicable diseases.

Some commonly used terms in medical records

(a) Hospital Death : Death of a patient admitted as an inpatient in the hospital is considered as a hospital death. Death of a patient in casualty, OPD, ambulance or anywhere in the hospital before actual admission is not termed as hospital death. Gross Hospital Deaths are hospital deaths irrespective of duration of admission, whereas Net Hospital Deaths are deaths of inpatients after 48 hours of admission.

$$\text{Gross death rate} = \frac{\text{Total number of hospital deaths during the given period}}{\text{Total discharges (Including deaths) during the same period}} \times 100$$

$$\text{Net death rate} = \frac{\text{Total number of deaths of inpatients after 48 hours of admission during a given period}}{\text{Total discharges (including deaths) during the same period}} \times 100$$

Net Death Rate of a hospital serves as an accurate indicator of quality of medical care provided by that hospital. It is natural that net death rate (hospital deaths after 48 hours of admission) will be low where quality of medical care is good. Excessive net death rates indicate poor quality of hospital care and should be investigated.

(b) Patient Day : It is defined as the duration of medical care rendered to an inpatient between the census taking hours of two successive days. While counting the patient days, the day of admission is always counted (irrespective of the time of admission) and the day of discharge is always excluded (irrespective of the time of discharge). Patient day is a useful unit of time for assessing various hospital related activities such as patient days of health care provided, cost incurred on ICU bed per patient day, cost of hospital food per patient day etc.

(c) Average Daily Census : It is the average number of patients in the hospital at any given time of the day and is expressed as:

$$\frac{\text{Sum of daily census for a given period}}{\text{Number of calendar days in the period}}$$

(d) Occupancy Rate : It is the ratio of actual patient days expressed as a percentage of the maximum possible patient days (based on bed complement) in a hospital during any given period. It is :

$$\frac{\text{Number of patient days (based on discharges) during a given period}}{\text{Bed complement} \times \text{days during the same period}} \times 100$$

(e) **Average length of stay** : It is the average number of days of medical care rendered to each discharged patient during a given period of time and can be compiled from the discharge summary of patients. It is expressed as :

$$\frac{\text{Total patient days during a given period}}{\text{Total discharges (including deaths) during the same period}}$$

(f) **Turnover Interval (T interval)** : It is the average number of days that bed remains vacant between a discharge and subsequent admission. It is expressed as :

$$\frac{\text{Maximum possible patient days -- Actual patient days (bed complement x days) during a given period}}{\text{Number of discharges (including deaths) during that period}}$$

A negative value of T interval indicates a scarcity of hospital beds whereas a prolonged positive T interval indicates under-utilization of hospital beds (vacant beds) due to inadequate admissions or poor quality of medical care offered by the hospital. T interval is a sensitive index of hospital bed utilization and a short positive T interval indicates optimum utilization of beds.

Legal aspects of Medical Records : Medical Records, besides recording the complete diagnosis, treatment and outcome of a patient in a hospital, is also an important legal document and hence must be complete (must contain adequate data to identify the patient, justify diagnosis & treatment and outcome and must contain all bedside recordings of various medical & nursing procedures), adequate (must contain all necessary clinical information), accurate (information recorded should be quantifiable and assessable for correctness and legible (records must be legible and names of all medical professionals endorsing the records should be recorded clearly). The medical records are property of the hospital and not of the patient or the treating doctor. Since a medical record pertaining to an individual is a personal document, the contents ordinarily should not be divulged to anyone without consent of the patient. However, details may be divulged to the patient concerned in form of brief summary and findings of investigations. Relevant details may be released to press under exceptional circumstances only by the administrator of the hospital. Details of hospitalization can be released to LIC even without consent of patient to dispose claims arising from insurance policies and to police in case of medico-legal cases, injury reports etc. Police should ordinarily not be allowed to record a patient's statement without prior certification by MO (compos mentis). According to Indian Evidence Act, hospital documents including medical records are admissible as evidence. Courts can subpoena any document or medical record and can summon any doctor for evidence under law of torts. Medical documents can also be used for education, research & public health when used as impersonal details. At times, some personal information has to be divulged in public interest for communication & notification of certain diseases.

Safety & retention of medical documents : It is the responsibility of hospital administration to safely store medical records pertaining to patients. Medico-legal documents should be especially kept safely as these are required in courts of law subsequently. The general guideline for retention of hospital

documents is that OPD records should be stored for 5 years, indoor records for upto 10 years and medico-legal documents should be stored permanently.

Linen & Laundry Services

Linen & laundry services are one of the important support services of a hospital, which not only contributes to patient satisfaction, but also assists in healing by reducing cross infection among patients. Hospital linen can be defined as all clothing made of cotton, linen, wool or synthetic fabrics which are used by the patient or used for him while in hospital.

Importance of laundry services for a hospital

(a) **Prevention of cross infection among patients** : Frequent change & adequate cleaning of patient linen reduces the chances of cross infection among patients, thereby assisting in faster healing of wounds.

(b) **Comfort & patient satisfaction** : Clean and appropriate clothing for patients invariably leads higher levels of comfort and satisfaction among patients.

(c) **Aesthetic aspect** : Clean linen in hospital wards provide a neat and cheerful look to the wards, which makes the patients stay more comfortable. In addition, clean linen in hospital also improves the job satisfaction of nursing and paramedical staff in the hospital, by providing a clean working environment.

(d) **Public Relations** : A clean ward serves as an important public relation factor wherein all visitors and patients carry a favorable impression of the services and medical care rendered at the hospital.

Types of Laundry Services

- (a) **In-plant System** is a hospital owned laundry and is best suited for large teaching or referral hospitals with large number of beds and adequate patient turnover. It is costly to maintain but better control over quality can be exercised by the administration.
- (b) **Rental System** is where a hospital hires linen from a contractor who is also responsible for replacement and laundering of the linen. Though less costly for the hospital, quality control has to be monitored closely as it is dependent on the contractor.
- (c) **Contract System** is where the hospital owned linen is laundered by a contractor because the hospital does not have facilities for laundry.
- (d) **Cooperative System** is one of the most cost-effective methods for smaller hospitals where a single laundry is shared by more than one hospital.

Classification of linen : Laundry linen is classified as under based on the cleaning process required for the linen.

- (a) **Soiled linen** that has been used by patients and has to be cleaned by routine procedures of washing, conditioning and ironing.
- (b) **Infected linen** which has been contaminated by infective material such as blood or Pus. Such linen is collected in polythene bags, is handled least and has to be first disinfected before routine washing.
- (c) **Foul linen** is linen which is contaminated with faeces, excreta or blood and has to be passed through sluicing before washing.

- (d) *Radio-active linen* is linen contaminated with radioactive substances and has to be suitably decontaminated & monitored before washing and re-using for patients.

Life of hospital linen is a major concern for administrators since it involves a recurring expenditure. Generally, 15-20% of linen becomes unusable after 35 washes (or after 3 months) and has to be replaced. The overall life of hospital linen would depend on availability of linen in adequate quantity type of laundry system (in-plant system will lead to longer life) and type of detergents used etc.

Types of Linen Distribution System : One out of the following systems of linen distribution is followed in all hospitals.

(a) Centralized linen services

- (i) *'Clean for Dirty' exchange system* where laundered linen is issued whenever used/soiled linen is deposited in laundry by user departments.
- (ii) *Topping up system* where a pre-decided laundry stock (calculated on the basis of one day's requirement) is replenished every morning by laundry staff in each user department.
- (iii) *Exchange Trolley system* where daily stock of linen is supplied to each ward in a trolley and replaced the next day. This reduces handling of clean laundry by too many people in the hospital.
- (iv) *Pack system* where complete requirement of linen patient-wise is prepared in laundry itself in form of packs and supplied to user departments.

(b) Decentralized linen services : Linen is issued to wards on their inventory and used linen is sent to a central laundry by the ward nursing staff. Every linen is marked to identify the user department and laundered linen is issued to user wards out of the stock maintained for each department.

(c) Mixed linen services : These are followed where some key areas like Operation Theatre, ICU etc. are issued with their own linen as in decentralized system but rest of the hospital follows the centralized system of laundry.

Hospital Dietary Services

Dietary services of a hospital is one of the main supportive services, which contributes to recovery of health through scientifically prepared diets, dietary counseling of patients and training of health care providers in dietary requirement & planning. Hospital dietary services can be described as supportive services which cater to the needs of outpatients regarding diet counseling and provision of appropriate diets to the inpatients, as per their requirements.

Conventional dietary system in most hospitals consists of menu items prepared in a kitchen on the premises where meals are prepared and held for a short time and maintained either hot or cold until serving time. This system is more adaptable to regional, ethnic & individual preferences and ensures quality control. However, because of differences in menu, this system is more stressful for workers. In addition, skilled workers may be assigned tasks that could be done by non-skilled workers and the system needs two shifts of employees.

In the Commissary (large central kitchen) system, there is centralized food purchasing & delivery of prepared food to

satellite units located in different hospital areas for final preparation and service to patients. This system is economical because of bulk cooking & quality control is better because there is only one unit to supervise. However, poor food safety during distribution may result in contamination. In the ready prepared (Cook & Chill) system, foods are prepared in advance & stored under refrigeration. There is thus no peak period pressure & no delay in preparation. But the system needs cold storage and freezers for chilling the food items immediately after they are prepared.

Summary

A hospital can be described as an organisation which provides health care services (preventive, promotive and curative) by pooling in the various skills & services of health professionals, supportive staff and ancillary staff, with the overall objective to provide health care to patients. It is a highly complex institution which brings together highly qualified and highly technical professionals for common cause of providing comprehensive health care and medical care to patients, in the most cost-effective manner, within the limited available resources. A hospital can be broadly divided into Clinical Areas, Diagnostic Areas, Auxiliary Services and Support Services. Emergency Medical Services (EMS) can be described as medical services undertaken with the aim to transport the right patient to the right hospital at the right time so that right treatment can be given. Role of A&E services in a hospital includes such functions as to function as an information centre about seriously injured patient, to provide ambulance services and so on.

Location, Space requirements, Planning of facilities and Architectural design (such as considerations on Entrance, Waiting area, Reception, Registration & Records, Examination & Treatment area) are the vital considerations while planning an A&E Dept. An Out-Patient Department (OPD) can be defined as that part of the hospital with allotted physical and medical facilities and staff in adequate numbers, with regularly scheduled hours, to provide care for patients who are not registered as indoor patients. They are the first point of contact between the patients/their relatives and the hospital staff. Functions of OPD include provision of day care investigative, diagnostic and treatment specialist procedures, health education and health promotion and so on. Location, Patient flow, Interdepartmental Resource Sharing, Physical facilities, Space provisions, Clinical areas, Pathology laboratory & Auxiliary facilities are some of the factors that have to be considered while planning an OPD. Overcrowding and long waiting time are some of the problems faced in OPDs.

An Operation Theatre (OT) is a specialized facility of the hospital where life saving / life improving procedures are carried under strict aseptic conditions. Surgical operations have been classified broadly as emergency surgeries and elective surgeries. Objectives to remember while planning an OT include flexibility, complete asepsis and maximum safety. In order to attain maximum asepsis, an OT should ideally include Disposal zone, Protective zone, Clean Zone, Sterile Zone. The intensive care unit (ICU) is a place where seriously sick patients, highly skilled medical and nursing staff with knowledge and experience & sophisticated medical

equipment are brought together for better health care at an optimum cost. Based on organizational structure, ICUs can be classified into Open unit, closed unit and Semi- Closed unit. ICU should have a medical officer, one Resident round the clock and a junior resident, apart from nursing staff. Physical facilities and design of ICU should factor in the appropriate location, space requirement, patient services and facilities for nursing station in ICU. Illumination, ventilation etc. are the other considerations in designing an ICU. A 'ward' in a hospital can be defined as a section of a hospital, including a nursing station, bed and necessary storage service, work and public areas, where nursing care is provided to in patients. The main factor to be kept in mind while designing a ward is that nursing staff should be able to hear & see all patients and should be able to react accordingly with maximum efficiency and least stress and strain. Open ward (pavilion type) and Rig's ward are some of the types of wards. 20-30 beds per ward with 2-3 single-bed rooms for patients requiring special nursing care has been prescribed as a norm. The objective of Ward Management is to provide the best possible medical & nursing care to patients by using the abilities of every member of the staff to fullest extent possible. Ward management comprises of Patient Management (including assignment of patient care, planning of work schedule) and management of Supplies, Equipment, Environment and personnel. Common problems in Ward Management include inadequate staff, untrained staff, lack of supervision and the like. The diagnostic and supportive services in any hospital broadly consist of the laboratory services, radio-diagnostic and imaging services, blood transfusion services and pharmacy services. The functions of a laboratory would include training of professional & technical staff and provision of comprehensive & accurate analytical test results, among others. Major considerations while planning a hospital laboratory would include Space, Staffing etc.. A blood bank is an organisation for carrying out all or any of the operations pertaining to storage processing & distribution of blood drawn from a donor &/or preparation, storage & distribution of blood components. Component preparation, collection of blood in an aseptic manner and screening are the main functions of a blood bank. Blood banks can be broadly classified into three categories based on consumption of blood. Planning considerations for establishing blood transfusion services should cater for proper public access areas, laboratory areas, storage & issue areas and administrative areas. The Central Sterile Supply Department is responsible for collecting & receiving used patient care items with the view to decontaminate, process, sterilize, store and dispose these items to all other parts of the hospital comprises of the services within the hospital which receives, stores, processes, sterilizes, distributes and controls professional supplies and equipments, both sterile and non sterile, to all departments of the hospital for the care and safety of patients. The objectives of a CSSD includes provision of sterile supplies centrally, Advisory role to Hosp Infection Control Committee (HICCOM) and the like. CSSD must be located close to and be easily accessible to areas which it serves. The functional layout of CSSD should be so planned so that sterile and contaminated items do not come in contact and are not handled in the same area. CSSD is divided into Dirty Zone, Clean Zone and Sterile Zone. CSSDs in various hospitals may follow any one of the

distribution systems like Clean for Dirty Exchange system, Topping system, Requisition system or Exchange Trolley system. A medical record is defined as a clinical, scientific, administrative and legal document related to patient care in which is recorded sufficient data in sequence of events to justify the diagnosis, warrant the treatment given to the patient and results. The various types of Medical Records are those that are Directly or indirectly related to patient care. The Importance of medical records is manifold, like for the patient, for public health and so on. Death of a patient admitted as an inpatient in the hospital is considered as a hospital death. Patient Day is defined as the duration of medical care rendered to an inpatient between the census taking hours of two successive days. Average Daily Census is the average number of patients in the hospital at any given time of the day and Occupancy Rate is the ratio of actual patient days expressed as a percentage of the maximum possible patient days. Average length of stay is the average number of days of medical care rendered to each discharged patient during a given period of time. Turnover Interval (T interval) is the average number of days that bed remains vacant between a discharge and subsequent admission is also an important legal document. Medical Records should be complete, accurate, legible and adequate. It is the responsibility of hospital administration to safely store medical records pertaining to patients. Hospital linen can be defined as all clothing made of cotton, linen, wool or synthetic fabrics which are used by the patient or used for him while in hospital. The Importance of laundry services for a hospital includes mainly aesthetic aspect, public relations and the like. Types of Laundry Services include In-plant System, Rental System, Contract System and Cooperative System. Soiled linen, infected linen, foul linen and radio-active linen are the various types of Linen. Distribution System for linen includes Centralized linen services & Decentralized linen services. Dietary services of a hospital is one of the main supportive services, which contributes to recovery of health through scientifically prepared diets, dietary counseling of patients and training of health care providers in dietary requirement & planning. Conventional dietary system and Commissary (large central kitchen) system are the main types of hospital dietary services.

Study Exercises

MCQs and Exercises

1. The word 'product' in a hospital setting would actually mean (a) number of patients (b) income generated (c) medical care (d) variety of specialists.
2. All of the following are types of Support Services in a hospital except : (a) laundry services (b) medical records dept (c) dietary services (d) pharmacy services.
3. Average recommended space per patient visiting the A&E (Accident & Emergency) Dept in a hospital is (a) 10 square meters (b) 20 square meters (c) 30 square meters (d) 40 square meters.
4. Against an inpatient load of 25 patients per bed per year, a hospital OPD load on an average, is around (a) 400 patients per bed per year (b) 500 patients per bed per year (c) 600 patients per bed per year (d) 800 patients per bed per year.
5. Public toilets should be provided in hospitals separately

for males and females at the rate of one toilet each for (a) 200 patients/ visitors (b) 100 patients/ visitors (c) 300 patients/ visitors (d) 400 patients/ visitors.

6. The following are the zones are identified in an Operation Theatre, except (a) Disposal zone (b) Protective zone (c) Clean Zone (d) Fertile zone.
7. The type of Intensive Care Unit (ICU) where the medical team in charge of the intensive care unit must review and approve all admissions into ICU, is known as (a) Open unit (b) Semi-closed unit (c) closed unit (d) Quasi- open unit.
8. The open type of ward is also known as the Rig's ward. Yes/ No.
9. The minimum distance between centre of adjacent beds in a ward should be at least (a) 2.4 metres (b) 1.0 metres (c) 0.4 metres (d) 1.4 metres.
10. A hospital laboratory broadly consists of all of the following areas, except (a) Primary space (b) Secondary space (c) Tertiary space (d) Circulation space.

11. The space requirements recommended for CSSD (Central Sterile Supply Department) in a hospital with 201 - 300 beds is (a) 10 square feet per bed (b) 08-09 square feet per bed (c) 07-08 square feet per bed (d) 06-07 square feet per bed.
12. The duration of medical care rendered to an inpatient between the census taking hours of two successive days, is known as (a) Patient Day (b) Hospital Day (c) Average length of stay (d) Bed occupancy duration.
13. Where a single laundry is shared by more than one hospital, the type of laundry service system is known as (a) In-plant System (b) Rental System (c) Contract System (d) Co-operative System.
14. Large central kitchen system in hospital dietary system, is also known as (a) Commissary system (b) Conventional dietary system (c) Ready Prepared system (d) Cook & Chill system.

Answers : (1) c; (2) d; (3) a; (4) b; (5) a; (6) d; (7) d; (8) No; (9) a; (10) c; (11) c; (12) a; (13) d; (14) a.

Advanced Diagnostic Technologies in Public Health

Rohit Tewari

A diagnostic test is any kind of medical test performed to aid in the diagnosis or detection of disease. It may be used to diagnose diseases or measure the progress or recovery from disease or confirm that a person is free from disease.

Some medical tests are parts of a simple physical examination which require only simple tools in the hands of a skilled practitioner and can be performed in an office environment. Some other tests require elaborate equipment used by medical technologists or the use of a sterile operating theatre environment. Some tests require samples of tissue or body fluids to be sent off to a pathology lab for further analysis. Some simple chemical tests such as urine pH, can be measured directly in the physicians office. However, with advancements in health care, a large array of diagnostic tests have become available. The aim of this chapter is to provide an introductory overview of the various modern (and often, expensive) diagnostic modalities which are often discussed routinely in contemporary medical world.

According to IPHS standards stated as a part of NRHM, the laboratory facilities which should be available at various levels are (Table-1) :

Table - 1 : IPHS Standards for Availability of laboratory Services at various levels of care (31-50 Bedded Hospital)

Speciality	Diagnostic Services / Tests
Haematology	Haemoglobin estimation, Total Leucocyte count, Differential Leucocyte count, Absolute Eosinophil count, Reticulocyte count, Total RBC count, E. S. R. , Bleeding time, Clotting time, Peripheral Blood Smear, Malaria/Filaria Parasite, Platelet count, Packed Cell volume, Blood grouping, Rh typing, Blood Cross matching
Urine Analysis	Urine for Albumin, Sugar, Deposits, Bile salts, Bile pigments, Acetone, Specific gravity, Reaction (pH)
Stool Analysis	Stool for Ova cyst (Eh), Hanging drop for V. Cholera, Occult blood
Sputum	Sputum cytology
Microbiology	Smear for AFB, KLB (Diphtheria), Grams Stain for Throat swab, sputum etc. KOH study for fungus
Serology	RPR Card test for Syphilis, Pregnancy test (Urine gravindex), WIDAL test, Rapid Test for HIV, HBs Ag, HCV
Biochemistry	Blood Sugar, Urea, Serum Bilirubin, Liver function tests, Kidney function tests, Blood Cholesterol, Blood Uric acid

For 51-100 Bedded (All as in 31-50 bedded with the following additional facilities) (Table - 2)

Table - 2 : For 51-100 Bedded	
Speciality	Diagnostic Services / Tests
Haematology	Prothrombin time, ELISA for HIV, HBsAg and HCV
Semen Analysis	For count, morphology and motility
CSF Analysis	Cell count cytology
Aspirated fluids	Cell count cytology
Others	Stocking of rapid H2S based test for bacteriological examination of water, Stocking of OT test for residual chlorine in water

For 201-300 Bedded (All as in 51-100 bedded with the following additional facilities) (Table - 3)

Table - 3 : For 201-300 Bedded	
Speciality	Diagnostic Services / Tests
Haematology	Prothrombin time
Semen Analysis	For count, morphology and motility
CSF Analysis	Cell count cytology
Aspirated fluids	Cell count cytology
Others	Stocking of rapid H2S based test for bacteriological examination of water, Stocking of OT test for residual chlorine in water.
Microbiology	Culture and sensitivity for blood, sputum, pus, urine etc., Stool culture for Entero pathogen, Supply of different Specimen collection and transportation media for peripheral Laboratories, KOH Study for Fungus
Biochemistry	Lipid Profile, Serum calcium, sodium, potassium, Serum Phosphorous, Serum Magnesium, Blood gas analysis, Thyroid T3 T4 TSH, CPK, Chloride

The various modern diagnostic technologies that shall be discussed in this chapter can be classified under the following groups :

- Immunopathology
- Molecular Biology
- Clinical Chemistry
- Haematology
- Cytopathology
- Histopathology
- Radiology
- Electrophysiology

Diagnostic Technologies in Immunopathology

Antigens can be defined as any substance that can represent antigenic sites (epitopes) to produce corresponding antibodies, from small molecules such as haptens and hormones to macromolecules such as proteins and glycoproteins. Antibodies are produced in response to antigenic stimulation. Immunoassays (antigen antibody reactions) can be used for detection of either antigens or antibodies. For detecting antigens, the corresponding specific antibody should be used as one of the reagents and vice versa.

The technologies available are –

Precipitation immunoassays : It is based on the occurrence of precipitation when large complexes of antigens and antibodies combine to form an insoluble lattice. These techniques suffer from poor sensitivity. The lower limit of sensitivity remains in the range of 0.1-0.4 mg/dl. Typical examples of precipitation immunoassay are the Widal test and the Weil-Felix test.

Particle immunoassay : Here specific antigens are coated onto a particle and on reaction with antibody under test, the agglutination is made more visible. Reverse agglutination where the antibody is coated onto the particle is also performed. The particle used may be RBC, latex or gelatin. The sensitivity of hemagglutination tests is upto 50 ng/ml for antigen detection.

Applications in public health : Hemagglutination test using RBC as the particle is widely used for *Treponema pallidum* called as the TPHA (*Treponema pallidum* Hemagglutination). Hemagglutination tests for hepatitis B and hepatitis C are also widely used. (for detection of antibody). Reverse passive hemagglutination (RPHA) has extensive application in detection of hepatitis B surface antigen (HBsAg). Latex agglutination is widely used in measurement of hCG for qualitative pregnancy tests.

Radioimmunoassay : Radioimmunoassay (RIA) is a scientific method used to test antigens (for example, hormone levels in the blood). Although the RIA technique is extremely sensitive and extremely specific, it requires a sophisticated apparatus and is costly. It also requires special precautions, since radioactive substances are used. Therefore, today it has been largely supplanted by the ELISA method, where the antigen-antibody reaction is measured using colorimetric signals instead of a radioactive signal. To perform a radioimmunoassay, a known quantity of an antigen is made radioactive, frequently by labeling it with gamma-radioactive isotopes of iodine attached to tyrosine. This radiolabeled antigen is then mixed with a known amount of antibody for that antigen and as a result, the two chemically bind to one another. Then, a sample of serum from a patient containing an unknown quantity of that same antigen is added. This causes the unlabeled (or "cold") antigen from the serum to compete with the radiolabeled antigen for antibody binding sites.

Applications in public health : These are limited to hormonal assays for example thyroid hormone levels in goiter endemic areas.

Enzyme Linked Immunosorbent Assay (ELISA) : This is a technique used mainly in immunology to detect the presence of an antibody or an antigen in a sample. In simple terms, in ELISA an unknown amount of antigen is affixed to a surface

and then a specific antibody is washed over the surface so that it can bind to the antigen. This antibody is linked to an enzyme and in the final step a substance is added that the enzyme can convert to some detectable signal.

Applications in public health : ELISA can be performed to evaluate either the presence of antigen or the presence of antibody in a sample, hence it is a useful tool both for determining serum antibody concentrations (such as with the HIV test or West Nile Virus) and also for detecting the presence of antigen. ELISA can also be used in toxicology as a rapid presumptive screen for certain classes of drugs. ELISA can be used for detecting tumour markers for certain cancers, e.g. Prostate Specific Antigen (PSA) in carcinoma prostate.

Fluorescent immunoassay : When fluorescent molecules are irradiated with light at appropriate wavelengths, an electron in the ground state is transitioned into the excited state. As the electron returns to the ground state, physical energy is released in the form of a photon which is detectable.

Applications in public health : Immunofluorescence assays have been extensively used for detecting antigens in tissue sections, e.g. kidney biopsies. Use of Auramine rhodamine stain in detection of tubercle bacilli in smears is well documented and shown to have better sensitivity than the conventional ZN stain. They have also been developed to detect the concentration of drugs, hormones and proteins and polypeptides.

Chemiluminescent immunoassay : These assays use chemiluminescence generating molecules as labels, such as luminol derivatives.

Applications : Assays of hormones and tumour markers can be performed. The detection limit has been reported as 0.2 to 0.4 ng/ml for Carcino-Embryonic Antigen (CEA) and 0.4 ng/ml for Alfa Feto Protein (AFP).

Diagnostic Technologies in Molecular Biology

Molecular biology is the study of biology at a molecular level. Molecular biology chiefly concerns itself with understanding the interactions between the various systems of a cell, including the interactions between DNA, RNA and protein biosynthesis and learning how these interactions are regulated. The tools of molecular biology have proven readily adaptable for use in the clinical diagnostic laboratory and promise to be extremely useful in diagnosis, therapy, epidemiologic investigations and infection control [8, 9]. Although technical issues such as ease of performance, reproducibility, sensitivity and specificity of molecular tests are important, cost and potential contribution to patient care are also of concern [10]. Molecular methods may be an improvement over conventional microbiologic testing in many ways. Currently, their most practical and useful application is in detecting and identifying infectious agents for which routine growth-based culture and microscopy methods may not be adequate

Gel electrophoresis : Gel electrophoresis is one of the principal tools of molecular biology. The basic principle is that DNA, RNA and proteins can all be separated by means of an electric field. In agarose gel electrophoresis, DNA and RNA can be separated on the basis of size by running the DNA through an agarose gel. Proteins can be separated on the basis of size by using an

SDS-PAGE gel, or on the basis of size and their electric charge by using what is known as a 2D gel electrophoresis.

Hybridisation assays : When the hybridization reaction is used to analyse the nucleic acid content of an unknown sample, the process is known as a hybridization assay. The property of complimentary base pairing allows fragments of known composition (the probes) to interrogate an unknown for the presence of matching (complimentary) sequences. The detection of the hybrids can be done a variety of technologies including radioisotope labels, fluorochrome based detection and enzyme based systems.

Liquid phase hybridization : When both sample and probe are in solution.

Solid support hybridization : In these assays, hybridization occurs in a biphasic environment, a solid phase (usually sample) and a liquid phase (usually probe).

Southern and Northern hybridization assays : These combine electrophoretic separation of test nucleic acids with transfer to a solid support and subsequent hybridization. Hence these assays give information of hybridization as well as the molecular weight of the hybridizing species. The original procedure was described by EM Southern and the test nucleic acid was DNA [11]. When RNA is the nucleic acid under test, the technique is called northern blotting by analogy. A further extension to the analogy is western blotting where proteins are subjected to the same procedure.

In situ hybridization : This is the detection of specific genetic information within a morphological context (intact tissue, cells or chromosomes affixed to glass slides).

Amplification technology : All the target amplification systems are enzyme based processes in which a single enzyme or multiple enzymes synthesize copies of target nucleic acid. All result in production of billions of copies of the amplified product in a few hours. These techniques are subject to contamination from product molecules of previous amplifications and hence false positivity is high. However, special lab design, practices and workflow have helped to reduce false positives to an acceptable range.

Polymerase Chain Reaction (PCR) : It is a simple in vitro chemical reaction that permits synthesis of large quantities of nucleic acid. This is brought about by heating the reaction mixture to separate the strands of the DNA, then cooled to permit the primers to anneal to the target DNA in a sequence specific manner. The DNA polymerase then initiates extension from 3' end. Thus the whole process is carried out in a programmable thermocycler which controls the temperatures at which various steps occur.

Reverse transcriptase PCR (RT-PCR) : PCR was initially described to amplify DNA. RT-PCR was developed to amplify RNA targets

Nested PCR : This variation increases the sensitivity and specificity of PCR. The products of the first round of amplification are subject to second round of amplification with a second set of primers.

Real time PCR : Here the target amplification and detection occur simultaneously. The computer software supporting the

thermocycler monitors the data throughout the PCR at every cycle and generates a plot.

Restriction Fragment Length Polymorphism (RFLP) based assays : Assays that utilize the sequence recognition property of restriction enzymes to demonstrate variations or polymorphisms in the DNA sequence of two samples are known as RFLP assays.

Arrays : A DNA array is a collection of spots attached to a solid support such as a microscope slide where each spot contains one or more single-stranded DNA oligonucleotide fragment. Arrays make it possible to put down a large quantity of very small (100 micrometre diameter) spots on a single slide. Each spot has a DNA fragment molecule that is complementary to a single DNA sequence (similar to Southern blotting). A variation of this technique allows the gene expression of an organism at a particular stage in development to be qualified (expression profiling). Since multiple arrays can be made with the exact same position of fragments they are particularly useful for comparing the gene expression of two different tissues, such as a healthy and cancerous tissue. Arrays can also be made with molecules other than DNA. For example, an antibody array can be used to determine what proteins or bacteria are present in a blood sample.

Applications of molecular biology in Public Health

Pathogen detection by hybridisation : The DNA of the infectious agent is detected directly in the clinical specimens by DNA probes. The disadvantage is that at least 10^4 or more copies are required for detection. In infectious diseases hybridization assays are unlikely to be a significant tool for diagnosis in the future due to low sensitivity. These formats are more applicable to batch processing of large numbers of specimens as in research labs.

DNA probes for culture identification : Probes are available for various organisms like *Mycobacterium tuberculosis*, *Chlamydia trachomatis*, *Neisseria gonorrhoeae*, *Human papilloma virus*, *Hepatitis C virus*, *Cytomegalovirus* and *Herpes simplex virus*.

This is especially important for slow growing organisms like Mycobacteria, fungi etc. Identification of cultured Mycobacteria by conventional methods is slow and time consuming. The use of probes for this purpose permits identification from cultures within one working day and sensitivity (95.4%) and specificity (99%) are excellent [12].

DNA amplification for diagnosis : Hepatitis C Virus-Detection of the virus by reverse transcriptase PCR confirms current infection and has a role in diagnosis and monitoring response to therapy [13]. Development of Quantitative PCR allows quantification of HCV which is important in prognosis and monitoring of therapy.

HIV : Molecular diagnosis is required in cases where serological testing results are indeterminate and neonates where serological detection of antibodies may be positive due to transplacental transfer of maternal antibodies and a prolonged follow up period (18 mths) may be needed to confirm infection by serologic methods. Quantitation of HIV virus is widely used for prognosis and for evaluation of response to antiretroviral therapy [14].

Mycobacterium tuberculosis : In general the sensitivity of these assays for specimens for which the smear for acid fast bacilli (AFB) is positive is excellent (95-100%). It is lower for specimens that are AFB smear negative (50-80%) [15]. Currently, the amplification processes cannot replace the AFB smear because the latter is used to determine the level of infectivity of patients and in gauging the initial response to therapy. At present the role of amplification assays remains complimentary to microscopy and culture.

Sexually Transmitted Diseases : Amplification assays have been developed for *Neisseria gonorrhoeae* and *Chlamydia trachomatis*.

Fungi : PCR assays for diagnosis of invasive Candidiasis and Aspergillosis have been developed.

Detection of antimicrobial resistance : Resistance of microbes to antimicrobials is one of the major public health problems of this decade. Molecular methods have contributed towards understanding of the genetics of antimicrobial resistance and the spread of resistance determinants. e.g. Molecular detection of the Mec-A gene is now considered a reference method for assessing Methicillin resistance in Staphylococci [16]. PCR amplification of DNA sequences from the rpoB (rifampicin resistance) and the kat G, inh A and ahp C genes (isoniazid resistance) followed by detection of mutations associated with resistance has a high sensitivity for detection of resistance to rifampicin (>96%) and isoniazid (87%) [17].

Molecular Epidemiology : The techniques of molecular typing are useful not only in research settings but also in real life clinical and public health problems. e.g. prediction of response to interferon therapy is important in patients with Hepatitis C virus infection. HCV genotypes 1b and 1a appear less likely to respond to interferons [18]. If molecular evidence of identity of multiple isolates of *Staphylococcus epidermidis* isolated from a single patient at different times can be shown, it indicates that the isolate is clinically significant.

Diagnostic Technologies in Clinical Chemistry

Colorimetry : This is performed in a device that measures the absorbance of particular wavelengths of light by a specific solution. This device, invented by Jan Szczepanik, is most commonly used to determine the concentration of a known solute in a given solution by the application of the Beer-Lambert law, which states that the concentration of a solute is proportional to the absorbance. Changeable optic filters are used in the colorimeter to select the wavelength of light which the solute absorbs the most, in order to maximize accuracy. The usual wavelength range is from 400 to 700 nanometres (nm). In modern colorimeters the filament lamp and filters may be replaced by several light-emitting diodes of different colors.

Applications in public health : These are far reaching and extensive since colorimetry forms the basis of assessing almost all parameters in clinical chemistry (including routine analytes like urea, creatinine, glucose, uric acid etc) and also hemoglobin in hematology. The technology involved is simple and made available at almost all levels of health care. Levels in blood of routine analytes forms the basis of the diagnosis of diabetes, hyperlipidemia, metabolic syndrome etc.

Nephelometry : This is a method for measuring the concentration of a solution that contains particles that are too large for colorimetry/ absorption spectroscopy. When a collimated light beam strikes a particle in suspension, portions of the light are absorbed, reflected, scattered and transmitted. Nephelometry is the measurement of the light scattered by a particulate solution.

Applications in public health : This is useful in measurement of antigen antibody complexes formed in immunoassays.

Electrophoresis : Electrophoresis is the separation of charged compounds based on their electrical charge. Common support media for electrophoresis in clinical work include cellulose acetate, agarose and polyacrylamide gel. Once separation has occurred, the support medium is treated with dyes to stain and identify the separated fractions. To obtain a quantitative profile of the separated fractions, densitometry is performed on the stained support medium.

Applications in public health :

Separation of serum proteins : Patterns of hypoproteinemia in malnutrition or gross loss of protein show decreases in all fractions with dramatic reduction in albumin. Cirrhosis of the liver shows a specific pattern with severe reduction of albumin and increased immunoglobulins. The pattern in monoclonal gammopathies (multiple myeloma) is very characteristic and shows an M band due to high levels of paraprotein secreted by a monoclonal proliferation of plasma cells.

Separation of hemoglobins : This is important in the diagnosis of various abnormal hemoglobins like thalassemia, sickle cell anemia etc.

Chromatography : Chromatography is a separation method based on the different interaction methods of the specimen compounds with the mobile phase and with the stationary phase, as the compounds travel through a support medium. The compounds interacting more strongly with the stationary phase are retained longer in the medium than those that favor the mobile phase.

Gas chromatography : It is a procedure used for compounds which are naturally volatile or those which can be easily converted to a volatile form.

Liquid chromatography : It is used for compounds that are too unstable or insufficiently volatile for gas chromatography.

Applications in public health : Routinely, chromatography is used for determination of drugs and chemicals in body fluids (toxicology). Detection of additives / chemicals in food is possible through High performance liquid chromatography. Environmental and water pollutants can be detected with accuracy through the use of various chromatographic procedures.

Automation in clinical chemistry : Automated analyzers allow labs to process a large volume of tests quickly. This is possible through the increased speed of testing. The increase in test throughput is possible by automating many steps involved. Most automated chemistry analyzers, photometric methods of analysis such as colorimetry, spectrophotometry or nephelometry etc. calculations, calibration curves and quality control are performed by the computers, thus reducing errors

and providing more accurate results. The testing pathway in an analyser may be

- a) Sequential testing- Multiple tests analysed one after another on a single specimen.
- b) Batch testing- All samples are loaded at the same time and a single test is conducted on each sample.
- c) Parallel testing- More than one test is analysed concurrently on a given clinical specimen.
- d) Random access testing- Any test can be performed on any sample in any sequence.

Diagnostic Technologies in Hematology

Automated Instruments : These instruments have many different components to analyze different elements in the blood. The cell counting components count the numbers and types of different cells within the blood. The results are printed out or sent to a computer for review. Blood counting machines aspirate a very small amount of the specimen through narrow tubing. Within this tubing, there are sensors that count the number of cells going through it and can identify the type of cell; this is flow cytometry. The two main sensors used are light detectors and electrical impedance. One way the instrument can tell what type of blood cell is present is by size. Other instruments measure different characteristics of the cells to categorize them. Because an automated cell counter samples and counts so many cells, the results are very precise. However, certain abnormal cells in the blood may be identified incorrectly and require manual review of the instrument's results and identify any abnormal cells the instrument could not categorize. In addition to counting, measuring and analyzing red blood cells, white blood cells and platelets, automated hematology analyzers also measure the amount of hemoglobin in the blood and within each red blood cell.

Diagnostic Technologies in Cytopathology

Exfoliative cytology : The microscopic examination of cells that have been shed from a lesion or have been recovered from a tissue for the diagnosis of disease.

Applications in public health

Cervical cytology : Exfoliative cytology from the uterine cervix is valuable in picking up premalignant lesions of the cervix and goes a long way in early detection of cervical cancer. Cervical cytology has been perhaps the most successful cancer screening technique of the 20th century. Technology used may be conventional i.e. where the smear is taken on a glass slide directly by the sampling device which may be an Ayres spatula or an endocervical brush or it may be Liquid based where the cells are suspended in a liquid fixative and subsequently spread onto a glass slide by a centrifugation process. In general, it has an overall sensitivity of 80% and a specificity of 99.4% for cytologic screening for cervical cancer. The sensitivity was slightly lower for mild and moderate dysplasia (78.1%) and slightly higher for carcinoma in situ and severe dysplasia (81.4%) and invasive carcinoma (82.3%) [19].

Fine Needle Aspiration Cytology : Fine Needle Aspiration Cytology (FNAC) is a technique where a fine needle is introduced into a lesion and with aspiration from a syringe, cellular material is obtained which can be spread on to glass slide, stained and evaluated cytologically. It is a technique

which is applicable not only to superficial accessible lesions but also to deep seated lesions under imaging guidance. A needle aspiration biopsy is safer and less traumatic than an open surgical biopsy and significant complications are usually rare, depending on the body site. Common complications include bruising and soreness. There is a risk, because the biopsy is very small (only a few cells), that the problematic cells will be missed, resulting in a false negative result. There is also a risk that the cells taken do not enable a definitive diagnosis. The technique is suitable to evaluation of lesions/nodules arising from breast, lymph nodes, thyroid, liver, kidney and soft tissue. The sensitivity and specificity varies according to the organ involved and also depends on the aspiration of a representativeness of the sample.

Diagnostic Technologies in Histopathology

Histopathology from the Greek *histos* (tissue) and *pathos* (suffering) refers to the microscopic examination of tissue in order to study the manifestations of disease. Specifically, in clinical medicine, histopathology refers to the examination of a biopsy or surgical specimen by a pathologist, after the specimen has been processed and histological sections have been placed onto glass slides. This is the most important tool of the anatomical pathologist in routine clinical diagnosis of cancer and other diseases. Histopathological examination of tissues starts with surgery, biopsy or autopsy. The tissue is removed from the body and then placed in a fixative which stabilizes the tissues to prevent autolysis. The samples are transferred to a cassette, a container designed to allow reagents to freely act on the tissue inside. This process is known as tissue processing. The processed tissue is then taken out of the cassette and set in a mold. Through this process of embedding, additional paraffin is added to create a paraffin block. The process of embedding then allows the sectioning of tissues into very thin (2 - 7 micrometer) sections using a microtome. The microtome slices the tissue ready for microscopic examination. The slices are thinner than the average cell and are layered on a glass slide for staining. To see the tissue under a microscope, the sections are stained with one or more pigments. The most commonly used stain in histopathology is a combination of hematoxylin and eosin.

Applications in public health : Histopathology is the gold standard of diagnosis in clinical medicine. It is eminently suited to diagnosis of diseases and conditions like malignancies and also some non neoplastic conditions like tuberculosis and other infections.

Immunohistochemistry : Immunohistochemistry or IHC refers to the process of localizing proteins in cells of a tissue section exploiting the principle of antibodies binding specifically to antigens in biological tissues. Immunohistochemical staining is widely used in the diagnosis of abnormal cells such as those found in cancerous tumors. IHC is also widely used in basic research to understand the distribution and localization of biomarkers and differentially expressed proteins in different parts of a biological tissue.

Applications in public health : Diagnosis of tumours/ non neoplastic conditions by histopathology occasionally is hampered by similar morphological appearances and hence

recognition of specific molecular markers by IHC like S100, Cytokeratin etc. helps in identifying the origin and hence the diagnosis of various tumours and conditions.

Radiological Techniques

X-ray : X-radiation (composed of X-rays) is a form of electromagnetic radiation, used primarily used for diagnostic radiography and crystallography. As a result, the term “X-ray” is metonymically used to refer to a radiographic image produced using this method, in addition to the method itself. X rays are produced by accelerating electrons which collide with a metal target (Tungsten/Molybdenum). These short X-ray pulses are shot through a body with radiographic film behind. The bones absorb the most photons by the photoelectric process, because they are more electron-dense. The X-rays that do not get absorbed turn the photographic film from white to black, leaving a white shadow of bones on the film. This technique is useful not only in the detection of pathology of the skeletal system, but also for detecting some disease processes in soft tissue. Some notable examples are the very common chest X-ray, which can be used to identify lung diseases such as pneumonia, lung cancer or pulmonary edema and the abdominal X-ray, which can detect ileus (blockage of the intestine), free air (from visceral perforations) and free fluid (in ascites). However they have a very little use in the imaging of soft tissues such as the brain or muscle.

Applications in public health : Chest x ray was the backbone of National Tuberculosis Control Programme in 1962 and had been an important component of battle against Tuberculosis in our country. But unfortunately it did not meet the criteria of being “Appropriate Technology” being expensive, requiring infrastructure and trained professionals for reporting and was left out in formulating the components of DOTS. However it is included in the diagnostic algorithm of RNTCP where one sputum sample is positive/ three negative smears in a symptomatic patient. In occupational health the ILO criterion for diagnosis of pneumoconiosis uses findings of x ray chest only.

DEXASCAN : DEXA Scan stands for Dual Energy X-Ray Absorptiometry. Two different types of X- ray scan the body and the images are subtracted by the computer giving a very accurate estimation of bone density/body fat. It is used to detect the presence of osteoporosis in men and women with particular risk factors, screen for osteoporosis, particularly in women making decisions about hormone replacement therapy at menopause, predict future fracture risk and monitor bone density in those with low normal levels and in those with osteoporosis. Dual energy X-ray absorptiometry or DXA (formerly DEXA), is a good method for estimating body fat percentage.

Angiography : It is the study of blood vessels with a contrast medium. It has a great role in study of coronaries to detect the status of these vessels and decide the treatment modality for the patient. With the epidemic of coronary artery disease in the country this investigation will go a long way in the final management of the patients.

Digital Subtraction Angiography (DSA) : In traditional angiography, we acquire images of blood vessels on films by

exposing the area of interest with time-controlled x-ray energy while injecting contrast medium into the blood vessels. The images thus obtained would also record other structure besides blood vessels as the x-ray beam passes through the body. In order to remove these distracting structures to see the vessels better, we need to acquire a mask images for subtraction. The mask image is simply an image of the same area without contrast administration. So, using manual darkroom technique, clear pictures of blood vessels are obtained by taking away the overlying background. In DSA, the images are acquired through digital format in computer. With the help of computer the images are subtracted automatically. As a result a near instantaneous film show of the blood vessel can be obtained.

Mammography : Mammography is the process of using low-dose X-rays, high contrast, high-resolution film and an X-ray system designed specifically for imaging the breasts to examine the human breast. The goal of mammography is the early detection of breast cancer, typically through detection of characteristic masses and/or micro calcifications. Mammography has been shown to reduce mortality from breast cancer.

Ultrasound : Medical sonography (ultrasonography) is an ultrasound-based diagnostic medical imaging technique used to visualize muscles, tendons and many internal organs, their size, structure and any pathological lesions. It is also used to visualize a fetus during routine and emergency prenatal care. Other uses include cardiac scan (echocardiography), renal, liver and gallbladder scans. It is also used for musculo-skeletal imaging of muscles, ligaments and tendons, ophthalmic ultrasound (eye) scans and superficial structures such as testicle, thyroid, salivary glands and lymph nodes. Because of the real time nature of ultrasound, it is often used to guide interventional procedures such as fine needle aspiration FNA or biopsy of masses for cytology or histology testing in the breast, thyroid, liver, kidney, lymph nodes, muscles and joints. Modifications of ultrasound include 3-D and 4-D ultrasonography for better visualization of the anatomy.

Applications in Public Health : This technique in antenatal cases is practiced to date the pregnancy (gestational age), confirm fetal viability, determine location of fetus, intrauterine vs ectopic, check the location of the placenta in relation to the cervix, check for the number of fetuses (multiple pregnancy), check for major physical abnormalities, assess fetal growth (for evidence of intrauterine growth restriction (IUGR), check for fetal movement and heartbeat and determine the sex of the baby. However it has been wrongly used extensively to find the sex of unborn child. This malpractice has altered the child sex ratio (0-6 yrs) of the nation to an abnormally low level of 819 in 2001 and 849 in 2008 and inhuman killing of unborn girl child. Ultrasound is also increasingly being used in trauma and first aid cases, with emergency ultrasound becoming a stable of most emergency response teams.

CT scan : CT scan works on the principle that cross sectional slices of the body are produced using X rays, followed by processing by the computers to study detailed anatomy of the specific location or slice. The modification of conventional CT is spiral where the X-ray tube/ detector combination rotates continuously around the patient creating a spiral and helps in generating high quality images.

Magnetic Resonance Imaging : Charged spinning particles such as protons behave like tiny bar magnets and are used to produce image of biological tissue in black and white depending upon the type of tissue and the specific imaging technique used. It does not use ionizing radiation hence is safe with no known biological hazards. It provides excellent tissue contrast with good spatial resolution. Images can be obtained in any plane (Multiplanar Imaging) and does not produce artifacts due to bone and is an ideal imaging modality for spine, posterior fossa and musculoskeletal system.

Applications of CT Scan and MRI in public health and clinical practice are shown in Tables - 4 and 5.

Radionuclide scan : A radionuclide scan is a way of imaging bones, organs and other parts of the body by using a small dose of a radioactive chemical. There are different types of radionuclide chemicals. The one used depends on which organ or part of the body is to be scanned. Radionuclide is put into the body, usually by a injection into a vein. Sometimes it is breathed in, or swallowed, depending on the test. Cells which are most 'active' in the target tissue or organ will take up more of the radionuclide. So, active parts of the tissue will emit more gamma rays than less active or inactive parts. The gamma rays which are emitted from inside the body are detected by the gamma camera, are converted into an electrical signal and sent to a computer. The computer builds a picture by converting the differing intensities of radioactivity emitted into different colours or shades of grey.

Public Health Importance

Bone scan : Used to detect areas of bone where there is cancer, infection or damage.

Kidney scan : Used to detect scars on the kidney and how well urine drains from the kidney to the bladder.

Lung Perfusion Scan ('VQ scan') : Detects pulmonary embolus.

IPHS Standards for Provision of Radiological Techniques: According to IPHS standards in NRHM radiological facilities which should be available at various levels are given in Table - 6.

Electrophysical Technologies

Despite existence of modern diagnostic imaging, biochemical and other techniques that enable detection of morphological and chemical changes within the body, there are also various functional disturbances sometimes detectable only via analysis of electric potentials produced by some organs (tissues) as a manifestation of their function (ECG, EEG, EMG, ERG, EOG and others). These methods can also be preferable in some cases because of their non-invasive character and economical efficiency.

Evaluation of these signals is performed either in the "time domain" (detection of particular specific peaks and wave complexes - "grapho-elements" - and description of their time and amplitude characteristics) or in the "frequency domain" (frequency spectrum characteristics). At present this is done almost exclusively with the use of computers. Since electrical activity analysis serves mainly for recognition of functional changes, pathophysiology deals with some of these signals

Modality	Remarks	Public health field
CT Angiography	Arteries and veins of any part of the body are visualized by giving a contrast medium.	Coronary Artery Disease Venous Thrombosis in smokers Diabetics
CT of Musculo-skeletal System	Musculoskeletal system is visualized and is used in detecting congenital anomalies and in trauma cases.	Trauma cases
CT Colonography	Thin CT sections of the abdomen are taken and is a useful tool over direct colonoscopy in detecting lesions specially in geriatric cases.	Geriatric field
CT Bronchoscopy	CT sections of the tracheobronchial tree are taken.	Smokers with lung cancer
Cardiac CT	Used as a marker of atherosclerosis and risk indicator for coronary event and coronary artery disease.	Coronary Artery Disease
Coronary Calcium scoring	Can be used to follow progression of Coronary atherosclerosis.	
CT Coronary angiography	Contrast medium is used to visualize the Coronary Artery Disease (CAD) to detect and study blockage.	
CT Perfusion of Brain	IV contrast is used to study Cerebral Blood Flow, Cerebral Blood Volume and Mean Transit time which can indicate presence of acute cerebral ischemia. It helps in early diagnosis of ischemic stroke.	Stroke

Technique	Remarks
MR Angiography	Used for display of vascular anatomy
MR Spectroscopy	Used in diagnosis of disorders of central nervous system
Diffusion Weighted MR imaging	Used for diagnosing ischaemic injury
Perfusion weighted MR imaging	Evaluation of viable but ischaemic brain tissue in stroke, assessment of cerebral blood volume and in patients with brain tumors Alzheimer's disease
BOLD Imaging	Useful in seizure evaluation
Cardiac MRI	Its applications include evaluation of congenital heart diseases, acquired heart diseases like pericardial effusion, pericarditis and pericardial masses. Cardiac MRI can be used to evaluate the myocardium cardiomyopathy and to assess myocardial viability in coronary artery disease.

Level of hospital (No of beds)	Facilities available
31-50	X-ray, Ultrasonography
51-100	X-ray, Ultrasonography, Colour Doppler, CT
101-200	X-ray, Ultrasonography, Colour Doppler, CT
201-300	X ray, OPG, HSG Ultrasonography Colour Doppler, Spiral CT scan, MRI 0.4 TESSLA
301-500	X-ray, Barium swallow, Barium meal, Barium enema, IVP, HSG, Dental X-ray, Ultrasonography, CT scan

(mainly with ECG, EEG) and instructs basic interpretation of some pathological findings.

Electroencephalography : This is the neurophysiologic measurement of the electrical activity of the brain by recording from electrodes placed on the scalp or in special cases, subdurally or in the cerebral cortex. The resulting traces are

known as an electroencephalogram (EEG) and represent an electrical signal (postsynaptic potentials) from a large number of neurons. In conventional scalp EEG, the recording is obtained by placing electrodes on the scalp, usually after preparing the scalp area by light abrasion and application of a conductive gel to reduce impedance. Each electrode is connected to an input of a differential amplifier, which amplifies the voltage between

them (typically 1,000-100,000 times). The resulting voltage signal is filtered which is shown on paper (in older systems), or displayed on a computer screen. It is widely used as a tool for monitoring and diagnosis in certain clinical situations :

- Epilepsy and syncope
- Sleep disorders
- Coma and brain death

Electrocardiography : An electrocardiogram (ECG or EKG, abbreviated from the German *Elektrokardiogramm*) is a noninvasive transthoracic graphic produced by an electrocardiograph, which records the electrical activity of the heart over time. Electrodes on different sides of the heart measure the activity of different parts of the heart muscle. An ECG displays the voltage between pairs of these electrodes and the muscle activity that they measure, from different directions, also understood as vectors. This display indicates the overall rhythm of the heart and weaknesses in different parts of the heart muscle.

Applications in public health : It is the best way to measure and diagnose abnormal rhythms of the heart, particularly abnormal rhythms caused by damage to the conductive tissue that carries electrical signals, or abnormal rhythms caused by levels of dissolved salts (electrolytes), such as potassium, that are too high or low. In myocardial infarction (MI), the ECG can identify damaged heart muscle.

Electromyography : Electromyography (EMG) is a technique for evaluating and recording the activation signal of muscles. EMG is performed using an instrument called an electromyograph, to produce a record called an electromyogram. An electromyograph detects the electrical potential generated by muscle cells when these cells contract and also when the cells are at rest. EMG is used to diagnose two general categories of disease : neuropathies and myopathies.

Summary

IPHS prescribed various standards for the availability of laboratory facilities as per the bed status of Health care setting and are stated as a part of NRHM. The various modern diagnostic technologies can be classified into various categories like Immunopathology, Molecular Biology, Clinical Chemistry, Haematology, Cytopathology, Histopathology, Radiology and Electrophysiology.

The available Diagnostic Technologies in Immunopathology are Precipitation immunoassays (Widal test and the Weil-Felix test), Particle immunoassay (hemagglutination tests), Radioimmunoassay (ELISA) and Immunofluorescence assays.

Hemagglutination tests are used for diagnosis of Syphilis, hepatitis B and hepatitis C and Latex agglutination is widely used in measurement of hCG for qualitative pregnancy tests. ELISA can be used for diagnosing HIV and detecting tumour markers for certain cancers, e.g. Prostate specific antigen (PSA) in carcinoma prostate. Immunofluorescence assays have been extensively used for ZN staining in TB and in detecting antigens in tissue sections, e.g. kidney biopsies.

The available Diagnostic Technologies in Molecular Biology are Gel electrophoresis, Hybridisation assays, Amplification technology, PCR (Polymerase chain reaction) and Restriction

Fragment Length Polymorphism (RFLP) based assays. DNA Probes are available for various organisms like Mycobacterium tuberculosis, Chlamydia trachomatis, Neisseria gonorrhoeae, Human papilloma virus, Hepatitis C virus, Cytomegalovirus and Herpes simplex virus. This is especially important for slow growing organisms like Mycobacteria, fungi etc. DNA amplification is used for diagnosis of Hepatitis C Virus, HIV, TB, STDs and for Detection of antimicrobial resistance.

The available Diagnostic Technologies in Clinical Chemistry are Colorimetry, Nephelometry, Electrophoresis, Chromatography and Automation in clinical chemistry.

Colorimetry forms the basis of assessing almost all parameters in clinical chemistry Nephelometry is useful in measurement of antigen antibody complexes formed in immunoassays. Electrophoresis is used for Separation of serum proteins and Separation of hemoglobins, which is important in the diagnosis of various abnormal hemoglobins like thalassemia, sickle cell anemia etc. Chromatography is used for determination of drugs and chemicals in body fluids (toxicology). Detection of additives / chemicals in food is possible through High performance liquid chromatography. Environmental and water pollutants can be detected with accuracy through the use of various chromatographic procedures.

The available Diagnostic Technologies in Hematology are Automated Instruments like the cell counting components, Blood counting machines, flow cytometry etc. In addition to counting, measuring and analyzing red blood cells, white blood cells and platelets, automated hematology analyzers also measure the amount of hemoglobin in the blood and within each red blood cell. The available Diagnostic Technologies in Cytopathology are Exfoliative cytology (used for cytologic screening for cervical cancer), Fine Needle Aspiration Cytology (used for evaluation of lesions/ nodules arising from breast, lymph nodes, thyroid, liver, kidney and soft tissue). The available Diagnostic technologies in Histopathology are Histopathological staining and Immunohistochemistry. Histopathology (the most commonly used stain in histopathology is a combination of hematoxylin and eosin) is used as gold standard of diagnosis in clinical medicine and it is eminently suited to diagnosis of diseases and conditions like malignancies and also some non neoplastic conditions like tuberculosis and other infections. Immunohistochemistry is used for diagnosis of tumours/ non neoplastic conditions by specific molecular markers like S100, Cytokeratin.

The available Radiological techniques are X-ray (e.g. for diagnosis of Chronic infections like TB), DEXA Scan (used for screening of osteoporosis, particularly in women), Angiography and Digital Subtraction Angiography(DSA) (mainly used for Cardiovascular diseases), Mammography (screening of Breast Ca), Ultrasound (e.g. Antenatal care), Radionuclide scan (used for Bone scan, Kidney scan, Lung Perfusion scan), CT scan and Magnetic Resonance Imaging (mainly used for Cardiovascular diseases).

The available Electrophysical Technologies are Electroencephalography, Electrocardiography and Electromyography. EEG is widely used as a tool for monitoring and diagnosis Epilepsy and syncope, Sleep disorders, Coma and brain death.

ECG is widely used for diagnosis of Arrhythmias and CAD. EMG is used to diagnose neuropathies and myopathies.

Study Exercises

Short Notes : (1) Applications of Radiological techniques in Public Health (2) Applications of Immunopathology techniques in Public Health (3) Applications of Hematological techniques in Public Health (4) Applications of Electrophysical techniques in Public Health.

MCQs

1. Which of the following is not a electrophysiological diagnostic technique : (a) EEG (b) EMG (c) DEXA SCAN (d) a & b.
2. Which of the following is usually used as gold standard of diagnosis in clinical medicine (a) Histopathology (b) Electrophysiology (c) X-ray (d) Clinical Chemistry.

Answers : (1) c; (2) a.

Accreditation of Health Care Facilities

Udai Bhaskar Misra

External assessment of healthcare has attained an ever increasing dimension globally. There are various models of External Assessment like ISO certification, business excellence, peer review, statutory inspection and accreditation. Accreditation can be regarded as one of the most attractive form of tool for External Quality Assessment of healthcare organizations. The concept was started in USA and at present many countries world over are practising this model of External Quality assessment (1).

Evolution of Accreditation

The inception of the process began with the development of Minimum Standards for Hospitals by American College of Surgeons in 1917. In 1951, the American College of Physicians, the American Hospital Association, the American Medical

Association and the Canadian Medical Association joined with the American College of Surgeons to create the Joint Commission on Accreditation of Hospitals (JCAH). The Canadian Medical association withdrew from the JCAH in 1959. In 1971, the JCAH established the Accreditation Council for Long-Term Care and subsequently Accreditation for ambulatory care began in 1975. In 1987, since the scope was further expanded, the name of the organization was changed to the Joint Commission on Accreditation of Healthcare Organizations (2). Accreditation for healthcare networks began in 1994 and JCAHO and Quality Healthcare Resources formed the Joint Commission International with the goal of serving hospitals in other countries. Joint Commission Resources now provides consultation worldwide on healthcare issues and Joint Commission International is the largest Accreditation organisation, concerned with global accreditation. Gradually, accreditation has become a national yardstick for healthcare organisations in many countries including Australia, UK and European Countries. In developing countries, though, some beginning has been made but it is still in infancy.

Definition

Accreditation may be defined as a formal process by which a recognized body, usually a non-governmental organization (NGO), assesses and recognizes that a healthcare organization meets pre-determined standards. It can also be defined as a system of external peer review of an organization for determining compliance against predetermined standards, usually as a voluntary process.

Accreditation standards are usually regarded as optimal and achievable and are designed to encourage continuous improvement in delivery of healthcare within accredited organizations. An accreditation decision about a specific healthcare organization is made following a periodic on-site evaluation by a team of peer reviewers, typically conducted every two to three years. It is usually a voluntary process in which organizations choose to participate, rather than one required by law and regulation. Accreditation has following principal components :

- (a) It is based on written and published standards.
- (b) Reviews are conducted by professional peers.
- (c) The accreditation process is administered by an independent body.
- (d) The aim of accreditation is to encourage organisational development.
- (e) It is usually a voluntary process.

The effectiveness of accreditation is dependent on its voluntary nature, non-threatening process and interaction with external reviewers as a means of attaining desired quality improvements. Accreditation programmes, if undertaken with careful planning, strong government support and organizational commitment have the potential to improve the quality of care available in hospitals and medical laboratories in many developing countries.

Purpose

Purpose of Accreditation is to :

- (a) Improve the quality of healthcare by establishing optimal achievement goals in meeting standards for healthcare organizations.
- (b) Stimulate and improve the integration and management of health services.
- (c) Establish a comparative database of healthcare organizations able to meet selected structure, process and outcome standards or criteria.
- (d) Reduce healthcare costs by focusing on increased efficiency and effectiveness of services.
- (e) Provide education and consultation to healthcare organizations, managers and health professionals on quality improvement strategies and “best practices” in healthcare.
- (f) Strengthen the public’s confidence in the quality of healthcare and reduce risks associated with injury and infections for patients and staff.
- (g) Accountability to professional bodies.

Accreditation Procedure

There are many recognized bodies providing Accreditation to Healthcare Institutions. These have diverse policies and procedures (3, 4). However, the common elements in a typical

Accreditation procedure are as under :

(a) Setting and publication of standards and elements of performance by a recognized body :

(i) Standard : A Standard is a Statement that defines the performance expectations and /or structure or processes that must be in place in order for an organization to provide safe, high quality care, treatment and services.

(ii) Elements of performance : The specific performance expectations and /or structures or processes that must be in place in order for an organization to provide safe, high-quality care, treatment and services.

(iii) Rationale : Some of the accrediting bodies have also included rationale for having standards in their document. Rationale is a statement that provides background, justification or additional information about a standard.

- (b) Application for registration by the healthcare institution.
- (c) Payment of fees.
- (d) Pre-survey activities.
- (e) Survey by the multidisciplinary team of Accreditation Body.
- (f) Resurvey, if the Institution is found deficient in certain areas of delivery of care.
- (g) Accreditation report and award of Accreditation.
- (h) Resurvey after a fixed period.

Health care accrediting bodies use a variety of evaluation approaches during the on-site survey in order to determine the healthcare organization’s performance with predetermined standards. These methods include any combination of the following (5) :

- (a) Interviews of the top level Administrators or the Managers of the organization
- (b) Clinical and support staff interviews.
- (c) Patient and family interviews.
- (d) Observation of patient care and services provided.
- (e) Tour of the building facilities, observation of patient care areas, equipment management and diagnostic testing services.
- (f) Review of written documents such as policies and procedures, training documents, financial documents and quality assurance plans.
- (g) Evaluation of the organization’s achievement of specific outcome measures (e.g. Immunization rates, hospital-acquired infection rates, patient satisfaction).
- (h) Evaluation of patients’ medical records.

Advantages of Accreditation

Although this area requires more research but many studies have indicated the advantages of Accreditation to the hospitals, staff and the patients. It forms an essential basis for Quality Assurance Programme in a healthcare organization (6, 7). The advantages of accreditation can be grouped as under :

Benefits to the Hospital

- (a) It Improves delivery of medical care and enhances the image of the hospital. Thus, for private healthcare organizations it also results in more business.
- (b) It stimulates a process of continuous improvement in delivery of medical care.

Benefits for the employees

- (a) It helps in education, training and development of professional staff.
- (b) Provides leadership for quality improvement within medical profession and nursing.
- (c) Increases satisfaction of employees with working conditions and leadership.
- (d) It aims for improved employee safety and security.
- (e) It promotes team work.

Benefits for Patients

- (a) Provides access to organizations providing quality medical care.
- (b) Patient's rights are respected and protected.
- (c) It increases patient's Involvement in medical care decisions.
- (d) Focuses on patient safety.

Review of Accreditation Systems in selected countries

The discussion on accreditation will not be completed without a review of status in selected countries, the same is appended below :

Accreditation System in USA : There are a number of organizations in US performing the function of accreditation of healthcare institutions as given below (8) :

- (a) The Joint Commission on Accreditation of Healthcare Organizations (JCAHO).
- (b) The National Committee for Quality Assurance (NCQA).
- (c) The American Medical Accreditation Program (AMAP).
- (d) The American Accreditation Health Care Commission / Utilization Review Accreditation Commission (AAHC/URAC).
- (e) Accreditation Association for Ambulatory Health Care (AAAHC).

JCAHO is the largest and oldest accrediting body of USA. It is an independent, non government and not-for-profit organization. It has provided accreditation to more than 20,000 healthcare organizations both in US and outside. It has a board of Commissioners including 28 members. The constitution of the board includes :

- (a) Administrators, Physicians, Medical directors and Nurses
- (b) Consumers
- (c) Providers of care
- (d) Employers, Human Resource and quality expert
- (e) Health Insurance expert and expert in Ethics
- (f) Corporate and Public Members.

The Corporate members include American College of Surgeons, the American College of Physicians, the American Dental Association, the American Hospital Association and the American Medical Association. JCAHO hospital standards can be grouped as under :

(a) Patient focused functions : These include standards on following :

- (i) Ethics, Rights and Responsibilities
- (ii) Provision of care, treatment and services
- (iii) Medication management
- (iv) Surveillance, Prevention and Control of Infection

(b) Organisational functions : Standards pertaining to following aspects are included in this section :

- (i) Improving organization performance
- (ii) Leadership
- (iii) Management of the environment of care
- (iv) Management of human resources
- (v) Management of Information

(c) Structures with functions : This section includes standards on following aspects :

- (i) Medical Staff
- (ii) Nursing

In 1997 Joint Commission initiated first step in establishing a link between accreditation and the outcomes of patient care, treatment and service issues using an ORYX tool. In order to apply this tool, initial core measure focus conditions for patient in a given location are identified in consultation with various professional bodies and field assessment. Subsequently, accredited hospitals choose 3 core measures out of the list earlier decided for example Acute Myocardial Infarction, Pneumonia and Heart failure.

During on site survey, the Joint Commission team assesses performance improvement in conditions related to selected core measures with the help of data from the hospital. ORYX Plus is a voluntary option, the requirements of which far exceeds those of ORYX. It is used by organizations that intend to contribute to a national database. The JCAHO expects home health agencies to establish their own performance measures, which gives these organizations the freedom to develop their own quality assurance programs and outcome measures (9).

Accreditation system in Australia (10, 11) : The Australian Council on Healthcare Standards (ACHS) is an institutional accreditation body established in 1974. At present Ninety percent of the country's healthcare organisations are its members. ACHS conducts a voluntary program of health facility accreditation modeled along the lines of the Joint Commission. To increase clinician involvement in the accreditation process, also in quality assurance programs and to enable some assessment of the outcome of care in a facility at the time of survey, the ACHS, together with the medical colleges, is developing objective measures of care (clinical indicators).

Ten medical colleges were incorporated in developing the clinical indicators. The first set of measures, the Hospital-Wide Medical Indicators (HWMIs) developed in conjunction with the Royal Australian College of Medical Administrators, was formally introduced into the accreditation process in January 1993. These indicators were developed by a combined working party of the Care Evaluation Program and the Royal Australian College of Medical Administrators. The HWMIs address the areas of trauma, postoperative pulmonary embolism, readmissions to hospital, returns to the operating room, hospital-acquired infection, medication errors, etc. Development of objective measures of care (clinical indicators) will facilitate the accreditation process. It will also enable Australian physicians to compare patient care throughout the healthcare system.

Accreditation system in UK (12) : The royal commission on the NHS recommended in 1979 that a special health authority be set up to develop and institutionalise standards for healthcare

organizations. In the early 1980s several monitoring agencies were suggested but, despite favourable response from national professional bodies, no such national agency featured in the government's white paper of 1989 "Working for Patients". In the absence of any governmental lead, several small and large peer review accreditation programmes emerged as external voluntary mechanisms for organisational development. There are now more than 35 such programmes equipped with standards and trained assessors. However, integration and consistency between these programmes are lacking.

NHS institutions also have their visits from clinical training programmes, inspectors (such as for fire regulations, environmental health, etc). In addition the NHS Information Authority and Information Management Centre for data quality, Controls Assurance for risk management. The Clinical Standard Board for Scotland, the National Institute for Clinical Excellence (NICE) and Commission for Health Improvement (CHI) for England and Wales have been established to improve standards in the NHS. At present the requirement is to provide public access to the valid standards, reliable assessment and fair judgment. The NHS system also suffers from duplication and inconsistency.

Accreditation System in India

Accreditation Boards under Quality Council of India (QCI) : QCI is an autonomous body set up jointly by Government of India and Industry to establish and operate accreditation structure in the country. Initially it started with product certification and inspection under ISO 9001 series. Subsequently QCI developed standards for accreditation of laboratories and the Hospital as different boards. The same are discussed below.

National Accreditation Board for Testing and Calibration Laboratories (NABL) : National Accreditation Board for Testing and Calibration Laboratories (NABL) is an autonomous body under the aegis of Department of Science & Technology, Government of India and is registered under the Societies Act. Government of India has authorised NABL as the sole accreditation body for Testing and Calibration laboratories.

NABL provides laboratory accreditation services to laboratories that are performing tests / calibrations in accordance with ISO/IEC 17025 : 1999 General Requirements for the Competence of Testing and Calibration Laboratories. These services are offered in a non-discriminatory manner and are accessible to all testing and calibration laboratories in India and abroad, regardless of their ownership, legal status, size and degree of independence.

Scope and duration : NABL Accreditation is currently given for Testing Laboratories like Electronics, Calibration Laboratories like Optical and Radiological, Clinical Laboratories and Forensic Laboratories. The accreditation granted to a laboratory is valid for a period of 3 years subject to satisfactory annual surveillance.

National Accreditation Board for Hospitals and Healthcare providers (NABH) : NABH is a constituent board of QCI set up with cooperation of the Ministry of Health and Family Welfare, Government of India and the health Industry. However, the Board has complete autonomy in its operation. NABH is a member of International Society for Quality in healthcare

(ISQua). The Technical Committee of NABH had formulated first edition of standards for hospitals in 2005 which have been revised and in November 2007 second edition of standards have been published.

Standards of NABH : There are 10 chapters in NABH document including 100 standards. The standards can be classified as :

(a) Patient Centered standards : These include :

- (i) Access, Assessment and Continuity of Care
- (ii) Care of patients
- (iii) Management of medication
- (iv) Patient Rights and Education
- (v) Hospital Infection Control

(b) Organisation Centered Standards : These include :

- (i) Continuous Quality Improvement
- (ii) Responsibilities of Management
- (iii) Facility Management and Safety
- (iv) Human Resource Management
- (v) Information management System

Each standard is further divided into variable number of objective elements. There are 515 objective elements for accomplishment of 100 standards. Objective elements frame the guidelines for achieving a particular standard.

Indian Confederation for Healthcare Accreditation (ICHA):

ICHA is a body of national associations / institutions in healthcare sector. The basic objective of ICHA is to establish a mechanism of comprehensive healthcare accreditation system. It is an autonomous not-for-profit but self sustaining organisation driven by healthcare professionals. In August 2002 ICHA was constituted with the members from major healthcare associations of the country like the National Associations of Physicians (API), Surgeons (ASI), Anaesthetists (ISA), Ophthalmologists (AIOS), Pharmacists (IPA), Hospital administrators (AHA) and Hospital Pharmacists (IHPA). At present there are about 25 National Associations as members, 4 affiliate associations, 12 Individual organisational affiliates and 179 individual affiliates. The basic methodology of ICHA in granting accreditation is similar to NABH, however, the system is not as comprehensive and popular as NABH. .

Future Challenges

Competitive rivalry amongst the healthcare organizations:

Accreditation is an important method for Healthcare Organizations to distinguish themselves amongst their competitors in India. This will promote competitive rivalry amongst Healthcare Organisations, to obtain Accreditation. It is intimated that about 20 Hospitals have already applied for Accreditation to NABH and 40 more are preparing for it in India (16). After obtaining Accreditation, our Healthcare Organisations will become tough competitors to International Hospitals as they will be delivering quality care at much lower cost compared to other countries.

However, considering the giant size of healthcare sector in our country, it is suggested that the development of infrastructure of Accreditation Agencies like NABH should keep pace with the number of Healthcare Organizations applying for accreditation; otherwise the process may continue more than a decade before the healthcare organizations are accredited. This will require

meticulous planning for trained assessors to undertake the survey.

Technological Boom : There will be increasing acquisition of high cost and advanced technology to over ensure the implementation of accreditation standards and to satisfy competitive rivalry amongst healthcare organisations. This will result into technological boom and haphazard mushrooming of equipment Industries. Such trends may lead to a requirement of accreditation of equipment agencies / OEM providing medical technology. Accreditation agencies like JCAHO are not only concerned with the proper technology but also whether the use information with regards to the equipment has been transferred to the ultimate users. Thus it is imperative on our part to work out some regulatory mechanism so that quality equipment is provided to users with assured after sale maintenance. Accreditation of equipment agencies will discourage mushrooming of substandard technology and facilitate the implementation of technology related standards of Accreditation for healthcare organizations.

Promotion of medical tourism : Many countries are already suffering with sky rocketing cost of care and long waiting line for definitive care. India has about 20 million individuals living abroad as NRIs or otherwise. They function as best of marketing ambassadors of medical care for brand India when they return to the Nation they are settled, after spending their leave back home. This is one of the major factors which have led to the promotion of Medical Tourism. The phenomenon can be further supported if our hospitals are accredited by a comprehensive Accreditation System and regulation of Tourism Industry. In some countries Medical Tourism is having an economic impact and similar predictions are made for our country in McKinsey Report submitted by the commission engaged for Study on Health care under the aegis of Confederation of Indian industry. Countries like USA are in an advantageous position for health tourism as about Ninety six percent of the hospital beds are in accredited hospitals. However, the cost of treatment in US is inhibitory for patients which is a definite advantage with Indian hospitals.

Accreditation of miscellaneous healthcare organisations other than hospitals and part-facilities : It is evident that the “first takers” for the Accreditation will be the Corporate Hospitals for the obvious reasons. Subsequently, other facilities like Ambulatory Care Centers, Nursing Homes and Clinics may come forward for obtaining Accreditation. Thus in the subsequent phase the Accreditation body should be ready with standards which are applicable to variety of healthcare organizations. However, Indian Accrediting bodies are not ready with the standards for various healthcare organizations. A workable solution could be to evolve the standards in the form of modules which are applicable to different organizations with addition / deletion of certain items.

Accreditation of disease specific care : Once the process of Accreditation is established in India, the Disease Specific Accreditation may be developed. The common diseases like Diabetes, Hypertension, Tuberculosis, COPD and IHD may be identified which cover about 80 to 90% population. The willing organisations which may not afford for Comprehensive

Accreditation may be considered for Disease Specific Accreditation Programme. JCAHO has already started with Disease Specific Accreditation in 2002. However, it may have both positive and negative aspects. For example the organisations may obtain Accreditation for limited number of diseases but this transparency may not be maintained during marketing campaigns. Thus it needs further deliberation and formulation of policies accordingly (4).

Accreditation of Clinical Care : Once the Accreditation process is well firmed up in India, a possible ramification of the process to introduce the Clinical Accreditation programme may be initiated in collaboration with apex Medical Institutions / experts. Initially, particular aspect of care for example Acute Care may be chosen for programme and gradually it may be extended. Australian Council of Healthcare Standards has already started an Accreditation Programme for Acute Care by identifying about 200 Indicators which are utilised to monitor the clinical services. The growth of this programme has been overwhelming and many nations have joined this programme. Such programmes can be beneficial in improving the clinical processes and the outcome aspect of care.

Accreditation of healthcare organisations providing alternative care : A large amount of Indian population is seeking healthcare from healthcare providers dealing in alternative medicine. With increasing awareness of clients, these healthcare organizations may also like to apply for Accreditation. This may involve further efforts at the part of Accreditation Providing Agencies in the form of formulation of policies, designing different set of Standards and other resources. In developed countries there are many agencies providing accreditation for alternative systems of medicine for example Royal College of Alternative Medicine UK, British Medical Acupuncture Society, The American Alternative Medicine Association and so on.

Accreditation of Public sector healthcare organization : It is contemplated that the Public Sector Healthcare organizations may be the last one to seek the Accreditation. However, with increasing awareness of clientele about the Accreditation of Healthcare organizations in Corporate Sector, the client pressure will compel the Public Sector Organisations to seek the accreditation. It is suggested that our ultimate goal should be to ensure reasonable standard of care at the grass root level by accreditation of Primary Health Care Centers through involvement of Central and State Governments.

Increasing empanelment of accredited organisations by Insurance agencies : It is evident that there will be rising trend for Insurance agencies to empanel the hospitals which are accredited. Insurance companies may use accreditation as a tool to decide which healthcare organisations to reimburse.

Cost Escalation : There may be miscellaneous reasons for escalation of the cost for healthcare during the process of accreditation. It is documented that the cost of accreditation by NABH is about one tenth of Joint Commission International (JCI). The cost of Accreditation process for a 500 bedded hospital is about 7 lakh. However, additional cost will be incurred in implementing the structure, process and outcome in accordance with NABH standards and then maintaining it. The question is

who will bear this cost ? Most likely this cost may be shifted to the patients. Secondly, the increase in paying capacity can also lead to rise in cost. The influx of foreign patients has already resulted in cost escalation in some of the areas of our country.

Care of unaffordable class : Accreditation of healthcare organisations does not provide an answer for the medical care of unaffordable class. If the accreditation process is not monitored / regulated in a disciplined way it may result in escalation of cost of care which will further hurt the poor class. There is a need for Government intervention in this regard to formulate adequate policies. The feasibility for cross subsidisation of the medical care of the poor class from the revenue earned by accredited hospitals through Medical Tourism should be worked out.

Medical trade : With growing recognition of Indian Hospitals having an accreditation tag and influx of foreign nationals for healthcare, doors of miscellaneous trade ventures will be opened. Sooner or later there will be involvement of third party between the patient and the hospital. Such agencies may offer different types of packages, starting from identification of a hospital to provision of transport and other administrative and logistics aspects including the hospice services if required at any point of time. It will be very essential to regulate such trade so that the image of our healthcare sector is not tarnished in the eyes of the other Nations.

To conclude, Accreditation is an International phenomenon. It is catching up in India in the right time as many countries are looking for alternative destinations to their healthcare organisations either due to cost escalation or due to a long waiting line for the procedures. However, it should be designed, regulated and monitored properly.

It is suggested that design of standards should be such so as to provide high inter assessor reliability and validity. Standards which are low on inter-assessor reliability should be revised or discarded. Similarly, assessing which factors contribute to inter-rater reliability and understanding how attitudes and behaviours of surveyors contribute to an effective system will influence the choice and training of surveyors.

While many claims are made about the benefits of accreditation processes, empirical evidence to sustain many such claims is currently lacking. Researching the impact of accreditation on individual and organisational performance is an important undertaking. The question arises as to how best to research the validity, impact and value of accreditation processes in healthcare. In countries where most healthcare organisations participate in some sort of accreditation process it may not be possible to study its merits using a randomised controlled strategy.

However, In India it is the right time for such research. As the sample will be available for a randomized controlled trials from the hospitals which are accredited and those without accreditation. Thus, research studies are necessarily required in India to discover the overall impact of Accreditation.

Summary

Accreditation can be regarded as one of the most attractive form of tool for External Quality Assessment of healthcare

organizations. Accreditation for healthcare networks began in 1994 and JCAHO and Quality Healthcare Resources formed the Joint Commission International with the goal of serving hospitals in other countries. Joint Commission Resources now provides consultation by Joint Commission worldwide on healthcare issues and Joint Commission International is the largest Accreditation body, concerned with global accreditation. One of the chief purposes of Accreditation is to Improve the quality of healthcare by establishing optimal achievement goals in meeting standards for healthcare organizations. Health care accrediting bodies use a variety of evaluation approaches during the on-site survey in order to determine the healthcare organization's performance with predetermined standards.

The advantages of accreditation can be grouped as benefits to the Hospital, which include improvement of delivery of medical care, benefits for the employees in providing education, training and development of professional staff and benefits for Patients which include provision of access to organizations providing quality medical care. There are a number of organizations in US performing the function of accreditation of healthcare institutions. JCAHO is the largest and oldest accrediting body of USA. It has provided accreditation to more than 20,000 healthcare organizations both in US and outside. It has a board of Commissioners including 28 members. JCAHO hospital standards can be grouped as Patient- focused functions and Organisational functions. The Australian Council on Healthcare Standards (ACHS) is an institutional accreditation body established in 1974. At present Ninety percent of the country's healthcare organisations are its members. The first set of measures, the Hospital-Wide Medical Indicators (HWMIs) developed in conjunction with the Royal Australian College of Medical Administrators, was formally introduced into the accreditation process in January 1993.

The royal commission on the NHS recommended in 1979 that a special health authority be set up to develop and institutionalize standards for healthcare organizations. There are now more than 35 such programmes equipped with standards and trained assessors. The Clinical Standard Board for Scotland, the National Institute for Clinical Excellence (NICE) and Commission for Health Improvement (CHI) for England and Wales have been established to improve standards in the NHS.

QCI is an autonomous body set up jointly by Government of India and Industry to establish and operate accreditation structure in the country. National Accreditation Board for Testing and Calibration Laboratories (NABL) provides laboratory accreditation services to laboratories that are performing tests/ calibrations in accordance with ISO/ IEC 17025. Indian Confederation for Healthcare Accreditation (ICHA) : ICHA is a body of national associations / institutions in healthcare sector. The basic methodology of ICHA in granting accreditation is similar to NABH. It is imperative on our part to work out some regulatory mechanism so that quality equipment is provided to users with assured after sale maintenance. In some countries Medical Tourism is having an economic impact and similar predictions are made for our country. A workable solution could be to evolve the standards in the form of modules which are applicable to different organizations with addition / deletion of certain items.

Once the Accreditation process is well firmed up in India, a possible ramification of the process to introduce the Clinical Accreditation programme may be initiated in collaboration with apex Medical Institutions / experts. With increasing awareness of clients, alternative medicine healthcare organizations may also like to apply for Accreditation. It is contemplated that the Public Sector Healthcare organizations may be the last one to seek the Accreditation.

There are miscellaneous reasons for escalation of the cost for healthcare during the process of accreditation. The feasibility for cross subsidisation of the medical care of the poor class from the revenue earned by accredited hospitals through Medical Tourism should be worked out.

With growing recognition of Indian Hospitals having an accreditation tag and influx of foreign nationals for healthcare, doors of miscellaneous trade ventures will be opened.

Accreditation is an International phenomenon. It is catching up in India in the right time as many countries are looking for alternative destinations to their healthcare organisations either due to cost escalation or due to a long waiting line for the procedures. However, it should be designed, regulated and monitored properly.

Study Exercises

MCQs

- The concept of accreditation was started in which country? (a) USA (b) UK (c) Germany (d) France.
- A Statement that defines the performance expectations and /or structure or processes that must be in place in order for an organization to provide safe, high quality care, treatment and services, is known as (a) Rationale (b) Element of performance (c) Vision (d) Standard.
- The largest and oldest accrediting body of USA is (a) Accreditation Association for Ambulatory HealthCare (AAAHC) (b) American Medical Accreditation Program (AMAP) (c) National Committee for Quality Assurance (NCQA) (d) Joint Commission on Accreditation of Healthcare Organizations (JCAHO).
- The autonomous body set up jointly by Government of India and Industry to establish and operate accreditation structure in the country is (a) Bureau of Indian Standards (BIS) (b) Quality Council of India (QCI) (c) National Accreditation Authority (NAA) (d) Indian Confederation for Healthcare Accreditation (ICHA).
- The cost of Accreditation process for a 500 bedded hospital is about (a) Rs. 10 Lakhs (b) Rs. 05 Lakhs (c) Rs. 07 Lakhs (d) Rs. 01 Lakh.

Answers : (1) a; (2) d; (3) d; (4) b; (5) c.

81 Health Care Financing

Sunil Nandraj, N Devadasan, Alaka Singh

Every health system has the responsibility not just to improve the health of the population, but also to protect them against the financial cost of illness and to treat them with dignity. The way a health system is financed is a key determinant of population health and well-being. In many of the poorest countries, the level of spending is still insufficient to ensure equitable access to basic and essential health services and interventions and therefore a major policy issue is how to ensure adequate and equitable resource mobilization for health. There is no single answer to the question of how to finance health systems. Not only do the specific challenges faced by countries differ, each country already has a system of health financing that has developed over a period of time.

Health policy and financing policy are inseparable because financing policy determines who has access to basic health care, how much is available, who controls the funds and how they are used; the technical, allocative and distributive efficiency of resource in use, social protection, what financial incentives are given to patients and providers and whether health care cost inflation can be controlled. Fig. - 1 shows conceptual framework of Health System.

Fig. - 1: Health System conceptual framework

Spending on health has been increasing world-wide. While cost-effective responses to preventable and communicable morbidity and mortality, there is a growing challenge from high-cost non-communicable and 'new' diseases. Advances in medical technology, higher population and providers' expectations, income growth, health system development are some determinants. Increased inequalities in health spending between and within countries. Health care financing is at the center of most health policy reforms. New medicines and other technological developments, rising expectations and aging populations fuel increased demand and hence put upward pressure on system costs. Concurrently, macroeconomic, demographic and fiscal constraints limit the extent to which governments can simply allocate more public revenues for health. The combination of upward pressure on costs and

limitations on the ability of governments to increase spending forces countries to consider reforms to the way that their health systems are financed.

Financing of Health Care in India

The current scenario in the health sector is plagued by high maternal and child mortality, dual burden of communicable & non-communicable diseases, poor health of majority, especially the poor. Inability of a large section of the population, especially from lower income to access good health care with spiraling health costs. Hospitalization for major illness is a cause of indebtedness for all income groups, especially those from the lower income. There is an increasing demand for health care services. The government is functioning under a resource crunch coupled with states facing financial crisis and unable to meet recurring expenditure of the health sector.

Like all countries in the world, India too faces difficult challenges and choices in financing its health systems. India has a mixed form of financing health care. The government is supposed to provide 'free' health care for all the citizens by raising funds from taxes. Unfortunately, the government's revenue is low, resulting in a small proportion being allocated for health care. Because of this chronic under funding, most government facilities are not able to provide health care to all its citizens. So, many patients go to the private sector institutions and pay for their health care which accounts for 72 percent from households (Chart 1). Thus, the Indian health service is financed by both tax based revenues and by out of pocket payments (OOP). Health insurance plays a very small part in financing health services in India. The total health expenditure in India for the year 2001-02 was Rs 1,057,341 million, which accounted for 4.6 percent of its GDP. Of the total expenditure, 20.3 percent was public / government expenditure, 77.4 percent was private expenditure and remaining 2.3 percent external support. (Table1) Over all, the per capita health expenditure for the year was Rs 1021 (about US\$ 25). Compare, this with amounts spent by high income countries (US\$ 3000 – 5,000).

Chart - 1 : Health Expenditure by Financing Sources (2001-02)

Health Care Functions and Mechanisms

A health system has many actors and many functions. One of this is to finance health care. There are three basic functions of a health financing system :

Revenue collection : Financial contributions to the health system have to be collected equitably and efficiently;

Pooling : Contributions are pooled so that the costs of health care are shared by all and not borne by individuals at the time they fall ill. This requires a certain level of solidarity in the society.

Purchasing : The contributions are used to buy or provide appropriate and effective health interventions.

- Provider Payment

Out of Pocket Payments (OOP)

This is the simplest form of health care financing i.e. a patient goes to a provider and pays for the services received. In India, this is commonly followed when a patient visits a private practitioner. User fees paid in government hospitals are an example of “out of pocket payments”. In India, this is the most common form of financing health care. While the revenue collection function may be good, the pooling and purchasing mechanism is negligible. Individual patients have very little negotiation power and information to purchase effective and appropriate care.

The main financier of health services in India is the individual household. They meet 72% of the total health care costs by paying out of pocket at the time of service. Thus patients go to dispensaries, clinics and hospitals and receive health care. In turn they pay money for this health care from their own funds. Indian households have one of the least protection in terms of OOP payments. In most high income countries, only about 5-10% of households have to pay OOP payments and these are usually in the form of pre/co-payments to contributory financial protection schemes e.g. social health insurance. In middle income and low income countries, the proportion increases to about 25-50% of households. OOP have two adverse consequences, they lower access to health care by creating financing barriers. Some people hesitate to go to hospitals or dispensaries as they may not be able to afford the fees. NSSO studies have shown that 18% of households do not access even OP care, mainly because of financial barriers. Secondly, they impoverish the households because of high medical costs. Studies have shown that at least 40% of Indian households have had to borrow or to sell their assets to pay hospital bills. A quarter of hospitalised patients in India have been impoverished because of high medical costs. (NSSO 60th Round : Morbidity, Health care and condition of the aged). Further, it is seen from Chart - 2 that there are wide variations of ratio of public to private expenditure across the major states in India.

General Tax Revenue

Governments collect revenue through taxes, both direct and indirect. This revenue is allocated to various sectors including the health sector. Equity and efficiency of government revenue-financed health systems ultimately depends on the overall tax collection structure. Financing health services through government is to raise sufficient and sustainable revenues in an efficient and equitable manner to provide individuals with both a basic package of essential services and financial protection against unpredictable catastrophic financial losses caused by illness and injury. The key issues in revenue collection are level of income, tax-base and fiscal space, tax incidence, transaction cost and size of informal sector. General revenues are considered to be the most equitable means for health financing. They may be considered a mechanism for sustainable risk pooling that allows financial protection based on political and societal choices – this may be subsidized primary care, public health interventions and / or services for targeted population groups. General revenues allow a broader

Ideally a financing system should be able to generate revenue, pool the funds so that there is cross-subsidy between the rich and the poor and also between the healthy and the sick. Finally, the financing system should be able to purchase appropriate and efficient health care services from the provider on behalf of the patient. A health care financing is assessed on feasibility, equity, efficiency and sustainability.

Broadly, there are various options and mechanisms for financing the health care services :

- Out of Pocket Payment
- General Tax Revenue
- Insurance : Social Health Insurance; Private Health Insurance; Community Based Health Insurance
- External Finance

range of taxes for financing health while earmarked taxes could potentially safeguards funds for health – from competing demands on general revenues from other sectors as well as for flexibility in use. Earmarked taxes are the ‘boundary’ between tax-based health financing and social insurance.

Government health services are usually financed by general revenue sources e.g. in India, most of the government health services are financed from this budgetary allocation. This is the second most important mechanism of financing health care in India. Here the collection and pooling functions are the best, but purchasing function may be limited. This is seen very obviously in our country where the government financing is low. As seen from Table 1, out of the total expenditure, 20.3 percent was public / government expenditure. The break up of the public expenditure shows that one third of the government spending was from the central government, the rest two thirds was from state and local governments. Thus the state governments are the main funding of public health services.

Given this scenario, the Government in India in its National Health Policy 2002 had suggested that the allocation to health be raised to 2-3%. In the recent past, the National Rural Health Mission (NRHM) has been formed with a view to increasing the expenditure in the health sector from a current 0.9% of GDP to 2% over the next five years and to focus on Primary Health Care. The Mission has been made operational from April 1, 2005. The NRHM financing for the period 2005-2012 would be around Rs. 300, 000 million for non recurring expenditure and recurring expenditure of more than Rs. 400, 000 million. This financing is to be shared between the Centre and the states (increase the share of central and state from 20-80 to 40-60 sharing in the long run).

Insurance

This is the most complex mechanism of financing health care. The revenue is generated either by individuals paying a premium or by employers contributing towards their employees

or even the government paying on behalf of the poor. This revenue (called premium) is pooled into an autonomous fund that is used specifically to finance health care. In this way, this mechanism is different from the tax based government funding as the taxes collected is not dedicated only to health care. The insurance fund subsequently purchases health services on behalf of the insured from providers – be it government or private. The objective is to manage the revenues to equitably and efficiently pool health risks allowing for subsidies from healthy to unhealthy, rich to poor and productive workers to dependents. Health insurance has a limited effectiveness in collecting revenue; it depends on the workforce in the formal sector and also the size of the better off population. However, it has the potential to pool the funds effectively, especially if funds are collected from both low income and high income individuals. And finally because it is autonomous, it has an enhanced ability to purchase health services.

Health insurance could be an alternative health financing mechanisms; however, factors on both demand side and supply side coupled with high administrative costs limit the smooth functioning of the market for insurance in health. Further, action to counter market failure requires mature financial systems and institutional capacity to enforce corrective measures.

Demand side limitations : Protection from the real cost of ill-health may make individuals less risk averse, causing them to neglect precautionary/preventative measures. Or, being covered, an individual may consume excessive amounts of health care. This change in health behaviour due to insurance is moral hazard. Further, given uncertainty and incomplete/asymmetric information regarding ill-health, each member of an insurance pool may have different individual expected losses from ill-health and where this is lower than that reflected in premium charged, members may drop out of the group, leaving only an ‘adverse selection’ of high expected losses in the pool.

Supply side limitations : With insurance, excess demand can be supplier - induced as well -- the provider has fuller information on health status than the patient and could have used this asymmetry in information to over-prescribe services covered under the insurance plan. Adverse selection on the supply side occurs when insurers ‘cream skim’ through risk selection by including only healthier individuals in the plan; or, conversely, skimp or exclude certain high cost disease or pre-existing conditions.

There are various types of health insurance namely, Indemnity insurance wherein the person spends first and gets it reimbursed from the insurer afterwards. Health Maintenance Organizations (HMO’s), which is broadly managed care, a health plan providing a full range of health services against a fixed monthly premium.

Broadly there are three major types of health insurance:

- Social Health Insurance (SHI)
- Private Health Insurance
- Community Health Insurance

Social Health Insurance

SHI is usually publicly mandated for specific groups, financed through payroll taxes, semi-autonomous administration, the care provided is through its own, public, or private facilities.

The law mandates employers to deduct a percentage of each employees monthly wage for health to be paid to a “social insurance fund”. This fund could be managed publicly or privately; they can be monopolies or competitive. The employer/employee deductions are earmarked for health and cannot be used for any other purpose. Usually, it is applicable largely to formal sector employers and employees. The main strengths of SHI are that they are an additional health revenue source, generally provides covered population with access to a broad package of services, can effectively redistribute between high and low risk and high and low income groups in covered population and often serves as the basis for the expansion to universal coverage. The major weaknesses are that the poor are often excluded unless subsidized by government, potential negative impact on employment, administrative cost can be high, can lead to cost escalation unless effective contracting mechanisms are in place, poor coverage for preventive services and often needs to be subsidized from general revenues. In India, there are two major SHI schemes namely the Employees State Insurance Scheme (ESIS) and the Central Government Health Services (CGHS).

Employees State Insurance Scheme (ESIS) : The ESIS is a social security system which provides both cash and medical benefits. The Employees State Insurance Corporation (ESIC) manages the scheme and is a corporate semi-government body headed by the Union Minister of Labour as Chairman and a Director General as the chief executive. The Act compulsorily covers : (a) all power using non-seasonal factories employing 10 or more persons; (b) all non-power using factories employing 20 or more employees and (c) service establishments like shops, hotels restaurants, cinema, road transport and news papers are covered. Contributions are paid through a payroll tax levied on the employer and a contribution levied on the employee and contribution by state governments. The benefits are comprehensive cover, including OP, IP and rehabilitation. All workers and their dependent relatives are eligible for the benefits. These include comprehensive health care at ESIS facilities, cash compensation for illness, maternity benefits, disability benefits, survivorship and funeral expenses in the event of death of the worker. ESIS has its own dispensaries, hospitals and medical staff. It also empanels select private practitioners to provide medical care. Presently the scheme is spread over 677 centres in 25 states and Union territories across India covering 7.8 million employees and more than 25 million beneficiaries (17). In 1992, of a total expenditure of Rs 3.8 billion, Rs 2.2 billion was spent on health care. In 2001, the ESIC had surplus funds of Rs 67 billion, invested mostly in government securities.

While the ESIS has managed to cover the low paid workers in many organizations and provided them with a degree of comprehensive health security, various studies have been critical for the following reasons : Less than half the enrollees use the ESIS facilities because of the low quality of care. This is further compounded by the shortage of staff, inadequate drug and supplies and non-functional equipment. Many of the staff are not aware of the benefits. The employers also do not disseminate the information to their staff. Also, because of the salary limits on eligibility, some staff keep shifting in and

out of the ESIS and they may not be aware of their eligibility status. There is very little penetration in rural areas.

Central Government Health Scheme (CGHS) : The CGHS was introduced in 1954 as a contributory health scheme to provide comprehensive medical care to the central government employees and their families. The list of beneficiaries includes all categories of current as well as former central government employees, members of Parliament, Supreme Court and High Court Judges. In 1997, there were approximately 4.2 million beneficiaries. The staff contributes a nominal amount (ranging from Rs 15 to Rs 150 per month) from their salaries. The benefit package includes both outpatient care and hospitalisation. OP care is provided through its own dispensaries, 320 in 2002 in 17 major cities. It also uses the facilities of the Government and approved private hospitals to provide inpatient care and reimburses the expenses to the patient. The entire scheme is funded by the government of India and is administered by a separate directorate. Various evaluations have noted that while it has been effective in providing health security for more than 4 million people, there are certain problems in the scheme that need to be addressed. In terms of demand side, *moral hazard* – it is noted that 83% of the hospitalised patients are self referred. It appears that most patients prefer to bypass the dispensaries and directly avail of specialist services. The number of annual visits per beneficiary was 3.5 (1994-95). *Poor quality care* – there are regular complaints about long waiting periods, inadequate supply of medicines and equipment and unhygienic conditions.

Private Health Insurance

Private health insurance emerges from voluntary actions in a market where buyers are willing to pay premium to insurance companies that pool people with similar risks and insure them for health expenses. Commercially run for-profit private insurance companies usually base contributions on risk-rating i.e. adjusted according to the anticipated cost of use of services, care reimbursed in private and public facilities who provide treatment for members. Private health insurance is generally motivated by the prospect of earning a profit and companies compete for clients on the basis of “price” and quality. The major strengths are that as a prepayment and risk pooling mechanism it is generally preferable to out of pocket expenditure. It may increase financial protection and access to health services for those able to pay. When there is “strategic purchasing” function is present it may also encourage better quality and cost-efficiency of health care providers. The main weaknesses are : it is associated with high administrative costs and profit, it is generally inequitable. Applicability in LICs and MICs requires well developed financial markets and strong regulatory capacity.

Private health insurance in India is usually associated with the “Mediclaime” policy. Introduced in 1986, it is a voluntary health insurance scheme offered by private insurance companies. While initially only “non-life insurance companies” were allowed to market health insurance products, the Insurance Regulatory & Development Authority (IRDA) has recently permitted even life insurance companies to introduce health insurance products. Currently there are 14 general insurance companies and three life insurance companies providing health insurance products.

With the introduction of Third Party Administrators (TPAs), the reimbursement policy has changed into a 'cashless' policy, where the TPA reimburses the hospitals and the entire treatment is cashless for the patient. While initially only hospitalisation expenses were covered, today health insurance products cover a variety of risks, ranging from hospitalisation to outpatient care to ambulance expenses and also pre & post hospitalisation expenses. While earlier, there were only individual or group insurance products, recently family floater products have slowly gained popularity. While earlier a family of four had to pay the individual premiums (e.g. Rs 2000 X 4 = Rs 8000) and get a cover of Rs 2 lakhs each, today under a family floater product, the family needs to pay a much lower premium (e.g. Rs 5, 000) and get a family cover of Rs 5 lakhs. This means that anybody who is sick in the family can avail of hospitalisation expenses upto Rs 5 lakhs. This is a much more attractive product to cover families. Today many of the products also provide a daily cash benefit for each day of hospitalisation. This is to take care of non-medical expenses like transport, food, attendant expenses etc. Yet another innovation has been the introduction of 'critical illness' cover. Under this, an individual is insured for a particular period. During that period, if the individual contracts one of the listed critical ailments like stroke or cancer or myocardial infarction (MI) or end stage renal failure (CRF), then the patient is paid a lumpsum amount and the policy is terminated. The patient is free to use this lumpsum for whatever need required. There is no need to submit any bills and receipts, just a proof of diagnosis of the critical ailment. Initially the senior citizens had very little opportunity to insure themselves, but today many companies have developed products tailor made to the needs of senior citizens. Similarly, more and more products are reducing the list of exclusions and providing a more comprehensive cover. While earlier pre-existing diseases were not insurable in the Indian market, today many of the companies include them in the cover after a fixed claim free period (usually two years). Today there are many different products catering to people.

Community Health Insurance

Community health insurance is mostly not-for-profit prepayment plans for health care, with community control and voluntary or compulsory membership, care is generally provided through NGO or private facilities. Members pre pay a set amount periodically for specified services. It is managed by community members and accountable back to members. Community based health insurance schemes have had some success in providing financial protection to the poor in the informal sector. These initiatives are based on the social insurance principle of solidarity, de-linking contributions from use and thus supporting equitable access to care. It promotes pre-payment and mobilizing additional resources, providing access and financial protection in LICs. Experience indicates that community health financing has been most successful where this has been associated with income generation activities. The major weakness are Community health initiative tends to be limited in scope by their capacity for financial risk pooling – while based on the principles of social insurance, they cannot establish similarly large pools. Also, such schemes rely on the existing network of public and private providers (rather their

own facilities). This has implications for the benefit package offered as well as long term sustainability. CHI can be a helpful complement but is not a substitute for SHI systems. CHI movement is slowly picking up momentum in India. Currently there are about 100+ CHIs in the country, many of which have begun operations in the past two to four years.

Unfortunately, in India, there is very little penetration of health insurance in the country. Estimates range from 3 to 8% (10, 11). This for a country of 1 billion is negligible. Most of those insured are in the formal sector and have security in terms of insurance policies as well as steady incomes. On the other hand, the rural populations are left at the mercy of ailments; and usually have to borrow and sell assets to meet even a small hospitalisation episode.

External Finance

There are two main forms of external contributions for development : loans and grants. Loan, administered largely through the Bretton Woods Institution, are non-commercial long-term loans at substantially low rates of interest. Eligibility for such 'soft' loans is based on country economic status/progress. Usually negotiated between the loan agency and the concerned ministries for a specific programme and with funds flowing through the national budget (albeit earmarked for programme activities), such external assistance does, in theory, allow country 'ownership'. Donor assistance in the form of grants traditionally took the form earmarked project funding, restricted to specific activities and implemented by the donor alone or in collaboration with the government, depending on national procedures. More recently, two new options are being used by donors to promote aid harmonisation and alignment in support of the overall national health strategies. Basket funding is a joint funding mechanism that pools donor contributions and provides un-earmarked funds for implementing planned national health strategies (usually developed in consultation with donors). Through general budget support, donor funds for health are released to ministries of finance and allow them the ultimate decision vis-à-vis actual allocation. For health, this means such funding is not necessarily secure for health activities. For national budget and macroeconomic planning, given experiences with volatility in donor contributions particularly during global economic downturns, this brings in elements of unpredictability and instability. Overall, external assistance may be effective for filling short/medium term funding gaps. For sustainable financing for health, this must in the long run depend primarily on domestic resources.

Development assistance, including loans and grants, contribute a small percentage of India's expenditure on the health sector and has never been more than 1–3% of the total public health expenditure. The overall foreign assistance to India in 1999 was 0.4% of GDP and per capita Overseas Development Assistance (ODA) was US\$1.6 in 1998 as against an average of US\$ 9 for developing countries. Of this, the share of health in the total assistance was 6.7%. In India, at present, assistance from only a few countries is accepted to be channeled through the Government. Other donors are requested to direct their contributions through UN agencies and non-governmental organizations.

Recent years have also seen the emergence of funding agencies that are not governments or part of the UN system. Important among these are the Global Alliance for Vaccine Initiative (GAVI), Global Fund for AIDS, TB and Malaria (GFATM) and the Bill and Melinda Gates Foundation, among others. These agencies could be expected to further influence the development assistance scenario in the medium term.

Provider Payments

The objectives in purchasing are to assure the purchase of health services is strategic and both allocatively and technically efficient (for whom to buy, what services to buy, from who to buy and how to pay). Provider payments may be made to individuals or at facility level and, these may be prospective or retrospective. The key issues are that purchasing is performance-based payments to promote quality and efficiency, equity and social protection, allocative efficiency. Provider payments mechanisms are the channels through which payments are transferred from the purchaser of care to the service provider. For health financing, they are an important part of the overall strategy to impact equity and efficiency. They have been used very successfully in Cambodia to increase access to hospital care for the poor (1). In India provider payment mechanism has been used under the Chiranjeevi scheme in Gujarat. For more details http://gujhealth.gov.in/Chiranjeevi%20Yojana/M_index.htm.

Mapping Resource Flows in National Health Systems through National Health Accounts (NHA)

Major financing reforms in the health sector concern securing sustainable financing for health care. Regular updates of NHA provide useful insights to governments as to what their further options are, or as to the level of public and private expenditure, as well as to modifying the allocation of these expenditures.

NHA provides a systematic, consistent, comprehensive information for any given year all the resources that flow through the country's health system over time and across countries both in absolute and relative terms. Time series information permits the use of NHA as a standard management tool for situation analysis, planning, monitoring and evaluation purposes. NHA are designed to capture the full range of information contained in these resource flows and to reflect the main functions of health care financing : resource mobilisation and allocation, pooling and insurance, purchasing of care and the distribution of benefits. NHA enable stakeholders to identify policy concerns and to simulate the impact of solutions to the problems monitored. NHA address four basic sets of questions : where do resources come from, where do they go, what kinds of services and goods do they purchase and whom do they benefit ? In doing so, NHA captures total national health expenditure from all sources, public and private. NHA are a standard set of tables showing and describing the financial flows of health system. They are presented in two-way tables (matrix format) and the tables are interconnected. The tables provide key indicators to policymakers as well as researchers to diagnose the financial health of the health system. It shows the flow of financing from a source of funding to a particular use, to a user of that expenditure or to beneficiaries following a standard classification of health expenditure. Six dimensions

are considered :

Financing sources : Defined as resources for health goods and services, whether from tax-based, social security, other private entities such as firms, NGOs, households or other entities.

Financing agents : Defined as institutions receiving and managing funds from financing sources to pay for or purchase health goods and services, including social security schemes, ministries of health, medical private insurance, NGOs and firms.

Providers : Defined as entities that receive financial resources and use those resources to produce health goods and services, include public and private hospitals, clinics, nursing homes, community health centres, private practitioners etc.

Functions : Defined as the categories of goods and services consumed, include inpatient services, ambulatory services, public health interventions, etc. Health related functions, part of the total, refer to investment, training and R&D.

Cost of Factors of Production (often referred to as "line items") : Defined as the type of resources allocated to health care. It includes variables such as labour, drugs and pharmaceuticals, medical equipment etc.

Beneficiaries : Defined through distributional tables in which the value of goods and services produced are classified according to : geographic boundaries, demographic characteristics, economic strata and disease categories/interventions.

For more details a good reference is 'Guide to Producing National Health Accounts : With special applications to low and middle income countries, WB, WHO and USAID, 2003. Link- [http : // www. who. int/nha/docs/English_PG. pdf](http://www.who.int/nha/docs/English_PG.pdf).

In India the work on National Health Accounts is underway, The MOHFW, GOI in collaboration with WHO India Country office has brought out the NHA for 2001-02 which is available at link- [http : //mohfw. nic. in/NHA%202001-02. pdf](http://mohfw.nic.in/NHA%202001-02.pdf).

Health Financing Issues in India

As seen from above public health financing is very low as a ratio to GDP, total health expenditure and per capita expenditure. Seventy percent of public spending is by the states where a major part of it is on salary and administration. Eighty percent of all health spending is from out-of-pocket at the point of service use. More than forty percent of the people hospitalized borrow money / sell assets to cover expenses. A quarter of those hospitalized fall below the poverty line because of high costs. Only around four to six percent of people in India have some form of health insurance coverage. Health financing policy questions broadly would be : Are we investing enough in health? Is there a minimum efficient level of spending? What would be "optimum" investment by public funding? Do external funds help? What amount and how to use? What are the opportunity costs of investing more for health? Is the financial risk protection feasible? If so, how? Can user charges play a useful role? Is there a role for community-based financing?

Summary

The way a health system is financed is a key determinant of population health and well-being. There is no single answer to the question of how to finance health systems. Health policy

and financing policy are inseparable because financing policy determines who has access to basic health care, how much is available, who controls the funds and how they are used. While cost-effective responses to preventable and communicable morbidity and mortality, there is a growing challenge from high-cost non-communicable and 'new' diseases. The combination of upward pressure on costs and limitations on the ability of governments to increase spending forces countries to consider reforms to the way that their health systems are financed. Like all countries in the world, India too faces difficult challenges and choices in financing its health systems. India has a mixed form of financing health care. The total health expenditure in India for the year 2001-02 was Rs 1,057,341 million, which accounted for 4.6 percent of its GDP. Of the total expenditure, 20.3 percent was public / government expenditure, 77.4 percent was private expenditure and remaining 2.3 percent external support. There are three basic functions of a health financing system; Revenue collection, Pooling and Purchasing. Broadly, there are various options and mechanisms for financing the health care services. Out of Pocket Payments is the simplest form of health care financing. In India, this is the most common form of financing health care. The main financier of health services in India is the individual household. They meet 72% of the total health care costs by paying out of pocket at the time of service. In most high income countries, only about 5 – 10% of households have to pay OOP payments and these are usually in the form of pre/co-payments to contributory financial protection schemes e.g. social health insurance. In middle income and low income countries, the proportion increases to about 25 - 50% of households. Governments collect General Taxes, both direct and indirect, which is allocated to various sectors including the health sector. General revenues are considered to be the most equitable means for health financing. Government health services are usually financed general revenue sources e.g. in India, most of the government health services are financed from this budgetary allocation. The Government in India in its National Health Policy 2002 had suggested that the allocation to health be raised to 2-3%. Insurance is the most complex mechanism of financing health care. The revenue is generated either by individuals paying a premium or by employers contributing towards their employees or even the government paying on behalf of the poor. Health insurance could be an alternative health financing mechanisms, however, factors on both demand side and supply side coupled with high administrative costs limit the smooth functioning of the market for insurance in health. Protection from the real cost of ill-health may make individuals less risk averse, causing them to neglect precautionary/ preventative measures. With insurance, excess demand can be supplier- induced as well -- the provider has fuller information on health status than the patient and could use this asymmetry in information to over-prescribe services covered under the insurance plan. There are various types of health insurance namely, Indemnity insurance, Social Health Insurance (SHI), Private Health Insurance and Community Health Insurance. The Employees State Insurance Scheme (ESIS) is a social security system which provides both cash and medical benefits. All workers and their dependent relatives are eligible for the benefits. Central Government Health Scheme (CGHS) was introduced in 1954 as a contributory health scheme

to provide comprehensive medical care to the central government employees and their families. The benefit package includes both outpatient care and hospitalisation. Private health insurance emerges from voluntary actions in a market where buyers are willing to pay premium to insurance companies that; pools people with similar risks and insure them for health expenses. Private health insurance in India is usually associated with the "Mediclaime" policy. With the introduction of Third Party Administrators (TPAs), the reimbursement policy has changed into a 'cashless' policy, where the TPA reimburses the hospitals and the entire treatment is cashless for the patient. Community health insurance is mostly not-for-profit prepayment plans for health care, with community control and voluntary or compulsory membership, care is generally provided through NGO or private facilities. Experience indicates that community health financing has been most successful where this has been associated with income generation activities. In India, there is very little penetration of health insurance in the country. Most of those insured are in the formal sector and have security in terms of insurance policies as well as steady incomes. There are two main forms of external contributions for development: loans and grants. Loan, administered largely through the Bretton Woods Institution, are non-commercial long-term loans at substantially low rates of interest. Development assistance, including loans and grants, contribute a small percentage of India's expenditure on the health sector and has never been more than 1–3% of the total public health expenditure. Recent years have also seen the emergence of funding agencies that are not governments or part of the UN system. Regular updates of National Health Accounts (NHA) provide useful insights to governments as to what their further options are, or as to the level of public and private expenditure, as well as to modifying the allocation of these expenditures. NHA address four basic sets of questions : where do resources come from, where do they go, what kinds of services and goods do they purchase and whom do they benefit? The flow of financing from a source of funding to a particular use, to a user of that expenditure or to beneficiaries following a standard classification of health expenditure. Six dimensions are considered : Financing sources, Financing agents, Providers, Functions, Cost of Factors of Production and Beneficiaries. Health financing policy questions broadly would be like Are we investing enough in health and Is there a minimum efficient level of spending.

Study Exercises

MCQs

1. The most common form of financing health care in India is (a) Provider Payment (b) General Tax Revenue (c) Out of Pocket Payment (d) External Finance.
2. What percentage of hospitalised patients in India have been impoverished because of high medical costs (a) 25% (b) 10% (c) 50% (d) 35%.
3. The National Rural Health Mission (NRHM) has been formed with a view to increasing the expenditure in the health sector from a current 0.9% of GDP to ___ over the next five years (a) 1% (b) 2% (c) 3% (d) 4%.
4. The most complex mechanism of financing health care is (a) Provider Payment (b) General Tax Revenue (c) External Finance (d) Insurance.

5. Central Government Health Scheme was introduced in the year (a) 1952 (b) 1954 (c) 1955 (d) 1957.
6. Penetration of health insurance in India is in the range of (a) 3-8% (b) 9-15% (c) 16-20% (d) 25-40%.

Answers : (1) c; (2) a(3) b; (4) d; (5) b; (6) a.

Trade and Public Health

Kumar K M Gopa, Syam Nirmalya

In the recent times the impact of trade on public health has come under sharp attention of governments, policy makers, academia and civil society. A few explanations can be given for this growing interest in trade and public health. During the last part of 20th century most countries shifted their development strategy from self-sufficiency to export oriented growth strategy. This was then complemented with the establishment of world Trade Organization (WTO) and a web of Free Trade Agreements (FTA) with developed countries. The underline rationale of this shift towards export oriented growth strategy was that growing trade would help countries to achieve over all development including alleviation of poverty. As a result most of the countries made a series of policy change to facilitate gains from international trade. However, these policy shifts were not accepted without criticism because much of these policy changes were aiming at increasing competing capacity of the manufacturers within a country. As a result, policy changes were introduced to many countries to liberalize labour markets and environmental regulations. These changes constituted vast changes in the public health scenario of many countries especially developing countries.

However, the most important issue with regard to trade and public health is the loss of policy space of developing country government related to public health. This erosion of policy space is the result of a set of international trade agreements regulating international trade and trade related subject matters.

International Trade Regime

International trade regime is regulated through various institutions and international agreements. However, the most important institution and agreement relevant the discussion here is WTO and the agreement establishing WTO. Another set of relevant international trade agreements are FTA entered

between developed and developing countries. The first attempt to establish an international trade agreement was in 1948 to establish and international trade organization. However, the organization did not get establish mainly due to the internal resistance from the USA. However, an ad hoc arrangement known as General Agreement on Trade Tariff (GATT) was established and it continued to function till 1994. In 1995 GATT was replaced by WTO. The agreement establishing WTO contains a set of international agreements regulating specific aspects of trade. Two of these agreements deal with intellectual property protection and trade in services. These agreements reduces the policy space of countries with regard to access to medicines and access to health services. Since these agreements are part of the agreement establishing WTO, member countries cannot be members of WTO without accepting these agreements. Similarly, member countries are not allowed to make any reservation in the provisions of these agreements. As a result, all WTO members are to accept these agreements in its entirety. However, these agreements provide certain transition periods for developing countries and least developing countries to full comply with this agreements.

However, free trade agreements between developed and developing countries forces developing countries to undertake more commitments than WTO agreements in areas of intellectual property and trade in services. As a result, developing countries are on the verge of loosing the existing policy space in those areas. As mentioned earlier, the trade itself has the potential to impact the people life negatively as well as positively. However, the following paragraphs discuss the impact of intellectual property provisions and services on public health.

Intellectual Property Rights

The term intellectual property rights generally refer to a set of exclusive rights granted to the owner of intellectual property. Generally speaking, intellectual property refers to the extension, of property rights to intangible assets including the intellectual efforts like invention. There are nearly seven types of intellectual property rights viz. patents, trademark, copyrights, industrial designs, plant varieties protection, trade secrets and geographical indications. International intellectual

property regime is governed through a series of international agreements regulating various procedural and substantial aspects of intellectual property rights. Till the conclusion of Agreement on trade related aspects of Intellectual Property Rights (TRIPS), these international agreements did not put minimum level of protection. In other words, these IP agreements gave member countries sufficient policy space to determine the level of intellectual property protection.

TRIPS is one of the most controversial agreements administered under the World Trade Organisation's (WTO) frame work because it took away the freedom of member countries to determine the level of intellectual property protection. It prescribes a universal minimum standard of protection to all types of intellectual properties irrespective of member countries developmental needs. This universal minimum standard put an end to hitherto freedom of determining the level of intellectual property protection in member countries. In other words, every member country is to offer a minimum level of all types of intellectual property. The most controversial provisions TRIPS are related to the patent protection. TRIPS patent regime resulted in the denial of access to medicine to the people in developing and least developing countries.

Often monopoly results in abuse of monopoly position and extracts high prices from the consumer. Patents especially product patents create a statutory monopoly for a limited number of years and increases the chance of abuse of patents. This statutory monopoly will have undesired consequence on vital sectors especially in the health sector because pharmaceutical industry rely heavily on the patents to market their product using the monopoly rights provided by the patents. For instance, till 2000 anti-retro viral (ARV) drugs for the treatment of HIV/AIDS were not affordable to people due to the exorbitant price charged by the multinational pharmaceutical companies. The price of first line ARV drugs used to be USD 10,000-12,000 per patient per year (PPY). In 2001, the Indian pharmaceutical companies using the advantage of absence of product patent protection in India at that time introduced the cheap generic version of first line ARV drugs to USD 350 PPY. This generated competition in the market and reduced the price of first line ARV drugs especially price of first line ARV drugs for bulk procurement. Currently various governments and international agencies are procuring first line ARV drugs at USD 132 PPY. After the introduction of product patent protection, Indian pharmaceutical companies cannot produce the generic version of new drugs because most of the new drugs are patent protected. Therefore, the product patent protection eliminates the possibility of availability of affordable generic drugs in the market. Hence, countries need to take utmost care while framing their patent laws to address the bad effects of patents especially to facilitate access to medicines.

Nature of TRIPS Obligation

As mentioned above, TRIPS prescribes a universal minimum standard to different forms of intellectual property viz. Trademarks, designs, Copyrights, Geographical Indications, Topography of Integrated circuits, patents, plant varieties, trade secrets etc. Regarding patents it obligates member countries to provide the following : compulsory product patents for pharmaceuticals and agro-chemicals, 20 years duration of

protection, recognise importation as part of exclusive rights of the patent holder, reversal of burden of proof in the case of process patent infringement proceedings, certain procedural regulation on the granting of compulsory license and exclusive marketing rights during the transitional period. However, TRIPS provides a ten-year transitional period (1-1-1995-31-12-2004) for developing countries like India to fully comply with TRIPS patent regime. Further, TRIPS permits a three-stage time frame (1995, 2000 and 2005) for compliance. Patents especially product patents create monopoly and eradicate competition. Patent monopoly often abused by the patent holder and fixes a higher price for the patented medicines. Hence, patents on drugs compromise the accessibility and availability of medicines, two important components of right to health. Today, there is ample evidence to show how patents adversely affect the accessibility and availability of medicines. The main task before lawmakers during the implementation of TRIPS patent regime is to provide strong public interest provisions to curb the abuse of patent monopoly. Hence, the approach to the implementation of TRIPS is to place provisions to ensure accessibility of medicines and not to strengthen patent protection. In other words, the task is how can WTO member country implement TRIPS agreement without compromising the policy objective ensuring access to affordable medicines.

Question often asked is whether TRIPS permits use of public interest provisions to safeguard accessibility and availability of medicines in the product patent era. The answer is that TRIPS does recognise such approach. Even, though product patent *per se* creates barriers to access to affordable medicines the damage can be minimise to certain extent by incorporating the flexibility available within the TRIPS in the domestic legislation. The domestic legislation should incorporate the flexibilities to the maximum extent. The following paragraphs explain the nature of TRIPS obligation and the flexibility available within the TRIPS.

The Preamble of TRIPS states that measures and procedures to enforce intellectual property rights should not themselves become barriers to legitimate trade. Further, the Preamble recognises the underlying public policy objectives of national systems for the protection of intellectual property, including developmental and technological objectives. Hence, the implementation of TRIPS should not undermine the developmental and technological objectives including public health goals of the implementing country. In other words, it states that under TRIPS protection of intellectual property is not an end itself but a means to achieve developmental goals.

According to Article 1 of TRIPS, members "*shall not be obliged to, implement in their domestic law more extensive protection than required by this Agreement*". Thus, there is no obligation under TRIPS to provide extra protection to any intellectual property rights other than what is mentioned in the TRIPS Agreement. Further, TRIPS permits states to "determine the appropriate method" to implement the provisions of the TRIPS Agreement within their legal system. As a result, it is up to each state to decide the manner in which it should implement TRIPS Obligations. India along with other developing countries stated in their submission to TRIPS Council on 29 June 2001 (IP/C/W/296) states : " ... *more extensive protection in national*

legislation than is required by the TRIPS Agreement may result in limitations for the implementation of health policies. We consider that Members should be free to implement the TRIPS Agreement in ways that best accommodate the protection of health policies in national legislation” Hence, there is no need for India country to implement provisions which goes beyond TRIPS patent regime.

The objective of TRIPS mentioned in Article 7 states that “the protection and enforcement of intellectual property rights should contribute... to the mutual advantage of producers and users of technological knowledge and in a manner conducive to social and economic welfare...”. On objectives, India’s submission states : “ ...patent rights should be exercised coherently with the objectives of mutual advantage of patent holders and the users of patented medicines, in a manner conducive to social and economic welfare and to balance of rights and obligations. Where confronted with specific situations where the patent rights over medicines are not exercised in a way that meets the objectives of Article 7, Members may take measures to ensure that they will be achieved...”. Thus, the submission put the question of access above the patent rights and assert the right to take measures to achieve the objectives of Article 7.

Further, principles of implementation under Article 8 states “members may, in formulating or amending their national laws and regulations, adopt measures necessary to protect public health and nutrition and to promote the public interest in sectors of vital importance to their socio-economic and technological development...”. According to the submission “any interpretation of the provisions of the Agreement should take into account the principles set forth in Article 8. The reading of such provision should confirm that nothing in the TRIPS Agreements will prevent Members from adopting measures to protect public health, as well as from pursuing the over-arching policies defined in Article 8”. Thus, the domestic legislation should strike a balance between public and private rights and the rights of patentee should not be at the cost of public health concerns.

In 2001, WTO Ministerial Conference in Doha endorsed the same approach for the implementation of TRIPS patent provisions at the domestic level by adopting the Doha Declaration Public Health and the TRIPS Agreement (Doha Declaration). According to Doha Declaration “...TRIPS Agreement does not and should not prevent members from taking measures to protect public health. Accordingly, while reiterating our commitment to the TRIPS Agreement, we affirm that the Agreement can and should be interpreted and implemented in a manner supportive of WTO Member’s right to protect public health and, in particular, to promote the access to medicines for all”. Further, the Declaration reaffirms “the right of WTO Members to use, to the full, the provisions in the TRIPS Agreement, which provide flexibility for this purpose”. Hence, India has a legal right to interpret and implement the TRIPS Agreement to promote access to drugs.

Further, Doha Declaration explicitly recognises the following flexibilities viz. using the customary rules of interpretations of public international law and the interpretation of TRIPS provisions in the light of objectives and principles, right to grant compulsory license and freedom to determine the grounds

of granting compulsory license, right to determine what circumstances constitute a national emergency, freedom to adopt suitable exhaustion regime. Further, there is a flexibility to determine the scope of patentability by providing suitable definitions three basic criteria viz. novelty, inventive step and industrial applications. Furthermore, flexibility also exists to define the subject matter of patents. For instance in the absence of a definition to microorganisms in TRIPS through a definition certain microorganisms can be excluded from patentability.

The general understanding on TRIPS is that obligations under TRIPS do not create any hierarchy of international obligations and therefore does not override obligations under other treaties. Therefore, TRIPS implementation should not compromise any of the rights guaranteed by any previous international treaty. India as a party to the International Covenant on Economic, Social and Cultural Rights (ICESCR), it cannot compromise the right to health (Article 12, ICESCR) and the right to enjoy the benefits of scientific progress and its applications (Article 15, ICESCR) while implementing TRIPS patent regime. The right to health also falls within Article 21 of the Indian Constitution (*Vincent Panikurlangara v Union of India 1987 (2) SCC 165*). The Supreme Court has recognised that Article 21 has to be interpreted in consonance with international treaties. Hence, the implementation of any provision in TRIPS should not result in the denial of any of the rights guaranteed under the ICESCR and the Constitution of India. In the absence of a contrary statute enforceability of ICESCR and the International Covenant on Civil and Political Rights (ICCPR) in India has been upheld by the Supreme Court through a number of judgements (*Vishaka v State of Rajasthan (1997) 6 SCC 241*).

Even though TRIPS per se is objectionable and need to be reviewed in the coming days to ensure accessibility and availability of drugs the flexibility within TRIPS provides some manoeuvring space to Members States to address the issue of access to drugs. According to Commission on Intellectual Property Rights (CIPR) “developing countries should adopt a pro-competitive strategy that, as one observer suggests, is tilted towards second comers rather than distant patentees. This is especially important in those areas of technology such as pharmaceuticals and agriculture where, as we have already considered, the cost of providing strong protection is likely to be greatest”.

Thus, the flexibilities available within the TRIPS offer some policy options for the developing countries to mitigate the adverse affects of product patent protection on the availability of affordable medicines. However, the intellectual property rights provisions within the FTAs between developed and developing countries eliminate the possibilities of TRIPS flexibilities. Most of the FTAs entered between USA with developing countries obligates developing countries to limit the scope of TRIPS flexibilities. For instance, US FTAs insists that patent protection should be extended to the new use of known substance. Further these FTAs limits the circumstances under which a country can use the compulsory licence or a government use of patented invention. These FTAs also insists for extension of patents beyond 20 years prescribed under TRIPS. Hence, IP provisions of FTAs goes beyond TRIPS patent regime and considerably restrict the policy space of developing countries.

India and TRIPS Implementation

India, as a member of the WTO has an obligation under TRIPS to comply with its patent provisions. A TRIP provides three time frames for developing countries like India for its absolute compliance, with the patent regime in particular. The first dead line was in 1995 to introduce mail box protection and exclusive marketing rights (EMR). The second was in 2000 to comply with TRIPS provisions on duration of patent protection, compulsory license, extension of patent protection to micro organism etc. India amended its Patents Act in 1999 and 2002 (well beyond the dead line) to comply with these obligations. The third deadline was to introduce product patent protection for pharmaceuticals and agrochemicals by 1 January 2005. To meet the deadline, Government of India issued an Ordinance on 26 December, to amend Patents Act 1970. The Ordinance carried out 77 amendments to the Act. Later, the ordinance was replaced through an amendment Act passed by the parliament in March 2005.

Thus, countries like India gave importance to the question access to affordable medicines and survival of its generic industry over the protection of intellectual property while implementing the TRIPS Agreement. India has incorporated restricted approach to the scope of patentability. As a result, a known substance is not eligible for patent protection in India unless there is a significant improvement in India. Similarly, substance obtained from by a mere admixture resulting in the aggregation of properties is excluded from patent protection. Further, the Indian Patents Act provides strong provisions against abuse of patented invention. The Act contains compulsory license and government use provisions. For instance, a compulsory license can be granted if patented article is not available at an affordable price. Compulsory license allows a third party to use the patented without the authorisation of the patent holder. However, a compulsory license is issued by the patent office after examining the application for compulsory license. However, the critiques point out that compulsory licence provisions under the Patents Act, procedure wise, is cumbersome and therefore little use to curb the abuse of patents. Government use provisions allow government or its authorised agent to use the patent without the permission of patent holder. Patent Act also allows parallel importation, which allows third parties to import the patented article from any where in the world without the permission of the patent holder provided the product is introduced legally in that market. Patent Act contains the early working of patents in order to obtain the regulatory clearance. Hence, the generic companies can produce the patented drug during the life of the patent to obtain marketing approval. As a result, the generic companies can introduce the generic version immediately after the expiry of patent. Even though India implemented most of the TRIPS flexibilities in the Patents Act, it needs lot of fine tuning to use it as an effective tool to ensure access to affordable medicine under the product patent regime.

Trade in Service

Traditionally, health services in most countries have been largely provided by the State. Healthcare services were seen as essentially public welfare services and were not regarded as commercial in nature. However, in many developing

countries, the public health system could not meet the demand for healthcare services. In this context, it was felt that private participation in health services might be the solution for meeting the demand for adequate healthcare services. The underlying assumption was that facilitating trade in healthcare services by liberalising healthcare services will not only increase the supply of healthcare services but will also provide a boost to the economic growth of the State, which in turn will lead to better standards of health in the country by enabling people to spend more on healthcare. A culmination of this logic was the push for liberalising health services. As a result, many developing countries started liberalising health services. Initially liberalisation of health services took place in two ways viz. autonomous liberalisation and liberalisation due to structural adjustment programmes under the instruction of the World Bank and the International Monetary Fund (IMF). Of late, countries entered into legally binding agreements to maintain the level of liberalisation through General Agreement in Trade and Service (GATS) and FTAs.

GATS attempts to establish a framework within the WTO for regulating international trade in services and it envisages the progressive liberalisation of all trade in services. To that end it locks in the level of liberalisation to which a State commits a particular service sector under the GATS. The current approach to GATS, negotiations involves a two-stage process wherein each Member makes specific requests on every sector to every other Member and every Member makes their offers on each sector. The GATS can be applied to all services including health services. In respect of liberalisation of health services under GATS, the WTO regards the current level of liberalisation as inadequate (1). Hence, liberalisation of health services within the framework of the GATS is a thrust area of current GATS negotiations.

However, there is a concern expressed by health policy analysts and the civil society as to the adverse implications of GATS disciplines on health services. The concern is that it may reduce the space available to governments to devise policies and regulations for the health sector, particularly with regard to access and affordability of health services (2). This is based on the belief that many public health measures may be deemed to be unnecessarily restrictive of trade in health services under GATS. This concern assumes significance in the light of the fact that the right to health is a human right.

Trade in Health Services

Health services have not been considered traditionally as a commercially tradable service. However, the traditional notion of health as non-commercial services has undergone a paradigm change. The growing potential for trade in health services is driven by various factors such as

- Decline in public sector expenditure on health services and the rise of private sector participation in healthcare;
- Liberalisation of related sectors like insurance and telecommunications services;
- Increasing mobility of consumers and health service providers;
- Technological developments enabling cross-border delivery of health services (3).

While the ultimate delivery of a health service necessarily involves physical contact between the health professionals like doctors and nurses with the patient, owing to technological developments the extent to which physical contact is required can be reduced significantly. For instance, a team of doctors in one country may seek the opinion of some specialist in another country through electronic exchange of medical data in real time without having the patient to visit that specialist in a foreign country. Such services are called telemedicine services. Similarly, a hospital can reduce its expenses of maintaining medical records by outsourcing the same to firms in other countries where the records can be maintained at lesser costs while their transcripts can be communicated back in real time to the concerned hospital whenever needed. The health sector comprises various kinds of health services including medical and dental service, hospital services, diagnostic services, nursing and midwifery services, medical education services, veterinary services and medical data processing services. Hospital services comprises not only services that include treatment of patients, these also include services like hospital management services that facilitate the treatment of patients.

However, while health services comprise a host of health related services, countries do not follow a uniform system of classification of such services. Services are usually classified in the GATS in accordance with the Services Sectoral Classification List of the WTO, which closely follows the UN Central Products Classification system (UNCPC), which provides a more detailed breakdown of the services that fall within each service sector. In scheduling their GATS commitments, Members are free to follow either the Services Sectoral Classification List or the UNCPC or their own system of classification. Hence, every Member's commitment on a particular service sector has to be seen in the context of the system of classification that it follows. In terms of classification of services under GATS, nursing services and services of doctors are classified as professional services and not health services. Hence, many health related services do not fall within the health services. For instance, medical education services would be classified as education services and medical transcription services as data processing services under GATS. Trade in health services involves 4 modes of services delivery.

For example, services like telemedicine and teliagnosis can be delivered through cross-border supply, health tourism can be facilitated through movement of patients, hospitals of one country may set up commercial presence in another and medical and paramedical professionals may move abroad to offer their services. Table - 1 illustrates the kinds of health and health related services that can be delivered in each mode.

It is necessary to examine the impact of trade in health services in each of the four modes on access of all to health services. A joint study by WHO and UNCTAD has examined this issue. The WHO has identified three policy objectives in terms of which the impact of liberalisation of health services may be measured viz. equitable access to health services, quality of health services and efficient allocation of resources for health services (4). Hence, the liberalisation of health services should not compromise any of the three policy objectives.

Issues of Concern

In India the public sector provides health services through the central governments, state governments, municipal corporations and other local bodies. The private sector includes health services provided by charitable institutions, missions, trusts, non-governmental organisations (NGOs), etc. as well as clinics, nursing homes and hospitals providing such services for profit. The private sector has comprised the largest constituent of the country's healthcare delivery system ever since India's independence and has expanded rapidly since the 1980s even before the creation of the GATS. In 1990, 57.95 per cent of hospitals and 29.12 per cent hospital beds in India were in the private sector (5). According to the National Health Accounts India (2001-02), 77.4 per cent of the total health expenditure in India was private expenditure while only 20.3 per cent was government expenditure, while the total health expenditure accounted for only 4.6 per cent of the GDP. However, there is a strong concentration of bed occupancy in the public health sector at a ratio of about 62 per cent(6). While developed countries like USA, Germany, France, Canada and UK spent from about 7 to 14 per cent of their GDP on health, their government's share of this expenditure was in the range of 44 to 84 per cent (7). This clearly shows that even in developed countries, the government has a substantial share in the expenditure on

Table - 1

Mode of delivery of the Service	Kind of service delivered
Cross-border service (mode 1)	Shipment of samples, diagnosis, clinical consultation via traditional mail channels. Electronic delivery of health services like telemedicine, telesurgery, teliagnosis services; medical back office services, medical transcription services and online medical education services.
Consumption abroad (mode 2)	Medical tourism for super specialty medical services and alternative systems of healthcare.
Commercial presence (mode 3)	Establishment of super specialty hospitals and clinics, diagnostic and treatment centres in collaboration between domestic and foreign health services providers, health insurance services and hospital management services.
Movement of natural persons (mode 4)	Services of doctors, surgeons, nurses and midwives in foreign countries.
Source : Rupa Chanda, 'Liberalizing Trade in Health Services : Issues and Concerns for India', presentation made at the National Workshop on Health Services Liberalisation under WTO / GATS - Whither and How?, organised by the Ministry of Health and Family Welfare and the WHO India Office, 15 Feb 2006.	

health sector and this factor certainly helps in maintaining equity in access to healthcare in this sector. Hence, a further liberalization without addressing equity in access to healthcare would worsen the situation.

There is evidence of a strong concentration of hospitals in India in economically developed areas including a strong concentration in economically developed urban areas (8). From 1991 to May 2001 there have been 62 cases of approval of foreign investments in hospitals or diagnostic centres in India. An overwhelming majority of these investments are concentrated in urban areas with the most investments being in Chennai, Delhi and Kolkata (9).

Noting the growing presence of super-specialty private hospitals in India established with foreign collaboration and India's emergence as a hub for medical tourism, the report of the National Commission on Macroeconomics and Health (NCMH) has observed that this '... will increase the overall cost of healthcare in the country and generate pressures for increased budgetary allocations for government hospitals to stay competitive.' On the basis of a survey of the health sector, the report draws the following conclusions :

- The resources in the health sector are distributed unevenly with 88 per cent concentration of resources in towns;
- 75 per cent of specialists and 85 per cent of technology is in the private sector;
- 49 per cent of beds are in the private sector with an occupancy ratio of 44 per cent while the public sector has an occupancy ratio of 62 per cent;
- There is an acute shortage of human resources in the health sector with an average of 0.49 doctors and 0.79 nurses per 1000 people while the global norm is 2.25 per 1000 people. This shortage is further compounded in rural areas with about two-thirds concentration of health professionals in urban centres;
- 75 per cent service delivery for dental health, mental health, orthopaedics, vascular and cancer diseases are provided by the private sector (10).

Thus, while there is a severe shortfall in the availability of doctors and nurses in proportion to the population, most of the human resource is concentrated in the private sector, which is primarily based in urban centres. On the other hand the understaffed public sector with less resource has a higher occupancy ratio than the private sector. Therefore, the growth of the private sector with foreign collaboration has not reduced the load on the public sector. Indeed while the economy was growing at about 8 per cent in 2005, the Infant Mortality Rate (IMR), considered, as the most important indicator of how the resources are distributed for health, in India was 60 per thousand live births (11). The NCMH report also shows that there is already a two-tier system with internal and external brain drain is exiting in India. The following discussion examines how far the existing regulatory mechanism addresses the concerns on health service liberalisation.

Trade and Health : Human Rights Implications

The issue of impact of liberalisation on access to health services including access to health medicines should be seen from a human rights perspective. Multilateral trade agreements adopt

a commercial approach towards trade issues which reduces the policy making space for states. Rights based approach to trade liberalisation the promotion, protection and fulfilment of human rights as an integral and fundamental objective of trade liberalisation, which seeks to make the States primarily responsible under international human rights law for ensuring that human rights are not compromised in the process of trade liberalisation.

The human rights based approach to trade liberalisation regards certain goods and services that are essential for leading a life in dignity as entitlements, which must be accorded to all. In accordance with this approach, the international community has been examining the possible ways of ensuring the availability of these entitlements for all peoples through the process of trade liberalisation.

The UN Sub-Commission on the Promotion and Protection of Human Rights has examined the relationship between the liberalisation of trade in services and the enjoyment of human rights including the right to health. The right of everyone to the enjoyment of the highest attainable standard of physical and mental health is recognised in Article 12 of the International Covenant on Economic, Social and Cultural Rights (ICESCR). To achieve the full realisation of this right States have the responsibility to create conditions that would ensure to everyone medical service and medical attention in the event of sickness (12).

The content of the right to health has been explained in general comment no.14 of the Committee on Economic, Social and Cultural Rights (CESCR). Accordingly, the essential elements of the right to health are :

- The availability of a functioning public health system and health-care facilities including hospitals, clinics, trained medical professionals and essential drugs.
- Universal access to health services in both physical as well as economic terms. Thus, there should not be an over-promotion of investments in expensive curative health services instead of primary and preventive healthcare services which benefits a larger section of the population.
- The State must ensure the quality of health services (13).

Besides the UN, the right to health as a fundamental human right has also been recognised by the Alma-Ata Declaration of the International Conference on Primary Health Care. The Declaration had set the attainment by all people of the world a level of health suitable for leading a socially and economically productive life by the year 2000, as a main social target for governments, international organisations and the world community (14). Though it is evident that the timeline set by the Alma-Ata Declaration has been missed, the objectives set therein still remain valid and they should be observed in the process of liberalisation of health services.

Thus, in spite of TRIPS and GATS commitments on patent rights and liberalising health services or autonomous liberalisation of such services, all States are primarily responsible for creating and sustaining conditions that promote, protect and fulfill the access of all peoples to a functioning, affordable, accessible and high quality health service. This primary responsibility of States under international human rights law extends to the

trade liberalising commitments that they negotiate in the WTO and other regional trading arrangements.

Summary

During the last part of 20th century most countries shifted their development strategy from self-sufficiency to export oriented growth strategy. Most important issue with regard to trade and public health is the loss of policy space of developing country government related to public health. The most important institution and agreement relevant the discussion here is WTO and the Agreement establishing WTO. The agreement establishing WTO contains a set of international agreements regulating specific aspects of trade. It reduces the policy space of countries with regard to access to medicines and access to health services. Developing countries are on the verge of loosing the existing policy space in those areas. The term intellectual property rights generally refer to a set of exclusive rights granted to the owner of intellectual property.

TRIPS is one of the most controversial agreements administered under the World Trade Organisation's (WTO) frame work because it took away the freedom of member countries to determine the level of intellectual property protection. Patents especially product patents create a statutory monopoly for a limited number of years and increases the chance of abuse of patents. As mentioned above, TRIPS prescribes a universal minimum standard to different forms of intellectual property. Patent monopoly often abused by the patent holder and fixes a higher price for the patented medicines. Hence, patents on drugs compromise the accessibility and availability of medicines, two important components of right to health. The domestic legislation should incorporate the flexibilities to the maximum extent. The Preamble of TRIPS states that measures and procedures to enforce intellectual property rights should not themselves become barriers to legitimate trade. The domestic legislation should strike a balance between public and private rights and the rights of patentee should not be at the cost of public health concerns. India has a legal right to interpret and implement the TRIPS Agreement to promote access to drugs. TRIPS implementation should not compromise any of the rights guaranteed by any previous international treaty. Even though TRIPS *per se* is objectionable and need to be reviewed in the coming days to ensure accessibility and availability of drugs, the flexibility within TRIPS provides some manoeuvring space to Members States to address the issue of access to drugs. The flexibilities available within the TRIPS offer some policy options for the developing countries to mitigate the adverse affects of product patent protection on the availability of affordable medicines.

India, as a member of the WTO has an obligation under TRIPS to comply with its patent provisions. Countries like India gave importance to the question access to affordable medicines and survival of its generic industry over the protection of intellectual property while implementing the TRIPS Agreement. The generic companies can introduce the generic version immediately after the expiry of patent. In many developing countries, the public health system could not meet the demand for healthcare services. General Agreement in Trade and Service (GATS) attempts to establish a framework within

the WTO for regulating international trade in services and it envisages the progressive liberalisation of all trade in services. However, there is a concern expressed by health policy analysts and the civil society as to the adverse implications of GATS disciplines on health services. The traditional notion of health as non-commercial services has undergone a paradigm change. While the ultimate delivery of a health service necessarily involves physical contact between the health professionals like doctors and nurses with the patient, owing to technological developments the extent to which physical contact is required can be reduced significantly. Trade in health services involves 4 modes of services delivery. In India the public sector provides health services through the central governments, state governments, municipal corporations and other local bodies. Even in developed countries, the government has a substantial share in the expenditure on health sector. While there is a severe shortfall in the availability of doctors and nurses in proportion to the population, most of the human resource is concentrated in the private sector, which is primarily based in urban centres. The NCMH report also shows that there is already a two-tier system with internal and external brain drain is exiting in India. The following discussion examines how far the existing regulatory mechanism addresses the concerns on health service liberalisation. Multilateral trade agreements adopt a commercial approach towards trade issues which reduces the policy making space for states. The human rights based approach to trade liberalisation regards certain goods and services that are essential for leading a life in dignity as entitlements, which must be accorded to all. The content of the right to health has been explained in the Committee on Economic, Social and Cultural Rights (CESCR). In spite of TRIPS and GATS commitments on patent rights and liberalising health services or autonomous liberalisation of such services, all States are primarily responsible for creating and sustaining conditions that promote, protect and fulfill the access of all peoples to a functioning, affordable, accessible and high quality health service.

Study Exercises

MCQs

1. The most important institution and agreement regulating International trade regime at present is (a) Free Trade Agreements (FTA) (b) Doha Declaration (c) UN Central Products Classification system (UNCPC) (d) World Trade Organization (WTO)
2. The most controversial provisions TRIPS are related to (a) Patent protection (b) Trademark (c) Copyrights (d) Industrial designs
3. Members "shall not be obliged to, implement in their domestic law more extensive protection than required by this Agreement". This is enshrined in which article of TRIPS ? (a) 1 (b) 2 (c) 3 (d) 4.
4. In 2001, WTO Ministerial Conference endorsed the same approach for the implementation of TRIPS patent provisions at the domestic level in (a) Johannesburg (b) New Delhi (c) Doha (d) New York

Answers : (1) d; (2) a; (3) a; (4) c.

The fact that the world is but a global village and health and disease can not be limited by the boundaries of the nations, was recognized long ago. Way back in 1377, the first recorded quarantine legislation was promulgated for prevention of transshipment of rodents to Venice from foreign ports. The International Sanitary Conference, convened in Paris in 1851, was the first step towards seeking international cooperation in prevention of communicable diseases with epidemic potentials. This conference, in spite of not succeeding in framing the uniform code for quarantine, gave rise to many such conferences in quick succession which in turn led to the establishment of *Office International d'Hygiene Publique* (OIHP) in 1907 – a precursor of League of Nations and World Health Organization (WHO).

The term "International Health" first appeared sometime in early twentieth century and became well known following the establishment of International Health Commission in 1913 in United States. The commission played a vital role in the opening of first school of public health in 1917 in the United States at John Hopkins University but it was only in 1960 that the international health division was established in the school. Since then the activities in the field of international health has increased by leaps and bounds and has involved many governmental, inter-governmental and non- governmental organizations.

Definition of International Health

Simply said international health means public health with an international dimension. The predominant notion refers to the interactions taking place in the field of health at international level. This not only includes the risks and hazards to health

faced by individuals and populations owing to the mobility of health hazards and people but also includes various measures taken for the promotion, protection, prevention and restoration of health. It uses tools of public health, takes into account the information received from other disciplines and addresses questions that transcend the frontiers of a country. The term 'international health' has been defined as *a field of research and intervention embracing the international dimensions of health, disease process and care systems*.

While research refers to the analysis of health determinants and the health states of the individuals and populations, the intervention refers to the actions taken at economic, political and administrative levels. Broadly speaking, international health is *a systematic comparison of the factors that affect the health of all human populations*.

However, international health means differently to different people e.g. for a public health worker it means protection of population from illness, for an epidemiologist it means a study of distribution and control of diseases, for a clinician it means practice of medicine in a remote area, for an administrator it means organization and operation of health services, for an economist it means a study of health resource allocation and financing and for a politician it means controlling spheres of influences. The popular view, as shaped by media and perceived by masses, is that the international health deals with situations like tsunami, SARS or pandemic influenza, giving little importance to inequity in health sector globally or even the hard core issues of public health.

Contents of International Health

International health is seen as a conglomeration of various aspects of public health, as follows :

- It uses principles of epidemiology while appreciating the root causes of ill health in the world in general and in defined populations in particular, with an aim of alleviating the global burden of diseases.

- It deals with psychosocial aspects while understanding the psychosocial effects of diseases or health related events on individuals, families and communities.
- Demographic aspects are important for understanding the composition of population segments in individual countries and of populations in different countries.
- Economic aspects come into play when it deals with public health expenditure and out of pocket expenditure on health, resource allocations and the cost of illness to individuals, families, communities and countries.
- It also dwells upon health system and governance while discussing the health systems of the countries, their health infrastructure and their governance and also of the health ministries and their interactions with other ministries which have a direct impact on the health.
- It also includes certain miscellaneous aspects like ethical issues, utilization of alternative medicine by various population segments, humanitarian response to disasters and emergencies and the participation of various governmental, non-governmental and private agencies.

Organizations Involved in International Health

A number of governmental, inter-governmental and non-governmental organizations are actively involved in International health. They can be classified as government sponsored international agencies and non-governmental organizations further subdivided into private voluntary organizations and philanthropic organizations. Among government sponsored international agencies are included several United Nations (UN) organizations of which World Health Organization (WHO) is the most important. A brief about some of these organizations are given in succeeding paragraphs.

World Health Organization (WHO)

Following World War II and creation of intergovernmental organizations like United Nations (UN), a need of having an international health agency was felt by many of the countries who experienced the devastating after effects and were still reeling under colonial rule. Brazilian and Chinese delegations submitted a joint declaration to United Nations for inclusion of health in the charter of UN and when diplomats met, one of the things they discussed was setting up a global health organization. As a result the landmark international health conference was held in New York in Jun – Jul 1946. At this conference, all the 61 members approved the constitution of World Health organization (WHO) on 22 Jul 1946. This constitution, after many deliberations and ratifications, came into force on 7 April 1948 – a date we now celebrate every year as World Health Day.

Thus WHO became the United Nations' specialized agency for Health with its headquarters in Geneva, Switzerland. It inherited the mandate and all the resources of its predecessor, the League of Nations and acts as a coordinating authority on international public health.

Mission

Its objective, as set out in its Constitution, is the attainment by all peoples of the highest possible level of health. The Constitution defines health as a state of complete physical,

mental and social well-being and not merely the absence of disease or infirmity.

Role in Public Health

WHO fulfils its objectives through its core functions, which are:

- (a) **Leadership** : Providing leadership on matters critical to health and engaging in partnerships where joint action is needed
- (b) **Setting standards** : Setting norms and standards and promoting and monitoring their implementation
- (c) **Policy formulation** : Articulating ethical and evidence-based policy options
- (d) **Capacity building** : Providing technical support, catalysing change and building sustainable institutional capacity;
- (e) **Monitoring** : Monitoring the health situation and assessing health trends
- (f) **Research** : Shaping the research agenda and stimulating the generation, translation and dissemination of valuable knowledge.

Organisation

The WHO has its Headquarters comprising of the world health assembly and the executive board, at Geneva and its regional offices for six regions covering all the member states, at six different places.

The World Health Assembly is the supreme decision-making body for WHO. It deals with the administration, finances and international policies and programmes. It also elects the Director General of the WHO who is the chief technical and administrative officer of WHO. It meets each year in May in Geneva and is attended by delegations from all 193 Member States.

The Executive Board, which is like a cabinet, is composed of 34 members technically qualified in the field of health. Members are elected for three-year terms. The main Board meeting, at which the agenda for the forthcoming Health Assembly is agreed upon and resolutions are adopted for forwarding to the Health Assembly, is held in January, with a second shorter meeting in May, immediately after the Health Assembly, for more administrative matters. The main functions of the executive board is to give effect to the decisions and policies of world Health assembly and to facilitate its work.

In the year 1998, all the existing programmes were reduced to 35 departments grouped into nine clusters which are enumerated as follows :

- (a) Health system and community health
- (b) Communicable diseases
- (c) Non-communicable diseases
- (d) Sustainable development and healthy environments
- (e) Evidence and information for policy
- (f) Health technology and pharmaceuticals
- (g) External relations and governing bodies
- (h) Social change and mental health
- (i) General management

Each cluster was headed by an executive director who in turn had a high profile senior management and decision making

team called a Cabinet. These cabinets carried out and monitored the projects assigned to them.

Regions : The six different regions of WHO and their headquarters are as given in Table - 1 :

Regions	Headquarters
The Americas	Washington D. C. (U. S. A.)
Europe	Copenhagen (Denmark)
Eastern Mediterranean	Alexandria (Egypt)
Western Pacific	Manila (Philippines)
South East Asia	New Delhi (India)
Africa	Harare (Zimbabwe)

Each regional organization is headed by a regional director who is assisted by administrative officers and technical officers. Representatives of the member states form the regional committee which meets once a year to review the ongoing health projects, their continuation and further development in their respective countries.

Activity Areas in India

In India, WHO provides technical assistance and collaborates with the Government of India and major stakeholders in health development efforts. It assists notably in Policy Development; Capacity Building and Advocacy. Technical assistance to the Government is provided through the following Core Programme Clusters :

(a) Health system and community health : Reproductive Health and Research; Child and Adolescent Health; Gender and Women Health; Immunization; Nursing and Midwifery; Nutrition and AYUSH (Ayurveda, Yoga and Naturopathy, Unani, Siddha and Homeopathy).

(b) Communicable diseases : Leprosy; Malaria; Filariasis; Tuberculosis; HIV/AIDS and International Health Regulations.

(c) Non-communicable diseases : Cardiovascular Diseases; Tobacco Control; Health Care for the Elderly; Prevention of Deafness; Prevention of Blindness; Health Promotion; Oral Health; Cancer; Non-Communicable Disease Risk Factors Surveillance and other Non-Communicable Diseases.

(d) Sustainable development and healthy environments: Chemical Safety; Emergency & Humanitarian Action; Food Safety; Health & Environment; Healthy Cities; Environmental Epidemiology and Water Sanitation.

(e) Evidence and information for policy : National Health Accounts; Policies; Medical Ethics; Information System; Burden of Diseases; World Health Survey.

(f) Health technology and pharmaceuticals : Essential Drugs and Medicines; Development of Vaccines.

(g) Social change and mental health : Mental Health and Substance Abuse; Disability, Injury Prevention and Rehabilitation.

(h) General management : Health Finance; Trade Agreements and Reform Issues.

Special Programmes

WHO has also facilitated some special health programmes like National Polio Surveillance Programme, Revised National Tuberculosis Control Programme, 3 by 5 for HIV / AIDS, Leprosy Elimination, Roll Back Malaria, Tobacco Free Initiative, Lymphatic Filariasis and Health networking. WHO, in the recent past, has assisted the government of India in emergency and humanitarian action in Gujarat and Rajasthan, in the aftermath of the tsunami and for epidemic outbreaks like the Japanese Encephalitis. WHO is also working with the Ministry of Health in the pandemic preparedness plans for the Avian Influenza.

United Nations Children's Fund (UNICEF)

United Nations International Children's Emergency Fund (UNICEF) was originally created to deal with the issue of child poverty in Europe after World War II. But it could gain official permanent status in the UN only in 1953, six years after its birth as United Nations Relief and Rehabilitation Agency (UNRRA). Over a period, it dropped the terms International and Emergency from its name, but because of the difficulty in pronunciation of UNCF it kept the acronym UNICEF. In 1961, UNICEF also included the rights of children to education and proper health care under the umbrella of its activity. Four years later, it was awarded the Nobel Peace Prize "for the promotion of brotherhood among nations. "

Objectives

"UNICEF identifies young child survival and development as the first right of the child. It advocates quality basic education for all children - girls and boys - with an emphasis on gender equality and eliminating disparities of all kinds.

Its priorities include promotion of breast feeding, immunization, growth monitoring, oral rehydration, education of girl child, child spacing and nutritional supplementation.

As the mandate of the organization is to protect a child's right to survival and to ensure that children are given the basic right to an education, needs are analyzed primarily at a local level, assisted regionally by UNICEF and ultimately funded and administrated by UNICEF international.

Structure and Funding

The administrative and organizational headquarter of UNICEF is at New York City. Eight regional offices and 125 external offices permit UNICEF to carry out its role efficiently and provide cover to almost all children of the world. It is governed by an Executive Board made up of 36 members. Each of these members is elected for a three-year term. The election system is based on rotation, so as to take all countries into account. The Executive Director of UNICEF is nominated by the Secretary General of the UN.

UNICEF is funded exclusively by voluntary contributions. This comes through contributions from corporations, civil society organizations and more than 6 million individual donors worldwide.

UNICEF in India

UNICEF has been working in India since 1949 and today, it has a network of 13 state offices in the country. These enable

the organization to focus attention on the poorest and most disadvantaged communities and to ensure that each child born in this vast and complex country gets the best start in life, thrives and develops to his or her full potential. It is currently implementing a \$400 million programme from 2003 to 2007.

The milestones in the history of UNICEF's work in India are as follows :

- (a) 1949 : UNICEF begins working in India.
- (b) 1967 : UNICEF's association with GOI's rural water programme provides emergency relief to tackle severe drought. Since then, the national water programme has expanded to provide access to protected sources of drinking water to 95% of India's villages.
- (c) 1975 : UNICEF supports piloting and launch of Integrated Child Development services (ICDS).
- (d) 1985-86 : UNICEF supports launch of GOI's Universal Immunization Programme (UIP).
- (e) 1986 : UNICEF works with GOI to launch Oral Rehydration Therapy Programme for treatment of diarrhoea.
- (f) 1996 : UNICEF supports launch of GOI's Reproductive and Child Health (RCH) programme.
- (g) 2000 : UNICEF partners with GOI to ensure eradication of guinea worm.
- (h) 2004 : UNICEF joins Government of India's (GOI) efforts to eradicate polio.

Besides this, UNICEF, within the context of National AIDS Control Plan III, also collaborates with the Government of India and other partners in four key areas which include primary prevention among young people, prevention of Parent-To-Child Transmission (PPTCT), paediatric HIV/AIDS and protection, care and support for affected children.

United Nations Educational, Scientific and Cultural Organization (UNESCO)

UNESCO - the heir of the League of Nations' International Commission on Intellectual Cooperation - was founded on 16 November 1945. Today it has 193 Member States and 6 Associate Members. The organizational headquarter is at Paris. It has over 50 field offices and many specialized institutes and centres throughout the world. The organization aims at promotion of international co-operation among its Member States in the fields of education, science, culture and communication.

Through its strategies and activities, UNESCO is actively pursuing the Millennium Development Goals, especially those aiming to :

- (a) halve the proportion of people living in extreme poverty in developing countries by 2015
- (b) achieve universal primary education in all countries by 2015
- (c) eliminate gender disparity in primary and secondary education by 2005
- (d) help countries implement a national strategy for sustainable development by 2005 to reverse current trends in the loss of environmental resources by 2015.

Mission

The mission of UNESCO is to contribute to sustainable human development and create the conditions for dialogue, based upon respect for commonly shared values and the dignity of each civilization and culture, through programmes and projects in UNESCO's fields of competence - education, the natural and social sciences, culture and communication and information.

Structure

The day-to-day administration, governance, policy making and activities of UNESCO are carried out by the General Conference, the Executive Board and the Secretariat.

The General Conference consists of the representatives of member states. It meets every two years and is attended by representatives of member states, observers from non-member states, intergovernmental organizations and non-governmental organizations (NGOs). Each country has one vote, irrespective of its size or the extent of its contribution to the budget. The General Conference determines the policies and programmes and elects Members of the Executive Board. The working languages of the General Conference are Arabic, Chinese, English, French, Russian and Spanish.

The Executive Board, is responsible for the overall management of UNESCO. It meets twice a year and outlines the work of the General Conference and sees that its decisions are properly carried out. The functions and responsibilities of the Executive Board are derived primarily from the Constitution and from rules or directives laid down by the General Conference.

The Secretariat consists of the Director-General and his staff and is responsible for the day-to-day running of the organization. The Director-General is elected by the General Conference for a term of four-years. The Secretariat is divided into various administrative offices and five programme sectors viz. education, natural sciences, social and human sciences, culture and communication and information. These sectors reflect the organization's major areas of focus.

UNESCO in India

India joined UNESCO on November 4, 1946. The Cluster Office in New Delhi covers Bangladesh, Bhutan, India, Maldives, Nepal and Sri Lanka and helps them to build their human and institutional capacities in diverse fields. It, as the Organization's contribution towards the six Millennium Development Goals, has identified six broad areas for providing assistance and directing its activities. These are :

- (a) Universal Primary Education
- (b) Promoting gender equity and equality
- (c) Implementation of the new commitment to science
- (d) Protecting world's cultural diversity
- (e) Equitable access to information and knowledge to all
- (f) Sustainable Development

Education is a top priority in India's cooperation with UNESCO. The fourth UNESCO Regional Conference in Support of Global Literacy was held on 29 and 30 November 2007 in New Delhi.

India also participates in a variety of UNESCO activities related to cultural heritage and to intercultural dialogue. The Maitreya Temples (Ladakh, India) received the Award of Excellence in

the 2007 UNESCO Asia-Pacific Heritage Awards for Culture Heritage Conservation.

The UNESCO project in Sikkim has been found to be successful. The project promotes community participation in developing tourism in the Central Asia/Himalayan region, by helping to generate employment for local people.

Food and Agriculture Organization (FAO)

The FAO was founded in 1945. It is an intergovernmental organization with its headquarter at Rome. As of now, it has 174 Member Nations plus a member organization, the European Community. It is the largest specialized agency in the United Nations system and the lead agency for agriculture, forestry and rural development.

Activities

Its activities comprise four main areas:

(a) Putting information within reach : FAO serves as a knowledge network. It collects, analyses, interprets and disseminates information relating to nutrition, food, agriculture, forestry and fisheries. Through newsletters, reports and books, magazines and host dozens of electronic for a, it assists governments and planners to make rational decisions on planning, investment, marketing, research or training.

(b) Sharing policy expertise : FAO lends its years of experience to member countries in devising agricultural policy, supporting planning, drafting effective legislation and creating national strategies to achieve rural development and hunger alleviation goals.

(c) Providing a meeting place for nations : FAO provides a neutral forum where all nations - rich and poor, developing and developed - can meet to build a common understanding and to discuss and formulate policy on major food and agriculture issues.

(d) Bringing knowledge to the field : FAO provides the technical know-how and funds, only to a limited extent, for thousands of field projects throughout the world.

Mission

FAO aims at achieving food security for all. Its efforts are directed to make sure that all people of the world have regular access to enough high-quality food and lead an active, healthy lives. Its mandate is to raise levels of nutrition, improve agricultural productivity, better the lives of rural populations and contribute to the growth of the world economy.

Structure

FAO is governed by the Conference of Member Nations, which meets every two years to review the work carried out by the Organization. The Conference elects the Director-General and a Council of 49 Member Nations to act as an interim governing body. Members serve three-year on a rotation basis.

FAO currently has five regional offices, nine sub-regional offices, five liaison offices and 74 fully-fledged country offices in different parts of the world.

FAO is composed of eight departments viz. agriculture and consumer protection; economic and social department; fisheries and aquaculture; forestry; human, financial and physical resources; knowledge and communication; natural resource

management and environment and technical cooperation.

FAO in India

The FAO, with its regional office at Bangkok, provides regular support to India in the field of Food Security and Nutrition. Its current focus is mainly on plant production activities, forestry, fisheries, nutrition and food quality & safety. A special interests lies in the field of vulnerability mapping through the establishment of a Food Insecurity and Vulnerability Information and Mapping System (FIVIMS) and the preparation of a Nutrition Country Profile for India. In addition, under its Special Programme for Food Security, FAO supports the design of a large scale maize production scheme. Under its Technical Cooperation Programme (TCP), the various projects in India are as follows :

- (a) Transfer of technology for vegetative propagation of walnuts in Jammu & Kashmir
- (b) Development of integrated plant nutrition systems methodology
- (c) Training in sea safety development programmes
- (d) Greenhouse technology for floriculture
- (e) Food quality control

International Labour Organization (ILO)

The ILO was founded in 1919 to improve the living and working conditions of the working population all over the world. In 1946, it became the first specialized agency of the UN. It has its headquarter at Geneva, Switzerland.

With 175 Members, ILO is unique in having a tripartite character i.e. at every level in the organization, governments with the two other social partners, namely the workers and employers jointly shape policies and programmes. This helps in setting minimum standards of basic labour rights : freedom of association, the right to organize, collective bargaining, abolition of forced labour, equality of opportunity and treatment and other standards addressing conditions across the entire spectrum of work-related issues. The overall purpose is to bring decent work and livelihoods, job-related security and better living standards to the people of both poor and rich countries.

Objectives

The objectives of ILO are :

- (a) To promote and realize standards and fundamental principles and rights at work.
- (b) To create greater opportunities for women and men to secure decent employment and income.
- (c) To enhance the coverage and effectiveness of social protection for all.
- (d) To strengthen tripartism and social dialogue.

Structure

The administration and functioning of ILO is carried out by its three organs :

- (a) International Labour Conference, which is the General Assembly of the ILO, meets every year in the month of June.
- (b) Governing Body, which is the executive council of the ILO, meets three times in a year in the months of March, June and November.
- (c) International Labour Office is the permanent secretariat.

ILO in India

India is a founder member of ILO and has a branch office in New Delhi since 1929. The Branch Office became an Area Office of ILO in 1970. It coordinates and provides technical assistance to India and Bhutan in the field of rural labour, women workers, employment generation, occupational safety and health etc.

ILO's interest in child labour, young persons and their problems is well known. In India, within a framework of the Child Labour (Prohibition and Regulations) Act, 1986 and through the National Policy on Child Labour, ILO has funded the preparation of certain local and industry specific projects. In two Kanor projects, viz. Child Labour Action and Support Programmes (CLASP) and International Programme on Elimination of Child Labour (IPEC), the ILO is playing a vital role.

The implementation of IPEC programmes in India has created a very positive impact towards understanding the problem of child labour and in highlighting the need for elimination of child labour. A major contribution of the IPEC programme in India is that it has generated a critical consciousness among all the 3 social partners for taking corrective measures to eliminate child labour.

United Nations Development Programme (UNDP)

Founded in 1965, the UNDP is an executive board within the United Nations General Assembly. Its Administrator is the third highest ranking member of the United Nations after the United Nations Secretary-General and Deputy Secretary-General. It has its headquarter in New York City and country offices in 166 countries where it works with governments and local communities to help find solutions to global and national development challenges.

UNDP provides expert advice, training and grant support to developing and least developing countries (a) to meet developmental challenges (b) to develop local capacity and (c) to accomplish MDGs. It focuses on developmental challenges. It encourages the protection of human rights and the empowerment of women in all of its programmes. It also publishes an annual Human Development Report which critically analyze and present the developmental progress made by the countries of the world.

Functions

UNDP focuses primarily on five developmental challenges :

(a) Democratic governance: UNDP supports existing democratic institutions by increasing dialogue, enhancing national debate and facilitating consensus on national governance programs. It also supports the transition to democracy by providing policy advice, technical assistance, increasing awareness and capacity building.

(b) Poverty reduction : UNDP works with governments, NGOs and local leaders to provide opportunities to impoverished people and improve their predicament. It assists governments to evolve strategies to combat poverty by linking poverty alleviation programmes to major national programmes and to find ways and means for economic opportunities.

(c) Crisis prevention and recovery : During disasters and armed conflicts UNDP assists governments in early recovery.

Recovery programs include disarmament, demobilization and reintegration of ex-combatants, programs to reintegrate displaced persons and restoration of basic services for countries recovering from warfare.

(d) Environment and Energy : As the poor are disproportionately affected by environmental degradation and lack of access to clean, affordable energy services, UNDP seeks to address environmental issues in order to improve developing countries' abilities to develop sustainably.

(e) HIV/AIDS : UNDP works to help countries prevent further spreading of HIV/ AIDS and reduce its impact.

UNDP in India

UNDP has been India's partner in development since 1951. Some of its success stories are as under :

- (a) In 1980s, it supported the institution building and technology transfer to apex scientific research institutions like the Council for Scientific and Industrial Research (CSIR) and the Indian Council for Agricultural Research (ICAR).
- (b) In 1990s, UNDP launched a project on social sector strategy to enhance the incomes of the poor and disadvantaged people employed in leather and jute industries. Subsequently the project was extended to other sectors like textiles, fibres and handicrafts that employed people from these groups.
- (c) In response to the Orissa cyclone and the Bhuj earthquake, UNDP launched a disaster mitigation and preparedness programme. The community-based disaster preparedness approach tried out by UNDP in Orissa following the 1999 super-cyclone has now been scaled up nationally in 169 multi-hazard prone districts in 17 states through the UNDP-Government of India Disaster Risk Management Programme.
- (d) The model of poverty alleviation developed and piloted under the UNDP South Asia Poverty Alleviation Programme (SAPAP) in Andhra Pradesh successfully demonstrated the value of women's unity and mobilisation for their social, economic and political empowerment.
- (e) In Maharashtra, under the Community-based Pro-poor Initiatives (CBPPI) Programme, UNDP supported the Swayam Shikshan Prayog (SSP), a local NGO, to build alliances between women's groups and panchayats (local elected bodies) to operationalise community monitoring of development programmes, particularly for identifying and measuring the barriers that restrict women's access to public services.

The current country programme document for India (2008 - 12) is in harmony with the eleventh five-year plan of the Government and is based on a comprehensive review of lessons from past cooperation.

The United Nations Population Fund (UNFPA)

United Nations Fund for Population Activities (UNFPA) was founded under the administration of the United Nations Development Fund in 1969. In 1987, its name was changed to United Nations Population Fund but the acronym UNFPA was retained. It is the world's largest international source of

funding for population and reproductive health programs.

UNFPA is an international development agency that promotes the right of every woman, man and child to enjoy a life of health and equal opportunity. UNFPA supports countries in using population data for policies and programmes (a) to reduce poverty (b) to ensure that every pregnancy is wanted (c) to ensure that every birth is safe (d) to ensure that every young person is free of HIV/AIDS and (e) to ensure that every girl and woman is treated with dignity and respect.

The Fund works with governments and non-governmental organizations in over 140 countries with the support of the international community, supporting programs that help women, men and young people.

UNFPA is guided in its work by the Programme of Action adopted at the International Conference on Population and Development held at Cairo in 1994. At the conference, 179 countries agreed that meeting needs for education and health, including reproductive health, is a prerequisite for sustainable development over the long term. The main goals of Programme of Action, as refined in 1999, are :

- (a) Universal access to reproductive health services by 2015
- (b) Universal primary education and closing the gender gap in education by 2015
- (c) Reducing maternal mortality by 75 per cent by 2015
- (d) Reducing infant mortality
- (e) Increasing life expectancy
- (f) Reducing HIV infection rates

UNFPA in India

UNFPA has been providing assistance to India since 1974. Following the adoption of the Programme of Action, the approach has been to empower women and to expand access to education, health services and employment opportunities.

UNFPA supported Integrated Population and Development (IPD) Projects in approximately 40 districts in 6 states in India (Maharashtra, Gujrat, Madhya Pradesh, Kerala, Rajasthan and Orissa) are aimed to address the needs of individuals and couples to achieve their personal reproductive intentions, to help in eliminating discrimination against girls and to help in providing quality reproductive health services.

UNFPA supports the Government of India in the following key areas :

- Integrating population issues within a wider development context
- Implementing the draft national policy for the empowerment of women
- Developing special programmes to improve women's status and address gender disparities
- Strengthening the logistics system for distribution of contraceptives and broadening the choice of available contraceptive methods
- Enhancing advocacy efforts to promote the concept of reproductive health and gender equality

Joint United Nations Programme on HIV / AIDS (UNAIDS)

Established in 1994 by a resolution of the UN Economic and Social Council and launched in January 1996, UNAIDS is

the main advocate for global action on the HIV epidemic. It brings together ten UN agencies in a common effort to fight the epidemic. Cosponsors include UN High Commission for Refugees (UNHCR), UN Children's Fund (UNICEF), World Food Programme (WFP), UN Development Programme (UNDP), UN Population Fund (UNFPA), United Nations Office on Drugs and Crime (UNODC), International Labour Organization (ILO), UN Educational, Scientific and Cultural organization (UNESCO), World Health Organization (WHO) and the World Bank. It has its headquarter at Geneva, Switzerland. The Cosponsors and the UNAIDS Secretariat comprise the Committee of Cosponsoring Organizations, which meets annually.

Mission

UNAIDS' mission is to lead, strengthen and support an expanded response to HIV and AIDS that includes preventing transmission of HIV, providing care and support to those already living with the virus, reducing the vulnerability of individuals and communities to HIV and alleviating the impact of the epidemic.

Role

UNAIDS help mount and support an expanded response – one that engages the efforts of many sectors and partners from government and civil society. Its role can be summarized in five major components :

- (a) Leadership and advocacy for effective action on the epidemic
- (b) Strategic information and technical support to guide efforts against AIDS worldwide
- (c) Tracking, monitoring and evaluation of the epidemic and of responses to it
- (d) Civil society engagement and the development of strategic partnerships
- (e) Mobilization of resources to support an effective response

UNAIDS – WHO HIV Vaccine Initiative

UNAIDS and WHO, taking advantage of their complementary expertise – UNAIDS contributing with its expertise in social and behavioural research, ethical issues, political mobilization and its strong link with community and WHO bringing in its experiences in vaccine development, its administration and delivery for public health prevention programmes – joined forces to give a boost to the new HIV Vaccine Initiative (HVI). It is guided by a WHO-UNAIDS Vaccine Advisory Committee (VAC), which provides to scientists from different agencies and disciplines, a unique forum for exchange of information and a common ground for collaboration.

UNAIDS in India

UNAIDS works closely with the Government through the National AIDS Control Organization, government and private institutions, NGOs etc. In its fight against HIV/ AIDS it shares knowledge, skills and its worldwide experience. Specifically it supports the national response to HIV/ AIDS by promoting :

- (a) Strengthened leadership and resource mobilization
- (b) Improved planning, financing, technical assistance and coordination at all levels for a sustainable multi-sectoral response to the epidemic
- (c) Strengthened evidence base of the response through greater

availability and use of strategic information from better monitoring and evaluation, surveillance and resource tracking

- (d) Enhanced human resources and robust delivery system at all levels
- (e) Policies to reduce stigma and discrimination
- (f) Increased coverage and sustainability of programmes for injecting drug users, men having sex with men and sex workers
- (g) Increased coverage and sustainability of programmes to address the vulnerability of women and girls, young people, emergency-affected populations and uniformed personnel.

United States Agency for International Development (USAID)

History of creation of USAID dates back to 1947 Marshall Plan – European Recovery Programme following World War II – and Foreign Assistance Act. But it was only in 1961 when USAID was created by an executive order for administering economic assistance programmes. It has its headquarter at Washington, D. C.

USAID is an independent federal government agency that extend assistance to countries recovering from disaster, trying to escape poverty and engaging in democratic reforms. It supports long-term and equitable economic growth and advances U. S. foreign policy objectives by supporting economic growth, agriculture and trade; global health; and democracy, conflict prevention and humanitarian assistance.

The strength of USAID is its field offices around the world where it works in close partnership with governments, private voluntary organizations, indigenous organizations and international agencies. It provides assistance in five regions of the world :

- (a) Sub-Saharan Africa
- (b) Asia
- (c) Latin America and the Caribbean
- (d) Europe and Eurasia
- (e) The Middle East

USAID in India

In India, USAID has been providing assistance in the following areas :

(a) Economic Growth : For the sustained economic growth of the country, USAID supports agricultural reforms, links small scale farmers to newer markets, strengthens financial institutions and provides know how for generating finances for urban services.

(b) Health : USAID has made considerable contribution for prevention of HIV/ AIDS and for improving maternal and child health. It is because of its efforts that the use of contraception in Uttar Pradesh increased from 27 percent in 1992–1993 to 44 percent in 2005–2006; the HIV prevalence rate in Tamil Nadu reduced from 1.13 percent in 2001 to 0.4 percent in 2005. In Muslim communities with persistent polio, USAID works with faith-based organizations to battle misconceptions about the polio vaccine, creating community support and ensuring that children are immunized.

(c) Disaster Management : Floods, droughts, landslides, cyclones and earthquakes are regular features in India. USAID collaborates with the Indian government and local communities to improve their capacity in disaster risk reduction to save lives and minimize threats from large-scale financial, infrastructure, crop and productivity losses. USAID is also providing scientists and engineers with state-of-the-art tools for better early warning, for providing architecture to government buildings in Delhi which can withstand earthquakes; and for training of Indian disaster management professionals.

(d) Energy and Environment : USAID provides assistance to increase viability in the power sector to meet consumer needs, conserve energy and water resources. By leveraging private funds along with government resources, USAID's urban program is promoting better city governance and improving water and sanitation services for over 18 million people by the end of 2008.

(e) Opportunity and Equity : USAID's education program works with Indian non-governmental organizations, state governments and private corporations to reach the vulnerable groups. USAID also supports activities that keep girls in school, improve the legal rights of women, address the problem of female feticide and combat human trafficking. Partnerships with the private sector provide disadvantaged youth with the skills they need to participate in India's growing economy.

World Bank

The world bank was established as International bank for Reconstruction and Development (IBRD) in 1944 following United Nations Monetary and Financial Conference organized by the U. S. government. It was established to provide financial and technical assistance to developing countries around the world. But by mid- 1950s it became clear that many poor countries were unable to repay standard IBRD loans. This led to the establishment of International Development Association (IDA) in 1960. Today World bank is made up of two unique development institutions owned by 185 member countries - the IBRD and the IDA. The IBRD focuses on middle income and creditworthy poor countries, while IDA focuses on the poorest countries in the world. Together they provide low interest loan, interest-free credit and grants to developing countries for education, health, infrastructure, communications and many other purposes.

In addition to IBRD and IDA, three other institutions viz International Finance Corporation (IFC), Multilateral Investment Guarantee Agency (MIGA) and International Centre for Settlement of Investment Dispute (ICSID) are also closely associated with the world bank. Together these five make the World Bank Group.

Mission

The mission of the world bank is to help developing countries achieve Millennium Development goals by alleviating poverty and providing opportunities for sustained development.

Organization

The world bank is like a cooperative with 185 member countries. These countries are represented by Board of Governors who are the policy makers and usually meet once a year. The functioning

of the World Bank is carried out by its 24 executive Directors. The five largest shareholders i.e. US, France, Germany, Japan and United Kingdom contribute one director each. The other 19 come from the remaining countries on rotation basis. The headquarter of the world bank is at Washington, D. C. Its president is a US national and is nominated by the United States, the bank's largest shareholder.

World Bank in India

India is one of the oldest members of the World Bank. The bank's New Delhi office, established in 1957, is the oldest continuously running country office. India is the bank's largest single borrower and receives half of its loans interest-free. The World Bank is the largest financiers of India's National AIDS Control Program (NACP) with a commitment of around US\$275 million in interest-free credits. Its four-year Country Strategy for 2005 - 2008 focuses on lending for infrastructure, human development and improving rural livelihoods. The Bank is increasingly focusing on providing analytical reports on the country's major development challenges and extending practical advice to policy makers by sharing good practices and experience from within the country and abroad.

Ford Foundation

The Ford Foundation is a private foundation based in New York City. It was founded in 1936 by Henry Ford and Edsel Ford in Michigan with an aim "to receive and administer funds for scientific, educational and charitable purposes, all for the public welfare". Its grant making teams work in three broad program areas viz strengthen democratic values, reduce poverty and injustice, promote international cooperation and advance human achievement.

The foundation's first international field office opened in New Delhi, India in 1952. In 1976, the foundation helped to launch the *Grameen Bank*, which offers small loans to the rural poor of Bangladesh. In the late 1980s, the foundation began making grants to fight the AIDS epidemic, which included support for the establishment of a programme to improve AIDS education and treatment in communities around the country. In 2000, the foundation launched the International Fellowships Program (IFP) to provide fellowships to students from marginalized communities outside the U. S. to pursue graduate studies at universities anywhere in the world.

For many years, the foundation topped annual lists compiled by the Foundation Center of U. S. foundations with the most assets and the highest annual giving; but with the establishment of the Bill and Melinda Gates Foundation in 2000, the Ford Foundation fell far behind the Gates Foundation in terms of assets and 4th in terms of annual grant giving.

Ford Foundation in India

Ford foundation has helped India in following projects :

- Establishment of National Institute of Health Administration (NIHAE) and education at Delhi for training of health administrators
- Establishment of training centres at Singur, Najafgarh and Poonamalle for training of medical and paramedical persons in the field of public health
- Research-cum-action projects for organization of rural

health services and use of hand-flushed sanitary latrines in rural areas

- Supporting research in reproductive biology and fellowship programmes in family planning
- Collaborating with other agencies for improving the water supply and drainage in the urban areas of Kolkata.

Rockefeller Foundation (RF)

The Rockefeller Foundation (RF), based in New York City, is the most prominent philanthropic organization and private foundation in the field of International Health. Its central historical mission is to "promote the well-being" of humanity. The international health commission, set up within RF in 1913 and subsequently designated as International Health division (IHD) cooperated, in its early years, with 75 governments for the control of 21 separate diseases including tuberculosis, malaria, yaws, hookworm and yellow fever. The most prominent achievement being the development of 17D vaccine for yellow fever and ridding the southern United States of malaria and hookworm.

Besides its role in disease control, RF has also been closely associated with medical education. RF supported medical schools in Beirut, Bangkok, Brussels and elsewhere but the most famous being Peking Union Medical college (PUMC), China which was created and operated by RF. RF also financed and supported School of public Health at John Hopkins University. An interesting initiative of RF is the establishment of International Clinical Epidemiology Network (INCLIN) which is an independent non-profit organization with its headquarter at Philadelphia. The network includes clinical epidemiologists, biostatisticians, health economists and social scientists who are interested in health care research leading to development of preventive and treatment strategies. INCLIN supports the young researchers, provides training opportunities and a platform for international communications.

In India, RF began its activities in 1920 with a scheme for control of hookworm disease in Madras Presidency. Since then, RF is associated with many public health programmes and medical education. The establishment of All India Institute of Hygiene and Public Health in Kolkata is largely due to the cooperation of RF. Clinical Epidemiology Network - India (IndiaCLEN), a part of regional INCLIN, has 7 Clinical Epidemiology Units across the country and has played important role in the development of Integrated Disease surveillance Project (IDSP), NACP III and evaluation of Pulse polio immunization.

International Red Cross and Red Crescent Movement

Henry Dunant, a Swiss businessman, in his book "A Memory of Solferino" gave a vivid description of his experiences with the wounded soldiers of Battle of Solferino in June 1859 and advocated the formation of national voluntary relief organizations to help and nurse wounded soldiers in the case of war. In addition, he called for the development of international treaties to guarantee the protection of neutral medics and field hospitals for soldiers wounded on the battlefield. It was because of his efforts that the first Geneva Convention "for the Amelioration of the Condition of the Wounded in Armies in the Field" was adopted on August 22, 1864 and "International

Committee of the Red Cross" (ICRC), which is still its official designation today, came into being. For his work, Henry Dunant was awarded the Nobel Prize for Peace in 1901.

The Red Crescent Movement is an international humanitarian movement with approximately 97 million volunteers worldwide. Its mission is to protect human life and health, to ensure respect for the human being and to prevent and alleviate human suffering, without any discrimination based on nationality, religious beliefs, or political opinions. The movement consists of several distinct organizations that are legally independent from each other, but are united within the Movement through common basic principles, objectives, symbols, statutes and governing organs. These include :

The International Committee of the Red Cross (ICRC) : founded in 1863 in Geneva, Switzerland it has a unique authority under international humanitarian law to protect the life and dignity of the victims of international and internal armed conflicts.

The International Federation of Red Cross and Red Crescent Societies (IFRC) : founded in 1919 and based in Geneva, Switzerland, it coordinates activities between the 186 National Red Cross and Red Crescent Societies within the Movement. On an international level, the Federation leads and organizes, in close cooperation with the National Societies, relief assistance missions responding to large-scale emergencies.

National Red Cross and Red Crescent Societies exist in nearly every country in the world. Currently 186 National Societies are recognized by the ICRC and admitted as full members of the Federation. Each entity works in its home country according to the principles of international humanitarian law and the statutes of the international Movement.

The Red Cross Symbol

The Red Cross on white background was the original protection symbol declared at the 1864 Geneva Convention. It is, in terms of its color, a reversal of the Swiss national flag, a meaning which was adopted to honor Swiss founder Henry Dunant and his home country. According to an agreement within the Red Cross and Red Crescent Movement, the shape of the cross should be a cross composed of five squares. However, regardless of the shape, any Red Cross on white background should be valid and must be recognized as a protection symbol in conflict.

Red Cross in India

In India, the red cross society was established in 1920. During peace time, while working with Military hospitals, it provides news papers and periodicals, musical instruments and indoor games to the indoor patients. While working outside the military hospitals, its role is diverse like running of blood banks, organizing voluntary blood donations, providing opportunities to young boys and girls for getting associated with activities like Pulse Polio Immunization on National immunization day (NID), village upliftment, first aid in the event of an emergency and building up of international friendliness. The Red Cross Home at Bangalore for disabled ex-servicemen is one of the pioneering institutions of its kind in Asia.

Swedish International Development Agency (SIDA)

Swedish International Development Agency (SIDA) has been assisting India since 1964. The broad priority areas of assistance are (a) Poverty oriented projects in the primary health sector with special emphasis on reproductive health and rights of girls and women (b) Environment and urban development with focus on water and sanitation and waste management, air and noise pollution; and (c) Mutual exchange and research cooperation in the field of knowledge and technology. After 1976, Swedish bilateral development assistance has been in the form of grants and is available for mutually agreed projects. Since 1979, SIDA has been supporting the National Tuberculosis Control Programme of India. The grants given for this purpose is utilized for procuring supplies like microscopes, x-ray units and anti-tuberculosis drugs.

Danish International Development Assistance (DANIDA)

Denmark's development co-operation with India started in 1959 and within a decade India became one of the three main recipients of bilateral Danish aid. The areas of activity included health (especially blindness control, polio, leprosy and tuberculosis), agriculture and water and sanitation mainly in the states of Tamil Nadu, Karnataka, Orissa and Madhya Pradesh.

In 1998, consequent to India's nuclear weapons policy, the Government of Denmark officially announced its intention to phase out Danish development assistance to the country. In 2003, however, it was mutually agreed between the two governments to complete the phasing out of the Indo-Danish bilateral official development cooperation by end 2005. During the 45 years of cooperation, Denmark has channelled around 6 billion Danish Kroner (about 1.1 billion US dollars) to the support of the development process in India.

Aga Khan Foundation (AKF)

Founded in 1967 by Aga Khan IV, AKF is a non-governmental development network working to promote social development in the low income countries of Asia and Africa. It has its headquarters in Geneva and is currently active in Afghanistan, Bangladesh, Canada, India, Kenya, the Kyrgyz Republic, Mozambique, Pakistan, Portugal, Switzerland, Syria, Tajikistan, Tanzania, Uganda, the United Kingdom and the United States of America. With affiliates that are important national institutions in North America and Europe and grant-making offices in Africa as well as in South and Central Asia, the Foundation has genuine roots in both the developed and developing worlds. Experience and skills flow in both directions.

The foundation supports primary health care projects in several countries, including a large scale community based system that provides tetanus toxoid to mothers and iodinated oil to prevent goiter and cretinism in children in the rugged mountains of northern Pakistan. Besides, it also supports more than 200 educational and 166 health institutions.

Oxford Committee for Famine Relief (OXFAM)

Originally founded in England in 1942 as the Oxford Committee for Famine Relief by a group of Quakers, social activists and Oxford academics; today OXFAM International is a confederation of 13 organizations working with over 3,000 partners in more than 100 countries to find lasting solutions to poverty and injustice.

Though OXFAM's initial concern was the provision of food to relieve famine, over the years OXFAM has developed strategies to combat the causes of famine. It has three main points of focus viz. (a) development work to lift communities out of poverty with long-term, sustainable solutions; (b) humanitarian work to assist those affected by conflict and natural disasters and (c) advocacy and popular campaigning, to affect policy decisions on the causes of conflict at local, national and international levels.

OXFAM's areas of activities also include works on HIV/AIDS, gender equality, natural disasters, democracy and human rights and climate change.

Programme for Appropriate Technology in Health (PATH)

Based in Seattle, Washington, PATH is an international, nonprofit organization that by collaborating with diverse public- and private-sector partners and with the help of innovative ideas and appropriate technologies try to find sustainable, culturally relevant solutions, for communities worldwide to break long-standing cycles of poor health. Its mission is to improve the health of people around the world by advancing technologies, strengthening systems and encouraging healthy behaviors.

Activities

With country offices in more than 70 countries, collaboration is always at the core of PATH's activities. It focuses on :

- Solutions for emerging and epidemic diseases, like AIDS, tuberculosis and malaria.
- Health technologies designed for low-resource settings, by the people who will use them.
- Safer childbirth and healthy children.
- Health equity for women, among the world's most vulnerable - and influential - populations.

Co-operative for Assistance and Relief Everywhere (CARE)

Founded in North America following World War II, CARE, today, is a leading humanitarian organization with more than 14,500 employees worldwide, fighting global poverty. It is a non-political, private voluntary organization operating in more than 65 countries in Africa, Asia, Latin America, the Middle East and Eastern Europe. It is often one of the first to deliver emergency aid to survivors of natural disasters and war.

CARE's mission is to serve individuals and families in the poorest communities in the world. It works hand in hand with vulnerable families, especially women and girls to help them access their rights.

In India, CARE is operational since 1950. Its main area of focus

had been to provide food support to school children and to ICDS programme. Over the years it has spread its wings and is supporting many projects run by Central Government as well as by State Governments. Notable among these are Integrated Nutrition and Health Projects, Anaemia Control Project, Adolescent Girl's project, Improving Women's Reproductive health and Family Spacing Project. CARE is also conducting a social audit on infant and maternal mortality in Jharkhand to identify and classify all causes of maternal and infant deaths.

International Health Regulations (IHR)

International Sanitary Regulations, first approved in 1892, was revised and adopted by WHO in 1951. It focused on the control of communicable diseases mainly cholera, plague, small pox, yellow fever and enteric fever. These regulations were further modified and adopted as International Health Regulation (IHR) in 1969. It required member states to report outbreaks of certain communicable diseases to WHO. With ever changing physical, social and biological environment, with increasing urbanization and decreasing distances, with mounting threats of natural and man-made disasters and with the risk of emerging and reemerging diseases, IHR required amendments in 1973 and 1981. Subsequent epidemiological evidences demonstrated the need for regulations for broader disease coverage and measures to stop their spread across borders. Accordingly, IHR was completely revised in 2005 to provide the legal framework for international cooperation. The stated purpose of IHR is to control and prevent the spread of disease, protect against it and evoke an international response commensurate with the existing public health practices without unnecessarily affecting the trade and the traffic.

IHR (2005) : The Objectives

The IHR (2005) entered into force with effect from 15 June 2007 with its main objectives as follows :

- (a) The appropriate application of routine, preventive measures (e.g. at ports and airports) and the use by all countries of internationally approved documents (e.g. vaccination certificates).
- (b) The notification to WHO of all events that may constitute a public health emergency of international concern.
- (c) The implementation of any temporary recommendations should the WHO Director General have determined that such an emergency is occurring.

Scope and Notification

IHR (2005) has radically changed the international notification requirements of States to WHO. Member states are no longer required to notify the occurrence of Cholera, plague and yellow fever. Notification is now based on the identification of an "event that may constitute a public health emergency of international concern" (PHEIC). PHEIC has been defined in the Regulations as an extraordinary public health event which constitutes a public health risk to other States through the international spread of disease and may require a coordinated international response.

This non-disease specific definition of notifiable events expands the scope of the IHR (2005) and include events (beyond communicable diseases) arising from any origin or

source. Such events are required to be reported, using decision instrument given in Annex II of the IHR (2005) to WHO (Fig. -1). If the event is identified as notifiable, it must be notified giving detailed public health information, number of cases and deaths and available lab results, to WHO immediately i.e. within 24 hours after having carried out the initial assessment.

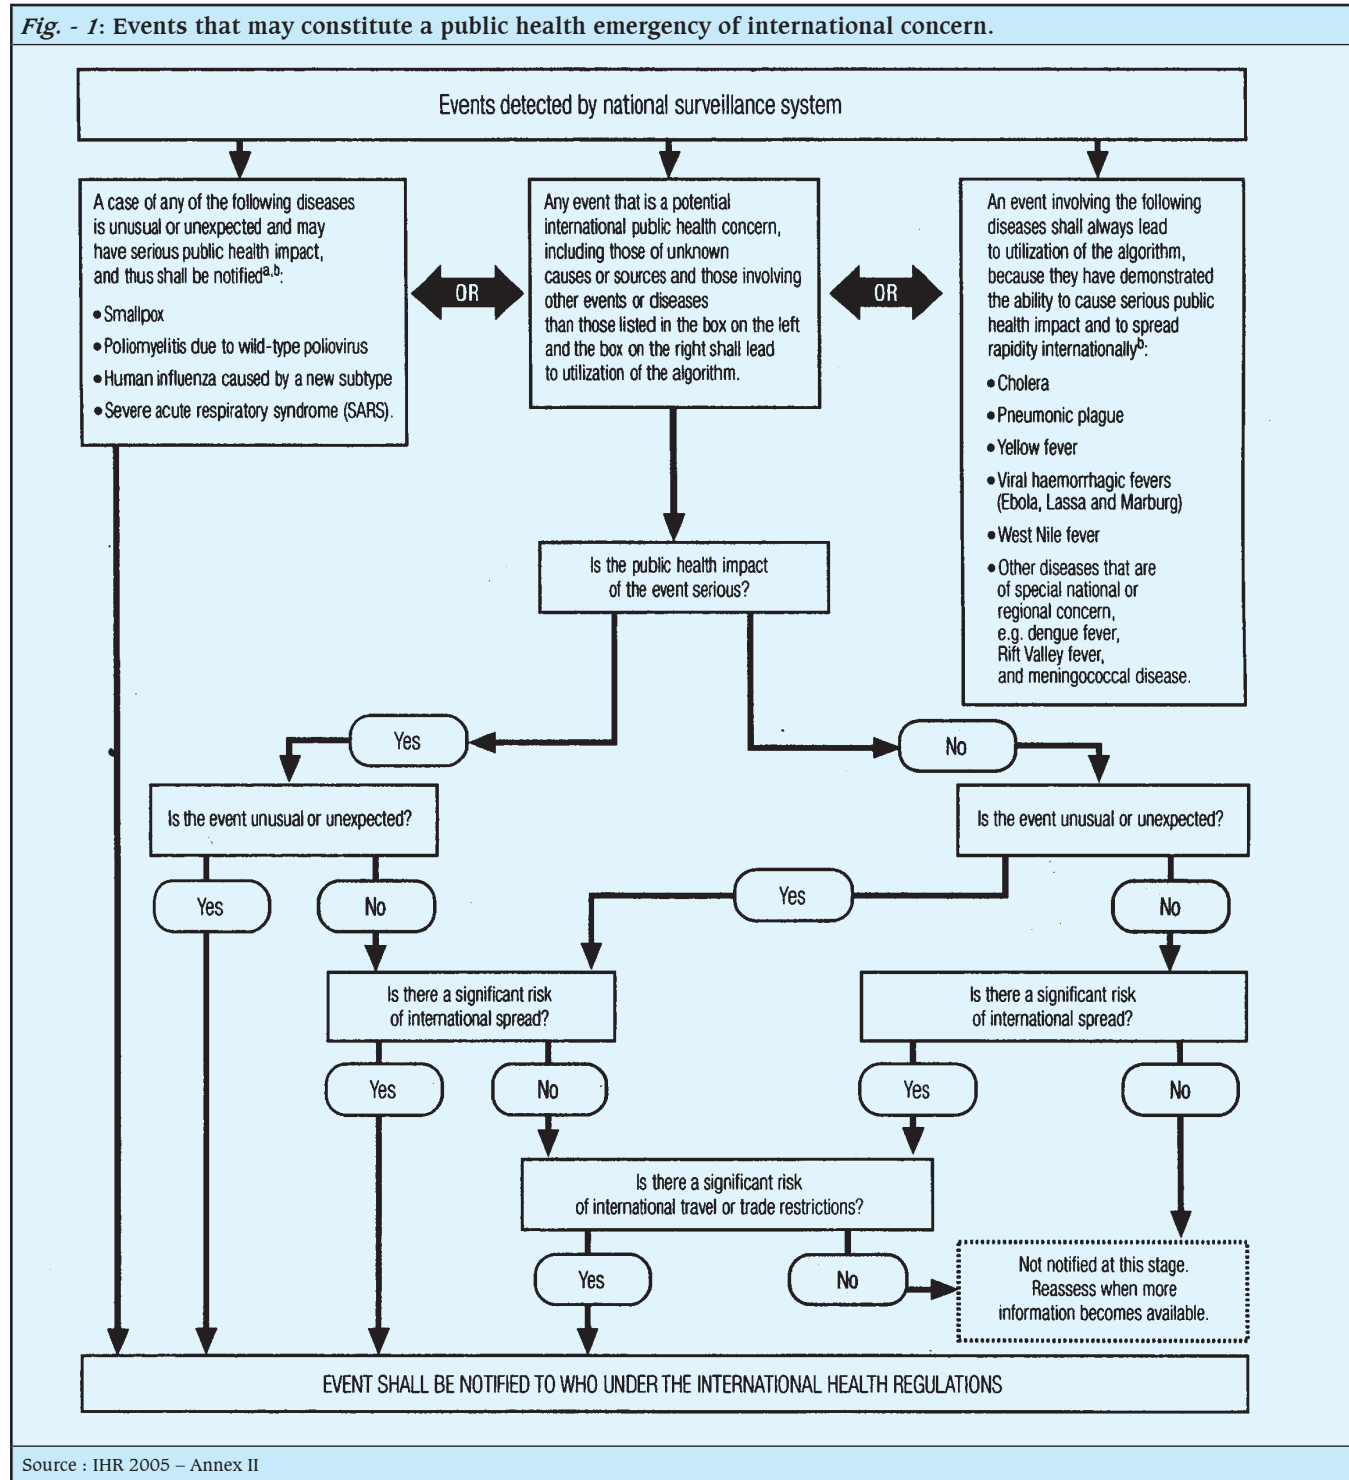

The four decision criteria to be used in the assessment of a

public health event are :

- (a) The seriousness of the event's public health impact.
- (b) The unusual or unexpected nature of the event.
- (c) The risk of international disease spread.
- (d) The risk that travel or trade restrictions will be imposed by other countries.

In essence, the events which must be assessed are those that

Fig. - 1: Events that may constitute a public health emergency of international concern.

Source : IHR 2005 – Annex II

may fulfil one or more of the four decision instrument criteria and the events which must be notified are those that meet at least any two of the criteria therein.

Mandatory notification

While any urgent event can be assessed for notification, the decision instrument identifies two groups of diseases which raise particular concerns :

(a) Group 1 : A single case of smallpox, poliomyelitis due to wild type poliovirus, human influenza caused by a new subtype and severe acute respiratory syndrome (SARS) must be immediately notified to WHO, irrespective of the context in which it occurs.

(b) Group 2 : Events involving epidemic-prone diseases of special national or regional concern which “have demonstrated the ability to cause serious public health impact and to spread rapidly internationally” must always be assessed using the decision instrument but only notified when fulfilling the requirements of the algorithm.

Consultation

IHR (2005) also provide for a “consultation” process between a State Party and WHO. This consultation process provides States Parties with the opportunity to keep WHO informed and to have, similarly to notification, a confidential dialogue with WHO on further event assessment and any appropriate investigative or health response measures.

Other Reporting Requirements

In addition to notification and consultation, States Parties are required to inform WHO within 24 hours of receipt of evidence of public health risks occurring outside their territory that may cause international disease spread. The evidence may be manifest by imported or exported human cases, or the identification of infected or contaminated vectors or contaminated goods.

Points of Entry Provisions

Points of entry provisions in the IHR (2005) are designed to minimize public health risks caused by the spread of diseases through international traffic. The IHR (2005) define a point of entry as “a passage for international entry or exit of travellers, baggage, cargo, containers, conveyances, goods and postal parcels, as well as agencies and areas providing services to them on entry or exit”. There are three types of points of entry: international airports, ports and ground crossings.

The two specific applications of IHR (2005) at point of entry include (a) the requirement of yellow fever vaccination of travelers as imposed by certain countries; and (b) the disinsection of aircrafts to prevent importation of disease vectors. These requirements are intended to help prevent the international spread of the diseases.

Roles for Competent Authorities and Conveyance Operators

States Parties to the IHR (2005) are required to identify the competent authorities to carry out :

- (a) development of core capacities at designated points of entry;
- (b) implementation at points of entry of appropriate levels

of hygiene and sanitation as well as ensuring effective vector, rodent and environment control measures and procedures;

- (c) application of health measures at points of entry in affected areas.

Ship Sanitation Certificates

Under the IHR (2005), the current Deratting and Deratting Exemption certificates have been replaced by Ship Sanitation Control and Ship Sanitation Control Exemption certificates which address a broader range of public health risks on sea going vessels.

Guidance on IHR (2005) Implementation at Points of Entry

Guidance materials are being developed in the following areas:

- 1 Management of public health risks at points of entry
- 2 Provision of technical assistance in developing points of entry capacities
- 3 Maintenance of accessible data for designated points of entry, including capacity to issue Ship Sanitation Control Exemption and Ship Sanitation Control certificates
- 4 Inspection and WHO certification criteria for airports and ports
- 5 Recommended measures for affected travellers, conveyances, containers, cargo and goods
- 6 Ship sanitation and hygiene and sanitation in aviation
- 7 Application of health measures at ground crossings

Health Advice to Travellers

Number of people who are undertaking international travels, is increasing with every passing year and with that, is increasing the travel related risks to their health. These health risks are due to sudden changes in altitude, climate and physical and biological environment.

Determinants of the Health Risks

Determinants of the health risks to which travellers are exposed to are as follows :

(a) Health state before undertaking the travel : Underlying health condition of the traveller is the most important determinant of the health of traveller during the period of the travel e.g. a traveller with low immunity is more susceptible to the infectious diseases prevalent in developing countries.

(b) Place of travel : Destinations where accommodation, hygiene-sanitation, water quality and medical care are of high standard, pose little risk for the travellers.

(c) Purpose of travel : Travellers going on business trips, staying in hotels/ business centres and away from exposure to natural physical and biological environments have lesser risks compared to those who go on adventure trips or for field works and stay in resorts or temporary shelters.

(d) Duration of travel : Duration of the visit determines the nature of exposure to climatic conditions. A shorter duration of visit and inability to acclimatize to local conditions may adversely affect the health.

(e) Behaviour of traveller : Behaviour also plays an important role e.g. going out-doors in the evening in malaria endemic

areas without taking adequate precautions poses the risk of malaria infection to the traveller.

Actions to be Taken

In order to protect the health, every traveller is required to be proactive and prepared. The travel must be planned well in advance and following actions must be taken :

(a) Actions taken before the travel

(i) Learn about the destination : Collect as much information about the place of travel as possible. Find out about the health risks in the area, altitude of the place, type of available accommodation, availability of health care facility etc.

(ii) Have the medical consultation : Visit a travel clinic at least six to eight weeks prior to travel to ensure enough time to get the necessary immunizations. Even the last minute medical consultation is better than no consultation. If you have an ongoing health concern, discuss your travel plans with your doctor. Ask your doctor for a letter stating your medical history and prescribed medications. Dental, ophthalmological and - for women - gynaecological check-ups are advisable before travel to developing countries.

(iii) Health insurance : Obtain special travellers' health insurance for destinations where health risks are significant and medical care is expensive or is not readily available.

(iv) Medical kit : Make or buy a first aid kit for common health concerns. Its contents should include :

- First-aid items like adhesive tape, antiseptic wound cleaner, bandage, emollient eye drops, insect repellent, nasal decongestant, oral rehydration salt, sterile dressing, scissors and safety pins, thermometer, simple analgesic and antipyretic
- Additional items according to destination and individual needs like anti-diarrhoeal medication, anti-malarial medication, condoms, anti-fungal cream, water disinfectant, medication for any pre-existing medical condition, sterile syringes and needles etc.

(b) Actions taken during the travel : The following action must be taken while travelling to the destination and during the period of stay :

(i) While Travelling to Destination : Travel can be tiring, hence get plenty of sleep before leaving. Wear loose and comfortable clothes; eat light meals, drink plenty of water and avoid alcohol and caffeine; when possible, walk around to improve circulation.

(ii) Food and Water Safety : Always wash your hands after going to the toilet and before handling food or eating. Eat fresh and well cooked food, avoid raw vegetables, salads, cut fruits or food kept in open. Do not eat undercooked or raw meat, fish or shellfish. Drink only boiled or bottled water and beverages made with boiled water. Use dairy products that are pasteurized and refrigerated. If in doubt, avoid them.

(iii) Sun Protection : To avoid skin and eye damage caused by the sun, wear clothing that covers your skin and eyes such as a hat with a wide brim and sunglasses with proper UV filter. Apply a sunscreen with a SPF 15 (sun protection factor) about 15 to 30 minutes before going out into the sun.

(iv) Safe sex : Always use a condom for sexual intercourse. Women who only use diaphragms should insist that their male partners use condoms as well.

(v) Injury Prevention : Wear closed-toe shoes to prevent cuts, wounds, insect or snake bites, or infection from parasites.

(vi) Swimming : Swim only in pools filled with clean, disinfected water. Do not swim in tropical waters, streams, canals or lakes, which may be infested with parasites. Try not to swallow water while swimming.

(vii) Road safety : Traffic accidents are the major cause of death among travellers. Whether you're driving or walking, always check the local traffic regulations. Be very careful when driving in a foreign country and on unfamiliar roads. Use your seat belts. Do not drink alcohol and drive. Be sure to use common sense and caution.

(viii) Insect and animal bites : Use an insect repellent and keep your arms and legs covered if there's a chance of being bitten. Animal bites can lead to serious – and even fatal – infections like rabies. Keep away from animals, even if they seem tame. If bitten, cleanse the wound with soap and clean water immediately. Consult local health authorities regarding the possible need for rabies treatment.

(c) Actions taken after the travel.

All travellers, after return, must undergo a medical examination if :

- (i) they spent more than three months in a developing country
- (ii) they suffer from a chronic disease or the existing disease condition has worsened
- (iii) they consider that they have been exposed to a serious infection during the travel
- (iv) they experience illnesses like fever, persistent diarrhoea, jaundice, skin or genital infections, in the weeks following their return

Checklist for the Traveller

(a) Obtain information on local conditions (the destination)

- Risks related to the area (urban or rural)
- Type of accommodation available
- Length of stay
- Altitude
- Security problems in the area
- Availability of health care facility in the area of visit

(b) Prevention

- Vaccination requirement
- Malaria-risk of infection, preventive measures, prophylaxis
- Food hygiene
- Specific local diseases and the preventive measures for them

(c) Accidents related to

- Traffic (carry health card showing blood group)
- Animals (beware of snakes and rabid dog)
- Allergies – common allergens in the area and their prevention
- Sun – carry sunglasses and sunscreen

(d) Get the following check-ups

- Medical – medical kit and health card showing underlying health condition and prescription for medication
- Dental
- Ophthalmological – carry an extra pair of spectacles
- Checkup for specific conditions e.g. pregnancy

(e) Subscribe to a medical insurance

Responsibilities of the Traveller

By and large, travellers themselves are responsible for their health and well being while travelling. Responsibilities that they must accept as their own, are enumerated as under :

- Decision to travel
- Planning for travel
- Recognition and acceptance of the risk
- Seeking medical advice in time
- Compliance with the medical advice and recommended vaccination
- Carrying and understanding the use of medical kit
- Taking precautions before, during and after the journey
- Obtaining insurance cover
- Responsibility for the health and well being of the accompanying children

Summary

International Health has been defined as a field of research and intervention embracing the international dimensions of health disease process and care systems. While the research refers to the analysis of health determinants and the health state of the individuals and populations, the intervention refers to the actions taken at economic, political and administrative levels. Broadly speaking, international health is a systematic comparison of the factors that affect the health of all human populations. International health aims at promotion, maintenance, protection and prevention of health by an interdisciplinary approach. Dealing with problems of intersectoral nature, International cooperation for capacity building of countries, Strengthening technical cooperation among countries, Interaction – multidirectional, not unidirectional (i.e. not from developed countries to developing countries only) – among countries, Providing an instrument for diplomacy and solidarity and not a mechanism for domination. Content of international health covers a wide area like social, economic, behavioural cultural etc factors related to health. Its organization involves governmental and non governmental organization. Main international intergovernmental organizations include the World Health Organization (WHO), the International Labour Organization (ILO), the Food and Agriculture Organization (FAO), the UN Development Programme (UNDP), the UN Children's Fund (UNICEF), etc.

Regional office of WHO South East Asia is located in New Delhi in India. In India, WHO provides technical assistance and collaborates with the Government of India and major stakeholders in health development efforts. It assists notably in Policy Development; Capacity Building and Advocacy.

International Health Regulation was completely revised in 2005 to provide the legal framework for international cooperation in health. The purpose of IHR is to control and

prevent the spread of disease, protect against it and evoke an international response commensurate with the existing public health practices without unnecessarily affecting the trade and the traffic. Stated objective of IHR are the appropriate application of routine, preventive measures (e.g. at ports and airports) and the use by all countries of internationally approved documents (e.g. vaccination certificates), the notification to WHO of all events that may constitute a public health emergency of international concern, the implementation of any temporary recommendations should the WHO Director General have determined that such an emergency is occurring. Notification is now based on the identification of an “event that may constitute a public health emergency of international concern” (PHEIC).

“Public health emergency of international concern” means an extraordinary event which is determined, as provided in these Regulations : to constitute a public health risk to other States through the international spread of disease and to potentially require a coordinated international response.

The four decision criteria to be used in the assessment of a public health event are : the seriousness of the event's public health impact; the unusual or unexpected nature of the event; the risk of international disease spread; and the risk that travel or trade restrictions will be imposed by other countries.

Health Advice To Travellers : Travellers are exposed to health risks owing to sudden changes in altitude, climate and physical and biological environment. Determinants of the health risks to which travellers are exposed are health state of the traveller before undertaking the travel, place of travel and conditions prevailing therein, purpose of travel, duration of travel, behaviour of traveller.

In order to protect the health, every traveller is required to be proactive and prepared. The travel must be planned well in advance and following actions must be taken by traveller: learn about the destination not only about the ecological condition but also about the health facility, have the medical consultation, health insurance, medical kit - make or buy a first aid kit for common health concerns.

While travelling the traveller should take due precaution not to tire himself, maintain food and water hygiene, protection against physical condition prevailing in the destination, prevention of injuries and insect and animal bites, safe sex etc.

All travellers after travel must undergo medical examination if they spent more than three months in a developing country, they suffer from a chronic disease or the existing disease condition has worsened, they consider that they have been exposed to a serious infection during the travel, they experience illnesses like fever, persistent diarrhoea, jaundice, skin or genital infections, in the weeks following their return.

By and large, travellers themselves are responsible for their health and well being while travelling. Responsibilities that they must accept as their own, are decision to travel, planning for travel, recognition and acceptance of the risk, seeking medical advice in time, compliance with the medical advice and recommended vaccination, carrying and understanding the use of medical kit, taking precautions before, during and after the

journey, obtaining insurance cover, responsibility for the health and well being of the accompanying children.

11. IHR was completely revised recently in (a) 2005 (b) 2007 (c) 2009 (d) 2004.

Answers : (1) b; (2) c; (3) b; (4) d; (5) a; (6) a; (7) b; (8) d; (9) c; (10) c; (11) a.

Leo S. Vaz

The Health Care Services Organization in the country extends from the national level to village level.

Central level

The organization at the national level consists of the Union Ministry of Health and Family Welfare. The Ministry has three departments, viz. - Department of Health & Family Welfare, Department of Ayurveda, Yoga-Naturopathy, Unani, Sidha & Homeopathy (AYUSH) and Department of Health Research. Each of these departments is headed by respective secretaries to Govt of India. The department of Health & Family Welfare is supported by a technical wing, the Directorate General of Health Services, headed by Director General of Health Services (DGHS).

State level

The organization at State level is under the State Department of Health and Family Welfare in each State headed by Minister and with a Secretariat under the charge of Secretary/Commissioner (Health and Family Welfare). The State Directorate of Health Services, as the technical wing, is an attached office of the State Department of Health and Family Welfare and is headed by a Director of Health Services. The area of medical education which is with the Directorate of Health Services at the State, is known as Directorate of Medical Education and Research. This Directorate is under the charge of Director of Medical Education, who is answerable directly to the Health Secretary/Commissioner of the State. Some states have created the posts of Director (Ayurveda) and Director (Homeopathy). These officers enjoy a larger autonomy, although sometimes they still fall under the Directorate of Health Services of the State.

Regional level

In some states like Bihar, Madhya Pradesh, Uttar Pradesh, Andhra Pradesh, Karnataka and others, zonal or regional or divisional set-ups have been created between the State Directorate of Health Services and District Health Administration. Each regional/zonal set-up covers three to five districts and acts under authority delegated by the State Directorate of Health Services.

District level

All health care programmes in a district are placed under a unified control. It is a link between the State/ regional structure on one side and the peripheral level structures such as PHC/ sub-centre on the other side. The district officer with the overall control is designated as the Chief Medical and Health Officer (CM & HO) or as the District Medical and Health Officer (DM & HO). These officers are popularly known as DMOs or CMOS, and are overall in-charge of the health and family welfare programmes in the district. These DMOs/CMOs are assisted by Dy. CMOs and programme officers.

Community level

For a successful primary health care programme, effective referral support is to be provided. For this purpose one Community Health Centre (CHC) has been established for every 80, 000 to 1, 20, 000 population, and this centre provides the basic specialty services in general medicine, pediatrics, surgery, obstetrics and gynecology.

Community Health Centres (CHCs)

CHCs are being established and maintained by the State Government. It is manned by four medical specialists i.e. Surgeon, Physician, Gynecologist and Pediatrician supported by 21 paramedical and other staff. It has 30 in-door beds with one OT, Xray, Labour Room and Laboratory facilities. It serves as a referral centre for 4 PHCs and also provides facilities for obstetric care and specialist consultations. As on March, 2007, there are 4, 045 CHCs functioning in the country. The present staffing pattern of CHCs is as in Box - 1.

Primary Health Centre (PHC)

PHCs are the cornerstone of rural health services- a first port of call to a qualified doctor of the public sector in rural areas for the sick and those who directly report or referred from Sub-centres for curative, preventive and promotive health care. The Bhor

Committee in 1946 gave the concept of a PHC as a basic health unit to provide as close to the people as possible, an integrated curative and preventive health care to the rural population with emphasis on preventive and promotive aspects of health care. The health planners in India have visualized the PHC and its Sub-Centres (SCs) as the proper infrastructure to provide health services to the rural population. The central Council of Health at its first meeting held in January 1953 had recommended the establishment of PHCs in Community Development Blocks. These centres were functioning as peripheral health service institutions with little or no community involvement. They were not able to provide adequate health coverage, partly, because they were poorly staffed and equipped and lacked basic amenities. The 6th Five year Plan (1983-88) proposed reorganization of PHCs on the basis of one PHC for every 30,000 rural population in the plains and one PHC for every 20,000 population in hilly, tribal and backward areas for more effective coverage.

PHC is the first contact point between village community and the Medical Officer. The PHCs were envisaged to provide an integrated curative and preventive health care to the rural population with emphasis on curative, preventive, Family Welfare Services and promotive aspects of health care. One Primary Health Centre covers about 30,000 (20,000 in hilly, desert and difficult terrains) or more population. Many rural dispensaries have been upgraded to create these PHCs. At present, a PHC is manned by a Medical Officer supported by 14 paramedical and other staff. It acts as a referral unit for 6 sub-centres and refer out cases to Community Health Centres (CHCs-30 bedded hospital)/sub-district/district hospitals. It has 4-6 indoor beds for patients. There are 22, 370 PHCs functioning as on March 2007 in the country. The staffing pattern of new primary health centre is shown in Box - 2.

Sub-Centre

The Sub-Centre is the most peripheral and first contact point between the primary health care system and the community. Sub-Centres are assigned tasks relating to interpersonal communication in order to bring about behavioral change and provide services in relation to maternal and child health, family welfare, nutrition, immunization, diarrhoea control and control of communicable diseases programmes. The Sub-Centres are provided with basic drugs for minor ailments needed for taking care of essential health needs of men, women and children. There are 1,45,272 Sub Centres functioning in the country as on March 2007. Currently a Sub-centre is staffed by one Female Health Worker commonly known as Auxiliary Nurse Midwife (ANM) and one Male Health Worker commonly known as Multi Purpose Worker (Male). One Health Assistant (Female) commonly known as Lady Health Visitor (LHV) and one Health Assistant (Male) located at the PHC level are entrusted with the task of supervision of all the Sub-centres (generally six subcentres) under a PHC. The Ministry of Health & FW, GOI provides assistance to all the Sub-centres in the country since April 2002 in the form of salary of ANMs and LHVs, rent (if located in a rented building) and contingency, in addition to drugs and equipment kits. The salary of Male Health Worker is borne by the State Governments. The staffing pattern of sub-centre is depicted in Box - 3.

Box - 3 : Staffing Sub centre			
S. No	Staff For Sub-Centre	Existing	IPHS proposed
1.	Health Worker(Female)/ANM	1	2
2.	Health Worker (Male)	1	1
3.	Voluntary Worker (optional on honorarium)	1	1
Total		2/3	3/4

The shortfall in the rural health infrastructure, based on 2001 population census, has been depicted in Box - 4.

Box - 4 : Shortfall in Rural Health Infrastructure All India				
As per 2001 Population	Required	Existing (as on 31 Mar 2007)	Shortfall	% Shortfall
Sub-Centres	158792	145272	20855	13. 13
PHCs	26022	22370	4833	18. 57
CHCs	6491	4045	2525	38. 90

Note : All India shortfall is derived by adding state-wise figures of shortfall ignoring the existing surplus in some of the states.

Indian Public Health Standards (IPHS)

The overall objective of IPHS is to provide health care that is quality oriented and sensitive to the needs of the community. In order to provide optimal level of quality health care, a set of standards are being recommended for Community Health

Centre /Primary Health Centre/sub centre. The IPHS for Primary Health Centres has been prepared keeping in view the resources available with respect to functional requirement for Primary Health Centre with minimum standards such as building manpower, instruments, and equipments, drugs and other facilities etc. These standards would help monitor and improve the functioning of the PHCs. The objectives of IPHS for PHCs are :

- i. To provide comprehensive primary health care to the community through the Primary Health Centres.
- ii. To achieve and maintain an acceptable standard of quality of care.
- iii. To make the services more responsive and sensitive to the needs of the community.

Minimum Requirements at the Primary Health Centre for meeting the IPHS :

1. Medical care :

(a) OPD services : 4 hours in the morning and 2 hours in the afternoon / evening. Minimum OPD attendance should be 40 patients per doctor per day.

(b) 24 hours emergency services : Appropriate management of injuries and accident, First Aid, Dog bite/snake bite/scorpion bite cases, and other emergency conditions

(c) Referral services

(d) In-patient services (6 beds)

2. Maternal and Child Health Care including family planning:

a) Antenatal care : Early registration of all pregnancies and minimum 3 antenatal checkups with minimum laboratory investigations.

b) Intra-natal care : (24-hour delivery services both normal and assisted) Promotion of institutional deliveries, appropriate and prompt referral for cases needing specialist care.

c) Postnatal Care : Two postpartum home visits, first within 48 hours of delivery, 2nd within 7 days through Sub-centre staff, essential new born care, provision of facilities under *Janani Suraksha Yojana* (JSY).

d) New Born care

e) Care of the child : Emergency care of sick children including Integrated Management of Neonatal and Childhood Illness (IMNCI), full Immunization of all infants and children against vaccine preventable diseases, Vitamin A prophylaxis to the children.

f) Family Planning : Education, Motivation and counseling towards family planning, Provision of contraceptives.

3. Medical Termination of Pregnancies using Manual Vacuum Aspiration (MVA) technique. (wherever trained personnel and facility exists)

4. Management of Reproductive Tract Infections / Sexually Transmitted Infections

5. Nutrition Services (coordinated with ICDS)

6. School Health : Regular check ups, appropriate treatment including deworming, referral and follow-ups.

7. Adolescent Health Care : Life style education, counseling, treatment.

8. Promotion of Safe Drinking Water and Basic Sanitation

9. Prevention and control of locally endemic diseases like malaria, Kalaazar, Japanese Encephalitis, etc.

10. Disease Surveillance and Control of Epidemics : Disinfection of water sources and Promotion of sanitation.

11. Collection and reporting of vital events

12. Education about health / Behaviour Change Communication (BCC)

13. National Health Programmes including Reproductive and Child Health Programme (RCH), HIV/AIDS control programme, Non communicable disease control programme, Revised National Tuberculosis Control Programme (RNTCP)

14. Referral Services : Appropriate and prompt referral of cases needing specialist care.

15. Training : Training of Health workers and traditional birth attendants; Initial and periodic training of paramedics in treatment of minor ailments; Training of ASHAs. Periodic training of Doctors through Continuing Medical Education, Training of ANM and LHV in antenatal care and skilled birth attendance.

16. Basic Laboratory Services : Essential Laboratory services

17. Monitoring and Supervision : Monitoring and supervision of activities of sub-centre.

18. AYUSH services as per local people's preference : (Mainstreaming of AYUSH).

19. Rehabilitation : Disability prevention, early detection, intervention and referral.

20. Selected Surgical Procedures : The vasectomy, tubectomy (including laparoscopic tubectomy), MTP, hydrocelectomy and cataract surgeries as a camp/fixe day approach have to be carried out in a PHC having facilities of O.T.

21. Record of Vital Events and Reporting

Charter of Patients' Rights for Primary Health Centres : Primary Health Centres exist to provide health care to every citizen of India within the allocated resources and available facilities.

1. The Charter seeks to provide a framework, which enables citizens to know

- What services are available and users' charges if any.
- The quality of services they are entitled to.
- The means through which complaints regarding denial or poor qualities of services will be addressed.

2. Objectives

- To make available health care services and the related facilities for citizens.
- To provide appropriate advice, treatment, referral and support that would help to cure the ailment to the extent medically possible.
- To redress any grievances in this regard.

3. Commitments of the Charter

- To provide access to available facilities without discrimination.
- To provide emergency care, if needed on reaching the PHC.

- To provide adequate number of notice boards detailing the location of all the facilities and the schedule of field visits.
- To provide written information on diagnosis, treatment being administered.
- To record complaints and respond at an appointed time.

4. **Grievance redressal** : Grievances that citizens have will be recorded. Aggrieved user after his/her complaint recorded would be allowed to seek a second opinion at CHC.

5. **Responsibilities of the users** : Users of PHC would attempt to understand the commitments made in the charter and would not insist on service above the standard set in the charter because it could negatively affect the provision of the minimum acceptable level of service to another user. Instructions of the PHC personnel would be followed sincerely, and in case of grievances, the redressal mechanism machinery would be addressed by users without delay.

6. **Performance audit and review of the charter** : Performance audit may be conducted through a peer review every two or three years after covering the areas where the standards have been specified.

Duties of Medical Officer, Primary Health Centre

The Medical Officer of Primary Health Centre (PHC) is responsible for implementing all activities grouped under Health and Family Welfare delivery system in PHC area. He/she is responsible in his individual capacity, as well as over all in charge.

I. Curative Work

1. The Medical Officer will organize the dispensary, outpatient department and will allot duties to the ancillary staff to ensure smooth running of the OPD.
2. He/she will attend to cases referred to him/her.
3. He/she will screen cases needing specialized medical attention including dental care and nursing care and refer them to referral institutions.
4. He/she will provide guidance to the Health Assistants, Health Workers, Health Guides and School Teachers in the treatment of minor ailments.
5. He/she will visit each Sub-centre in his/her area at least once in a fortnight on a fixed day not only to check the work of the staff but also to provide curative services.
6. Organize and participate in the "health day" at Anganwadi Centre once in a month.

II. Preventive and Promotive Work

1. The Medical Officer will ensure that all the members of his/her Health Team are fully conversant with the various National Health & Family Welfare Programs including NRHM to be implemented in the area allotted to each Health functionary. He/she will further supervise their work periodically both in the clinics and in the community setting to give them the necessary guidance and direction.
2. He/she will keep close liaison with Block Development Officer and his/her staff, community leaders and various social welfare agencies in his/her area.
3. He/she will coordinate and facilitate the functioning of AYUSH doctor in the PHC.
4. He will plan and implement the Reproductive and Child Health Programme.

5. Universal Immunization Programme (UIP) : He/she will plan and implement UIP in line with the latest policy and ensure cent percent coverage of the target population in the PHC (i.e. pregnant mothers and new born infants).
6. National Vector Borne Disease Control Programme (NVBDCP) : He/she will be responsible for all NVBDCP operations for Malaria, Kala Azar and JE in his/her PHC area and will be responsible for all administrative and technical matters.
7. Control of Communicable Diseases : He/she will ensure that all the steps are being taken for the control of communicable diseases and for the proper maintenance of sanitation in the villages.
8. Leprosy : He/she will provide facilities for early detection of cases of Leprosy and confirmation of their diagnosis and treatment.
9. Tuberculosis : He/she will provide facilities for early detection of cases of Tuberculosis, confirmation of their diagnosis and treatment and also ensure functioning of Microscopic Centre (if the PHC is designated so) and provision of DOTS.
10. Sexually Transmitted Diseases (STD) : He/she will ensure that all cases of STD are diagnosed and properly treated and their contacts are traced for early detection.
11. School Health : He/she will visit schools in the PHC area at regular intervals and arrange for Medical Checkups, immunization and treatment with proper follow up of those students found to have defects.
12. National Programme for Prevention of Visual Impairment and Control of Blindness : He/she will make arrangements for rendering treatment for minor ailments and testing of vision.

III. Training : He/she will organize training programmes including continuing education for the staff of PHC and ASHA under the guidance of the district health authorities and Health & Family Welfare Training centres.

IV. Administrative Work : He/She will carry out all administrative activities required for smooth running of the PHC.

Job Responsibilities of Health Educator

The Health Educator will function under the technical supervision and guidance of the Block Extension Educator. However, he/she will be under the immediate administrative control of the PHC Medical Officer. He/she will be responsible for providing support to all health and family welfare programmes in the block. His duties and functions are :

- 1) He/she will have with him/her all information relevant to development activities in the block, particularly concerning health and family welfare, and will utilize the same for programme planning.
- 2) He/she will develop his/her work plan in consultation with the medical officer of his/her PHC and the concerned Block Extension Educator.
- 3) He/she will collect and interpret the data in respect of extension education work in his/her PHC area.
- 4) He/she will be responsible for regular maintenance of records of educational activities, tour programmes, daily dairies and other registers, and will ensure preparation and display of

relevant maps and charts in the PHC.

5) He/she will assist the Medical Officer, PHC in conducting training of health workers under the MPW and ASHA and other schemes under NRHM.

6) He/she will organize the celebration of health days and weeks and publicity programmes at local fairs, on market days, etc.

7) He/she will organize orientation training for health and family welfare workers, opinion leaders, local medical practitioners, school teachers, dais and other involved in health and family welfare work.

8) He/she will assist the organizing of mass communication programmes like film shows, exhibition, lecturers and dramas.

9) He/she will supervise the work of field workers in the area of education and motivation.

10) He/she will supply education material on health and family welfare to health workers in the block.

11) While on tour he/she will verify entries in the eligible couple register for every village and do random checking of family welfare acceptors.

12) While on tour he/she will check the available stock of conventional contraceptive with the depot holders and the kits with MPHWS and ASHAs.

13) He/she will help field workers in winning over resistant cases and drop-outs in the health and family welfare programmes.

14) He/she will maintain a complete set of educational aids on health and family welfare for his/her own use and for training purpose.

15) He/she will organize population education and health education sessions in schools and for out-of school youth.

16) He/she will maintain a list of prominent acceptors of family planning method and opinion leaders village wise and will try to involve them in the promotion of health and family welfare programmes.

17) He/she will prepare a monthly report on the progress of educational activities in the block and send it to the higher authority.

Job Responsibilities of Health Assistant Female (LHV - Lady Health Visitor) (Female Supervisor)

Under the Multipurpose Workers Scheme, a Health Assistant Female is expected to cover a population of 30,000 (20,000 in tribal and hilly areas) in which there are six Sub-centres, each with the health worker female. The health assistant female will carry out the following duties :

1. Supervise and guide

- Supervise and guide the Health Worker Female, Dais and guide ASHA in the delivery of health care service to the community.
- Visit each sub-centre at least once a week on a fixed day to observe and guide the Health Worker Female in her day to day activities under various National Health Programmes.

2. Team Work

- Assist the Medical Officer of the primary health centre in the organization of the different health services in the area.

- Participate as a member of the health team in mass camps and campaigns in health programmes.
- Help the health workers to work as part of the health team.

3. Supplies, equipment and maintenance of Sub-centres : In collaboration with the health assistant male, check at regular intervals the stores available at the sub-centre and help in the procurement of supplies and equipment.

4. Records and Reports :

- Scrutinize the maintenance of records by the Health Worker Female and guide her in their proper maintenance.
- She will carry with her the proper record forms, diary and guidelines for identifying suspected Kala-Azar and JE cases.
- She will be responsible along with Health Assistant Male for ensuring complete treatment of Kala-Azar and JE patients in his area.
- She will be responsible along with health assistant male for ensuring complete coverage during the spray activities and search operation.

5. Training

- Organize and conduct training for dais/ASHA with the assistance of the health worker female.
- Assist the medical officer of the primary health centre in conducting training programme for various categories of health personnel.

6. Maternal and Child Health :

- Conduct weekly MCH clinics at each Sub-centre with the assistance of the health worker female and dais.
- Conduct deliveries when required at PHC level and provide domiciliary and midwifery services.

7. Family Planning and Medical Termination of Pregnancy

- She will ensure that health worker female maintains up-to-date eligible couple registers all the times.
- Conduct weekly family planning clinics along with the MCH clinics at each Sub-centre with the assistance of the health worker female. Provide information on the availability of services for medical termination of pregnancy and refer suitable cases to the approved institutions.
- Personally motivate resistant case for family planning.

8. Nutrition

- Ensure that all cases of malnutrition among infants and young children (0-5 years) are given the necessary treatment and advice and refer serious cases to the primary health centre.
- Ensure that iron and folic acid, vitamin A are distributed to the beneficiaries as prescribed.

9. Universal Immunization Programme : Supervise the immunization of all pregnant women and children (0-5 years).

10. Acute Respiratory Infection :

- Ensure early diagnosis of pneumonia cases.
- Provide suitable treatment to mid/moderate cases of ARI.
- Ensure early referral in doubtful/severe cases.

11. School Health : Help medical officers in school health services.

12. Primary Medical Care : Ensure treatment for minor ailments provide ORS & first aid for accidents and emergencies

and refer cases beyond her competence to the primary health centre or nearest hospital.

13. Health Education : Carry out educational activities for MCH, Family Planning, Nutrition and Immunization, Control of blindness, Dental care and other National Health Programmes like leprosy and Tuberculosis with the assistance of the Health Worker Female.

Job Responsibilities of Health Assistant Male (Supervisor)

Under the Multipurpose workers scheme, a health assistant male is expected to cover a population of 30,000 (20,000 in tribal and hilly areas) in which there are six Sub-centres, each with the health worker male. The Health Assistant Male will carry out the following duties :

1. Supervise and guide

- Strengthen the knowledge and skills of the health worker male and supervise and guide him in the delivery of health care service to the community.
- Visit each Health Worker Male and at least once a week to observe and guide him in his day to day activities.
- Assess monthly the progress of work of the Health Worker Male.
- Carry out supervisory home visits in the area of the health worker male.

2. Team Work

- Help the health workers to work as part of the health team.
- Coordinate his activities with those of the Health Assistant Female and other health personnel including the dais and health guide.
- Coordinate the health activities in his area with the activities of workers of other departments and agencies and attend meeting at PHC level.
- Conduct staff meetings fortnightly with the health workers in coordination with the Health Assistant Female at one of the Sub-centres by rotation.
- Attend staff meetings at the Primary Health Centre.
- Assist the medical officer of the Primary Health Centre in the organization of the different health services and conducting training programmes for various categories of health personnel.
- Participate as a member of the health team in mass camps and campaigns in health programmes.

3. Supplies, equipment and maintenance of Sub-centres

- In collaboration with the Health Assistant Female, check at regular intervals the stores available at the Sub-centre and ensure timely placement of indent for and procure the supplies and equipment in good time.
- Check that the drugs at the Sub-centre are properly stored and that the equipment is well maintained.

4. Records and Reports : Scrutinize the maintenance of records by the Health Worker Male and guide him in their proper maintenance.

5. Malaria

- He will supervise the work of Health Worker Male. He should check minimum of 100 of the houses in a village to verify the work of the Health Worker Male.
- He will carry with him a kit for collection of blood smears

during his visit to the field and collect thick and thin smears from any fever case he comes across and he will administer presumptive treatment of prescribed dosage of Anti-malarial drugs.

- He will be responsible for prompt radical treatment to positive cases in his area.
- Supervise the spraying of insecticides during local spraying along with the Health Worker Male. Where Kala-Azar and JE is endemic he will supervise the work of Health Worker Female.
- He should verify that the Health Worker Male really visited those houses and identified suspected Kala-Azar and JE cases and ensured complete treatment has been done properly.
- He will carry with him the proper record forms, diary and guidelines for identifying suspected Kala-Azar and JE cases.
- He will be responsible for ensuring complete coverage treatment of Kala-Azar and JE patients in his area.
- He will be responsible for ensuring complete coverage during the spray activities and search operation.
- He will also undertake health education activities particularly through interpersonal communication, arranging group meetings with leaders and organizing and conducting training of community leaders with the assistance of health team.

6. Communicable Disease

- Be alert to the sudden outbreak of epidemics of diseases, such as diarrhoea/dysentery, fever with rash, jaundice, encephalitis, diphtheria, whooping cough or tetanus poliomyelitis, tetanus neonatorum, acute eye infections and take all possible remedial measures.
- Take the necessary control measures when any noticeable disease is reported to him.
- Carryout the destruction of stray dogs with the help of the Health Worker Male.

7. Leprosy

- In cases suspected of having leprosy take skin smears and send them for examination.
- Ensure that all case of leprosy take regular and complete treatment and inform the medical officer PHC about any defaulters to treatment.

8. Tuberculosis

- Check whether all cases under treatment for Tuberculosis are taking regular treatment, motivate defaulters to take regular treatment and bring them to the notice of the Medical Officer, PHC.
- Ensure that all cases of Tuberculosis take regular and complete treatment and inform the Medical Officer, PHC about any defaulters to treatment.

9. Environmental Sanitation

- Help the community sanitation for safe water sources, Soakage pits, Manure pits, Compost pits, Sanitary latrines, Smokeless chullas and supervise their construction.
- Supervise the chlorination of water sources including wells.

10. Universal Immunization Programme : Conduct immunization of all school going children with the help of the

Health Workers Female.

11. Family Planning

- Personally motivate resistant case for family planning.
- Guide the Health Worker Male in establishing female depot holders.
- Assist M.O. PHC in organization of family planning camps and drives.
- Provide information on the availability of services for medical termination of pregnancy and refer suitable cases to the approved institutions.
- Ensure follow up of all cases of vasectomy, tubectomy, IUD and other family planning acceptors.

Job Responsibilities of Health Worker Female (ANM)

1. Maternal and Child Health : She will register and provide care to pregnant women throughout the period of pregnancy. She will ensure that every pregnant woman makes at least 3 (three) visits for ante natal check-up, estimate their haemoglobin level and test urine of these women for albumin and sugar. She will refer all pregnant women to PHC for RPR test for syphilis and refer cases of abnormal pregnancy and cases with medical and gynaecological problems to Health Assistant Female (LHV) or the Primary Health Centre. She will conduct deliveries in her area when called for and supervise deliveries conducted by Dais and assist them whenever called in. She will refer cases of difficult labour and newborns with abnormalities, help them to get institutional care and provide follow up to the patients referred to or discharged from hospital. She will identify the ultimate beneficiaries, complete necessary formalities and obtain necessary approvals of the competent authority before disbursement to the beneficiaries under *Janani Suraksha Yojana*. She will make at least two post-natal visits for each delivery in her areas and render advice regarding care of the mother and care and feed of the newborn. She will also assess the growth and development of the infant and take necessary action required to rectify the defect. She will educate mothers individually and in groups in better family health including maternal and child health, family planning, nutrition, immunization, control of communicable diseases, personal and environmental hygiene.

2. Family Planning : She will utilise the information from the eligible couple and child register for the family planning programme. She will be responsible for maintaining eligible couple registers and updating at all times. She will spread the message of family planning to the couples and motivate them for family planning individually and in groups. She will distribute conventional contraceptives and oral contraceptives to the couples, provide facilities and to help prospective acceptors in getting family planning services, if necessary, by accompanying them or arranging for the Dai/ASHA to accompany them to hospital. Provide follow-up services to female family planning acceptors, identify side effects, give treatment on the spot for side effects and minor complaints and refer those cases that need attention by the physician to the PHC/Hospital. She will establish female depot holders, help the Health Assistant Female in training them, and provide a continuous supply of conventional contraceptives to the depot holders.

3. Medical Termination of Pregnancy : She will identify the women requiring help for medical termination of pregnancy

and refer them to nearest approved institution. Educate the community of the consequences of septic abortion and inform them about the availability of services for medical termination of pregnancy.

4. Nutrition : She will identify cases of malnutrition among infants and young children (zero to five years) give the necessary treatment and advice and refer serious cases to the Primary Health Centre. She will distribute Iron and Folic Acid (IFA) tablets as prescribed to pregnant nursing mothers and administer Vitamin A solution to children. She will educate the community about nutritious diet for mothers and children in coordination with Anganwadi Workers.

5. Universal Programme on Immunization (UIP) : She will immunize pregnant women with tetanus toxoid, administer DPT, oral polio, measles and BCG vaccine to all infants and children, (Hepatitis-B in pilot areas) as per immunization schedule.

6. Dai Training : She will list Dais in her area and involve them in promoting Family Welfare and help the Health Assistant Female / LHV in the training programme of Dais.

7. Communicable Diseases : She will notify the Health Worker Male/MO PHC immediately about any abnormal increase in cases of diarrhoea/dysentery, fever with rigors, fever with rash, fever with jaundice or fever with unconsciousness which she comes across during her home visits, take the necessary measures to prevent their spread. If she comes across a case of fever during her home visits she will take blood smear, administer presumptive treatment and inform Health Worker male for further action. She will identify cases of skin patches, especially if accompanied by loss of sensation, which she comes across during her homes visits and bring them to the notice of the Health Worker Male/MO (PHC). She will give oral rehydration solution to all cases of diarrhoea/dysentery/vomiting and identify and refer all cases of blindness including suspected cases of cataract to MO PHC.

8. Vital Events : She will record and report to the health authority of vital events including births and deaths, particularly of mothers and infants.

9. Record Keeping : She will register (a) pregnant women from three months of pregnancy onward (b) infants zero to one year of age; and (c) women aged 15 to 44 years. She will maintain the pre-natal and maternity records and child care records and prepare the eligible couple and child register. She will maintain the records as regards contraceptive distribution, IUD insertion, couples sterilized, clinics held at the sub-centre and supplies received and issued. While maintaining passive surveillance register for malaria cases, she will record : No. of fever cases, No. of blood slides prepared, No. of malaria positive cases reported, No. of cases given radical treatment.

10. Treatment of minor ailments : She will provide treatment for minor ailments, provide first-aid for accidents and emergencies and refer cases beyond her competence to the PHC/CHC/hospital.

11. Team Activities : She will attend and participate in staff meetings at PHC/Community Development Block or both. She will coordinate her activities with the Health Worker Male and other health workers including the Health volunteers/ASHA

and Dais.

12. Role of ANM as a facilitator of ASHA : Auxiliary Nurse Midwife (ANM) will guide ASHA in performing the following activities :

She will hold weekly / fortnightly meeting with ASHA and discuss the activities undertaken during the week/fortnight. She will guide her in case ASHA had encountered any problem during the performance of her activity. She will act as a resource person for the training of ASHA. She will take help of ASHA in updating eligible couple register of the village concerned. She will utilize ASHA in motivating the pregnant women for coming to subcentre for initial checkups and bringing married couples to sub centres for adopting family planning. She will guide ASHA in motivating pregnant women for taking full course of IFA Tablets and TT injections etc. ANMs will educate ASHA on danger signs of pregnancy and labour so that she can timely identify and help beneficiary in getting further treatment.

Job Responsibilities of Health Worker (Male)

The Health worker Male will make a visit to each family once a fortnight. He will record his visit on the main entrance to the house according to the instructions of the State/UT. His duties pertaining to different National Health Programme are :

(A) Malaria and other diseases under NVBDCP : From each family, he shall enquire about presence of any fever cases; whether there was any fever case in the family in between his fortnightly visits; whether any guest had come to the family and had fever ; whether any member of the family who had fever in between his fortnightly visit had left the village. He shall collect thick and thin blood smears on one glass slide from case having fever or giving history of fever. He shall begin presumptive treatment for Malaria after blood smear has been collected. He will follow the instructions given to him regarding administration of presumptive treatment under NVBDCP. He shall contact the ASHA, FTD during their fortnightly visit to the village and (i) collect blood smears already taken by the ASHA, FTD (ii) also collect details of each case in MF-2 (iii) replenish both drugs and glass-slides and Rapid Diagnostic Kits (RDKs) and look into the account of consumption of Anti malarial drugs and use of RDKs. He shall dispatch blood smears along with MF-2 collected from the ASHA, FTD, multipurpose worker female and those collected during their visit in his area to the PHC Laboratory twice a week. He shall see the results obtained by the use of RDKs and verify the radical treatment administered by the ASHA, FTD if any during his visit. He shall administer radical treatment to the positive cases as per drug schedule prescribed and as per instructions issued by the Medical Officer PHC and take laid down action if toxic manifestations are observed in a patient receiving radical treatment with primaquine. He shall contact the ASHA and FTD and inform him of the spray dates and assist the Health Supervisor Male in supervising spraying operations and training of field spraying staff.

Where Kala-Azar / Japanese Encephalitis is endemic : From each family he shall enquire about presence of any fever cases of more than 15 days duration or fever with encephalitic presentation. He will identify the fever cases detected by him during his visits and direct such a case to report to PHC for

confirmatory diagnosis. He will guide the suspected cases to the nearest diagnostic and treatment centre for diagnosis and treatment by the MO. He will keep a record of all such cases and shall verify from PHC about their diagnosis during the monthly meeting or through health supervisor during his visit. He will carry a list of all Kala-azar/JE cases in his area for follow up and will ensure administration of complete treatment. He will assist during the spray activities in his area. He will conduct all health education activities particularly through interpersonal communication by carrying proper charts etc. and also assist health supervisors and other functionaries in their education activities.

(B) National Leprosy Eradication Programme : He will identify cases of skin patches especially if accompanied by loss of sensation, refer the above cases to PHC Medical Officer for diagnosis. If Leprosy patients want to take MDT from sub-centre, he will provide treatment and maintain patient card.

(C) National Blindness Control Programme : He will identify and refer all cases of blindness including suspected cases of cataract to Medical Officer, PHC.

(D) Revised National Tuberculosis Control Programme : He will identify persons especially with fever for 15 days and above with prolonged cough or spitting blood and take sputum smears from these individuals and refer these cases to the M. O. PHC for further investigations. He will check whether all cases under treatment for Tuberculosis are taking regular treatment, motivate defaulters to take regular treatment and bring them to the notice of the medical officer PHC.

(E) Universal Immunization Programme : He will administer DPT, oral Polio, measles and BCG vaccine to all infants and children in his area in collaboration with health worker female and assist her in administration of tetanus toxoid to all pregnant women. He will assist the health supervisor male/ health supervisor female in the school health programme.

(F) Reproductive and Child Health Programme : He will utilize the information from the eligible couple and child register for the family planning programme. He will distribute conventional contraceptives and oral contraceptives to the couples and provide follow up services to male family planning acceptors, and refer those cases that need attention by the physician to PHC/Hospital. He will assist the health supervisor male in training the community and its leaders in family welfare. He will identify the women requiring help for medical termination of pregnancy, refer them to the nearest approved institution and inform the health worker female.

(G) Other Communicable Diseases : He will identify cases of diarrhoea/dysentery, fever with rash, jaundice encephalitis, diphtheria, whooping cough and tetanus, poliomyelitis, neonatal tetanus, acute eye infections and notify the health supervisor male and MO PHC immediately about these cases. He will carry out control measures until the arrival of the health supervisor male and assist him in carrying out these measures.

(H) Environment Sanitation : He will chlorinate the public water sources including wells at regular intervals. Educate the community on (a) The method of disposal of liquid wastes (b) The method of disposal of solid waste (c) Home sanitation

- (d) Advantage and use of sanitary type of latrines
(e) Construction and use of smokeless chulhas.

(I) Primary Medical Care : He will provide treatment for minor ailments provide first aid for accidents and emergencies and refer cases beyond his competence to the PHC/hospital.

(J) Health Education : He will educate the community about various health services.

(K) Nutrition : He will identify cases of malnutrition among infants and young children (0-5 years) in his area, give the necessary treatment and advice or refer them to the anganwadi for supplementary feeding and refer serious cases to the PHC. Educate the community about the nutrition diet for mothers and children from locally available food.

(L) Vital Events : He will Enquire about births and deaths occurring in his area, record them in the births and deaths register and report them to the Health Supervisor Male / ANM and educate the community on the importance of registration of births and deaths.

Accredited Social Health Activists (ASHA)

A trained female community health worker - ASHA - is being provided in each village in the ratio of one per 1000 population. For tribal, hilly, desert areas, the norm could be relaxed for one ASHA per habitation depending on the workload. ASHA must be a primary resident of the village with formal education upto Class VIII and preferably in the age group 25-45. She would be selected by the Gram Sabha following an intense community mobilization process. She would be fully accountable to Panchayat. Induction training of ASHA is to be of 23 days in all (five modules), spread over 12 months. On the job training would continue throughout the year.

Though she would not be paid any honorarium, she would be entitled for performance based compensation. It is expected that on an average an ASHA working with reasonable efficiency would be able to earn Rs. 1000 per month. Since as per the existing approval, the compensation for ASHA is not factored in the scheme, it is proposed to modify the programmes mentioned in the ASHA compensation package, wherever necessary, to enable the payment of compensation to her. The cost of training and drug kits to ASHAs would be supported by the Centre in the 18 high focus states. The other states would have the flexibility to have Health link workers to support it out of the RCH II flexible fund. As a special case, ASHAs could be supported in very remote backward regions in non-focus States.

ASHAs would reinforce community action for universal immunization, safe delivery, newborn care, prevention of water-borne and other communicable diseases, nutrition and sanitation. She will also help the villagers promote preventive health by converging activities of nutrition, education, drinking water, sanitation etc. In order that ASHAs work in close coordination with the AWW, she would be fully anchored in the Anganwadi system. ASHAs would also be provided with a 'drug kit' which would help her in providing immediate and easy access for the rural population to essential health supplies like ORS, contraceptives, a set of ten basic drugs. She would also have a health communication kit and other IEC materials developed for villages.

At present, Health Day's are organized every month at the Anganwadi level in each village in which immunization, ante/post natal check ups and services related to mother and child health care including nutrition are being provided. Space at each Anganwadi to serve as the hub of health activities in the village could be considered under other Rural Development Programmes. This space could also serve as depot for medicines and contraceptives.

A revolving fund would be set up at the village level for providing referral and transport facilities for emergency deliveries as well as immediate financial needs for hospitalization. The fund would be operated by the VHSC. Untied fund would also be made available to VHSC for various health activities including IEC, household survey, preparation of health register, organization of meetings at the village level etc. Since VHSC would be asked to play a leading role in the health matters of the village, its members would be given orientation training to equip them to provide leadership as well as plan and monitor the health activities at the village level.

For those villages which are far away from the Sub-Centre, a TBA with requisite educational qualifications would be identified for training and support. She would assist the ANM at the Sub Centre. ASHAs willing to play this role would be given preference. In places where even an ANM's services are not reaching and there is no accredited ASHA available, the RMPs would be identified for training so that they could upgrade their skills and get accredited. Efforts would also be made to regulate quacks and untrained dais. ASHA will assist the villagers in referral services for AYUSH/testing HIV/AIDs, STI, RTI, also preventive, promotive health already with AWW/SHGs etc. ASHA will provide them information on the treatments available under AYUSH.

Summary

The health care services' organization in the country extends from the national level to village level. At the national level it consists of the Union Ministry of Health and Family Welfare, which has three departments, viz. - Department of Health & Family Welfare, Department of AYUSH and Department of Health Research. Each of these departments is headed by respective secretaries to Govt of India. The department of Health & Family Welfare is supported by a technical wing, the Directorate General of Health Services, headed by Director General of Health Services (DGHS). At State level it is under the State Department of Health and Family Welfare in each State headed by Minister and with a Secretariat under the charge of Secretary/Commissioner (Health and Family Welfare). The State Directorate of Health Services, as the technical wing, is an attached office of the State Department of Health and Family Welfare and is headed by a Director of Health Services. At Regional level, in some states each regional/zonal set-up covers three to five districts and acts under authority delegated by the State Directorate of Health Services. At District level, all health care programmes are placed under a unified control and is a link between the State/ regional structure on one side and the peripheral level structures such as PHC/Sub-centre on the other side. The district officer with the overall control is designated as the Chief Medical and Health Officer (CM & HO)

or as the District Medical and Health Officer (DM & HO).

One Community Health Centre (CHC) has been established for every 80, 000 to 1, 20, 000 population, and this centre provides the basic specialty services in general medicine, pediatrics, surgery, obstetrics and gynecology. CHCs are being established and maintained by the State Government. It is manned by four medical specialists i.e. Surgeon, Physician, Gynecologist and Pediatrician supported by 21 paramedical and other staff. It has 30 in-door beds with one OT, Xray, Labour Room and Laboratory facilities. It serves as a referral centre for 4 PHCs.

PHCs are the cornerstone of rural health services- a first port of call to a qualified doctor of the public sector in rural areas for the sick and those who directly report or referred from Sub-centres for curative, preventive and promotive health care. One Primary Health Centre covers about 30, 000 (20, 000 in hilly, desert and difficult terrains) or more population. At present, a PHC is manned by a Medical Officer supported by 14 paramedical and other staff. It acts as a referral unit for 6 sub-centres and refer out cases to Community Health Centres (CHCs-30 bedded hospital)/sub-district/district hospitals. It has 4-6 indoor beds for patients.

The Sub-centre is the most peripheral and first contact point between the primary health care system and the community. Sub-centres are assigned tasks relating to interpersonal communication in order to bring about behavioral change and provide services in relation to maternal and child health, family welfare, nutrition, immunization, diarrhoea control and control of communicable diseases programmes. The Sub-centres are provided with basic drugs for minor ailments needed for taking care of essential health needs of men, women and children. Currently a Sub-centre is staffed by one Female Health Worker commonly known as Auxiliary Nurse Midwife (ANM) and one Male Health Worker commonly known as Multi Purpose Worker (Male). One Health Assistant (Female) commonly known as Lady Health Visitor (LHV) and one Health Assistant (Male) located at the PHC level are entrusted with the task of supervision of all the Sub-centres (generally six sub centres) under a PHC.

The overall objective of Indian Public Health Standards (IPHS) is to provide health care that is quality oriented and sensitive to the needs of the community. In order to provide optimal level of quality health care, a set of standards are being recommended for Community Health Centre /Primary Health Centre/Sub centre with reference to Infrastructure, Functioning and Staffing including responsibilities of each.

The Medical Officer of Primary Health Centre (PHC) is responsible for implementing all activities grouped under Health and Family Welfare delivery system in PHC area. He/she is responsible in his individual capacity, as well as over all in charge for his curative, preventive and promotive care of the patients. He will organize training programmes including continuing education for the staff and carry out all administrative activities required for smooth running of the PHC.

The health assistant female will supervise, guide and train the Health Worker Female, Dais and ASHAs; and also visit each Sub-centre at least once a week. The Health Assistant Male will strengthen the knowledge and skills of the health worker male and supervise and guide him in the delivery of health care

service to the community; and visit each Health Worker Male at least once a week. They maintain records and carry out a team work at PHC.

Health Worker Female (ANM) provides MCH care, Family planning, identify the women requiring help for MTP and identify cases of malnutrition among infants and young children and refer them. She will immunize pregnant women with tetanus toxoid, administer DPT, oral polio, measles and BCG vaccine to all infants and children, (Hepatitis-B in pilot areas) as per immunization schedule. Dai Training, identifying, notifying and referring various Communicable Diseases and recording the vital events are some of her important jobs. The Health worker Male will make a visit to each family once a fortnight and performs the prescribed duties pertaining to different National Health Programmes like NVBDCP, NLEP, RNTCP, UIP, National Blindness Control Programme and others. He will chlorinate the public water sources including wells at regular intervals and educate the community.

A trained female community health worker - ASHA - is being provided in each village in the ratio of one per 1000 population. She must be a primary resident of the village with formal education upto Class VIII and preferably in the age group 25-45. She would be selected by the Gram Sabha and would be fully accountable to Panchayat. Though she would not be paid any honorarium, she would be entitled for performance based compensation. ASHAs would reinforce community action for universal immunization, safe delivery, newborn care, prevention of water-borne and other communicable diseases, nutrition and sanitation.

Study Exercises

Long Questions : (1) Describe the Health care organization in India. Explain how "Primary Health Care" is provided to all. (2) Describe the Staffing and functioning of PHC. (3) Describe the duties of Medical Officer at PHC.

Short Notes : (1) ASHA (2) Duties of Health worker Male (3) Duties of Health worker Female (ANM) (4) Duties of Health Assistant Female (5) Duties of Health Assistant Male. (6) Staffing pattern of PHC (7) Functioning of CHC (8) Functioning of Sub-centre

MCQs

- (1) According to the national health policy, one sub-centre for the hilly areas covers a population of (a) 3000 (b) 5000 (c) 1000 (d) 4000
- (2) All are grass root workers except (a) Anganwadi workers (b) Traditional birth attendants (c) Village health guide (d) Health assistants.
- (3) A female multipurpose worker should be able to detect all of the following except (a) Anemia (b) Renal disease (c) Hydramnios (d) Malpresentation
- (4) Which is true about Community health centre : (a) It covers a population of one lakh (b) It has 60 beds with specialties in surgery, medicine and gynecology (c) Community health officer is selected with a minimum of 5 years of exposure (d) New medical post of community health officer is created
- (5) One PHC should be present in hilly areas for every

- (a) 10,000 people (b) 20,000 people (c) 30,000 people (d) 50,000 people
- (6) Guideline for selection of village health guide are all except
 (a) They should be permanent resident of local community
 (b) They should have minimum formal education at least upto 10th standard (c) Acceptable to all sections of society
 (d) They should be able to spare at least 2-3 hrs daily for community health work
- (7) A dai is trained for (a) 30 working days (b) 90 working days (c) four months (d) six months
- (8) Govt trains a health guide from a village (a) every year (b) once in three years (c) once in five years (d) only once
- (9) Which is not a duty of a traditional birth attendant
 (a) Aseptic delivery (b) Health education (c) Injection of Tetanus toxoid (d) Registration of birth
- (10) The minimum number of beds recommended for CHC by IPHS is (a) 30 (b) 35 (c) 40 (d) 60
- (11) Health Assistants visit Sub-centre / Health Workers once in every (a) week (b) 2 weeks (c) 3 weeks (d) month
- (12) One Health Assistant (Male) is entrusted with the task of supervision of ____ Sub centres (a) 2-3 (b) 5-6 (c) 7-8 (d) only 2
- (13) Which is false regarding ASHA : (a) Provided in each village in the ratio of one per 1000 population (b) A primary resident of the village with formal education upto Class IV (c) Preferably in the age group 25-45 (d) Selected by the Gram Sabha
- Answers :** (1) a; (2) d; (3) b; (4) a; (5) b; (6) b; (7) a; (8) b; (9) c; (10) a; (11) a; (12) b; (13) b.

Sunil Agrawal

In the pre-independence period, the British had started a number of Public Health initiatives. Quarantine act was passed in 1825. Commission of Public Health in 1859 had pointed out the need of safe water and environmental sanitation to prevent occurrence of epidemics. In 1864, Sanitary commissioners were appointed in all three provinces of Bombay, Madras and Bengal to study the health problems and initiate measures for improvement. Local self government act was passed in 1885. Decentralization of health administration had begun in 1919 with Montague-Chelmsford constitutional reforms. The colonial era was marked by the dichotomy which continues to operate in the country's health policy to date. They acknowledged the existence of the gaps in coverage of health services, proclaiming the responsibility for the same and recommending suitable action while simultaneously not providing resources for implementation. This trend was unfortunately perpetuated even in free India.

In 1940, the resolution adopted by the National Planning Committee based on the Sokheys Committee's recommendations recommended integration of preventive and curative functions and the training of a large number of health workers. Bhore committee constituted in 1943 laid the framework on which the health care was eventually built in the independent India. The health care in India has since moved from bureaucratic government based top down approach to decentralized community based bottom-up system after the Panchayati Raj came into being. This model was long ago propagated by the Father of the nation "Mahatma Gandhi".

Bhore Committee (1943-1946)

During pre independence era, to improve the preventive, promotive and curative health services of country, a National Planning Commission was set up by the Indian National Congress in 1938. The rulers of that time, the British Empire realised the importance of Public Health and instituted the 'Health Survey and Development Committee,' in the year 1943 under the chairmanship of Sir Joseph Bhore. The committee was tasked to survey the then health conditions and health organisations in the country, and to make recommendations for future development. The committee submitted its report in 1946. The integration of preventive, promotive and curative health services and establishment of Primary Health Centres in rural areas were the major recommendations made by this committee (Box - 1).

Box-1 : Important recommendations of the Bhore committee

- Integration of Preventive, Promotive and Curative services at all administrative levels.
- The development of Primary Health Centres for the delivery of comprehensive health services to the rural India. Each PHC should cater to a population of 40, 000 with a Secondary Health Centre (now called Community Health Centre) to serve as a supervisory, coordinating and referral institution.
- In the long term (3 million plan), the PHC would have a 75 bedded hospital for a population of 10,000 to 20,000.
- It also reviewed the system of medical education and research and included compulsory 3 months training in Community Medicine.
- Committee proposed the development of National Programmes of health services for the country.

This document laid the utmost emphasis on primary health care; it needs no emphasis that primary health care was later on recognised as the key strategy to achieve Health for All (HFA) by 2000 during Alma-Ata conference. The Bhore committee model was based on the allopathic system of medicine. The traditional health practices and indigenous system of medicine prevalent in rural India, which had great influence and were part of their socio-cultural milieu were not included in the model proposed by Bhore committee. The approach was not entirely decentralized but had a top down approach. However it provided a ready-made model at the time of independence and thus was adopted as a blueprint for both health policy and development of the country.

Post Independence Era : Since, the dawn of independence, rapid strides have been made in effecting improvements in the quality and out reach of health care services to the people. After Independence in 1947, the Indian Government constituted Planning Commission in 1950, and started Five year plan system for socioeconomic development of the country of which health was the important and integral part. Besides the planning commission the government also set up various committees to plan specific public health services or review existing health situations.

Mudaliar committee (1962)

During second five year plan, Government decided to relook at the health needs and resources of the country to provide necessary guidelines to national health planning. Also to review the progress made since submission of Bhore committee report, Government appointed "*Health Survey and Planning Committee*" under the chairmanship of Dr A Lakshmanswami Mudaliar in 1959 to make future recommendations for development and expansion of health services. It admitted that the basic health facilities had not reached at least half the nation and there was gross mal distribution of hospitals and beds in favour of urban areas. The committee found that the quality of services provided by PHCs were grossly inadequate with poor functioning, lack of referral system, and gross under staffing due to insufficient resources. Important recommendations of the Mudaliar committee are depicted in Box - 2.

Box - 2 : Important recommendations of the Mudaliar committee

- Strengthening of existing PHCs and development of referral centres before new centres were established.
- Strengthening of subdivisional and district hospitals.
- Integration of medical and health services.
- It also suggested constitution of an All India Health Service in the pattern of Indian Administrative service.

Chadah Committee (1963)

Dr MS Chadha, the then DGHS, was appointed to study the details of the necessary requirements related to PHCs and maintenance of National Malaria Eradication Program. Important recommendations of the Chadah committee are shown in Box - 3.

Box - 3 : Important recommendations of the Chadah committee

- Strict monitoring and vigilance of implementation of NMEP is responsibility of general health services at all levels i.e. health workers of PHC, CHC, ZP.
- One basic health worker (now called Multi Purpose worker) for every 10, 000 population was recommended.
- Basic health workers should visit house to house once in a month to implement malaria activities.
- Basic Health worker should take additional duties of collection of vital statistics, family planning etc.

Mukerji Committee, 1965

By recommending basic health workers to take on additional responsibilities and work as multi purpose worker, both NMEP and family planning programme got a major set back. A committee under the chairmanship of Shri Mukerji, then Health Secretary to GOI was appointed to review the health system at different levels from the point of manpower and financial planning. Important recommendations of the Mukerji committee are in Box - 4.

Box - 4 : Important recommendations of the Mukerji committee

- Strengthening of the administrative set up at different levels from PHC to state health services.
- Separate staff was recommended for family planning program.
- Basic health worker to be utilised for all duties except for family planning.

Jungalwalla Committee, 1967

In 1967, Central Council of Health appointed "*Committee on integration of Health Services*" headed by Dr N. Jungalwalla, then Director, National Institute of Health Administration and Education. Important recommendations of the Jungalwalla committee are represented in Box - 5.

Box - 5 : Important recommendations of the Jungalwalla committee

- Integrated health services with :
 - Unified cadre
 - Common seniority
 - Recognition of extra qualifications
 - Equal pay for equal work
 - No private practise
 - Special pay for specialised service
 - Improvement in their service conditions
- Medical care of the sick and conventional public health programmes functioning under single administrator.

Kartar Singh Committee, 1973

The Committee headed by then additional secretary, MOH and Family planning, Shri Kartar Singh, was constituted to study and make recommendations on the structure for integrated health services at peripheral and supervisory levels. It was to

study the feasibility of bi purpose and multipurpose workers in the field. Important recommendations of the Kartar Singh committee are shown in Box - 6.

Shrivastav Committee (1974-75)

This is known as “Group on Medical Education and Support Manpower” constituted in 1974 by the Government. The concept of community participation in the health sector originated which has given concept of “people’s health in people’s hand”. Convened under the chairmanship of Dr J B Shrivastav, Director General Health Services, this committee made the recommendations as in Box - 7.

Box - 6 : Important recommendations of the Kartar Singh committee

- It recommended “Female Health Worker” in place of ANM and “Male Health Worker” in place of malaria surveillance worker, vaccinators, health education assistants and family planning health assistants.
- The committee proposed a PHC per 50, 000 population with 16 subcentres, each covering a population of 3000-3500. (4)
- Each subcentre to have one male and one female health worker.
- There should be one male and one female health supervisor at PHC to monitor and supervise the activities of staffs of 3-4 sub centres.
- The MO i/c PHC will be the overall in charge of all peripheral staff.
- Training for all workers engaged in the field of health, family planning and nutrition should be integrated.

Box - 7 : Important recommendations of the Shrivastav committee

- Creation of Village Health Guide (VHG) or community health volunteers from the community itself like teachers, postmasters, gram sevaks who can provide comprehensive health services as paraprofessionals.
- Primary health care be provided within the community itself through specially trained workers so that the health of the people is placed in the hands of people themselves.
- Creation of MPW and Health Assistants (HA) in between the VHG and MO i/c PHC.

Based on these recommendations “Rural Health Scheme” was launched by the government in 1977-78. The programme of training of community health workers was initiated during 1977-78. The major steps initiated were :

- a) Involvement of medical colleges in health care of selected PHCs with the objective of reorienting medical education according to rural population called Re Orientation of Medical education (ROME). It led to teaching and training of undergraduate students and Interns at PHCs.
- b) Training of Village Health Guides and utilising their services in the general health service system.

Shivaraman Committee health report

A Committee on Basic Rural Doctors was framed under the guidance of Shri Shivaraman, then member of planning commission. The committee recommended establishment of countrywide cadre of basic rural doctors consisting of trained paraprofessionals to extend comprehensive health care delivery to rural community.

V Ramalingaswamy Committee Health Report

This committee under the chairmanship of Dr V Ramalingaswamy, then DGHS, recommended as in Box-8.

Box - 8 : Important recommendations of the Ramalingaswamy committee

- Involvement of community for health planning and health programme implementation
- 30 bedded hospital for every 1 lakh population
- Integration of health services at all levels
- Redefined the role of doctor in the community
- Recommended that PHC and District health centres should be under the control of three tier Panchayati Raj System.

Bajaj Committee health report 1986

An expert committee for ‘health manpower planning, production and management’ was constituted under the chairmanship of Dr JS Bajaj, then member of planning commission, to tackle the problem of health manpower planning, production and management. Important recommendations of the Bajaj committee are in Box - 9.

Box-9 : Important recommendations of the Bajaj committee

- Recommended for Formulation of National Health Manpower planning based on realistic survey.
- Educational Commission for health sciences should be developed on the lines of UGC.
- Recommended for National and Medical education policy in which teachers are trained in health education science technology.
- Uniform standard of medical and health science education by establishing universities of health sciences in all states.
- Establishment of health manpower cells both at state and central level.
- Vocational courses in paramedical sciences to get more health manpower.

Krishnan Committee Health Report 1992

The committee under the chairmanship of Dr Krishnan reviewed the achievements and progress of previous health committee reports and also made comments on shortfalls. The committee address the problems of urban health and devised the health post scheme for urban slum areas. The committee had recommended one voluntary health worker (VHW) per

2, 000 population with an honorarium of Rs 100. Its report specifically outlines which services have to be provided by the health post. These services have been divided into outreach, preventive, family planning, curative, support (referral) services and reporting and record keeping. Outreach services include population education, motivation for family planning, and health education. In the present context, very few outreach services are being provided to urban slums.

Summary

Public Health initiatives like Quarantine act, safe water and environment sanitation, appointment of sanitary inspectors were started in the pre-independence era. Bhole committee laid the framework on which the Indian health care is built in independent India. The health care in India has since moved from top down approach to bottom- up approach. The 'Health Survey and Development Committee, ' was instituted in the year 1943 under the chairmanship of Sir Joseph Bhole. The committee submitted its report in 1946 with following important recommendations like the integration of preventive, promotive and curative health services and establishment of Primary Health Centres (for 40, 000 population) in rural areas. Later on it forms the key strategy to achieve Health for All (HFA) by 2000 during Alma-Ata conference. It was based on allopathic system. It provided a ready-made model adopted as a blueprint for both health policy and development of the country.

In post independent era planning commission and several committees were set up to plan specific public health services or review existing health situations. *Mudaliar committee* (1962) found that the quality of services provided by PHCs were grossly inadequate with poor functioning, lack of referral system, and gross under staffing due to insufficient resources and its major recommendations were strengthening of existing PHCs and development of referral centres, strengthening of subdivisional and district hospitals, integration of medical and health services, and suggested constitution of an All India Health Service in the pattern of Indian Administrative service etc. *Chadha committee* (1963) was appointed to study the details of the necessary requirements related to PHCs and maintenance of National Malaria Eradication Program. Main recommendations were basic health worker for every 10, 000 population who will supervise malaria activities along with additional duties of family planning. Due to set back in both malaria and family planning *Mukerji committee* (1965) was appointed. It recommended separate staff for family planning. In 1967, Central Council of Health appointed "*Committee on integration of Health Services*" headed by Dr N. Jungalwalla (1967) which recommended no private practice for govt doctors. The Committee (1973) headed by *Shri Kartar Singh*, was constituted to study and make recommendations on the structure for integrated health services at peripheral and supervisory levels. The committee proposed a PHC per 50, 000 population with 16 sub-centres, each covering a population of 3000-3500. Each sub-centre to have one male and one female health worker. There should be one male and one female health supervisor at PHC to monitor and supervise the activities of staffs of 3-4 sub centres, The MO i/c PHC will be the overall

in charge of all peripheral staff. *Srivastava committee* (1974) recommended Creation of Village Health Guide (VHG) or community health volunteers based on its recommendation rural health scheme was launched. It recommended establishment of countrywide cadre of basic rural doctors consisting of trained paraprofessionals to extend comprehensive health care delivery to rural community. Important recommendations of the *Ramalingaswamy committee* were 30 bedded hospital for every 1 lakh population, PHC and District health centres should be under the control of three tier Panchayati Raj System. A expert committee for 'health manpower planning, production and management' was constituted under the chairmanship of Dr JS Bajaj and recommended (1986) Formulation of National Health Manpower planning based on realistic survey etc. The committee under the chairmanship of Dr Krishnan (1992) reviewed the achievements and progress of previous health committee reports and also made comments on shortfalls.

Study Exercises

Long Question : Describe various health committees in post-independent era.

Short Notes : (1) Recommendation of Bhole committee
(2) Recommendation of Jungalwala committee
(3) Recommendation of Kartar Singh committee.

MCQs :

1. Quarantine act was passed in _____ (a) 1840 (b) 1825 (c) 1852 (d) 1882
2. Bhole committee was formed in _____ (a) 1943 (b) 1934 (c) 1948 (d) 1938
3. According to Bhole committee each PHC cater for _____ population (a) 20,000 (b) 40,000 (c) 25,000 (d) 30, 000
4. Which committee recommended a Basic Health worker per 10, 000 population (a) Bhole committee (b) Mudaliar committee (c) Chadha committee (d) Kartar Singh committee
5. Which committee recommended 'No private practise' for govt. Doctor (a) Mudaliar committee (b) Chadha committee, (c) Kartar Singh committee (d) Jungalwalla committee
6. Rural health scheme was based on recommendation of which committee (a) Srivastav committee (b) Chadha committee (c) Kartar Singh committee (d) Jungalwalla committee
7. Which committee proposed a PHC per 50,000 population with 16 subcentres, each covering a population of 3000-3500 (a) Mudaliar committee (b) Chadha committee (c) Kartar Singh committee (d) Jungalwalla committee
8. Which committee suggested constitution of an All India Health Service in the pattern of Indian Administrative Service (a) Mudaliar committee (b) Chadha committee (c) Kartar Singh committee (d) Jungalwalla committee
9. Which committee recommended establishment of countrywide cadre of basic rural doctors consisting of trained paraprofessionals to extend comprehensive health care delivery to rural community (a) Shivaraman committee (b) Chadha committee (c) Kartar Singh committee (d) Jungalwalla committee

10. Match the following

1. Bhore committee	a. 1963
2. Chadah committee	b. 1967
3. Mudaliar committee	c. 1943
4. Jungalwala committee	d. 1973
5. Kartar Singh committee	e. 1962

Answers : (1) b; (2) a (3) b; (4) c; (5) d; (6) a; (7) c; (8) a; (9) a; (10) 1-c; 2-a; 3-e; 4-b; 5-d.

Health Planning Process in India

Sunil Agrawal

Health of a nation is an essential component of development, vital to a nation's economic growth and internal stability. Assuring a minimal level of health care to the population is a critical constituent of the development process. Since Independence, India has built up a vast health infrastructure and health personnel at primary, secondary, and tertiary care in public, voluntary, and private sectors. For producing skilled human resources, a number of medical and paramedical institutions including Ayurveda, Yoga and Naturopathy, Unani, Siddha & Homeopathy (AYUSH) institutions have been set up.

The strong link between poverty and ill health needs to be recognized. The onset of a long and expensive illness can drive the non-poor into poverty. Ill health creates immense stress even among those who are financially secure. High health care costs can lead to entry into or exacerbation of poverty. The importance of public provisioning of quality health care to enable access to affordable and reliable health services cannot be underestimated. This is specially so, in the context of preventing the non-poor from entering into poverty or in terms of reducing the suffering of those who are already below poverty line. The country has to deal with rising costs of health care and growing expectations of the people. The challenge of quality health services in remote rural regions has to be urgently met. Given the magnitude of the problem, we need to transform public health care into an accountable, accessible, and affordable system of quality services. The role of scientific health planning at the national level, to achieve this goal, needs no highlighting.

Among socialist countries, India is the first and foremost country to show tradition of health planning. During British India, the National congress had a planning committee under the chairmanship of Pandit Jawaharlal Nehru. A committee was

appointed by the British, with Sir Joseph Bhore as Chairman, for survey and planning; their report is a major event in the history of Indian Health Planning.

As on today, India is the world's 12th largest economy and the third largest in Asia behind Japan and China, with total GDP of around 1 trillion (\$1,000 billion). Nearly two-thirds of the population depends on agriculture for its livelihood. 700 million Indians live on Rs.42 per day or less, but there is a large and growing middle class of 325-350 million with disposable income for consumer goods. Real GDP growth for the fiscal year ending March 31, 2007 was 9.4% up from 9.0% growth in the previous year. Growth for the year ending March 31, 2008 is expected to be between 8.5-9.0%.

The Planning Commission

After independence in 1950 the present Planning Commission was established, which launched first five year plan in 1951. The Planning Commission was set up to make an assessment of the material, capital and human resources of the country, and to draft developmental plans for the most effective utilisation of these resources addressing the needs of the community and country at large. It gives suggestions and recommendations to the cabinet on the various issues of the country's development in consultation with ministers of the state and central government. There are 29 divisions in the Planning Commission like agriculture, health, nutrition, education, environment, family welfare, housing, water supply, manpower, rural development, multilevel planning and monitoring, etc. In 1957, the Planning Commission was provided with a Perspective Planning Division which makes projections into the future over a period of 20-25 years.

The membership of the planning commission is highly distinguished and from the very beginning it is chaired by the Prime Minister of the country. The planning commission consists of Chairman, Deputy Chairman and 5 members. The Planning Commission works through 3 major divisions :

- Programme Advisors
- General Secretariat
- Technical Divisions

Planning Commission reviews, from time to time, the progress made in various directions and makes recommendations to Government on problems and policies relevant to rapid and balanced economic development.

Health Sector Planning

The Planning Commission gave considerable importance to health programmes in overall development of the country. The health sector is divided into the following subsectors:

<i>Subsectors of Health in Planning Commission</i>
<ul style="list-style-type: none"> • Water supply and sanitation • Communicable diseases • Medical education, training and research • Curative services i.e., Hospitals, PHCs, etc. • Public Health Services • Family Planning • Indigenous Systems of Medicine

All the above subsectors receive due importance in five year plans, however the priority changes from plan to plan depending upon the felt needs of the community, technical considerations and the progresses made. A Bureau of Planning was constituted in 1965 in the Ministry of Health to have better coordination between Centre and State Governments. The working of the national plans is reviewed time to time by National Development Council (NDC), which decides the social and economic policy affecting national development.

Health Finance Indicators

Health finance indicators include allocations under five year plans, expenditure on health, trends in public and private spending. It provides an understanding of patterns of investments, expenditure, sources of funding and proportion of allocation in the health sector, vis a vis other total allocations.

Budgetary Allocations: Health in India, like most social sectors, is a state subject and the contribution of the state governments to health spending is between 80 and 85 per cent. While in the recent years the Union government has substantially hiked its contribution to the health budget increasing at 30 per cent per annum, in itself this makes a very small impact on the overall health budget. Presently, the health budget of state and central governments combined is less than one percent of GDP.

In India there has been a growing analysis of health budgets and health expenditures. The economic reforms of the 90's have created a trajectory of public health spending that shows a downward trend both in terms of share of the government budget as well as a proportion of the Gross Domestic Product. Prior to economic reforms in the mid- 80s, public health expenditures had peaked 1.6 per cent of the GDP and was 3.95 per cent of government's budget. By 2001, these figures read a dismal 0.9 per cent and 2.7 per cent, respectively, and further down to 0.8 and 2.4 per cent in 2005. What was worse was the decline in new investments by the Ministry of Health as reflected in the decline in capital expenditures from a robust 12 per cent in 1986-87 to a mere four per cent in 2000-01 and only a slight improvement in 2004-05 at five per cent.

Government expenditure on health as percentage of total expenditure on health is 24.8% while that of Private Expenditure

is 75.2%. Public spending on health has increased from 0.22% of GDP in 1950-51 to 1.05% of GDP during the mid 1980s and stagnated at around 0.9% of GDP during the later years. India spent approx Rs 1,08,732 Crores on health and health related expenditure during 2001-02. This amounted to about 4.8% of the estimated GDP at market prices in 2001-02. National health expenditures, when taken as a proportion of GDP at factor cost, were 5.2%. Since 1995-96 household expenditure on health has been growing at the current rate of approx 14% overall. In 1995-96, households in India spends an estimated Rs 33,253 crores at nominal prices which is estimated to have increased to Rs 72,759 crores in 2001-02. With an overall growth rate of 14% household spending, it is likely to be close to Rs 1,00,000 crores in nominal terms during 2003-04.

Table - 1 : Allocations for Selected Key Programs in the Union Health Budget (Rs Crores)			
Programme	2004-05	2005-06	2006-07
Hospitals & Dispensaries	240.75	268.70	263.25
Medical edn & Research	912.82	1397.33	1436.64
AYUSH	225.73	405.98	447.89
NACO - HIV/AIDS	232.00	476.50	636.67
RCH	710.51	881.73	1765.83
Pulse Polio		832.00	1004.00
Routine Immunisation	1186.40	472.60	326.50
FW services & contraception	1948.71	2412.41	1942.61
Area Projects	123.01	501.26	205.57
NRH Mission Flexible Funds			1530.88
Source: Demand for Grants, respective Budget years, Ministry of Finance, GOI, New Delhi			

Table -1 looks at and summarises some of the key programmatic allocations in the Union Health Budget. Here we see that traditional sectors like hospitals, medical education and family planning services are now receiving a smaller chunk of the health budget in comparison to the "new" sectors like RCH, HIV/AIDS, immunization (especially pulse polio). From the 2005-06 budget onwards, NRHM has taken a large share of the RCH and Family Planning budgets giving a boost to rural health allocations.

Five Year Plans

The five year plans were conceived for organised development of the country by planning a long term road map focussing on sustained development instead of short term gains. It lays main emphasis on rebuilding rural India, industrial development, health for all and balanced development in all sectors. Planning Commission laid special emphasis on health programmes with the broad objectives of:

- a) Control and eradication of major communicable diseases of public health importance.
- b) Strengthening basic rural health services by establishing

Sub-centres and Primary Health Centres.
 c) Population Control.
 d) Development of health manpower resources.
 Health planning has been ensured of proper investment through successive five year plans, which is as under showing pattern of allocation since inception. The overall outlays during the various plan periods are shown in Fig. - 1 & Table-2 respectively.

First plan (1951-1956)

The first Indian Prime Minister, Shri Jawaharlal Nehru presented the first five-year plan to the Parliament of India on December 8, 1951. The total plan budget of 206.8 billion INR (23.6 billion USD in the 1950 exchange rate) was allocated to seven broad areas: irrigation and energy (27.2 percent), agriculture

and community development (17.4 percent), transport and communications (24 percent), industry (8.4 percent), social services (16.64 percent), land rehabilitation (4.1 percent), and other (2.5 percent).

The target growth rate was 2.1 percent annual gross domestic product (GDP) growth; the achieved growth rate was 3.6 percent. During the first five-year plan the net domestic product went up by 15 percent. Lower increase of per capita income as compared to national income was due to rapid population growth. The World Health Organization, with the Indian government, addressed children's health and reduced infant mortality, contributing to population growth.

Second plan (1956-1961)

The second five-year plan focused on industry, especially heavy industry. Domestic production of industrial products was encouraged, particularly in the development of the public sector.

Third plan (1961-1966)

The third plan stressed on agriculture and improving production of rice, but the brief Sino-Indian War in 1962 exposed weaknesses in the economy and shifted the focus towards defence. In 1965-1966, the Green Revolution in India advanced agriculture. The war led to inflation and the priority was shifted to price stabilization.

In an effort to bring democracy to the grassroot level, Panchayat elections were started and the states were given more development responsibilities.

Gross Domestic Product rate during this duration was lower at 2.7% due to 1962 Sino-Indian War and Indo-Pakistani War of 1965.

Table - 2 : Pattern of central Allocation (Rs in Crores) in Five Year Plans

S No	Period	Total Investment	Health	Family Welfare	AYUSH	SubTotal
1	First Plan (1951-56)	1960.00	65.2 (3.3)	0.1(0.1)		65.3(3.4)
2	Second Plan (1956-61)	4672.00	140.8 (3.0)	5.0 (0.1)		145.8 (3.1)
3	Third Plan (1961-66)	8576.5	225.9 (2.6)	24.9 (0.3)		250.8 (2.9)
4	Annual Plans (1966-69)	6625.4	140.2 (2.1)	70.4 (1.1)		210.6 (3.2)
5	Fourth Plan (1969-74)	15778.8	335.5 (2.1)	278.0 (1.8)		613.5 (3.9)
6	Fifth Plan (1974-79)	39426.2	760.8 (1.9)	491.8 (1.2)		1252.6 (3.1)
7	Annual Plan (1979-80)	12176.5	223.1 (1.8)	118.5 (1.0)		341.6 (2.8)
8	Sixth Plan (1980-85)	109291.7	2025.2 (1.8)	1387.0 (1.3)		3412.2 (3.1)
9	Seventh Plan (1985-90)	218729.6	3688.6 (1.7)	3120.8 (1.4)		6809.4 (3.1)
10	Annual Plan (1990-91)	61518.1	960.9 (1.6)	784.9 (1.3)		1745.8 (2.9)
11	Annual Plan (1991-92)	65855.8	1042.2 (1.6)	856.6 (1.3)		1898.8 (2.9)
12	Eight Plan (1992-97)	434100.0	7494.2 (1.7)	6500.0 (1.5)	108.0 (0.02)	14102.2 (3.2)
13	Ninth Plan (1997-02)	859200.0	19818.4 (2.31)	15120.2 (1.76)	266.35 (0.03)	35204.95 (4.09)
14	Tenth Plan (2002-07)	1484131.3	31020.3 (2.09)	27125.0 (1.83)	775.0 (0.05)	58920.3 (3.97)
15	Eleventh Plan (2007-12)	2156571.0	136147.0 (6.3%)		3988.0 (0.18%)	140135.0 (6.5%)

Notes:- (a) Dept of ISM & H (now AYUSH) was created during 8th plan period (b) Figures in bracket indicate percentage to total plan investment outlay (c) Deptt of Health and Family Welfare were merged from 2005

Fourth plan (1969-1974)

At this time Smt Indira Gandhi was the Prime Minister. The Indira Gandhi government nationalized 19 major Indian banks. In addition, the situation in East Pakistan (now independent Bangladesh) was becoming dire as the Indo-Pakistani War of 1971 and Bangladesh Liberation War took place.

Fifth plan (1974-1979)

Stress was laid on employment, poverty alleviation, and justice. The plan also focused on self-reliance in agricultural production and defense. In 1978, the newly elected Morarji Desai government rejected the plan.

Sixth plan (1980-1985)

Called the Janata government plan, the sixth plan marked a reversal of the Nehruvian model. When Rajiv Gandhi was elected as the prime minister, the young prime minister aimed for rapid industrial development, especially in the area of information technology. Family planning was expanded in order to prevent overpopulation. In contrast to China's harshly-enforced one-child policy, Indian policy did not rely on the threat of force. More prosperous areas of India adopted family planning more rapidly than less prosperous areas, which continued to have a high birth rate.

Seventh plan (1985-1989)

The Seventh Plan marked the comeback of the Congress Party to power. The plan lay stress on improving the productivity level of industries by up gradation of technology.

Period between 1989-91

1989-91 was a period of political instability in India and hence no five year plan was implemented. Between 1990 and 1992, there were only Annual Plans. At that time Dr. Manmohan Singh (currently, Prime Minister of India) launched India's free market reforms that brought the economic stability in the country. It was the beginning of privatization and liberalization in India.

Eighth plan (1992-1997)

Modernization of industries was a major highlight of the Eighth Plan. This plan can be termed as Rao and Manmohan model of Economic development. The major objectives include Containing population growth, poverty reduction, employment generation, strengthening the infrastructure, institutional building, HUMAN RESOURCE DEVELOPMENT, Involvement of Panchayat raj, Nagarapalikas, NGOs and Decentralisation and people's participation.

Ninth plan (1997-2002)

During the Ninth Plan period, the growth rate was 5.35 per cent, a percentage point lower than the target GDP growth of 6.5 per cent.

Tenth plan (2002-2007)

The main objectives of the 10th Five-Year Plan were:

- Reduction of poverty ratio by 5 percentage points by 2007;
- Providing gainful and high-quality employment to the labour force;
- All children in India in school by 2003; all children to

complete 5 years of schooling by 2007;

- Reduction in gender gaps in literacy and wage rates by at least 50% by 2007;
- Reduction in the decadal rate of population growth between 2001 and 2011 to 16.2%;
- Increase in Literacy Rates to 75 per cent within the Tenth Plan period (2002-3 to 2006-7);
- Reduction of Infant mortality rate (IMR) to 45 per 1000 live births by 2007 and to 28 by 2012;
- Reduction of Maternal Mortality Ratio (MMR) to 2 per 1000 live births by 2007 and to 1 by 2012;
- All villages to have sustained access to potable drinking water within the Plan period.

Goals & Achievements during Tenth Plan are given in Table-3.

Indicator	Goal for Tenth Plan	Achievements
Decadal Rate of Population Growth	16.2%	15.9% for 2001-11 (Projected) ¹
Infant Mortality Rate	45 per 1000 live births	58 per 1000 live births ²
Maternal Mortality Ratio	2 per 1000 live births	3.01 per 1000 live births ³

Source: 1. Technical Group on Population Projections set up by National Commission on Population (Dec 2006), RGI, GOI; 2. SRS 2005; 3. 2001-03 Special Survey of Deaths using RHIME (routine, resampled, household interview of mortality with medical evaluation), RGI (2006) GOI.

Review of Tenth Plan Schemes : The Tenth Five-Year Plan (2002-07) indicated the dismal picture of the health services infrastructure and emphasized the need to invest more on building good primary-level care and referral services. To review the health services framework, design, and approach within which the policies were formulated the National Rural Health Mission was launched.

The original approved health and family welfare outlay for the Tenth Plan centrally sponsored and central sector schemes was Rs 36,378 crore. However, the sum of annual outlay increased to Rs 41,585 crore. Against this, the actual expenditure has been Rs 34,950.45 crore, that is, 84.05% of the sum of annual outlay. In 2005-06, all family welfare schemes and major disease control programmes were put under the umbrella of the National Rural Health Mission.

Review of the National Rural Health Mission at the end of the Tenth Plan reveals that in order to improve the public health delivery, the situation needs to change on a fast track mode at the grassroots.

The status as on 30 April, 2008 is as under:

- (a) State Health Missions have been constituted in all states.
- (b) ASHA training modules developed and revised.
- (c) Over 1500 management professionals (CA/MBA) appointed in Program Management Units (PMU) to support the programme management. This is being planed at the level of the block also.
- (d) RCH- II launched and under implementation.
- (e) IMNCI started in 142 districts.

- (f) Legal changes brought about to allow ANMs to dispense medication and MBBS doctors to dispense anesthesia.
- (g) At 1,611 PHCs AYUSH doctors have been co-located
- (h) 228413 Village Health & Sanitation Committees (VHSCs) have been constituted and operational by 30 April 2008.
- (j) Against the target of 5 lakh fully trained Accredited Social Health Activists (ASHAs) by 2008, the initial phase of training (first module) has been imparted to 5.36 lakh. ASHAs in position with drug kits are 224951 in number.
- (k) Out of the 145272 Sub-centres (SCs) expected to be functional with 2 Auxiliary Nurse Midwives (ANMs) by 2008, only 22471 had the same.
- (l) 22,370 Primary Health Centres (PHCs) are functional and out of which 3450 PHCs are functional with three staff nurses by 2008.
- (m) There has been a shortfall of 5,498 (>50%) specialists at the Community Health Centres (CHCs). Total CHCs functional are 4,045 out of which 2,966 have been selected to be upgraded to IPHS.
- (n) Number of Districts where annual integrated action plan under NRHM have been prepared for 2007-08 are 485.

Eleventh plan (2007-2012)

The Eleventh Five Year Plan provides an opportunity to restructure policies to achieve a New Vision based on faster, broad-based, and inclusive growth.

Goal : To achieve good health for people, especially the poor and the underprivileged.

Strategies

1. A comprehensive approach that encompasses individual health care, public health, sanitation, clean drinking water, access to food, and knowledge of hygiene and feeding practices.
2. To increase aggregate spending on health by the Centre and the states.
3. The contribution of the private sector in providing primary, secondary, and tertiary services.
4. Good governance, transparency, and accountability in the delivery of health services.
5. Health as a right for all citizens is the goal that the Plan will strive towards.

Time-Bound Goals for the Eleventh Five Year Plan

1. Income & Poverty

- Accelerate GDP growth from 8% to 10% and then maintain at 10% in the 12th Plan in order to double per capita income by 2016-17.

2. Education

- Reduce dropout rates of children from elementary school from 52.2% in 2003-04 to 20% by 2011-12
- Increase literacy rate for persons of age ≥ 7 years to 85%
- Lower gender gap in literacy to 10 percentage points
- Increase the percentage of each cohort going to higher education from the present 10% to 15% by the end of the plan

3. Health

- Reduce infant mortality rate to 28 and maternal mortality ratio to 1 per 1000 live births

- Reduce Total Fertility Rate to 2.1
- Provide clean drinking water for all by 2009 and ensure that there are no slip-backs
- Reduce malnutrition among children of age group 0-3 to half its present level
- Reduce anaemia among women and girls by 50% by the end of the plan

4. Women and Children

- Raise the sex ratio for age group 0-6 to 935 by 2011-12 and to 950 by 2016-17
- Ensure that all children enjoy a safe childhood, without any compulsion to work

5. Infrastructure

- Provide homestead sites to all by 2012 and step up the pace of house construction for rural poor to cover all the poor by 2016-17

6. Environment

- Attain WHO standards of air quality in all major cities by 2011-12
- Treat all urban waste water by 2011-12 to clean river waters

Eleventh Five Year Plan Agenda in Health Sector : Thrust areas to be pursued during the Eleventh Five Year Plan are summarized below:

1. Improving Health Equity

- i. National Rural Health Mission (NRHM)
- ii. National Urban Health Mission (NUHM)

2. Adopting a system-centric approach rather than a disease-centric approach

- i. Strengthening Health System through upgradation of infrastructure and public private partnership
- ii. Converging all programmes and not allowing vertical structures below district level under different programmes

3. Increasing Survival

- i. Reducing Maternal mortality and improving Child Sex ratio through Gender Responsive Health care
- ii. Reducing Infant and Child mortality through Home Based Neonatal Care (HBNC) and Integrated Management of Neonatal and Childhood Illnesses (IMNCI)

4. Taking full advantage of local enterprise for solving local health problems

- i. Integrating AYUSH in Health System
- ii. Increasing the role of Registered Medical Practitioners
- iii. Training the Traditional Birth Attendants (TBAs) to make them Skilled Birth Attendants (SBAs)
- iv. Propagating low cost and indigenous technology

5. Preventing indebtedness due to expenditure on health/ protecting the poor from health expenditures

- i. Creating mechanisms for Health Insurance
- ii. Health Insurance for the unorganized sector

6. Decentralizing Governance

- i. Increasing the role of PRIs, NGOs, and Civil Society
- ii. Creating and empowering Health committees at various levels

7. Establishing e-Health

- i. Adapting IT for governance
- ii. Establishing e-enabled Health Management Information System
- iii. Increasing role of telemedicine

8. Improving access to and utilization of essential and quality health care

- i. Implementing flexible norms for health care facilities (based on population, distance and terrain)
- ii. Reducing travel time to two hrs for emergency obstetric care
- iii. Implementing Indian Public Health Service Standards for health care institutions at all levels
- iv. Accrediting private health care facilities and providers
- v. Redeveloping hospitals/institutions
- vi. Mirroring of centres of excellence like AIIMS

9. Increasing focus on Health Human Resources

- i. Improving Medical, Paramedical, Nursing, and Dental education and availability
- ii. Reorienting AYUSH education and utilization
- iii. Reintroducing licentiate course in medicine
- iv. Making India a hub for health care and related tourism

10. Focusing on excluded/neglected areas

- i. Taking care of the Older persons
- ii. Reducing Disability and integrating disabled
- iii. Providing humane Mental Health services
- iv. Providing Oral health services

11. Enhancing efforts at disease reduction

- i. Reversing trend of major diseases
- ii. Launching new initiatives (Rabies, Fluorosis, Leptospirosis)

12. Providing focus to Health System and Bio-Medical research

- i. Focusing on conditions specific to our country
- ii. Making research accountable
- iii. Translating research into application for improving health

Schemes and Outlays for Eleventh Five Year Plan : To achieve the desired outcomes in the health sector, a substantially enhanced outlay for the Department of Health and Family Welfare has been earmarked during the Eleventh Five Year Plan (2007-12). The total projected GBS for the Eleventh Plan is Rs 1,20,374.00 crore (at 2006-07 prices) and Rs 1,36,147.00 crore (at current prices). This enhanced outlay is about four times the initial outlay for the Tenth Plan (Rs 36,378.00 crore). A large proportion of this amount i.e. Rs 89,478.00 crore (65.72 %) is for NRHM, the flagship of the Government of India. Another Rs 625 crore is to be contributed by the Dept. of AYUSH to make a total of Rs 90,103 crore for NRHM during the Eleventh Five Year Plan. For the other ongoing schemes, a total of Rs 23,995.05 crore has been earmarked. For the new initiatives it is Rs. 20,846.95 crore. Rs. 1,827.00 crore has also been earmarked for Oversight Committee.

Summary

Since Independence, India has built up a vast health infrastructure and health personnel at primary, secondary, and tertiary care in public, voluntary, and private sectors.

The country has to deal with rising costs of health care and growing expectations of the people. The role of scientific health planning at the national level, to achieve this goal, needs no highlighting. Among socialist countries, India is the first and foremost country to show tradition of health planning. During British India, the National congress had a planning committee under the chairmanship of Pandit Jawaharlal Nehru. A committee was appointed by the British, with Sir Joseph Bore as Chairman, for survey and planning; their report is a major event in the history of Indian Health Planning. After independence in 1950 the present Planning Commission was established, which launched first five year plan in 1951. The Planning Commission was set up to make an assessment of the material, capital and human resources of the country, and to draft developmental plans for the most effective utilisation of these resources addressing the needs of the community and country at large. There are 29 divisions in the Planning Commission. In 1957, the Planning Commission was provided with a Perspective Planning Division which makes projections into the future over a period of 20-25 years. The membership of the planning commission is highly distinguished and from the very beginning it is chaired by the Prime Minister of the country. The planning commission consists of Chairman, Deputy Chairman and 5 members. The Planning Commission works through 3 major divisions: Programme Advisors; General Secretariat & Technical Divisions. The health sector is divided into the following subsectors: Water supply and sanitation, Communicable diseases, Medical education, training and research; Curative services i.e., Hospitals, PHCs, etc, Public Health Services, Family Planning & Indigenous Systems of Medicine. A Bureau of Planning was constituted in 1965 in the Ministry of Health to have better coordination between Centre and State Governments. The working of the national plans is reviewed time to time by National Development Council (NDC), which decides the social and economic policy affecting national development. The five year plans were conceived for organised development of the country by planning a long term road map focusing on sustained development instead of short term gains. It lays main emphasis on rebuilding rural India, industrial development, health for all and balanced development in all sectors. Planning Commission laid special emphasis on health programmes with the broad objectives of: a) Control and eradication of major communicable diseases of public health importance, b) Strengthening basic rural health services by establishing Subcentres and Primary Health Centres, c) Population Control, d) Development of health manpower resources. Health planning has been ensured of proper investment through successive five year plans, which is as under showing pattern of allocation since inception.

Study Exercises

Long Question : Discuss the strategies, time bound goals & schemes of 11th five yr plan.

Short Notes : (1) Planning commission (2) Health sector planning (3) Achievements of 10 five yr plan.

MCQs:

1. The 3 major divisions of Planning Commission are all except: (a) Programme Advisors (b) General Secretariat

- (c) Technical Divisions (d) Executive Division
2. All are the sub-sectors of health in planning commission except (a) Water supply and sanitation (b) Medical education, training and research (c) Indigenous Systems of Medicine (d) Agriculture
 3. Broad objectives of Five year plan are: (a) Control and eradication of major communicable diseases of public health importance (b) Strengthening basic rural health services by establishing Sub-centres and Primary Health Centres (c) Population Control (d) All
 4. One of the following is not the strategies of 11th plan: (a) To increase aggregate spending on health by the Centre and the states (b) The contribution of the private sector in providing primary, secondary, and tertiary services (c) To establish medical colleges in rural sectors of country (d) Health as a right for all citizens is the goal.
 5. 11th Plan will strive towards: (a) Accelerate GDP growth from 8% to 10% and then maintain at 10% in the 12th Plan in order to double per capita income by 2016-17 (b) Raise the sex ratio for age group 0-6 to 935 by 2011-12 and to 950 by 2016-17 (c) Attain WHO standards of air quality in all major cities by 2011-12 (d) All
 6. India is the world's 10th largest economy and the third largest in Asia behind Japan and China, with total GDP of around 1 trillion. True / False
 7. Growth for the year ending March 31, 2008 is expected to be between 8.5-9.0%. True / False
 8. There are 22 divisions in the Planning Commission. True / False
 9. A Bureau of Planning was constituted in 1965 in the Ministry of Health to have better coordination between Centre and State Governments. True / False
 10. The working of the national plans is reviewed time to time by National Development Council (NDC), which decides the social and economic policy affecting national development. True / False
 11. Contribution of the state governments to health spending is between 80 and 85 per cent. True / False
 12. Presently, the health budget of state and central governments combined is less than one percent of GDP. True / False
 13. Traditional sectors like hospitals, medical education and family planning services are now receiving a greater chunk of the health budget in comparison to the "new" sectors like RCH, HIV/AIDS, immunization (especially pulse polio). True / False
 14. From the 2005-06 budget onwards, NRHM has taken a large share of the RCH and Family Planning budgets giving a boost to rural health allocations. True / False
 15. Government expenditure on health as percentage of total expenditure on health is 24.8% while that of Private Expenditure is 75.2%. True / False
 16. Public spending on health has increased from 0.22% of GDP in 1950-51 and stagnated at around 10% of GDP during the later years. True / False
 17. Planning Commission was provided with a Perspective Planning Division which makes projections into the future over a period of 20-25 years. True / False
- Answers :** (1) d; (2) d; (3) d; (4) c; (5) d; (6) False; (7) True; (8) False; (9) True; (10) True; (11) True; (12) True; (13) False; (14) True; (15) True; (16) False; (17) True.

National Health Policy (NHP) - 2002

Policies are “courses” or “principles” of action adopted or proposed by a Government. In the developing countries like India, resources often fall short of requirements, the Government policies then guide us to set priorities and allocate resources to achieve our objectives. Health policies are intended to achieve a level of health status for most of the persons in the community. The policies enacted by various Government bodies have formal framework with legal backup. Health policy aims at the improvement of the conditions under which people live, including housing, education, nutrition, child care, reproductive health, transportation, information and communication.

Background

In 1977, the World Health Assembly at Alma Ata decided to launch an ambitious movement known as, “*Health for All (HFA) by 2000 AD*”. This broadly means attainment of level of health that will permit all people to lead economically and socially productive life. As a signatory to HFA strategy, the Government of India was committed to frame its own policy and implement to attain Health For All by 2000 AD. In pursuance of this objective, two important committees were framed to study this strategy in detail keeping in view local percept. These were, firstly, the Report of the study Group on ‘Health for All - an alternative strategy’, Sponsored by ICSSR and ICMR, and,

secondly, Report of the working group on ‘Health For All by 2000 AD’ sponsored by Ministry of Health and Family Welfare (MOHFW), Government Of India. These reports formed the basis of the National Health Policy formulated by MOHFW, GOI in 1983.

Since, the inception of National Health Policy there have been marked changes in the determinants of health. Some of the policy initiatives outlined in the NHP-1983 yielded results, while in several other areas, the outcome was not as expected. These include remarkable successes like eradication of Guinea Worm. Polio is on the verge of being eradicated. Leprosy, Kala Azar, and Filariasis can be expected to be eliminated in the foreseeable future. There has been a substantial drop in the total fertility rate and infant mortality rate. The success of the initiatives taken in the public health field is reflected in the progressive improvements of many demographic, epidemiological and infrastructural indicators over the period 1951 to 2007 (Box - 1).

Improvement of these health indicators were the outcome of several complementary initiatives of development sector covering rural development, agriculture, food production, animal husbandry, drinking water, sanitation, education etc. Despite the impressive public health gains, the morbidity and mortality levels in the country were high as compared to developed countries. Over the years the incidence of some of the communicable diseases like Malaria, Tuberculosis, HIV/AIDS, hepatitis and non communicable diseases like Cancers, life style diseases, diabetes etc were on the rise and much more dedicated efforts were required to achieve goal of, “Health For All by 2000 AD”. After the passage of year 2000, it was the time to take stock of situation and progress ahead with extra zeal to achieve ultimate goal of Health For All. Accordingly, the NHP -

Box - 1

Indicator	1951	1981	2000	2006
Life Expectancy	36.7	54	61 (M), 62.7 (F)	62.3 (M), 63.9 (F)
Crude Birth Rate per 1000	40.8	33.9(SRS)	26.1(99 SRS)	23.5
Crude Death Rate per 1000	25	12.5(SRS)	8.7(99 SRS)	7.5
IMR per 1000 live births	146	110	70 (99 SRS)	57
Total Fertility Rate	6	-	3.8	2.9
Malaria (cases in million)	75	2.7	2.2	1.78
Leprosy cases per 10,000 population	38.1	57.3	3.74	0.72
Small Pox (no of cases)	>44,887		Eradicated	
Guineaworm (no. of cases)		>39,792	Eradicated	
Polio		29709	265	116
SC/PHC/CHC	725	57,363	1,63,181	1,71,567
Dispensaries & Hospitals	9209	23,555	43,322 (95-96-CBHI)	
Beds (Pvt & Public)	117,198	569,495	8,70,161	
Doctors (Allopathy)	61,800	2,68,700	5,03,900	6,96,747
Nursing Personnel	18,054	1,43,887	7,37,000	15,09,196

(Sources : 1 - 3)

1983 was revised and a new, extensive NHP was enunciated by the Govt of India in 2002.

Objective of National Health Policy (NHP) 2002

The main objective of this policy is to achieve an acceptable standard of good health amongst the general population of the country. The noteworthy initiatives are presented in Box - 2

Box - 2 : Noteworthy initiatives under the National Health Policy 2002

- Comprehensive primary health care services
- Health volunteers
- Well worked out referral system
- Integrated network of evenly spread speciality and super speciality services

Strategies

The revised strategies adopted by GOI to achieve above objective are :

- (a) Increase access to the decentralized public health system by establishing new infrastructure in deficient areas, and by upgrading the infrastructure in the existing institutions.
- (b) Ensuring a more equitable access to health services across the social and geographical expanse of the country.
- (c) Increasing the aggregate public health investment through a substantially increased contribution by the Central Government. It is expected that this initiative will strengthen the capacity of the public health administration at the state level to render effective service delivery.
- (d) The contribution of the private sector in providing health

services would be much enhanced.

- (e) Primacy to preventive and first-line curative initiative at the primary health level.
- (f) Emphasis will be laid on rational use of drugs within the allopathic system.
- (g) Increased access to tried and tested systems of traditional medicine.

The endeavour of NHP-2002 is to achieve the time-bound goals mentioned in Box - 3, within the framework of strategies mentioned above.

On a short term basis, within the context of the NHP, the Important health related targets for the eleventh five year plan (2007 - 2012) are :

- Reducing Maternal Mortality Ratio (MMR) to 1 per 1,000 live births.
- Reducing Infant Mortality Rate (IMR) to 28 per 1,000 live births.
- Reducing Total Fertility Rate to 2.1.
- Providing clean drinking water for all by 2009 and ensuring no slip-backs.
- Reducing malnutrition among children of age group 0-3 to half its present level.
- Reducing anaemia among women and girls by 50%.
- Raising the sex ratio for age group 0-6 to 935 by 2011-12 and 950 by 2016-17.

Major Strategies of NHP-2002

(a) **Financial Resources** : It is concerning that Public Health expenditure has declined from 1.5% of GDP in 1990 to 0.9% of GDP in 1999. Given the difficult fiscal position of the State Governments, the Central Government will have to play a key

Box - 3 : Goals to be achieved by 2000 - 2015

Goals for which the target year is already over	Target Year	Result
Eradicate Polio	2005	Not achieved
Eradicate Yaws	2005	Achieved
Eliminate Leprosy	2005	Achieved
Achieve Zero level growth of HIV/AIDS	2007	Not achieved
Establish an integrated system of surveillance, National Health Accounts and Health Statistics.	2005	IDSP has been launched
Increase State Sector Health spending from 5.5% to 7% of the total budget	2005	Not achieved
Goals for which time is available	Target Year	
Eliminate Kala Azar	2010	
Reduce Mortality by 50% on account of TB, Malaria and Other Vector and Water Borne diseases	2010	
Reduce Prevalence of Blindness to 0.5%	2010	
Reduce IMR to 30/1000 and MMR to 100/Lakh	2010	
Increase utilization of public health facilities from current Level of <20 to >75%	2010	
Increase health expenditure by Government from the existing 0.9 % to 2.0% of GDP	2010	
Increase share of Central grants to Constitute at least 25% of total health expenditure	2010	
Increase State Sector Health spending from 5.5% to 7% of the budget and further increase to 8%	2010	
Eliminate Lymphatic Filariasis	2015	

role in augmenting public investments. It is planned, under the policy, to increase health sector expenditure by both central and state government as stated in Box 3 above. However, the higher public health investment should also be gainfully utilised by the public health administration for upliftment of health status of the community.

(b) Equitable distribution : To meet the objective of reducing various types of inequities and imbalances, i.e., interregional; across the rural - urban divide; and between economic classes - the most cost-effective method would be to increase the sectoral outlay in the primary health sector. Such outlets afford access to a number of individuals, and also facilitate preventive and early stage curative initiative. NHP-2002 sets out an increased allocation of 55 percent of the public health investment for the primary health sector, the secondary and tertiary health sectors being targeted for 35 percent and 10 percent respectively, for strengthening existing facilities and opening additional public service outlets.

(c) Delivery of National Public Health Programmes : The policy envisages a key role for the Central Government in designing national programmes with the active participation of the State Governments. Also, the policy ensures the provisioning of financial resources, in addition to technical support, monitoring and evaluation at the national level by the Centre. However, to optimize the utilization of the public health infrastructure at the primary level, NHP-2002 envisages the gradual convergence of all health programmes under a single field administration. Vertical programmes for control of major diseases like TB, Malaria, HIV/AIDS, as also the RCH and Universal Immunization programmes, would need to be continued till these diseases are no more a public health threat. The major change in programme implementation is through autonomous bodies at State and district levels whereas the role of district and state health departments will be limited to overall monitoring of achievements of programme targets and technical aspects. This will give better planning and operational flexibility and public health projects will be more suited to the local needs.

(d) The State of Public Health Infrastructure : The NHP 2002 envisages kick-starting the revival of the Primary Health System by providing some essential drugs under Central Government funding. This policy recognizes the need for more frequent in service training of public health medical personnel, at the level of medical officers as well as paramedics. Further, it also recognizes the practical need for levying reasonable user-charges for certain secondary and tertiary public health care services for those who can afford to pay.

(e) Extending Public Health Services : For better availability and distribution of medical personnel in their jurisdiction, State Governments will expand the pool of medical practitioners to include a cadre of licentiates of medical practice, practitioners of Indian Systems of Medicine and Homoeopathy. Simple services/procedures can be provided by such practitioners even outside their disciplines, as part of the basic primary health services in under-served areas after adequate training and subject to the monitoring of their performance through professional councils. The scope of expanding services of paramedical personnel from existing usage will be examined on lines of services rendered

by nurse practitioners in several developed countries.

(f) Role of Local Self-Government Institutions : NHP-2002 lays great emphasis upon the implementation of public health programmes through local self government institutions. The financial incentives will be provided by Central Government.

(g) Norms for Health Care Personnel : Minimal statutory norms for the development of doctors and nurses in medical institutions need to be introduced urgently under the provisions of the respective MCI and INC acts.

(h) Education of Health Care Professionals : Keeping in view the uneven distribution of colleges in the country, the policy envisages the setting up of a *Medical Grants Commission* for funding new Government Medical and Dental Colleges and upgradation of existing colleges in different parts of the country. The existing curriculum can be modified to a more need-based, realistic, skill oriented syllabus, at undergraduate level with a more significant component of practical training. This would make fresh doctors contribute effectively to providing of primary health services immediately after graduation. The policy recommends periodic skill updating through Continuing Medical Education (CME) programmes on important health issues.

(j) Need for Specialists In Public Health and Family Medicine : In order to alleviate the acute shortage of medical personnel in public health, the policy envisages to raise the proportion of postgraduate seats in the field of 'Public Health' and 'Family Medicine' progressively to reach a stage wherein 1/4th of the seats are earmarked for these disciplines. Since the public health discipline has an interface with many other developmental sectors, specialization in public health may be encouraged not only for medical doctors, but also for non-medical graduates from the allied fields of public health engineering, microbiology and other natural sciences.

(k) Nursing Personnel : In the interest of patient care, the policy emphasises the need for an improvement in the ratio of nurses vis-à-vis doctors/beds and an increase in degree holding nurses vis-a-vis diploma holding nurses and training of super speciality nurses.

(l) Use of Generic Drugs and Vaccines : NHP emphasizes the need for basing treatment regimens on generic drugs rather than proprietary drugs, except in special circumstances. This is a pre-requisite for cost effective public health care and production and sale of irrational combination of drugs would be prohibited through the drug standard statute. The UIP should be assured of uninterrupted supply of vaccines mainly from public sector institutions so that they are available at an affordable price.

(m) Urban Health : NHP-2002 envisages the setting up of an organized urban primary health care structure based on appropriate population norms. The structure conceived under NHP-2002 is a two-tiered one; the Primary centre covering a population of one lakh, with a dispensary providing an OPD facility and essential drugs, to enable access to all the national health programmes, and a second-tier of the urban health organization at the level of the Government general hospital, where referral is made from the primary centre. The funding of UHC will be jointly borne by state and centre. The policy

also recommends establishment of fully equipped trauma care networks to reduce accidental mortality and morbidity.

(n) Mental Health : NHP-2002 envisages a network of decentralized mental health services and the diagnosis of common disorders, and the prescription of common therapeutic drugs by general duty medical staff. Central Government has also committed to upgrade physical infrastructure of mental health institutions for indoor treatment of patients.

(o) Information, Education And Communication (IEC) : NHP-2002 envisages an IEC policy, which maximizes the dissemination of information to those population groups which cannot be effectively approached by using only the mass media. The focus would therefore be on the interpersonal communication of information and on folk and other traditional media to bring about behavioral change. Dispelling of myths and misconceptions about religious and ethical issues by the community leaders, particularly religious leaders is an effective way for behavioural change in the community. NHP 2002 also gives priority to school health programmes which aim at preventive health education, providing regular health check ups and promotion of health seeking behaviour amongst children.

(p) Health Research : The policy envisages an increase in Government funded health research to a level of 2 percent by 2010. Domestic medical research would be focused on new therapeutic drugs and vaccines for tropical diseases, such as TB and Malaria, as also on the sub-types of HIV / AIDS prevalent in the country. Private entrepreneurship will be encouraged in the field of medical research.

(q) Role of The Private Sector : In principle, this policy welcomes the participation of the private sector in all areas of health activities - primary, secondary or tertiary. It envisages the enactment of suitable legislation for regulating minimum infrastructure and quality standards in private clinical establishments / medical institutions along with statutory guidelines for the conduct of clinical practise. The NHP envisages the co-operation of private practitioners and NGOs in the national disease control programmes.

(r) The Role of the Civil Society : The policy emphasizes the need to simplify procedures for government - civil society interfacing in order to enhance the involvement of civil society in public health programmes.

(s) National Disease Surveillance Network : This Policy envisages the setting up of an integrated disease control network from the lowest rung of public health administration to the Central Government. This public health surveillance network will also encompass information from private health care institutions and practitioners. It is expected that real-time information will greatly strengthen the capacity of the public health system to counter local outbreaks of seasonal diseases.

(t) Health Statistics : The policy envisages the compilation of baseline estimates for the incidence of the common diseases. The policy proposes to enable the periodic updating of these baseline estimates through representative sampling, under an appropriate statistical methodology, so that the public health system would move closer to the objective of evidence-based policy-making.

(u) Women's Health : The policy envisages the increased access of women and underprivileged groups to basic health care of primary health sector and gives highest priority to the identified programmes relating to women's health.

(v) Regulation of standards of Para Medical Disciplines and Medical Ethics : The NHP 2002 recognises the need for the establishment of statutory professional councils for paramedical disciplines to register paramedic practitioners, maintain standards of training, and monitor performance. The policy also recommends that a contemporary code of ethics be notified and rigorously implemented by the Medical Council of India as well as the need to watch newer areas like gene manipulation, and stem cell research.

(w) Enforcement of Quality Standards for Food and Drugs : The NHP-2002 envisages that the food and drug administration will be progressively strengthened, in terms of both laboratory facilities and technical expertise. Food standards will be similar to Codex specifications and drug standards will be at par with the most rigorous ones adopted elsewhere.

(x) Environmental and Occupational Health : The policies and programmes of the environment related sectors be smoothly interfaced with the policies and the programmes of the health sector.

(y) Providing Medical Facilities to Users from Overseas : The policy strongly encourages the provision of secondary and tertiary health services on a payment basis to service seekers from overseas (Medical Tourism), due to comparatively cheaper cost.

(z) Impact of Globalisation on the Health Sector : The policy envisages a national patent regime for the future, which avails of all opportunities to secure for the country under its patent laws, affordable access to the latest medical and therapeutic discoveries.

National Population Policy (NPP) - 2000

In 1952, India became the first country in the world to launch a national program, emphasizing family planning to the extent necessary for reducing birth rates "to stabilize the population at a level consistent with the requirement of national economy". The evolution of the national family planning programme is presented in Box - 4.

The National Health Policy, 1983, stated that replacement levels of fertility rate (TFR) should be achieved by the year 2000. On 11 May 2000, India had 1 billion (100 crore) people, i.e., 16 percent of the world's population on 2.4 percent of the globe's land area. If current trends continue, India may overtake China in 2045, to become the most populated country in the world. While global population has increased threefold during 20th century, from 2 billion to approximately 6 billion, the population of India has increased nearly five times from 238 million (23 crores) to 1 billion in the same period. India's current yearly increase in population of 15.5 million is enough to neutralize efforts to conserve our efforts towards resource endowment and environment.

The National Population Policy (NPP) 2000 provides a policy framework for advancing goals and prioritizing strategies during the next decade, to meet the reproductive and child

Box - 4: Evolution of Family Planning Programme in India	
Year	Remarks
1925	Prof Raghunath Dhondo Karve opened the first birth control clinic in Mumbai
1938	National Planning Committee of the Indian National Congress set up in 1938 strongly supported Family Planning as a state policy
First five-year plan (1951-56)	India was the first country to have officially launched a well-defined family planning programme in 1951
Third five year plan (1961-66)	Extension wing was added to the existing programme, introduction of intrauterine device, integrated approach was adopted in 1966 and family planning formed an integral part of maternal and child health and nutritional services.
1968	Social marketing for condoms was introduced under which condoms or Nirodh were made available at highly subsidized price. And at this stage Lippies loop was introduced.
Fourth five year plan (1969-74)	Family planning services were integrated with Primary health care at this stage. 1970-All India Hospital Post Partum Programme (AIHHP) was launched. 1971-liberalisation of abortions by the govt. by passing MTP act.
Fifth five-year plan (1974-79)	The programme took the recourse in this time period with Mass Vasectomy Camp Approach leading to national emergency in 1975. The programme was renamed at this stage as Family Welfare Programme. Family welfare basket was filled with nutrition and child health programmes. 1975-Integrated Child Development Scheme. 1978-Child Marriage Restraint Act. India became signatory of Alma Ata declaration in 1978.
Sixth five-year plan (1980-85)	The national health policy diluted family planning and it became a part of concept of positive health and one of the means to achieve Health for All by 2000.
Seventh five-year plan (1986-90)	There was strengthening of Mother and child (MCH) services along with family welfare services. Other programmes as Oral Rehydration Therapy (ORT), control of respiratory group of infections and universal immunization programme were also included.
Eighth five-year plan (1992-97)	The programme was renamed again as Child survival and Safe Motherhood programme (CSSM) in 1992(7).
Ninth five-year plan (1997-2002)	Reproductive and Child Health programme was launched in 1997 comprising of Child Survival and Safe Motherhood (CSSM), Sexually transmitted infections (STI) and other components.
Tenth five year plan (2002-2007)	RCH II was launched with few modifications after evaluating RCH I

health needs of the people in India, and to achieve net replacement levels (TFR) by 2010. It is based upon the need to simultaneously address issues of child survival, maternal health and contraception, while increasing outreach and coverage of a comprehensive package of reproductive and child health service by government, industry and voluntary non-government sector, working in partnership. The NPP affirms the commitment of government towards voluntary and informed choice and consent of citizens while availing reproductive health care services, and continuation of the target free approach in administering family planning services. The objectives of NPP - 2000 are shown in Box - 5.

The major differences between the earlier approach and the newer approach, based on NPP - 2000 and RCH-II programme are shown in Box - 6.

National Socio Demographic Goals

In pursuance of these objectives, the following National Socio-Demographic Goals to be achieved by 2010 are formulated:

(a) Address the unmet needs for basic reproductive and child

health services, supplies and infrastructure.

- (b) Make school education up to age 14 free and compulsory, and reduce drop outs at primary and secondary school levels to below 20 percent for both boys and girls.
- (c) Reduce infant mortality rate to below 30 per 1000 live births.
- (d) Reduce maternal mortality ratio to below 100 per 100,000 live births.
- (e) Achieve universal immunization of children against all vaccine preventable diseases.
- (f) Promote delayed marriage for girls, not earlier than age 18 and preferably after 20 years of age.
- (g) Achieve 80 percent institutional deliveries and 100 percent deliveries by trained persons.
- (h) Achieve universal access to information / counselling, and services for fertility regulation and contraception with a wide basket of choices.
- (j) Achieve 100 percent registration of births, deaths, marriages and pregnancies.
- (k) Prevent and control communicable diseases.

Box - 5 : Objectives of NPP - 2000

Immediate objective	<ul style="list-style-type: none"> To address the unmet needs for contraception Strengthen health care infrastructure, and health personnel Provide integrated service delivery for basic reproductive and child health care.
Medium-term objective	<ul style="list-style-type: none"> To bring the TFR to replacement levels by 2010 Vigorous implementation of inter-sectoral operational strategies.
Long-term objective	<ul style="list-style-type: none"> To achieve a stable population by 2045, at a level consistent with the requirements of sustainable economic growth, social development, and environmental protection

Box - 6 : Differences between older and newer approach (8).

Old Approach (Family Planning)	New Approach (Reproductive and Child Health)
Population-Centered	People-centered
Over-emphasis on sterilization	Informed Choice of contraceptives
Quantitative targets	Qualitative targets
Family Planning in a separate basket	FP merged with Health: One package for Health, MCH & FP
Focus on 30 + women with 3 or 4 children	Focus on new operation, in particular, adolescents (15-25 years)
Insensitive to gender issues	Focus on gender issues and concern for gender equity and elimination of discrimination against women
No linkage with basic needs of the poor	Priority for fulfilling the Minimum Needs Programme
No consultation with people at the grassroot level	Decentralised programme run through panchayats & nagarpalikas
Family Welfare Department- the sole custodian of population matters	Abolish the Department and establish a Population and Social Development Commission and Fund

- (l) Integrate Indian System of Medicine (ISM) in the provision of RCH services, and in reaching out to households.
- (m) Promote vigorously the small family norm to achieve replacement level of TFR.
- (n) Contain the spread of Acquired Immuno Deficiency Syndrome (AIDS), and promote greater integration between the management of RTI and STI.
- (o) Bring about convergence in implementation of related social sector programmes so that family welfare becomes a people centered programme.

Targets set by NPP 2000 and Current Scenario

These are shown in Box - 7 and 8.

If the NPP - 2000 is fully implemented, we anticipate a population of 1107 million (110 crores) in 2010, instead of 1162 million (116 crores) projected by Technical Group on population Projections.

Causes of High Population Growth in India

Population growth in India continues to be high on account of following -

- (a) Large size of population in the reproductive age group (estimated contribution 58 percent).
- (b) Higher fertility due to unmet needs of contraception. (estimated contribution 20 percent).
- (c) High desire for fertility due to high Infant Mortality Rate (estimated contribution about 20 percent).
- (d) Approximately 50 percent of girls marry below the age of 18, resulting in a typical reproductive pattern of 'too early

- too frequent- too many'.

- (e) Preference of male child.
- (f) More children are preferred by poor parents as more work force.

Major Strategies in NPP - 2000

There are 12 strategic themes in order to achieve the socio demographic goals by 2010. These are enumerated below:

- (a) Decentralized Planning and Program Implementation.
- (b) Convergence of Service Delivery at Village Levels.
- (c) Empowering Women for Improved Health and Nutrition.
- (d) Meeting the Unmet Needs for Family Welfare Services.
- (e) Focus on Under-Served Population Groups.
 - Urban Slums
 - Tribal communities, hill areas, displaced/migrant populations
 - Adolescents
- (f) Involvement of men in planned parenthood
- (g) Action through diverse Health Care Providers.
- (h) Collaboration with and Commitments from Non-Government Organizations and the Private Sector.
- (i) Mainstreaming Indian System of Medicine and Homeopathy.
- (j) Contraceptive Technology and Research on Reproductive and Child Health.
- (k) Providing for the Older Population.
- (l) Information, Education and Communication.

Operational Strategies

These include the following :

Box - 7 : Targets set by NPP - 2000 and current scenario.		
Indicators	Target by 2010	Current status (2007)
Population	1107 Million	1103 Million (2005)
Reduce drop outs at primary and secondary school levels	< 20 percent for both boys and girls	School attendance: <ul style="list-style-type: none"> ● 6-10 yrs - 83% ● 11-14 yrs - 75% ● 15-17 yrs - 41% (NFHS-3)
Infant mortality rate	<30 per 1000 live births	57 per 1000 live births
Maternal Mortality Rate	<100 per 100,000 live births	301 per 100,000 live births (2001-2003)
Marriage for girls, not earlier than age 18	Promote delayed marriage	Marriage : <ul style="list-style-type: none"> ● Girls (Before 18yrs) - 46% ● Boys (before 21 yrs) - 27% (NFHS-3)
Achieve universal immunization of children.		44% of children fully vaccinated (NFHS-3)
Deliveries by trained persons.	100%	48%
CBR	21	23.5
TFR	2.1	2.9

Box - 8 : Targets under various plans.				
Indicator	Tenth Plan Goals (2002-2007)	RCH II Goals (2005-2010)	National Population Policy 2000 Goals (By 2010)	Millennium Development Goals
Infant Mortality Rate	<45/1000	<30/1000	<30/1000	-
Under Five Mortality Rate	-	-	-	Reduce by 2/3 from 1990 levels by 2015
Maternal Mortality Ratio	200/100000	<100/100000	<100/100000	Reduce by 3/4 from 1990 levels by 2015
Total Fertility Ratio	2.3	2.1	2.1	-
Couple Protection Ratio	65%	65%	100%	-

- (a) Utilize village self help groups to organize and provide basic services for reproductive and child health care, combined with the ongoing ICDS scheme.
- (b) Implement, at village levels, a one-stop integrated and coordinated service delivery package for basic health care, family planning and maternal and child health related services, provided by the community and for the community.
- (c) Wherever these village self-help groups have not developed for any reason, community midwives, practitioners of ISM, retired school teachers and ex-defence personnel may be organized to perform similar functions.
- (d) At village levels, the Anganwadi centre may become the pivot of basic health care activities, contraceptive counselling and supply, nutrition education and supplementation, as well as preschool activities. The Anganwadi centres can also function as depots for ORS/basic medicines and contraceptives.
- (e) A maternity hut should be established in each village to be used as the village delivery room with storage space for supplies and medicines. It should be adequately equipped with kits for midwifery, ante-natal care, and delivery; basic medication for obstetric emergency aid; contraceptives, drugs and medicines for common ailments.
- (f) Trained birth attendants as well as the vast pool of traditional dais should be trained and made familiar with emergency and referral procedures.
- (g) Provide wider basket of choices in contraception, through innovative social marketing schemes to reach household levels.
- (h) Improve district, sub-district and panchayat-level health management with coordination and collaboration between district health officer, sub-district health officer and the panchayat for planning and implementation activities.
- (j) Strengthen Community Health Centres (CHCs) and PHCs to provide comprehensive essential and emergency obstetric and neo-natal care.
- (k) Strengthening skills of health personnel and health providers through classroom and on-the-job training.
- (l) Focus attention on men in the information and education campaigns to promote the small family norm.
- (m) Sensitize, train and equip rural and urban health centres and hospitals towards providing geriatric health care.

Promotional and Motivational Steps for Adopting Small Family Norm in NPP

- (a) Rewards for Panchayats and Zila Parishads for exemplary performance.
- (b) *Balika Samridhi Yojana* - A cash incentive of Rs 500 is awarded at the birth of the girl child of birth order 1 or 2 to promote survival and care of girl child.
- (c) *Maternity Benefit Scheme* - A cash incentive of Rs 500 is awarded to mothers who have their first child after 19 years of age for the birth of first or second child only.
- (d) *Family Welfare* - linked Health Insurance Plan.
- (e) Couples below the poverty line, who marry and produce two children after age of 21 are rewarded.
- (f) Opening/Establishing creches and child care centres in rural areas and urban slums, to promote participation of women in paid employment.
- (g) Provision of wider and affordable choices of contraceptives.
- (h) Strengthening and expansion of safe abortion facilities.
- (j) Increased vocational training schemes for girls leading to self-employment.
- (k) Villagers will be provided soft loans and encouraged to run ambulance services for referrals.
- (l) Village level self help groups will be set up.

National Nutrition Policy

The adoption of National Nutrition Policy (NNP) by the Government under the aegis of the Deptt. of Women & Child Development in 1993 has been one of the significant achievements on Nutrition scene in the country. The Nutrition Policy recognized that “*Nutrition affects development as much as development affects nutrition*”. The Policy advocates a series of actions in different spheres like food production, food distribution, education, health and family welfare, people with special needs and nutritional surveillance. The direct and indirect instruments of Nutrition Policy were recommended to be institutionalized through inter-sectoral co-ordination mechanism at Central and State levels. It gives an integrated approach between broad sectors of agriculture, food and nutrition, Environment, animal husbandry etc and thereby improving the nutritional status of the society.

The major nutrition problems of India can be classified as follows :

- (1) Under-nutrition resulting in:
 - (a) Protein Energy Malnutrition (PEM);
 - (b) Iron deficiency;
 - (c) Iodine deficiency
 - (d) Vitamin A deficiency and other hypovitaminoses.
 - (e) Low Birth Weight children
- (2) Seasonal dimensions of Nutrition;
- (3) Natural calamities & the landless.
- (4) Market Distortion and Disinformation;
- (5) Urbanisation.
- (6) Special Nutritional Problems of Hill People, Industrial Workers, Migrant Workers, and other special categories;
- (7) Problems of over nutrition, overweight and obesity for a small section of urban population.

Goals

The National Nutrition Policy had following goals :

1. Reduction in the incidence of malnutrition and stunted growth among children.
2. Reduction in the incidence of low birth weight to less than 10 percent.
3. Elimination of blindness due to Vit A deficiency.
4. Reduction in the iron deficiency anemia among pregnant women to 25 percent.
5. Universal iodisation of salt for reduction of iodine deficiency disorders to below endemic level.
6. Special emphasis to geriatric nutrition.
7. Annual production of 250 million tonnes of food grain.
8. Improving household food security through poverty alleviation programme.
9. Promoting appropriate diets and healthy life style.

The Strategy

Nutrition is a multi-sectoral issue and needs to be tackled at various levels. It is important to tackle the problem of nutrition both through direct nutrition intervention for specially vulnerable groups as well as through various development policy instruments which will create conditions for improved nutrition.

A. Direct Short Term Interventions

(i) This envisages Nutrition Intervention for specially vulnerable groups:

- (a) Expanding the Safety Net through the Universal immunization Programme, oral rehydration therapy and the Integrated Child Development Services (ICDS)
- (b) With the objective of reducing the incidence of severe and moderate malnutrition by half by the year 2000 A.D.
- (c) Reaching the Adolescent Girls : The Government's recent initiative of including the adolescent girl within 'the ambit of' ICDS should be intensified so that they are made ready for a safe motherhood.
- (d) Ensuring better coverage of expectant women in order to achieve a target of 10% incidence of low birth weight by 2000 A.D.

(ii) Fortification of Essential Foods : Essential food items shall be fortified with appropriate nutrients. e.g. salt with iodine and/or iron.

(iii) Popularisation of Low Cost Nutritious Food : Efforts to produce and popularise low cost nutritious foods from indigenous and locally available raw material shall be intensified.

(iv) Control of Micro-Nutrient Deficiency amongst vulnerable Groups : Deficiencies of Vitamin A, iron and folic acid and iodine among children, pregnant women and nursing mothers shall be controlled through intensified programmes.

B. Indirect Policy Instruments : Long Term Institutional & Structural Changes :

(i) Food Security: In order to ensure aggregate food security a per capita availability of 215 kg/person/year of foodgrains needs to be attained.

(ii) Improvement of Dietary pattern through Production and Demonstration

(iii) Policies for Effecting Income transfers so as to improve the entitlement package of the rural and urban poor.

(a) *Improving the purchasing power:* Poverty alleviation programmes, like the Integrated Rural Development Programme (IRDP) and employment generation schemes like Jawahar Rozgar Yojana, Nehru Rozgar Yojana and DWCRA are to be re-oriented and restructured to make a forceful dent on the purchasing power of the lowest economic segments of the population.

(b) *Public Distribution System:* Ensuring an equitable food distribution, through the expansion of the public-distribution system.

(iv) Land Reforms: Implementing land reform measures so that the vulnerability of the landless and the landed poor could be reduced.

(v) Health & Family Welfare: The health and family welfare programmes are an inseparable part of the strategy through "Health for All by 2000AD".

(vi) Basic Health and Nutrition Knowledge: Basic health and nutrition knowledge. With special focus on wholesome infant feeding practices, shall be imparted to the people extensively and effectively.

(vii) Prevention of Food Adulteration: Prevention of food adulteration must be strengthened by gearing up the enforcement machinery.

(viii) Nutrition Surveillance: Nutritional surveillance is another weak area requiring immediate attention.

(ix) Monitoring of Nutrition Programmes: Monitoring of Nutrition Programmes (viz ICDS), and of Nutrition Education and Demonstration by the Food & Nutrition Board, through all its 67 centres & field units, should be continued.

(x) Research: Research into various aspects of nutrition, both on the consumption side as well as the supply side, is another essential aspect

(xi) Equal Remuneration: Special efforts should be made to improve the effectiveness of programmes related to women.

(xii) Communication: Communication through established media is one of the most important strategies to be adopted for the effective implementation of the Nutrition Policy.

(xiii) Minimum Wage Administration: Closely related to the market, is the need to ensure an effective minimum wage administration to ensure its strict enforcement and timely revision and linking it with price rise through a suitable nutrition formula.

(xiv) Community Participation: The active involvement of the community is essential not only in terms of being aware of the services available to the community but also for deriving the maximum benefit from such services by giving timely feedback necessary at all levels.

(xv) Education and Literacy: It has been shown that Education & Literacy particularly that of women, is a key determinant for better nutritional status.

(xvi) Improvement of the Status of Women : The most effective way to implement Nutrition with mainstream activities in Agriculture, Health, Education and Rural Development is to focus on improving the status of women, particularly the economic status.

Administration and Monitoring

The policy have been implemented and administered by several ministries and departments of Government of India and NGOs. The administration and monitoring of the programme is as under:

1. Implementation of National Nutrition Policy

(a) The measures enumerated above have to be administered by several ministries/departments of the Government of India and various governmental and non-governmental organisations. There should be a close collaboration between the Food Policy, the Agricultural Policy the Health Policy, the Education Policy, the Rural Development Programme and the Nutrition Policy as each complements the other.

(b) An Inter-Ministerial Co-ordination Committee will function in the Ministry of Human Resource Development under the Chairmanship of Secretary, Department of Women and Child Development, to oversee and review the implementation of nutrition intervention measures.

(c) A National Nutrition Council will be constituted in the Planning Commission, with Prime Minister as chairperson.

2. Monitoring of Nutrition situation : Nutritional surveillance of the country's population especially children and mothers, shall be the responsibility of the National Institute of Nutrition.

3. Role of State Governments : In a federal polity like ours, the cutting edge of governmental interventions commences from the state level. Full implementation of various special programmes being run for upliftment of nutritional status of country, will go a long way in ensuring success of the nutritional policy. The programmes have been discussed in detail in the section on nutrition in this book and include ICDS, Special Nutrition Programme, Balwadi Nutrition Programme, Wheat Based Supplementary Nutrition Programme, Tamil Nadu Integrated Nutrition Programme, Mid Day Meals Programme, Nutritional Anaemia Prophylaxis Programme, Goitre Control Programme and Programme for Prevention of Nutritional Blindness due to Vitamin A Deficiency.

Functions of the Food & Nutrition Board

The Food & Nutrition Board', as reconstituted on 26 July 1990, advises Government, coordinates and reviews the activities in regard to food and nutrition extension/education; development, production & popularisation of nutritious Foods and Beverages; measures required to combat deficiency diseases; and 'Conservation and efficient utilisation as well as augmentation of food resources by way of food preservation and processing.

National Nutrition Mission (NNM) was set up in 2002 with overall responsibility of reducing both macro and micro nutritional deficiency in the country. As part of NNM, a new programme for adolescent girls and expectant and nursing

mothers is being launched by Department of Women and Child Development during 2002-03. Under this programme food grains are supplied free of cost through targeted public distribution system (PDS) directly to identified families.

National Blood Policy

A well organised Blood Transfusion Service (BTS) is a vital component of any health care delivery system. An integrated strategy for Blood Safety is required for elimination of transfusion transmitted infections and for provision of safe and adequate blood transfusion services to the people. The main component of an integrated strategy include collection of blood only from voluntary, non-remunerated blood donors, screening for all transfusion transmitted infections and reduction of unnecessary transfusion.

The Blood Transfusion Service in our country is quite decentralised and lacks resources and good management. In spite of hospital based system, many large hospitals and nursing homes do not have their own blood banks and this has led to proliferation of stand-alone private blood banks. The blood component production/availability and utilisation is extremely limited. There is shortage of trained health-care professionals in the field of transfusion medicine and the requirements of good manufacturing practices and implementation of quality system management.

Thus, a need for modification and change in the blood transfusion service has necessitated formulation of a National Blood Policy and development of a National Blood Programme which will also ensure implementation of the directives of Supreme Court of India in 1996. Hon'able Supreme court directed to phase out unlicensed blood banks by May 2007 and professionals blood donors by December 1997.

Mission Statement : The policy aims to ensure easily accessible and adequate supply of safe and quality blood and blood components and transfusion under supervision of trained personnel for all who need it through comprehensive, efficient and a total quality management approach. The broad objectives and strategies to achieve as given in National Blood Policy are as under :

Objective - 1 : To reiterate firmly the Govt. commitment to provide safe and adequate quantity of blood, blood components and blood products.

Strategy

1. A National Blood Transfusion Programme (NBTP) shall be developed to ensure establishment of non-profit integrated National and State Blood Transfusion Services in the country.
2. National Blood Transfusion Council (NBTC) shall be the policy formulating apex body in relation to all matters pertaining to operation of blood centres. National AIDS Control Organisation (NACO) shall allocate a budget to NBTC for strengthening Blood Transfusion Service.
3. State/UT Blood Transfusion Councils shall be responsible for implementation of the Blood Programme at State/UT level.
4. The enforcement of the blood and blood products standards shall be the responsibility of Drugs Controller General India.

5. Trading in blood i.e. Sale & purchase of blood shall be prohibited.
6. The practice of replacement donors shall be gradually phased out in a time bound programme to achieve 100% voluntary non-remunerated blood donation programme.
7. State Blood Transfusion Councils shall organise the blood transfusion service through the network of Regional Blood Centres and Satellite Centres and other Government, Indian Red Cross Society & NGO run blood centres and monitor their functioning.
8. The Regional Centres shall be autonomous for their day to day functioning and shall act as a referral centre for the region assigned to it.
9. Due to the special requirement of Armed Forces in remote border areas, necessary amendments shall be made in the Drugs & Cosmetics Act/Rules to provide special licences to small garrison units. These units shall also be responsible for the civilian blood needs of the region.

Objective - 2 : To make available adequate resources to develop and re-organise the blood transfusion service in the entire country.

Strategy

1. National & State/UT Blood Transfusion Councils shall be supported/ strengthened financially.
2. Efforts shall be directed to make the blood transfusion service viable through non-profit recovery system.
3. Efforts shall be made to raise funds for the blood transfusion service for making it self-sufficient.
4. The mechanism shall be introduced in government sector to route the amounts received through cost recovery of blood/blood components to the blood banks for improving their services.

Objective - 3 : To make latest technology available for operating the blood transfusion services and ensure its functioning in an updated manner.

Strategy

1. Minimum standards for testing, processing and storage shall be set and ensured.
2. All mandatory tests as laid down under provisions of Drugs & Cosmetics Act/Rules shall be enforced.
3. Inspectorate of Drugs Controller of India and State FDA shall be strengthened to ensure effective monitoring and a vigilance cell shall be created under Central/State Licensing Authorities.
4. Quality Assurance Manager shall be designated at each Regional Blood Centre/any blood centre collecting more than 15,000 units per year.
5. An External Quality Assessment Scheme (EQAS) through the referral laboratories approved by the National Blood Transfusion Council shall be introduced to assist participating centres in achieving higher standards and uniformity.
6. NBTC shall identify a centre of national repute for quality control of indigenous as well as imported consumables, reagents and plasma products.
7. Each blood centre shall develop its own Standard Operating Procedures on various aspects of Blood Banking.

8. All blood centres shall adhere to bio-safety guidelines as provided in the Ministry of Health & Family Welfare manual "Hospital-acquired Infections : Guidelines for Control" and disposal of bio-hazardous waste as per the provisions of the existing Biomedical Wastes(Management & Handling) Rules - 1996 under the Environmental Protection Act - 1986.

Objective - 4 : To launch extensive awareness programmes for blood banking services including donor motivation, so as to ensure adequate availability of safe blood.

Strategy

1. Efforts shall be directed towards recruitment and retention of voluntary, non-remunerated blood donors through education and awareness programmes.
2. Activities of NGOs shall be encouraged to increase awareness about blood donation amongst masses.
3. All blood banks shall have donor recruitment officer/donor organizer and shall create and update a blood donor's directory which shall be kept confidential.
4. Enrolment of safe donors shall be ensured.
5. A Counsellor in each blood centre shall be appointed for pre and post donation counselling.
6. State/UT Blood Transfusion Councils shall recognise the services of regular voluntary non-remunerated blood donors and donor organisers appropriately.
7. National/State/UT Blood Transfusion Councils shall develop and launch an IEC campaign using all channels of communication including mass-media for promotion of voluntary blood donation and generation of awareness regarding dangers of blood from paid donors and procurement of blood from unauthorised blood banks/laboratories.

Objective - 5: To encourage appropriate clinical use of blood and blood products.

Strategy

1. Blood shall be used only when necessary. Blood and blood products shall be transfused only to treat conditions leading to significant morbidity and mortality that cannot be prevented or treated effectively by other means.
2. National Guidelines on "*Clinical use of Blood*" shall be made available and updated as required from time to time.
3. State/UT Governments shall ensure that the Hospital Transfusion Committees are established in all hospitals to guide, monitor and audit clinical use of blood.
4. Medical Council of India shall be requested to take following initiatives:
 - a) To introduce Transfusion Medicine as a subject at undergraduate and all post graduate medical courses.
 - b) To introduce posting for at least 15 days in the department of transfusion medicine during internship.
 - c) Blood and its components shall be prescribed only by a medical practitioner registered as per the provisions of Medical Council Act - 1956.
5. Adequate facilities for transporting blood and blood products including proper cold-chain maintenance shall be made available to ensure appropriate management of blood supply.

Objective - 6 : To strengthen the manpower through Human Resource Development.

Strategy

1. Transfusion Medicine shall be treated as a speciality.
2. A separate Department of Transfusion Medicine shall be established in Medical Colleges.
3. Medical Colleges/Universities in all States shall be encouraged to start PG degree (MD in transfusion medicine) and diploma courses in Transfusion Medicine.
4. In all the existing courses for nurses, technicians and pharmacists, Transfusion Medicine shall be incorporated as one of the subjects.
5. In-service training programmes shall be organised for all categories of personnel working in blood centres as well as drug inspectors and other officers from regulatory agencies.
6. Short orientation training cum advocacy programmes on donor motivation and recruitment shall be organised for Community Based Organisations(CBOs)/NGOs who wish to participate in Voluntary Blood Donor Recruitment Programme.
7. States/UTs shall create a separate cadre and opportunities for promotions for suitably trained medical and para medical personnel working in blood transfusion services.

Objective - 7: To encourage Research & Development in the field of Transfusion Medicine and related technology.

Strategy

1. A corpus of funds shall be made available to NBTC/SBTCs to facilitate research in transfusion medicine and technology related to blood banking.
2. A technical resource core group at national level shall be created to co-ordinate research and development in the country.

Objective - 8: To take adequate legislative and educational steps to eliminate profiteering in blood banks.

Strategy

1. For grant/renewal of blood bank licenses including plan of a blood bank, a committee, comprising of members from State/UT Blood Transfusion Councils including Transfusion Medicine expert, Central & State/UT FDAs shall be constituted which will scrutinise all applications as per the guidelines provided by Drugs Controller General India.
2. Fresh licenses to stand-alone blood banks in private sector shall not be granted.
3. Approved regional blood centres/government blood centres/Indian reduction cross blood centres shall be permitted to supply blood and blood products to satellite centres which are approved by the committee. The Regional Centre shall be responsible for transportation, storage, cross-matching and distribution of blood and blood products through satellite centres.
4. A separate blood bank cell shall be created under a senior officer not below the rank of DDC(I) in the office of the DC(I) at the headquarter. State/UT Drugs Control Department shall create such similar cells with the trained officers including inspectors for proper inspection and enforcement.

5. The existing provisions of drugs & Cosmetics Rules will be periodically reviewed to introduce stringent penalties for unauthorised/irregular practices in blood banking system.

Summary

In 1978, the World Health Assembly at Alma Ata launched an ambitious movement known as, "Health for All (HFA) by 2000 AD". As a signatory to HFA strategy, the Government of India was committed to frame its own policy and implement to attain Health For All by 2000 AD. This formed the basis of the National Health Policy formulated by MOHFW, GOI in 1983. Since its inception, there have been marked changes in the determinants of health. Improvement of these health indicators were the outcome of several complementary initiatives of development sector covering rural development, agriculture, food production, animal husbandry, drinking water, sanitation, education etc. Despite the impressive public health gains, the morbidity and mortality levels in the country were high. In the year 2000, it was the time to take stock of situation and progress ahead with extra zeal to achieve ultimate goal of Health For All. Accordingly, the NHP - 1983 was revised and a new, extensive NHP was enunciated by the Govt of India in 2002. The main objective of this policy is to achieve an acceptable standard of good health amongst the general population of the country. The revised strategies adopted by GOI to achieve above objective are : (a) Increase access to the decentralized public health system. (b) Ensuring a more equitable access to health services across the country. (c) Increasing the aggregate public health investment through a substantially increased contribution by the Central Government. (d) The contribution of the private sector in providing health services would be much enhanced. (e) Primacy to preventive and first-line curative initiative at the primary health level. (f) Emphasis will laid on rational use of drugs within the allopathic system. (g) Increased access to tried and tested systems of traditional medicine.

On a short term basis, within the context of the NHP, the important health related targets for the eleventh five year plan (2007 - 2012) are: Reducing Maternal Mortality Ratio (MMR) to 1 per 1,000 live births; Reducing Infant Mortality Rate (IMR) to 28 per 1,000 live births; Reducing Total Fertility Rate to 2.1; Providing clean drinking water for all by 2009 and ensuring no slip-backs; Reducing malnutrition among children of age group 0-3 to half its present level; Reducing anaemia among women and girls by 50% ; and Raising the sex ratio for age group 0-6 to 935 by 2011-12 and 950 by 2016-17.

In 1952, India became the first country in the world to launch a national program, emphasizing family planning to the extent necessary for reducing birth rates. The National Health Policy, 1983, stated that replacement levels of fertility rate (TFR) should be achieved by the year 2000. The National population Policy (NPP) 2000 provides a policy framework for advancing goals and prioritizing strategies during the next decade, to meet the reproductive and child health needs of the people in India, and to achieve net replacement levels (TFR) by 2010. The NPP affirms the commitment of government towards voluntary and informed choice and consent of citizens while availing reproductive health care services, and continuation of the target free approach in administering family planning

services. In pursuance of these objectives, the National Socio-Demographic Goals to be achieved by 2010 are formulated. If the NPP - 2000 is fully implemented, we anticipate a population of 1107 million (110 crores) in 2010, instead of 1162 million (116 crores) projected by Technical Group on population Projections.

Study Exercises

Long Question: Discuss the objectives and strategies adopted in National Health Policy 2000

Short Notes : National Socio Demographic Goals to be achieved by 2010.

MCQs

1. World Health Assembly at Alma Ata launched movement known as, "Health for All (HFA) by 2000 AD" in the year (a) 1988 (b) 1998 (c) 1978 (d) 1983.
2. The remarkable success of NHP 1983 includes elimination of : (a) Leprosy (b) Kala Azar (c) Filariasis (d) All.
3. Noteworthy initiatives under the National Health Policy 2002 includes all except : (a) Comprehensive primary health care services (b) Non involvement of health volunteers (c) Well worked out referral system (d) Integrated network of evenly spread speciality and super speciality services.
4. Important health related targets for the eleventh five year plan (2007 - 2012) are: (a) Reducing Maternal Mortality Ratio (MMR) to 1 per 1,000 live births (b) Reducing Infant Mortality Rate (IMR) to 28 per 1,000 live births (c) Reducing Total Fertility Rate to 2.1 (d) All.
5. The immediate/ short term objectives of NPP 2000 are: (a) To address the unmet needs for contraception (b) Strengthen health care infrastructure, and health personnel (c) Provide integrated service delivery for basic reproductive and child health care (d) All.
6. The major strategies under NPP 2000 include all except: (a) Empowering Women for Improved Health and Nutrition (b) Meeting the Unmet Needs for Family Welfare Services (c) Providing Medical Facilities to Users from Overseas (d) Focus on Under-Served Population Groups.

Fill in the blanks

1. NHP - 1983 was revised and a new, extensive NHP was enunciated by the Govt of India in _____.
2. In 2006 nation's CBR was at _____ & CDR was _____.
3. One of the targets for the eleventh five year plan (2007 - 2012) is to raise the sex ratio for age group 0-6 to _____ by 2011-12 and _____ by 2016-17.
4. NHP 2002 envisages to raise the proportion of postgraduate seats in the field of 'Public Health' and 'Family Medicine' wherein _____ of the seats are earmarked for these disciplines.
5. By 2010 the NHP 2002 envisages an increase in Government funded health research to a level of _____ percent.
6. India's current yearly increase in population is _____ million.
7. NPP 2000 aims at Promote delayed marriage for girls, not earlier than age _____ and preferably after 20 years of age.

8. A cash incentive of Rs 500 is awarded at the birth of the girl child of birth order 1 or 2 to promote survival and care of girl child. Name the yojna _____.

Answers : MCQs : (1) c; (2) d; (3) b; (4) d; (5) d; (6) c ; **Fill in the blanks:** (1) 2002; (2) 23.5, 7.5; (3) 935, 950; (4) one-fourth; (5) 2; (6) 15.5; (7) 18; (8) Balika Samridhi Yojna.

National Rural Health Mission (NRHM)

Sunil Agrawal

Recognizing the importance of Health in the process of economic and social development and improving the quality of life of our citizens, the Government of India has resolved to launch the National Rural Health Mission to carry out necessary architectural correction in the basic health care delivery system. The Goal of the Mission is to improve the availability of, and access to, quality health care by people, especially for those residing in rural areas, the poor, women and children. Under the Common Minimum Programme, health care system of the country was given prime importance in which the UPA government had pledged to increase public spending on health to at least 2 - 3 % of the Gross Domestic Product (GDP) over the next five years of its term with a focus on primary health care.

The National Rural Health Mission was launched by the Hon'ble Prime Minister on 12th April 2005, to provide accessible, affordable and accountable quality health services even to the poorest households in the remotest rural regions. The difficult areas with unsatisfactory health indicators were classified as special focus states to ensure greatest attention where needed. The thrust of the Mission was on establishing a fully functional, community owned, decentralized health delivery system with inter sectoral convergence at all levels, to ensure simultaneous action on a wide range of determinants of health like water, sanitation, education, nutrition, social and gender equality.

It also aims at mainstreaming the Indian systems of medicine to facilitate health care. The Plan of Action includes increasing public expenditure on health, reducing regional imbalance in health infrastructure, pooling resources, integration of

organizational structures, optimization of health manpower, decentralization and district management of health programmes, community participation and ownership of assets, induction of management and financial personnel into district health system, and operationalizing community health centers into functional hospitals meeting Indian Public Health Standards in each Block of the Country.

National Rural Health Mission (NRHM) : Will It Make A Difference?

Since independence, our country has created a vast public health infrastructure of Sub - centres, Public Health Centres (PHCs) and Community Health Centres (CHCs). There is also a large cadre of health care providers (Auxiliary Nurse Midwives, Male Health workers, Lady Health Visitors and Health Assistant Male). Yet, this vast infrastructure is able to cater to only 20% of the population, while 80% of health care needs are still being provided by the private sector. Rural India is suffering from a long - standing health care problem. Studies have shown that only one trained health care provider including a doctor with any degree is available per every 16 villages. Although, more than 70% of its population lives in rural areas, but only 20% of the total hospital beds are located there. Most of the health problems that people suffer in the rural community and in urban slums are preventable and easily treatable. In view of the above issues, the National Rural Health Mission (NRHM) has been launched by Government of India (GOI).

What is NRHM ?

The National Rural Health Mission (2005 - 12) was launched in April 2005 to provide effective health care to rural population throughout the country with special focus on 18 states, which have weak public health indicators and/or weak infrastructure. These states are Arunachal Pradesh, Assam, Bihar, Chhattisgarh, Himachal Pradesh, Jharkhand, Jammu and Kashmir, Manipur, Mizoram, Meghalaya, Madhya Pradesh, Nagaland, Orissa,

Rajasthan, Sikkim, Tripura, Uttaranchal and Uttar Pradesh.

Principles

The NRHM is conceived within the following set of guiding principles :

1. Promote equity, access, efficiency, quality and accountability in Public Health System.
2. Enhance people oriented and community based approaches.
3. Decentralize and involve local bodies.
4. Ensure Public Health Focus.
5. Recognized value of traditional knowledge base of communities.
6. Promote new innovations, method and process development.

The NRHM will cover all the villages in these 18 states through approximately 2.5 lakh village - based "Accredited Social Health Activists" (ASHA) who would act as a link between the health centers and the villagers. One ASHA will be raised from every village, who would be trained to advise village populations about Sanitation, Hygiene, Contraception, and Immunization to provide Primary Medical Care for Diarrhoea, Minor Injuries, and Fevers; and to escort patients to Medical Centers. They would also be expected to deliver direct observed short course therapy for tuberculosis and oral rehydration, to give folic acid tablets and chloroquine to patients and to alert authorities to unusual outbreaks. ASHA will receive performance - based compensation for promoting universal immunization, referral and escort services for RCH, construction of house - hold toilets, and other health care delivery programs (See Box - 1).

Box - 1 : Key Components of NRHM

- Provision of health activist in each village
- Village health plan to be prepared by village panchayat
- Strengthening of rural hospitals
- Integration of vertical health and family welfare programs at district level
- Strengthening delivery of Primary Health Care

Goals - The major goals of NRHM are :

- (a) Reduction in Infant Mortality Rate (IMR) and Maternal Mortality Ratio (MMR).
- (b) Universal access to public health services such as women's health, child health, water, sanitation & hygiene, immunization, and nutrition.
- (c) Prevention and control of communicable and non - communicable diseases, including locally endemic diseases.
- (d) Access to integrated comprehensive primary health care.
- (e) Population stabilization, gender and demographic balance.
- (f) Revitalize local health traditions and mainstream AYUSH.
- (g) Promotion of healthy life styles.

Specific Targets

The expected outcomes of NRHM are listed below :

- IMR - to be reduced to 30/1,000 live births by 2012.
- Maternal Mortality - to be reduced to 100/100,000 live births by 2012.

- TFR - to be reduced to 2.1 by 2012.
- Malaria Mortality - 50% reduction by 2010, additional 10% by 2012.
- Kala Azar Mortality Reduction - 100% by 2010 and sustaining elimination until 2012.
- Filaria/Microfilaria Reduction - 70% by 2010, 80% by 2012, and elimination by 2015.
- Dengue Mortality Reduction - 50% by 2010 and sustaining at that level until 2012.
- Cataract operations - increasing to 46 lakh until 2012.
- Leprosy Prevalence Rate - reduce from 1.8 per 10,000 in 2005 to less than 1 per 10,000 thereafter.
- Tuberculosis DOTS - maintain 85% cure rate through entire Mission Period and also sustain planned case detection rate.
- Upgrading all health establishments in the districts to Indian Public Health Standards (IPHS).
- Increase utilization of First Referral units from bed occupancy by referred cases of less than 20% to over 75%.
- Over 5 lakh ASHAs, one for every 1,000 population/large habitation, in 18 Special Focus States and in tribal pockets of all states by 2008.
- All Sub - centres (nearly 1.75 lakh) functional with two ANMs by 2010.
- All Primary Health Centres (nearly 30,000) with three staff nurses to provide 24x7 services by 2010.
- 6,500 Community Health Centres strengthened/established with seven specialists and nine staff nurses by 2012.
- 1,800 Taluka/Sub Divisional Hospitals and 600 District Hospitals strengthened to provide quality health services by 2012.
- Mobile Medical Units for each District by 2009.
- Functional Hospital Development Committees in all CHCs, Sub Divisional Hospitals, and District Hospitals by 2009.
- Untied grants and annual maintenance grants to every SC, PHC, and CHC released regularly and utilized for local health action by 2008.
- All District Health Action Plans completed by 2008.

Objectives

- a) Train and enhance the capacity of Panchayati Raj Institutions (PRIs) to own, control and manage public health services
- b) Preparation of Health plan for each village through Village Health Committee of the Panchayat
- c) Strengthening sub - centers through an untied fund to enable local planning and action (each sub - center will have an Untied Fund of Rs. 10,000 per annum). This Fund will be deposited in a joint Bank Account of the ANM and Sarpanch and operated by the ANM, in consultation with the Village Health Committee.
- d) Provision of 24 hour service in 50% PHCs by addressing shortage of doctors, especially in high focus States, through mainstreaming AYUSH manpower.
- e) Preparation and implementation of an intersectoral District Health Plan prepared by the District Health Mission, including drinking water, sanitation and hygiene and nutrition;
- f) Integrating vertical Health and Family Welfare programs at National, State, Block, & District levels.

Duration of NRHM

The duration of NRHM will be from 2005 to 2012. The total allocation for the Departments of Health and Family Welfare has been hiked from Rs. 8,420 crores to Rs. 90,103 crores in the budget proposals for the year 2007 - 08.

Core Strategies

The main focus in NRHM would be on the following issues :

- Decentralized village and district level health planning.
- Appointment of *Accredited Social Health Activist (ASHA)*: The selection criteria would be “women, resident of the concerned village, married / widow / divorced, 25 - 45 years age, formal education up to 8th, to be selected out of a panel by village health and action committee of Gram Sabha”. Norm would be 1 per 1000 population, but this norm may be changed for different areas. There would be NO pay or honorarium but she will be given compensation for various health and sanitation services provided. They will be given a kit of suitable drugs. They would be guided by Anganwadi Workers (AWW) and ANM. In 4 years, 2.5 lakh ASHAs will be deployed.
- Strengthening the public health service delivery system, particularly at village, primary and secondary level, by developing and implementing the Indian Public Health Standards; Developing CHCs as the First Referral Units (FRUs) by providing special care in the specialities of Medicine, Surgery, Obs & Gyn, and Pediatrics. Presently minimum standards of Indian Public Health for CHCs have been developed; later they will be developed for PHCs & subcentres also.
- Mainstreaming of AYUSH (Indian Systems of Medicine).
- Improved management capacity to organise health systems and services in public health.
- Emphasizing evidence based planning and implementation.

- Prompting non - profit factor to increase social participation, promoting health behaviors and improving intersectoral convergence.

Supplementary Strategies

- Regulation of private sector to improve equity and reduce “out of pocket” expenses.
- Foster Public Private Partnership (PPP) to meet national public health goals.
- Re - Orientation of Medical Education (ROME).
- Raising health security / insurance for the poor.

Organisational Structure

Organisational structure of NRHM from the apex till district level is shown in Box - 2.

To support the District Health Mission, every district will have an integrated District Health Society (DHS) and all the existing societies as vertical support structures for different national and state health programmes will be merged in the DHS. The DHS will be responsible for planning and managing all health and family welfare programmes in the district, both in the rural as well as urban areas.

The Delivery System

A generic public health delivery system envisioned under NRHM from the village to block level is illustrated in Figure - 1

Progress Under NRHM

The status as on 30 April, 2008 is as under :

- State Health Missions have been constituted in all states.
- ASHA training modules developed and revised.
- Over 1500 management professionals (CA/MBA) appointed in program management units (PMU) to support the programme management. This is being planned at the level of the block also.
- RCH - II launched and under implementation.
- IMNCI started in 142 districts.

Box - 2 : Organisational structure of NRHM	
Level	Organisation
Central level	<i>Mission Steering Group (MSG)</i> headed by the Union Minister for Health & Family Welfare and an Empowered Programme Committee (EPC) headed by the Union Secretary for Health & FW.
State level	<p><i>State Health Mission and State Health Society</i></p> <p>State Health Mission headed by the Chief Minister of the State. The functions under the Mission would be carried out through the State Health & Family Welfare Society</p> <p><i>Composition</i></p> <ul style="list-style-type: none"> ● Chairperson : Chief Minister ● Co - Chairperson : Minister of Health and Family Welfare, State Government ● Convener : Principal Secretary/ Secretary (Family Welfare) ● Nominated non - official members (5 to 8 members) such as health experts, representatives of medical associations, NGOs and Representatives of Development Partners <p><i>Frequency of meetings : At least once in every six months</i></p>
District level	<p><i>District Health Mission</i></p> <p>Chairperson : Chairman, Zilla Parishad</p> <p>Co - Chairperson : District Collector/DM</p> <p>Vice Chairperson : CEO Zilla Parishad</p> <p>Mission Director : Chief Medical Officer/ CMHO/ Civil Surgeon</p>

Fig. - 1 : NRHM - Illustrative Structure

- (f) Legal changes brought about to allow ANMs to dispense medication and MBBS doctors to dispense anaesthesia.
- (g) At 1,611 PHCs, AYUSH doctors have been co - located.
- (h) 2,28,413 Village Health & Sanitation Committees (VHSCs) have been constituted and operational by 30 April 2008.
- (j) Against the target of 5 lakh fully trained Accredited Social Health Activists (ASHAs) by 2008, the initial phase of training (first module) has been imparted to 5.36 lakh. ASHAs in position with drug kits are 224951 in number.
- (k) Out of the 145272 Sub - centres (SCs) expected to be functional with 2 Auxiliary Nurse Midwives (ANMs) by 2008, only 22471 had the same.
- (l) 22,370 Primary Health Centres (PHCs) are functional and out of which 3450 PHCs are functional with three staff nurses by 2008.
- (m) There has been a shortfall of 5,498 (>50%) specialists at the Community Health Centres (CHCs). Total CHCs functional are 4,045 out of which 2,966 have been selected to be upgraded to IPHS.
- (n) Number of Districts where annual integrated action plan under NRHM have been prepared for 2007 - 08 are 485.

Janani Suraksha Yojana

To change the behaviour of the community towards institutional delivery, the Government of India, under NRHM in 2005, modified the National Maternity Benefit Scheme (NMBS) from that of a nutrition - improving initiative to the *Janani Suraksha Yojana* (JSY). The Yojana has identified the Accredited Social Health Activist (ASHA) as an effective link between the Government and the poor pregnant women.

The scheme has the dual objectives of reducing maternal and infant mortality by promoting institutional deliveries. Though the JSY is implemented in all states and UTs, its focus is on 10 low performing states having low institutional delivery rate. The scheme is 100% centrally sponsored and integrates cash assistance with maternal care. It is funded through the flexi - pool mechanism. Under the NRHM, out of 184.25 lakh institutional deliveries in the country (as on 1 April 2007), JSY beneficiaries were 28.74 lakh. The eligibility criteria are shown

in Box - 3.

Category of states & cash assistance	Beneficiaries
<i>Low Performing States (LPS)</i> (Cash assistance in rural areas is Rs 1400 and Rs 600 for the mother & ASHA respectively; in urban areas it is Rs. 1000 and Rs 200 respectively).	All pregnant women / All SC/ST Women delivering in SC/PHC/CHC/ FRU/ Distt or state hospital or accredited private hospital
<i>High Performing States (HPS)</i> (Cash assistance for the mother in rural areas is Rs 700 and in urban areas it is Rs. 600).	BPL pregnant women aged 19 yrs and above/ All SC/ ST Women delivering in SC/PHC/CHC/FRU/ Distt or state hospital or accredited private hospital

National Urban Health Mission (NUHM)

The National Urban Health Mission (NUHM) will meet health needs of the urban poor, particularly the slum dwellers by making available to them essential primary health care services. This will be done by investing in high - caliber health professionals, appropriate technology through public - private partnership, and health insurance for urban poor. Recognizing the seriousness of the problem, urban health will be taken up as a thrust area for the Eleventh Five Year Plan. NUHM will be launched with focus on slums and other urban poor. The Eleventh Five Year Plan will aim for inclusive growth by introducing National Urban Health Mission (NUHM), which along with NRHM, will form *Sarva Swasthya Abhiyan*. The organisation would be :

At the state level : Besides the State Health Mission and State Health Society and Directorate, there would be a State Urban Health Programme Committee.

At the district level : There would be a District Urban Health Committee

At the city level : A Health and Sanitation Planning Committee.

At the ward slum level : There will be a Slum Cluster Health, Water and Sanitation Committee.

For promoting public health and cleanliness in urban slums, the Eleventh Five Year Plan will also encompass experiences of civil society organizations working in urban slum clusters. It will seek to build a bridge of NGO - GO partnership and develop community level monitoring of resources and their rightful use. NUHM would ensure the following :

- Resources for addressing the health problems in urban areas, especially among urban poor.
- Need based city specific urban health care system to meet the diverse health needs of the urban poor and other vulnerable sections.
- Partnership with community for a more proactive involvement in planning, implementation, and monitoring of health activities.

- Institutional mechanism and management systems to meet the health - related challenges of a rapidly growing urban population.
- Framework for partnerships with NGOs, charitable hospitals, and other stakeholders.
- Two - tier system of risk pooling : (a) Women's Mahila Arogya Samiti to fulfil urgent hard - cash needs for treatments; (b) A Health Insurance Scheme for enabling urban poor to meet medical treatment needs.

NUHM would cover all cities with a population of more than 100,000. It would cover slum dwellers and other marginalized urban dwellers like rickshaw pullers, street vendors, railway and bus station coolies, homeless people, street children, construction site workers, who may be in slums or on sites.

The existing Urban Health Posts (UHPs) and Urban Family Welfare Centres (UFWCs) would continue under NUHM. They will be marked on a map and classified as the Urban Health Centres on the basis of their current population coverage. All the existing human resources will then be suitably reorganized and rationalized. These centres will also be considered for upgradation. Intersectoral coordination mechanism and convergence will be planned between the Jawaharlal Nehru National Urban Renewal Mission (JNNURM) and the National Urban Health Mission.

The Challenges before NRHM and its key approaches: A Critique

It is clearly a gigantic task to bring about major changes in outcomes by simultaneous action on a wide range of determinants of health. NRHM has identified communitization, flexible financing, innovations in human resource management, monitoring against IPH Standards, and building capacities at all levels as the principal approaches to ensure quality service delivery, efficient utilization of scarce resources, and most of all, to ensure service guarantees to local households.

Health is a state subject and the NRHM will build partnership with the States to ensure meaningful reforms with more resources. Ultimately, the success of NRHM will depend on the ability of the Mission interventions to galvanize State Governments into action, pursuing innovations and flexibility in all spheres of public health action. Ensuring availability of fully trained and equipped resident health functionaries at all levels and large scale financing under initiatives like the *Janani Suraksha Yojana* for institutional deliveries are a few priorities for action. Partnerships with non governmental providers to strengthen public health delivery are also an important need given the distribution of Specialist doctors in India. While we have 30,000 MBBS graduates coming out of our Colleges every year, the entire rural health system for more than 750 million people never has more than 26000 doctors.

There is need to shift to decentralization of functions to hospital units/health centres and local bodies. The States need to move away from the narrow focus on the implementation of budgeted programmes and vertical schemes. They need to develop systems that comprehensively address the health needs of all citizens. Thus, in order to improve the health care services in the country, the Eleventh Five Year Plan will insist on Integrated District Health Plans and Block Specific Health

Plans, mandate involvement of all health related sectors and emphasize partnership with PRIs, local bodies, communities, NGOs, Voluntary and Civil Society Organizations.

Summary

The National Rural Health Mission was launched by the Hon'ble Prime Minister on 12th April 2005, to provide accessible, affordable and accountable quality health services even to the poorest households in the remotest rural regions. NRHM will give special focus to 18 states, which have weak public health indicators and/or weak infrastructure. The duration of NRHM will be from 2005 to 2012. The total allocation for the Departments of Health and Family Welfare has been hiked from Rs. 8,420 crores to Rs. 90,103 crores in the budget proposals for the year 2007 - 08.

Key component of NRHM are provision of health activist in each village, village health plan to be prepared by village panchayat, strengthening of rural hospitals, integration of vertical health and family welfare programs at district level, strengthening delivery of Primary Health Care.

The major goals of NRHM are (a) Reduction in Infant Mortality Rate (IMR) and Maternal Mortality Ratio (MMR), (b) Universal access to public health services, (c) Prevention and control of communicable and non - communicable diseases, including locally endemic diseases, (d) Access to integrated comprehensive primary health care (e) Population stabilization, gender and demographic balance (f) Revitalize local health traditions and mainstream AYUSH (g) Promotion of healthy life styles.

The expected outcomes of NRHM are by 2012 reduction in IMR and MMR to 30/1000 live births and 100/100,000 live birth respectively, reduction of TFR to 2.1 by 2012, Malaria Mortality - 50% reduction by 2010, additional 10% by 2012. Kala Azar Mortality Reduction - 100% by 2010 and sustaining elimination until 2012, Filaria / Microfilaria Reduction - 70% by 2010, 80% by 2012, and elimination by 2015, Dengue Mortality Reduction - 50% by 2010 and sustaining at that level until 2012, Cataract operations - increasing to 46 lakh until 2012, Leprosy Prevalence Rate - reduce from 1.8 per 10,000 in 2005 to less than 1 per 10,000 thereafter, Tuberculosis DOTS - maintain 85% cure rate through entire Mission Period and also sustain planned case detection rate, Upgrading all health establishments in the district to Indian Public Health Standards (IPHS), Increase utilization of First Referral units from bed occupancy by referred cases of less than 20% to over 75%, Over 5 lakh ASHAs, one for every 1,000 population/large habitation, in 18 Special Focus States and in tribal pockets of all states by 2008, All Sub - centres (nearly 1.75 lakh) functional with two ANMs by 2010, All Primary Health Centres (nearly 30,000) with three staff nurses to provide 24x7 services by 2010, 6,500 Community Health Centres strengthened/established with seven specialists and nine staff nurses by 2012, 1,800 Taluka/Sub Divisional Hospitals and 600 District Hospitals strengthened to provide quality health services by 2012, Mobile Medical Units for each District by 2009, Functional Hospital Development Committees in all CHCs, Sub Divisional Hospitals, and District Hospitals by 2009, Untied grants and annual maintenance grants to every SC, PHC, and CHC released regularly and utilized for local health action by 2008, All District Health Action Plans

completed by 2008.

The main focus in NRHM would be on (a) Decentralized village and district level health planning, (b) Appointment of Accredited Social Health Activist (ASHA) - "women, resident of the concerned village, married / widow / divorced, 25 - 45 years age, formal education up to 8th, to be selected out of a panel by village health and action committee of Gram Sabha". Norm would be 1 per 1000 population, (c) Strengthening the public health service delivery system, particularly at village, primary and secondary level, (d) Mainstreaming of AYUSH (Indian Systems of Medicine), (e) Improved management capacity in health systems, (f) Emphasizing evidence based planning and implementation, (g) Prompting non - profit factor to increase social participation, promoting health behaviors and improving intersectoral convergence. Supplementary Strategies are (a) Regulation of private sector to improve equity and reduce "out of pocket" expenses, (b) Foster Public - Private Partnership (PPP) to meet national public health goals, (c) Re - orientation Of Medical Education (ROME), (d) Raising health security / insurance for the poor.

At centre level there will be Mission Steering Group (MSG) headed by the Union Minister for Health & Family Welfare and an Empowered Programme Committee (EPC) headed by the Union Secretary for Health & FW. At state level State Health Mission headed by the Chief Minister of the State and will have minister of health and family welfare, state government and principal secretary (Family Welfare) plus 5 - 8 non - official members. At district level, district health mission with Chairman Zilla Parishad, District Collector / DM, CEO Zilla Parishad and Chief Medical Officer/ CMHO/ Civil Surgeon as its members. The delivery system is through strengthening health system.

Janani Suraksha Yojana is 100% centrally sponsored and integrates cash assistance with maternal care. It is funded through the flexi - pool mechanism. *Low Performing States* (LPS) beneficiaries are all pregnant women; cash assistance in rural areas is Rs 1400 and Rs 600 for the mother & ASHA respectively; in urban areas it is Rs. 1000 & Rs 200 respectively. *High Performing States* (HPS) : cash assistance for the mother in rural areas is Rs 700 and in urban areas it is Rs. 600. Beneficiaries are all pregnant ladies below poverty line.

The National Urban Health Mission (NUHM) will meet health needs of the urban poor, particularly the slum dwellers, by making available to them essential primary health care services. The organisation would be At the state level : the State Health Mission, State Health Society and Directorate; and

State and Urban Health Programme Committee. At the district level - District Urban Health Committee At the city level - A Health and Sanitation Planning Committee. At the ward slum level - Slum Cluster Health, Water and Sanitation Committee.

NUHM would ensure Resources for addressing the health problems in urban areas, especially among urban poor, need based city specific urban health care system to meet the diverse health needs of the urban poor and other vulnerable sections, Partnership with community for a more proactive involvement in planning, implementation, and monitoring of health activities, Institutional mechanism and management systems to meet the health - related challenges of a rapidly growing urban population, Framework for partnerships with NGOs, charitable hospitals and other stakeholders, Two - tier system of risk pooling : (i) women's Mahila Arogya Samiti to fulfil urgent hard - cash needs for treatments; (ii) a Health Insurance Scheme for enabling urban poor to meet medical treatment needs.

Study Exercises

Long Question : How does NRHM envisage to achieve goals of NHP - 2002 ?

Short Notes : (1) Key components of NRHM (2) Specific targets of NRHM (3) JSY (4) Functions of ASHA.

MCQs

1. NRHM was launched in (a) Apr 2005 (b) Mar 2006 (c) Nov 2003 (d) Dec 2004
2. According to NRHM IMR should be less than ___ per 1000 live births by 2012 (a) 30 (b) 28 (c) 32 (d) 35
3. According to NRHM MMR should be less than ___ per 1000 live births by 2012 (a) 1 (b) 2 (c) 1.5 (d) 3
4. According to NRHM Dengue mortality should be reduced by ___ by 2010 (a) 40% (b) 50% (c) 75% (d) 60%
5. According to NRHM target for cataract operation by the year 2012 (a) 40 lakh (b) 46 lakh (c) 51 lakh (d) 55 lakh
6. One ASHA is for _____ population in plain areas (a) 700 (b) 1000 (c) 300 (d) 1500

Answers : (1)a; (2)a; (3)a; (4)b; (5)b; (6)b.

Puja Dudeja & Ashok K. Jindal

The International Conference of Population and Development (ICPD) at Cairo in 1994 was the basis for the launch of RCH programme in our country in 1997. The RCH Programme is an umbrella programme to provide need based, client centered, demand driven, high quality services the beneficiaries with a view to enhancing the quality of reproductive life of the population and enabling country to achieve the population stabilization. The vision is to bring about outcomes as envisioned in the Millennium Development Goals, the National Population Policy 2000 (NPP 2000), the Tenth Plan document, the National Health Policy 2002 and Vision 2020 India, minimizing the regional variations in the areas of reproductive and child health and population stabilization through an integrated, focused, participatory program, meeting the unmet demands of the target population and provision of assured, equitable, responsive quality services. The programme now intends to gradually make a shift to address the entire gamut of women's health issues. The program will pay substantially more attention on the 8 states, (Empowered Action Group: EAG states) lagging behind in population stabilisation efforts viz. Bihar, Chattisgarh, Jharkhand, Madhya Pradesh, Orissa, Rajasthan, Uttar Pradesh & Uttaranchal. The programme also focuses on universalisation of immunization, ante-natal care, skilled attendance during delivery and other features of common childhood care.

Definition

World Health Organization (WHO) has defined reproductive health as follows:

Within the framework of WHO's definition of health as a state of complete physical, mental, and social well-being, and not merely the absence of disease or infirmity; reproductive health addresses the reproductive processes, functions and systems at all stages of life. Reproductive health therefore implies that people are able to have a responsible, satisfying and safe sex life and that they have the capability to reproduce and the freedom to decide, if when, and how often to do so(1). This definition focuses on right of men and women to be informed of and to have access to safe, effective, affordable, and acceptable methods of fertility regulation of their choice, and the right to access to appropriate health care services that will enable women to go safely through pregnancy and childbirth and provide couples with the best chance of having a healthy infant.

Accordingly, RCH - I was launched in 1997 as a part of 9th plan, while RCH - II was launched in 2002 as a part of 10th five year plan. Many lessons have been learned from RCH Phase I. The design of RCH Phase II specifically seeks to address the lessons learnt from RCH Phase I to effectively reach the national long-term goals through flexible, cohesive and strategic planning.

Essential Components of RCH-II Programme

The essential components of RCH - II programme (8) are illustrated in Fig. - 1. The individual components are discussed in detail herewith (See Table - 1).

Population Stabilization

The details of national family planning programme have been given in another chapter, in this book, on national health policy and national population policy (1-6) and you are advised to refer to the same.

Unmet need for family planning, 'which refers to the condition of wanting to avoid or postpone childbearing but not using any method of contraception' has been a core concept in international population for more than three decades(10). Unmet need for contraception arises from several reasons, such as weak motivation, low female autonomy, perceived health risks, and moral objection to the use of contraception. On a nationwide basis the family planning program currently offers five modern contraceptive options. The methods currently available for spacing are - oral contraceptive pills, condoms and intra-uterine devices. Male and female sterilization is often used for limiting family size.

Expanding contraceptive choices in RCH Phase II : International evidence shows that increasing the availability of method choice increases acceptance rates. It is estimated that every additional method increases the contraceptive prevalence rate by 12%. A wider contraceptive choice, including natural methods, helps meet the changing needs of couples during their lives. Multiple methods make switching easier, reduce method-specific discontinuation, and improve user satisfaction. Contraceptive choice can be expanded both by adding new methods to the existing range as well as increasing access to the services providing the choice. The details of contraceptives are dealt with in an exclusive chapter in the section on family health.

Table- 1: RCH Phase II - Improvements over RCH Phase I (9)	
Lessons learnt from RCH I	Corrective Measures in RCH II
Limited involvement of states and limited ownership by states of RCH Phase	States will prepare plans linked to clear outcomes after assessing their own priorities, allowing a needs-based state-specific plan to be developed.
Pace of implementation slow	Bottlenecks to fund flows will be removed by simplifying processes.
Low utilization of public health facilities	This has been diagnosed as being due to users' perceptions of low quality, frequent service unavailability and low acceptability of some services. This will be addressed through preservice and in-service training, with a particular focus on provider attitudes and making services more users friendly.
Infrastructure to be completed within the project time frame	Outsourcing will be undertaken with agreed institutional mechanisms to manage infrastructure and to ensure accountability and delivery of reliable and quality services. The processes of managing and construction of infrastructure will be simplified.
Limited management capacity	There will be a lateral infusion of skilled personnel to improve the management capacity structure at the national, state and district levels, with clearly defined functional responsibilities and roles.
Need to incorporate the system of smooth flow of funds	Financial management systems will be built into the program management structure.
RCH Phase I was implemented as a project; there was a need to incorporate well-defined outcome indicators	RCH is visualized as a long-term program, oriented towards achieving ambitious, but realistic health outcomes and improvements
RCH Phase I had a "one size fits all" design	States will have different requirements, levels of performance and capacities and will be able to take these into account when designing their state PIPs. Such a differential approach may be extended to the district level depending upon the performance of districts.
Need to move away from "stand alone" public health approach	RCH Phase II will adopt a program approach, bringing in key elements of sector management and reform and strengthening of systems.
RCH Phase I focused almost exclusively on the supply side	Whilst RCH Phase II necessarily includes supply side strategies, these will be complemented by an integrated and robust strategy to stimulate demand for services.
RCH Phase I was centrally designed with little consultation	RCH Phase II has been designed after wider consultation.

Strategies to expand contraceptive choice in RCH Phase II

- 1. Expanding the range of FP services:** Each CHC and PHC having an OT (operation theatre) facility will have at least one Medical Officer trained in one method of sterilization.
- 2. Improving and integrating RCH services in PHCs and sub-centers:** The capacity of Lady Health Visitors (LHVs) and Auxiliary Nurse Midwives (ANMs) will be built through skill-based clinical training for spacing methods including IUCD insertion and removal, lactational amenorrhea method (LAM), standard days method (SDM) and emergency contraception (EC). They will also be trained in infection prevention, counseling and follow-up for different family planning methods.
- 3. Training of District Hospital/CHC/PHC staff to offer an expanded choice of services:** Training providers to offer LAM, SDM, EC and injectables will help to increase the range of choice and ensure quality services and follow-up for clients.
- 4. Forging linkages with the ICDS division of women and child development department.**
- 5. Engaging the private sector to provide quality family planning services.**
- 6. Stimulating demand for quality family planning services**

by increasing compensation and by using media.

7. Involving Panchayati Raj Institutions, Urban Local Bodies and NGOs.

Maternal Health

The programme envisages a holistic strategy for bringing about a total intersectoral coordination at the grass root level and involving the NGOs, Civil Societies, Panchayati Raj Institutions and Womens' group in bringing down maternal mortality rate. The National Population Policy 2000 and National Health Policy 2002 have set the goal of reducing MMR to less than 10 per 100,000 live births by the year 2010(11). The maternal mortality rate in India is 301 per 100,000 live births (SRS, RGI 2001-03 Maternal Mortality Report). Various schemes under the programme are as under:

Essential Obstetric Care : The complete package of essential obstetric care includes antenatal care, institutional/ safe delivery services & postnatal care. It has been seen that a total of three antenatal checkups to be conducted where all components of essential obstetric care can be provided.

Provision of 24 hrs Delivery Services at PHC : Under RCH II all the CHCs and 50% of the proposed PHCs will be providing

round the clock delivery services.

Postnatal care for mother and new born: To ensure postnatal care within 24 hours of delivery and subsequent home visits on day 3 and 7 are the important components for identification and management of emergencies occurring during post natal period. The ANMs, LHVs and the staff nurses are being made aware of and also oriented for tackling these emergencies identified during these visits.

Skilled Attendance at Birth: To manage and handle some common obstetric emergencies at the time of birth the staff has been trained to give certain injections and perform certain interventions in emergency to save life.

Provision of Emergency Obstetric and Neonatal Care at First Referral Unit (FRU) : There are three critical elements of a facility being declared as FRU. They are availability of surgical interventions, newborn care and blood storage facility on a 24 hr basis.

Referral Services at both Community and Institutional level: Establishing referral linkages between the community and FRUs is an essential component for utilization of services particularly during emergencies. Since emergencies during the process of birth can not be predicted, it is essential to place effective referral linkages which can be accessed by all pregnant women in case of emergency.

Setting of Blood Storage Centers at FRUs : Timely treatment of complications associated with pregnancy is sometimes hampered due to non availability of Blood Transfusion services at FRUs. The drugs and cosmetics act has been amended to facilitate establishment of Blood Storage Centers at such FRUs.

Training of MBBS Doctors in Life Saving Anesthetics Skills for Emergency Obstetric Care : Provision of adequate and timely Emergency obstetric care has been recognized globally as the most important intervention for saving lives of pregnant women who may develop complications during pregnancy and child birth. It has not been possible till now due to lack of specialist man power gynecologist and anesthetist particularly at the district and subdistrict level. In view of above, a 18 weeks programme for training MBBS doctors in anesthetic skills has been started by govt. but at the same time it will not be a replacement of specialist.

Obstetric Management skills : GOI has also introduced training of MBBS doctors in obstetric management skills and has prepared a 16 weeks training programme in obstetric management skills including cesarean section operation.

Safe Abortion Services/ Medical Termination of Pregnancy (MTP) : Two thirds of all abortions take place outside the authorized health services by unauthorized often unskilled providers. Eight percent of all maternal deaths are due to complicated abortions. This is a preventable tragedy and an indication of unmet need for abortion. Provision of 24x7 MTP services at PHCs, CHCs and FRUs are being strengthened by training of medical manpower in techniques of MTP by the states. Following Strategies are being implemented:

Community Level

- Spread awareness regarding safe MTP in the community and the availability of services thereof

- Enhance access to confidential counseling for safe MTP, train ANMs, AWWs and link workers/ ASHA and AWWs while maintain confidentiality

Facility Level

- Provide quality Manual Vacuum Aspiration) facilities at all CHCs and at least 50% of PHCs that are being strengthened for 24 hrs deliveries
- Provide comprehensive and high quality MTP services at all FRUs
- Encourage private and NGO sectors to establish quality MTP services

Other interventions for improving maternal health

National Nutritional Anemia Prophylaxis Program (Now under RCH) : As per NFHS III, 56.1% of ever married women aged 15-49 yrs are anemic. The problem is more severe during pregnancy with 57.8% being anemic. A program for prophylaxis and treatment of nutritional anemia has been under implementation in the country since 1997-98. Under this programme all pregnant and lactating women are provided with one tablet (containing 100 mg of elemental iron and 0.5mg Folic acid) for 100 days. Those who have severe anemia are provided with double dose of these tablets; and health education apart from other services.

Village Health and Nutrition Day : Organizing village health and nutrition day at Anganwadi center at least once a month to provide antenatal / postpartum care for pregnant women, promote institutional delivery and health education apart from other services.

Janani Suraksha Yojana (JSY) : It is a safe motherhood intervention under NRHM being implemented with the objective of reducing maternal and neonatal mortality by promoting institutional delivery among the poor pregnant women. It was launched on 12 April 2005 and is being implemented in all states and is a 100 % centrally sponsored scheme. The main element in the *yojana* is ASHA who will act as a link between govt and the poor pregnant woman. She is to facilitate pregnant women to avail services of maternal care and to arrange for transport services. Cash assistance will be given both to the mother and ASHA worker on getting an institutional delivery.

Reproductive Tract Infections (RTIs) and Sexually Transmitted Diseases (STDs)

RTIs and STDs were not recognized as a public health problem till recently. The spread of HIV infection and the role that RTI / STD play in the transmission of HIV have brought urgency to the problem. Strategies under RCH II are :

1. The prevention, early detection and effective management of common lower reproductive tract infections have been included as a component of essential care through the existing primary health care infrastructure.
2. Convergence with National AIDS Control Programme is envisaged in provision of these services, in terms of utilization of these services for case management, laboratory services, counseling services, drugs, equipment, blood safety etc.
3. Under RCH II programme there is a commitment for implementing the RTI/STI services at the sub district level i.e. in 50% of the PHCs and all FRUs, including drugs,

training, disposable equipment and provision of laboratory technicians.

- National Guidelines for management of RTIs and STDs have been developed and disseminated to the states.

Newborn and Child Health

Under RCH II, the activities being undertaken to achieve the NRHM goals under newborn and child health are:

- Integrated Management of newborn and childhood illnesses
- Home Based Newborn Care(HBNC)
- Promotion of breastfeeding and complementary feeding
- Control of deaths due to ARI
- Control of Deaths due to Diarrhoeal Diseases
- Supplementation with micronutrients
- Universal Immunization Programme

Integrated Management of newborn and childhood illnesses: India is faced with an unparalleled challenge in the area of child survival and health. The country contributes 2.4 million of the global burden of 10.8 million under-five child deaths, which is the highest for any nation in the world. Nearly 26 million infants are born each year, of whom 1.2 million die before completing the first four weeks of life and 1.7 million die before reaching the first birthday.

Why integrated approach? Many well-known prevention and treatment strategies have already proven effective for saving young lives like Childhood vaccinations, Oral rehydration therapy, Effective antibiotics for pneumonia, Prompt treatment of malaria, breastfeeding practices etc have reduced childhood deaths. While each of these interventions has been successful, accumulating evidence suggests that an integrated approach is needed to manage sick children to achieve better outcomes. Because many children present with overlapping signs and symptoms of diseases, a single diagnosis can be difficult, and may not be feasible or appropriate. This is especially true for first-level health facilities where examinations involve few instruments, negligible laboratory tests, and no X-ray.

History : During the mid-1990s, the World Health Organization (WHO), in collaboration with UNICEF developed a strategy known as the Integrated Management of Childhood Illness (IMCI). This strategy has been expanded in India to include all neonates and renamed as 'Integrated Management of Neonatal and Childhood Illness (IMNCI)'. India has included care of new born and has modified generic IMCI and named it as IMNCI.

The differences are given in Table-2.

Components:

- Improvements in the case-management skills of health staff through the provision of locally-adapted guidelines on Integrated Management of Neonatal and Childhood Illness and activities to promote their use;
- Improvements in the overall health system required for effective management of neonatal and childhood illness;
- Improvements in family and community health care practices.

(Details of IMNCI are discussed in a chapter exclusively in the section on family health)

Home Based New Born Care : The Govt of India has approved the implementation of home based new born care where ASHAs will be trained in identified aspects of new born care during the second year training. The underlying principle of effective care at birth is that wherever an infant is born, home or facility, he/ she is provided clean care, warmth, resuscitation, and exclusive breastfeeding. He/she is weighed and examined, and if the clinical needs are not manageable at the place of delivery, he/she is referred and managed at an appropriate facility. A large proportion of deliveries would continue to occur at homes by the TBAs for some more years to come, especially in the EAG states. It is therefore, considered desirable to continue to impart newborn care skills to TBAs in areas with high rates of home deliveries. They will also be provided clean delivery kits. At the same time, the overall effort would be to promote childbirth by skilled birth attendants and in institutions, both in the public and private sector. Interventions for newborn have been summarized in Table-3.

Promotion of Breast Feeding and Complementary Feeding: Revival of the Baby Friendly Hospital initiative (BFHI) has been approved and implementation shall be initiated.

Control of Deaths due to Acute Respiratory Infections (ARI): Acute respiratory infections (ARI) in children can involve the upper respiratory tract (nose, throat) or the lower respiratory tract (bronchi, lungs). The lower respiratory tract infections (broadly termed as pneumonias) are a major cause of deaths of infants and children in India accounting for about 30% of under-five deaths. The actual deaths are much higher as many children die at home (12). Timely treatment based on well-researched algorithms can save most children with ARI. The ARI control program was initiated as a pilot project in

Features	Generic IMCI	India IMNCI
Coverage of 0-6 days (early new born period)	No	Yes
Basic health worker module	No	Yes
Home visit module by provider for care of newborn and young infant	No	Yes
Sequence of training	Child first then young infant	New born/Young infant first then child
Home-based training	No	Yes
Duration of training on Newborn/young infant	2 to 11 days	4 to 8 days
Sequence of training	Child first then young infant	New born/Young infant first then child

Table-3: Interventions for newborn care		
Level	Interventions	Key Players
Home and Community level	ANC : Focus to be on enhancing coverage among the poor and marginalized women, improving quality and promoting institutional deliveries, birth preparedness and care seeking for danger signs.	ANMs, AWWs
	Skilled care at birth : Institutional deliveries to be promoted through <i>Janani Suraksha Yojana</i> involving TBA; deliveries by ANMs to be encouraged ; piloting Community Skilled Birth Attendant (C-SBA) program to be completed; in populations where access to skilled birth attendants or institutional deliveries not available, clean deliveries by trained TBAs to be accepted.	ANMs, C-SBAs TBAs
	Home - based newborn and post-partum care : Using IMNCI protocol, AWWs to provide home-based care neonates with emphasis on warmth, breastfeeding, prevention of infection, extra care of LBW infants, early detection of sickness; at least three contacts in the first week of life stipulated starting with the first day, extra contracts for LBW and sick neonates ; maternal post-partum care also provided healthy family practices; TBAs to reach neonates and mothers and promote healthy family practices; ANMs to supervise, especially the care of LBW and sick babies and mothers.	AWWs supervised by ANMs ; TBAs
	Community - based management of sick neonates : Using IMNCI protocols, ANMs to assess neonates with sickness and manage mild/moderate sickness.	ANMs
	Referral of sick mothers and neonates : Funds for referral transport to be made available at village level, communities to be encouraged to map facilities and development mechanisms, AWWs and TBAs to facilitate referrals.	Families communities, AWWs, TBAs
	Behaviour Change Communication (BCC) : BCC strategy to aim at promoting early and complete ANC, institutional deliveries birth preparedness recognition and early care-seeking for maternal and neonatal danger signs, healthy newborn and maternal care practices.	Community, media, ANMs, AWWs, TBAs
Facility level	<p>PHCs/CHCs</p> <ul style="list-style-type: none"> 50% of PHCs (1000) and all CHCs (600) to be upgraded to provide ; 24 hour basic emergency obstetric care (EmOC) and inpatient care to inborn and outborn sick neonates and children; outpatient IMNCI to be implemented, neonatal, antenatal and post-partum care to be strengthened. Rest of the PHCs to provide antenatal care ANC, outpatient IMNCI and post-partum care. 	Nurse, ANMs LHVs, MOs

14 districts in the country in 1990. In 1992, the ARI control strategy became a part of CSSM program, which continued into the RCH Phase I project in 1997. Co-trimoxazole tablets are being provided at subcenters and above. ANMs are being trained to treat children with ARI.

Control of Deaths due to Diarrhoeal Diseases : Diarrhoeal diseases account for 17 percent of under five mortality in post neonatal period, and 3 percent of neonatal deaths(13). The Oral Rehydration Therapy (ORT) program was started in 1986-1987. The main objective of the program was to prevent deaths due to dehydration caused by diarrhoeal disease. Health education aimed at rapid recognition and appropriate management of diarrhoea has been a major component of the CSSM and RCH Phase I project. ORS packets are provided at sub-centers as part of the drug kit-A, under the RCH program. The use of home available fluids and ORS has resulted in a substantial decline in the mortality associated with diarrhoea from an estimated 1.0 -1.5 million children every year prior to 1985 to six to seven lakh deaths in 1996. In addition, social marketing and supply of ORS through the public distribution system is being done in some states.

Supplementation with micronutrients : National Programme for Prophylaxis against Blindness in Children caused due to Vitamin A deficiency is being implemented through RCH programme (See Box - 1). The objectives are to decrease the prevalence of Vit A deficiency to 0.3%.

Anemia among Children : Iron deficiency anaemia is widely prevalent in young children. NFHS II (1998-99) revealed that 74.3% children under the age of three years are anemic. *Under the National Nutritional Anemia Prophylaxis Program* (now part of RCH) Iron & Folic acid tablet containing 20 mg of elemental Iron and 0.1mg of Folic acid are provided at sub center level. 100 tablets are given to children who are clinically anemic. As per the revised policy, infants between 6-12months of age are also included in the program as a significant proportion of these infants are anemic. For children aged 6-60 months, Ferrous sulphate and Folic acid is to be provided in a liquid formulation. For safety sake liquid formulation should be dispensed in bottles so designed that only 1ml can be dispensed each time. School children 6-10yrs of age are also included in the programme. Children 6-10 yrs are to be provided 30 mg of elemental Iron 250mcg and Folic acid per child per day for 100

Box - 1 : Strategy for National Programme for Prophylaxis against Blindness in Children due to Vit 'A' deficiency		
Infancy	Childhood	Sick Children
Health and nutrition education is being taken up to encourage colostrums feeding, exclusive breastfeeding for the first six months and the introduction of complimentary feeding thereafter 1,00,000IU of Vitamin A is being given at nine months	<ul style="list-style-type: none"> Health education efforts to ensure adequate intake of vitamin A rich food throughout childhood Early detection and prompt treatment of infections Vitamin A dose of 1,00,000IU at nine months and 2,00,000IU thereafter at six monthly intervals up to three years of age 	<ul style="list-style-type: none"> All children with xerophthalmia to be treated at health facilities All children suffering from measles to be given one dose of vitamin A if they have not received it in the previous one month All cases of severe malnutrition to be given one additional dose of vitamin A

days. Adolescents are to be supplemented in the same dosage and duration as adults.

Universal Immunization Programme : National Immunization schedule is given in Table - 4. The impact of the UIP is measured in terms of Vaccine Preventable Diseases (VPD) burden. Over the last 15 years there has also been a general decline in the reported number of cases of the six main VPD. Despite the improvement indicated above, the stated goals were not fully achieved, thus there is an urgent need to address the immunization system deficiencies and emphasize the need for strengthening the system and vigilant monitoring and surveillance.

Table - 4 : National Immunization schedule	
Age	Vaccines
Birth	BCG, OPV
6 Weeks	DPT, OPV, Hepatitis B
10 Weeks	DPT, OPV, Hepatitis B
14 Weeks	DPT, OPV, Hepatitis B
9 months	Measles
16-24 months	DPT (1 st Booster), OPV
5 years	DPT (2nd Booster)
10 years	TT
Pregnant unimmunized	2 doses of TT with one month interval
Pregnant immunized	One booster dose of TT

Urban Measles Campaign : A special campaign was staged for slum areas in 1998 with assistance from UNICEF. In 1999-2000, 50 cities were covered. The emphasis is on covering all unprotected children up to age of 3 years with single dose of measles vaccine.

Neonatal Tetanus elimination : All women in reproductive age group should be covered with three doses of tetanus toxoid vaccine through a campaign approach. Such campaigns have been implemented in Rajasthan and Madhya Pradesh to achieve early elimination of neonatal tetanus.

Adolescent Health

Adolescents (10-19 years) in India represent almost one-third of the population. A large number of them are out of school, get married early, work in vulnerable situations, are sexually active, and are exposed to peer pressure. Some of the public health challenges for adolescents include pregnancy, excess

risk of maternal and infant mortality, sexually transmitted infections and reproductive tract infections in adolescence, and the rapidly rising incidence of HIV in this age group. In context of the RCH program goals, with special reference to reduction in IMR, MMR and TFR, addressing adolescents in the program framework will yield dividends in terms of delaying the age at marriage, reducing the incidence of teenage pregnancy, the prevention and management of obstetric complications including safe abortion services and the reduction of unsafe sex.

Strategy for addressing Adolescent Reproductive and Sexual Health (ARSH) in RCH Phase II : It is proposed to provide adolescent health services through the existing subcenters/PHCs and CHCs (See Table-5).

Initiatives for vulnerable groups

Vulnerable communities include those groups who are underserved due to problems of geographical access, (even in better off states) and those who suffer from social and economic disadvantages such as Scheduled Castes/Scheduled Tribes (SCs/STs) and the urban poor. Scheduled caste people (166.6 million) and scheduled tribe people (84.3 million) in India are considered to be socially and economically the most disadvantaged group. The SCs constitute 16.2% and STs 8.2% of the country's population (as per the 2001 Census). The RCH indicators for these groups of people are worse than the urban average due to following reasons:

- Poor connectivity to health centers because of distance, topography, and lack of public transport
- Lack of flexibility and reduced responsiveness to local diversity and needs
- Lack of appropriate Human Resource Development (HRD) policy to encourage/motivate the service providers to work in remote and tribal areas

Goals : To improve the health status of the vulnerable population by ensuring accessibility and availability of quality primary health care and family welfare services to them.

Objectives : The objectives of the Vulnerable Plan are :

- To improve accessibility, availability and acceptability of health services including RCH services by strengthening infrastructure including training and skill development of service providers, improving the supply of equipment, drugs etc. in an integrated and participatory manner
- To bring them at par in this respect with the rest of the population, and thus improving the aggregate indicators towards achieving the expected results set under RCH Phase II by the end of 2010.

Table - 5: Services to adolescents under RCH II			
Level of Care	Service Provider	Target Group	Services
Sub center	HW (F)	Unmarried & Married Females and males	<ul style="list-style-type: none"> ● Enroll newly married couples ● Provision of spacing methods ● ANC care & institutional delivery ● STIs/HIV prevention ● Anemia prevention
PHC/CHC	Health Assistant (F)/ LHV/ MO	Unmarried & Married Females and males	<ul style="list-style-type: none"> ● Contraceptives ● Management of menstrual disorders ● RTIs education and management ● Nutritional counseling and management of anemia ● Counseling and services for MTP

For tribal population and urban poor, separate health plans addressing specific needs of these groups have been made.

Mainstreaming Gender and Equity in RCH Phase II

In India there is significant disparity in health care utilization and health status between women and men. Poor women consume less health care resources and suffer worse health than men and a large and increasing share of health expenditure by poor people is taking place outside of the public sector. The aim of mainstreaming gender is to correct imbalances between the position of men and women in terms of access to resources and benefits as well as to understand the differences in terms of health status and health determinants. The RCH Phase II equity objective is to reduce the health inequities both between geographical areas and between social groups, and to respond to the needs of vulnerable populations.

Funds Flow Arrangement for RCH Program and Management of Funds

There are two routes through which the MoH&FW, GoI transfers funds to the state/Union Territory governments for implementation of the RCH program. Funds mainly for salary and grants-in-aid to institutions and purchase of contraceptives for social marketing are routed through state treasuries, while funds for other activities and a few selective components are provided through the State Committee on Voluntary Action (SCOVA) / state RCH /FW/Health Society, most of the funds for the day-to-day running and implementation of the RCH program are passed on to these societies directly by the MoH&FW, GoI.

Monitoring and Evaluation

A comprehensive integrated Health management information system will be functional in RCH - II. Community Need Assessment and Monitoring Approach (CNAMA) will be used. The work plans for a particular year will originate from the sub center level under each PHC and are subsequently aggregate with appropriate additions at the CHC and district levels. Based on district action plans, aggregated state action plans are prepared at the state headquarters with appropriate additions. A similar reporting system will be followed for the monthly progress reports.

Strengths

RCH II is an integrated and vast programme to address the

challenges of maternal and child health. The umbrella of RCH covers family planning, ORT, RTI, STD and CSSM. It has a participatory approach of all communities including ISM practitioners, Dais, opinion leaders, NGOs apart from intersectoral coordination of Govt. The programme lays great emphasis on training, IEC and research and development activities related to RCH. Procurement procedures and audit arrangements have been streamlined to ensure uniformity in accounting. The modern system of Management Information and evaluation will ensure accountability, especially at district level. Lessons learnt from RCH I have

been tackled well in RCH II. There is a scope for a separate plan for each state. The services are client-centered, demand driven and based on the needs of the community. Up gradations of level of facilities will contribute in reducing maternal and child mortality. Successful implementation will also provide out reach services to the vulnerable groups of population such as urban slums, tribal population and adolescents. Due to overlapping of expenditures there will be a reduction in costs inputs.

Critical appraisal

The goals set up in RCH II to be met by 2010 seem difficult to be met. It is well known that socioeconomic development is the biggest contraceptive. There has been no mention of socioeconomic development in population stabilization. Implementation of such a vast program on ground seems difficult. The contraceptive basket has very little to offer for the males. The appropriate technology of seven cleans during delivery has lost its importance. There is actually physical shortage of manpower in health institutions at the periphery. To add to this there is also shortage of kits, drugs, vaccines and contraceptives. Referral system and feedback are not smooth when real time implementation on ground takes place. With the launch of National Rural Health Mission (NRHM) the govt desires that RCH II to be implemented under NRHM which has created lot of confusion in the minds of middle level managers.. The algorithm for implementing IMNCI is very exhaustive and it will be difficult to be implemented by the grass root level worker.

Summary

India was the first country to have launched a Family Planning Programme in 1951 and again it is the first one to have converted the guidelines of International Conference of Population Development at Cairo in 1994 in the form of Reproductive and Child Health Programme (RCH) in 1997. RCH finished its Phase I and entered Phase II in 2002. The goals of RCH II are to reduce Infant Mortality rate to < 30/1000 and Maternal Mortality Ratio to <100/100,000 and attain a Total Fertility Ratio of 2.1. The immediate objective is to meet the unmet need of contraception, health care infrastructure and health personnel; medium term objective of attaining a Total Fertility Ratio of replacement level by 2010 : long term objective

of achieving population stabilization by 2045.

RCH II has been planned on the basis of lessons learnt from RCH I. Components of RCH II are Population Stabilization, Maternal Health, Reproductive Tract Infections (RTIs) and Sexually Transmitted Infections (STIs), Newborn and child health, Adolescent health, Initiatives for vulnerable groups, Mainstreaming gender and equity, Strengthening Systems and Partnerships.

To attain population stabilisation RCH II offers Expanding contraceptive choices in the form of injectables, non steroidal oral contraceptive, female condoms, Lactational amenorrhoea, safe days method and Non scapel Vasectomy.

For improving maternal health, various schemes as Essential Obstetric care, Provision of Emergency Obstetric and Neonatal Care at First Referral Unit (FRU), Safe Abortion Services/ Medical Termination of Pregnancy (MTP) and *Janani Suraksha Yojana* (JSY) have been started.

Prevention, early detection and effective management of common lower reproductive tract infections have been included. Guidelines for same have been made. Under RCH II, the activities being undertaken to achieve the NRHM goals under newborn and child health are : Integrated Management of newborn and childhood illnesses, Home Based Newborn Care (HBNC), Promotion of breast feeding and complementary feeding, Control of deaths due to ARI, Control of Deaths due to Diarrhoeal Diseases, Supplementation with micronutrients, Universal Immunization Programme. Integrated Management of newborn and childhood illnesses aims at training the health staff to refer/treat patient at out patient facility/ home based care, of neonates and children up to five years of age. Co-trimoxazole tablets are being provided at subcenters to control deaths due to Acute Respiratory Infections (ARI) and ORS packets are being provided to Control Deaths due to Diarrhoeal Diseases.

National Programme for Prophylaxis against Blindness in Children caused due to Vitamin A deficiency is being implemented through RCH programme. The objectives are to decrease the prevalence of Vit A deficiency to 0.3%. National Nutritional Anemia Prophylaxis Program is also now part of RCH. Iron and Folic acid tablets are being distributed to Children, adolescents and pregnant ladies. Under this programme all pregnant and lactating women are provided with one tablet (containing 100 mg of elemental iron and 0.5mg Folic acid) for 100 days. Those who have severe anemia are provided with double dose of these tablets health education apart from other services. For children Iron and Folic acid tablet containing 20 mg of elemental iron and 0.1mg of Folic acid are provided at sub center level. 100 tablets are given to children who are clinically anemic. As per the revised policy, infants between 6-12months of age are also included in the program as a significant proportion of these infants are anemic. For children 6-60 months, ferrous sulphate and Folic acid is to be provided in a liquid formulation. For safety sake liquid formulation should be dispensed in bottles so designed that only 1ml can be dispensed each time.

School children aged 6-10 yrs of age are also included in the programme. Children aged 6-10 yrs are to be provided 30 mg of elemental Iron and 250 mcg Folic acid per child per day for 100 days. Adolescents are to be supplemented in the same dosage and duration as adults.

Universal immunization programme is also being implemented through RCH and targets 6 vaccine preventable diseases. Recently Hepatitis B vaccination has been included and supply of auto disabled syringes is being ensured for immunisation. Adolescents have been included and are being provided services as dividends in terms of delaying the age at marriage, reducing the incidence of teenage pregnancy, the prevention and management of obstetric complications including access to early and safe abortion services and the reduction of unsafe sexual behavior.

Vulnerable communities include those groups who are underserved due to problems of geographical access, (even in better off states) and those who suffer from social and economic disadvantages such as Scheduled Castes/Scheduled Tribes (SCs/STs) and the urban poor. These have been included in RCH with specific goals and objectives to plans addressing specific needs of these groups. The RCH Phase II equity objective is to reduce the health inequities both between geographical areas and between social groups, and to respond to the needs of vulnerable populations. RCH II is an integrated and vast programme to address the challenges of maternal and child health.

In India today, two deaths occur every three minutes from tuberculosis (TB). But these deaths can be prevented. With proper care and treatment, TB patients can be cured and the battle against TB can be won.

Evolution of Tuberculosis Control in India : See Table - 1

RNTCP : Launch, Expansion and Coverage

National Tuberculosis Control Programme launched in 1962, suffered from weakness in the form of poor managerial control, inadequate funding, over-reliance on x-ray, non-standard treatment regimens, low rates of treatment completion, and lack of systematic information on treatment outcomes (Evolution of Tuberculosis Control in India is given in Table-1) (1). Program reviews showed that only 30% of estimated tuberculosis patients were diagnosed and only 30% of those were treated successfully. The Revised National Tuberculosis Control Programme (RNTCP), based on the DOTS strategy, took its roots in India in 1993 by pilot testing as Phase I project covering a population of about 18 million and was launched as a national Programme in 1997. The expansion began in late 1998 and at end of 2000, 30% of the country's population was covered, and by the end of 2002, 50% of the country's population was covered under the RNTCP (2). By the end of 2003, 778 million and at the end of year 2004, 997 million population was covered. By December 2005, around 97% (about 1080 million) of the population had been covered, and the entire country was covered under Directly Observed Treatment Short course (DOTS) by 24th March 2006(3). In the first phase of RNTCP (1998-2005), the programme's focus was on ensuring expansion of quality DOTS services to the entire country. The RNTCP has now entered its second phase in which the programme aims to firstly consolidate the gains made to date, to widen services both in terms of activities and access, and to sustain the achievements for decades to come in order to achieve ultimate objective of TB control in the country. Phase II of the RNTCP is a step towards achieving the TB-related Millennium Development Goal (MDG) targets. Directly Observed Treatment Short Course - 'DOTS' - remains the core strategy.

The Goal and Objectives of the RNTCP

Goal : The goal of TB Control Programme is to decrease mortality and morbidity due to TB and cut transmission of infection until TB ceases to be a major public health problem in India.

Objectives :

- To achieve at least 85 percent cure rate of the newly diagnosed sputum smear-positive TB patients; and
- To detect at least 70 percent of new sputum smear-positive patients after the first goal is met.

Strategy : DOTS is a systematic strategy which has five components (See Box - 1).

'DOTS' - remains the core strategy; however all components of new *Stop TB Strategy* are incorporated in the second phase of RNTCP. These are:

1. *Pursue quality DOTS expansion and enhancement*, by improving the case finding and cure through an effective patient-centered approach to reach all patients, especially the poor.
2. *Address TB-HIV, MDR-TB and other challenges* by scaling up TB-HIV joint activities, DOTS Plus and other relevant approaches. The guidelines for management of MDR-TB under DOTS-Plus strategy have been developed.
3. *Contribute to health system strengthening*, by collaborating with other health programmes and general services.
4. *Involve all health care providers*, public, nongovernmental and private, by scaling up approaches based on a public-private mix (PPM), to ensure adherence to the International Standards of TB care.
5. *Engage people with TB, and affected communities* to demand, and contribute to effective care. This will involve scaling-up of community TB care; creating demand through context-specific advocacy, communication and social mobilization.
6. *Enable and promote research* for the development of new drugs, diagnostics and vaccines. Operational Research will also be needed to improve programme performance.

RNTCP Structure and Service Delivery Mechanisms

At the center : The Central TB Division (CTD) is responsible for developing technical policies, procuring drugs, preparing training modules, programme and financial monitoring, quality assurance, advocacy, operational research priorities and mobilising funds.

Table 1: Evolution of Tuberculosis Control in India

Year	Remarks
1962	The National TB Control Programme (NTCP) launched. The strategy was based on early detection and treatment thereby converting infectious cases to noninfectious and preventing noninfectious cases from becoming infectious with treatment, Diagnosis through radiology and sputum microscopy, Free Domiciliary treatment through Primary Health Care Services, Establishing District Tuberculosis Centre in every district, Extend coverage under Short Course Chemotherapy (SCC), Strengthen state TB training and demonstration centers
1992	Government of India, together with the WHO and SIDA, reviewed the national programme and concluded that it suffered from various managerial and operational weaknesses. As a result, a Revised National Tuberculosis Control Programme (RNTCP) was designed
1993 -2005	Era of Directly Observed Treatment Short course(DOTS), RNTCP launched
2006-2010	RNTCP Phase II

Box - 1 : Components of DOTS	
1	<i>Political and administrative commitment</i> : It warrants the topmost priority, which it has been accorded by the Government of India. This priority must be continued and expanded at the state, district and local levels.
2	<i>Good quality diagnosis</i> : Good quality microscopy allows health workers to see the tubercle bacilli and is essential to identify the infectious patients who need treatment the most.
3	<i>Good quality drugs and an uninterrupted supply of good quality anti TB drugs</i> : In the RNTCP, a box of medications for the entire treatment is earmarked for every patient registered, ensuring the availability of the full course of treatment the moment the patient is initiated on treatment.
4	<i>Supervise treatment to ensure right treatment</i> : The heart of the DOTS programme is “directly observed treatment” in which a health worker, or another trained person who is not a family member, watches as the patient swallows the anti-TB medicines in their presence.
5	<i>Systematic monitoring and accountability</i> : The programme is accountable for the outcome of every patient treated. This is done using standard recording and reporting system, and the technique of ‘cohort analysis’. The cure rate and other key indicators are monitored at every level of the health system, and if any area is not meeting expectations, supervision is intensified. The RNTCP shifts the responsibility for cure from the patient to the health system.

At the State : The RNTCP is integrated with the general health care delivery systems in the states. At the State level, the State Tuberculosis Officer (STO) is responsible for planning, training, supervising and monitoring the programme in their respective states as per the guidelines of the State TB Control Society or its equivalent (STCS or its equivalent). The STO based at the State TB Cell is administratively answerable to the State Government and technically follows the instructions of the CTD, and coordinates with CTD and the districts for executing the duties mentioned above. The State TB Cell (STC) is responsible for the supervision and monitoring of the programme throughout the state.

At the District : District TB Centre (DTC) is the key organisational unit responsible for the implementation of the programme in the respective districts. The district is the key level for the management of primary health care services. The district level (or municipal corporation level) performs functions similar to those of the state level in its respective area. The Chief District Health Officer (CDHO) / Chief District Medical Officer (CDMO) or an equivalent functionary in the district is responsible for all medical and public health activities including control of TB. The District Tuberculosis Centre (DTC) is the nodal point for TB control activities in the district. In RNTCP, the primary role of the DTC has shifted from a clinical one to a managerial one. The District TB Officer (DTO) at the DTC has the overall responsibility of management of RNTCP at the district level as per the programme guidelines. The DTO is also responsible for involvement of other sectors in RNTCP and is assisted by an MO, Statistical Assistant and other paramedical staff. For each district, there should be a full-time DTO, who is trained in RNTCP at a central level institution.

The DTC is supported by sub-district TB Units (TUs) established for every 5, 00,000 population to serve as a link between the district level and the periphery. The TU is the lowest reporting unit under the RNTCP. At the TUs, a special cadre of dedicated TB supervisory staff, the Senior Treatment Supervisor (STS) and the Senior Tuberculosis Laboratory Supervisor (STLS), have been appointed on a contractual basis for carrying out supervisory work in the field under the charge of a Medical Officer-TB Control. To further decentralise the diagnostic and

treatment services, RNTCP Designated Microscopy Centres (DMCs) have been established for every 1, 00,000 population. Norms for the establishments of TUs and DMCs are relaxed to 2, 50,000 and 50,000 population respectively in hilly/difficult and tribal areas. In addition, a vast network of DOT centres (treatment centres), all with trained DOT providers, have been established in all RNTCP areas so that patients can have easy access to TB treatment. In addition, there are 17 State TB Training and Demonstration Centres (STDCs) which act as technical support units to the respective STC. Responsibilities of the STDCs include assisting the STC in training, supervision and monitoring of the programme, quality assurance of the RNTCP sputum microscopy services, advocacy and IEC, and operational research. The level of involvement of the STDCs, however, varies from state to state. Release of programme funds from the centre to the state and districts is channeled via the state and district TB control societies. State and district societies make decisions on budget formulation according to guidelines from the centre, hire contractual staff, purchase necessary items, oversee programme planning, implementation and monitoring, and perform other functions which greatly facilitate programme implementation.

Tuberculosis unit : A major organizational change in RNTCP is the creation of a sub-district level Tuberculosis Unit. The Tuberculosis unit (TU) consists of a designated Medical Officer-Tuberculosis Control (MO-TC) who does tuberculosis work in addition to his/her other responsibilities, as well as two full-time supervisory staff for tuberculosis work-a Senior Treatment Supervisor (STS) and a Senior Tuberculosis Laboratory Supervisor (STLS). TUs are generally based in a Community Health Centre (CHC), Taluk Hospital (TH) or Block Primary Health Centre (BPHC). The team of STS and STLS at the Tuberculosis Unit level (TU level) are under the administrative supervision of the DTO / MO-TC. The TU covers a population of approximately 500,000 (250,000 in tribal, desert, remote and hilly regions). The TU will have one Microscopy Centre for every 100,000 population (50,000 in tribal, desert, remote and hilly regions) referred to as the Designated Microscopy Centre (DMC). DMCs are also provided in Medical Colleges, Corporate hospitals, ESI, Railways, NGOs, private hospitals,

etc, depending upon requirements. The TU is responsible for accurate maintenance of the Tuberculosis Register and timely submission of quarterly reports to the district level. The TU is the nodal point for TB control activities in the sub-district.

Definitions - Types of Disease

Pulmonary Tuberculosis, Smear-Positive : TB in a patient with at least 2 initial sputum smear examinations (direct smear microscopy) positive for AFB or TB in a patient with one sputum smear examination positive for AFB and radiographic abnormalities consistent with active pulmonary TB as determined by the treating MO or TB in a patient with one sputum smear specimen positive for AFB and culture positive for *M.tuberculosis*.

Pulmonary tuberculosis, Smear-negative : TB in a patient with symptoms suggestive of TB with at least 3 sputum smear examinations negative for AFB, and radiographic abnormalities consistent with active pulmonary TB as determined by the treating MO followed by a decision to treat the patient with a full course of anti-tuberculosis therapy or Diagnosis based on positive culture but negative AFB sputum smear examinations.

Extra Pulmonary tuberculosis : TB of any organ other than the lungs, such as the pleura (TB pleurisy), lymph nodes, intestines, genitourinary tract, skin, joints and bones, meninges of the brain, etc. Diagnosis should be based on culture-positive specimen from the extra-pulmonary site, histological, radiological, or strong clinical evidence consistent with active extra pulmonary TB followed by decision of the treating MO to treat with a full course of anti-TB therapy. Pleurisy is classified as extra pulmonary TB. A patient diagnosed with both sputum smear positive pulmonary and extra pulmonary TB should be classified as pulmonary TB.

Definitions : Types of cases

New: A case who has never had treatment for tuberculosis or has taken anti-tuberculosis drugs for less than one month.

Relapse: A TB patient who was declared cured or treatment completed by a physician, but who reports back to the health service and is now found to be sputum smear positive.

Transferred in : A TB patient who has been received for treatment into a Tuberculosis Unit, after starting treatment in another unit where s/he has been registered.

Treatment after default : A TB patient who received anti-tuberculosis treatment for one month or more from any source and returns to treatment after having defaulted, i.e., not taken anti-TB drugs consecutively for two months or more, and is found to be sputum smear positive.

Failure : Any TB patient who is smear positive at 5 months or more after starting treatment. Failure also includes a patient who was treated with Category III regimen but who becomes smear positive during treatment.

Chronic : A TB patient who remains smear positive after completing a re-treatment regimen.

Others : TB patients who do not fit into the above mentioned types. Reasons for putting a patient in this type must be specified.

Definitions : Treatment Outcomes

Cured : Initially sputum smear-positive patient who has completed treatment and had negative sputum smears, on two occasions, one of which was at the end of treatment.

Treatment completed : Sputum smear-positive patient who has completed treatment, with negative smears at the end of the intensive phase but none at the end of treatment or Sputum smear-negative TB patient who has received a full course of treatment and has not become smear-positive during or at the end of treatment or Extra-pulmonary TB patient who has received a full course of treatment and has not become smear positive during or at the end of treatment.

Died : Patient who died during the course of treatment regardless of cause.

Failure : Any TB patient who is smear positive at 5 months or more after starting treatment. Failure also includes a patient who was treated with Category III regimen but who becomes smear positive during treatment.

Defaulted : A patient who has not taken anti-TB drugs for 2 months or more consecutively after starting treatment.

Transferred out : A patient who has been transferred to another Tuberculosis Unit/District and his/her treatment result (outcome) is not known.

Tuberculous infection : It is the presence of viable but not multiplying virulent tubercular bacilli within the cells of the human being without any manifestation of clinical symptoms.

Tuberculous disease : It is the presence of viable, multiplying, virulent tubercular bacilli within the cells or tissues, with the presence of clinical symptoms.

Diagnosis

Three samples of sputum are collected on two days [spot (I day), overnight/early morning (II Day), spot (II Day)] and are examined under microscope. Results of sputum microscopy are given in Table - 2. Algorithm for diagnosis and treatment is given as Fig. -1.

Table - 2 : Results of sputum microscopy			
If the slide has	Result	Grading	No of fields to be examined
More than 10 AFB per oil immersion field	Pos	3+	20
1-10 AFB per oil immersion field	Pos	2+	50
10-00 AFB per 100 oil immersion field	Pos	1+	100
1-9 AFB per 100 oil immersion fields	Pos	Scanty - B *	100
No AFB in 100 oil immersion fields	Neg		100

* Record actual number of bacilli seen in 100 fields - e.g " Scanty 4"

Fig. - 1: Algorithm for diagnosis of a tuberculosis

Fluorescent microscopes have been provided to the state designated Intermediate Reference Laboratories (IRLs) under RNTCP and at present, the use of fluorescence microscopy is linked to the culture and Drug Sensitivity Testing (DST) activities of the IRLs. The most important advantage of the fluorescence technique is that slides can be examined at a lower magnification, thus allowing the examination of a much larger area per unit of time.

Treatment under RNTCP

Treatment in RNTCP is under two phases : Intensive and continuation phase. Categorization of patients is given in Table - 3. Duration of treatment alongwith phases is given for each category in Table - 4. Duration of treatment if patient is still sputum positive at end of intensive phase (IP) is given in Table - 5, while details of anti-tubercular drugs are given in Table - 6 and 7. Treatment categories and their relation to sputum examination schedule is given in Table - 8.

Management of patients who interrupt treatment : The details are given in Table - 9 and 10.

Table - 3 : Classification of categories, types of patients, regimens adopted under RNTCP

Cat	Type of patient	Regimens	Duration in months
I	New sputum smear +ve	2(HRZE) ₃ 4(HR) ₃	6
	Seriously ill sputum -ve		
	Seriously ill sputum extra-pulmonary		
II	Sputum +ve relapse	2(HRZE) ₃	8
	Sputum +ve failure	1(HRZE) ₃	
	Sputum +ve treatment after default	5(HRE) ₃	
III	Sputum -ve Extra pulmonary not seriously ill	2(HRZ) ₃ 4(HR) ₃	6
IV	MDR TB	4(KOCZEEt) 12-18(OCEEt)	18-24

Cat	Duration (number of doses)		Total
	<i>Intensive Phase (IP)</i>	<i>Continuation Phase (CP)</i>	
I	8 weeks (24 doses)	18 weeks (54 doses)	26 weeks (78 doses)
II	12 weeks (36 doses)	22 weeks (66 doses)	34 weeks (102 doses)
III	8 weeks (24 doses)	18 weeks (54 doses)	26 weeks (78 doses)

Cat	Duration (number of doses)		Total
	<i>Intensive Phase (IP)</i>	<i>Continuation Phase (CP)</i>	
I	12 weeks (36 doses)	18 weeks (54 doses)	26 weeks (90 does)
II	16 weeks (48 doses)	22weeks (66 doses)	34 weeks (144 doses)

* Cat I - at the end of 2 months; Cat II - at the end of 3 months

Medication	Drug Action	Dose (thrice a week) ***	Dose in children (mg/Kg)	Number of pills in combipack
Isoniazid	Bactericidal	600mg	10-15	2
Rifampicin	Bactericidal	450mg*	10	1
Pyrazinamide	Bactericidal	1500mg	25	2
Ethambutol	Bacteriostatic	1200mg	15	2
Streptomycin	Bactericidal	0.75g**	15	-

* Patients who weigh 60 kg or more at the start of treatment are given an extra 150mg dose of rifampicin. ** Patients over 50 years of age & those who weigh <30 kg are given 0.5g of streptomycin. *** Adult patients weighing <30kg receive drugs in patients-wise from the weight band suggested for pediatric patients.

Drug	Side Effects
Isoniazid	Hepatitis, peripheral neuropathy, pellagra, like syndrome, skin rash, drowsiness, fatigue
Rifampicin	Hepatitis, flu-like syndrome, skin rash, gastritis, respiratory and hemolytic syndromes, orange discoloration of urine, sweat, saliva
Pyrazinamide	Hepatitis, joint pains like gout due to hyperuricemia
Ethambutol	Ocular toxicity, decreased visual acuity, blurring and red green colour blindness, gastrointestinal toxicity and peripheral neuropathy, not recommended in children less than 6 yrs of age.
Streptomycin	Vestibular damage leading to nystagmus, unsteadiness of gait, reduces hearing, hypersensitivity reaction, impairment in excretory functions of kidney. Contraindicated in pregnancy. Use of unsterile needles can transmit Hepatitis B and HIV.
O f l o x a c i n / Ciprofloxacin	GI symptoms like nausea, vomiting, anorexia, anxiety, dizziness, headache, convulsion, rupture of Achilles tendon
Kanamycin	Vestibular and auditory symptoms, cutaneous hypersensitivity
Ethionamide	GI symptoms like diarrhoea, abdominal pain, hepatotoxicity, convulsion, mental symptoms, impotency, gynecomastia

Chemoprophylaxis for Children

Household contacts of smear-positive TB cases, especially those below 6 years of age, must be screened for symptoms of tuberculosis. In case of symptoms being present, the diagnostic algorithm for pediatric TB should be followed and the child should be given a full course of anti TB treatment if he is diagnosed as a TB case. For asymptomatic children and those who are not found to be suffering from TB, chemoprophylaxis with Isoniazid (5 mg per kg body wt) should be administered daily for a period of six months. This is regardless of the BCG vaccination status.

Hospitalization of TB patients

Some TB patients may need hospitalization during their illness. All indoor patients are to be treated with RNTCP regimens. The treatment is given using prolongation pouches which will be supplied by District TB Officer through the STS of that TU. On discharge, patients may be given a maximum of three doses (1 week drug supply) to cover the intervening period prior to their continuation of treatment at their respective DOT Centre, which may/not be in the same district, hence ensuring no interruption in treatment. All indoor patients treated under RNTCP, should be registered under the local TU in which the hospital is located.

Table - 8 : Treatment categories and sputum examination schedule

Treatment Regimen			Sputum Examination For Pulmonary Tb			
Cat	Type of patient	Regimen*	Pre-Treatment sputum	Test at month (end IP)	If result is	Then
I	New Sputum smear-positive	2H ₃ R ₃ Z ₃ E ₃ +4H ₃ R ₃	+	2	-	Start continuation phase, test sputum again at 2 month in CP (4 months) and at the end of treatment (6 months)
					+	Continue intensive phase for one more month, test sputum again at end of extended IP (3 months), end then at 2 months in CP (5 months) and at the end of treatment (7 months) #
	Seriously ill ** Sputum smear-negative Seriously ill ** extra pulmonary		-	2	-	Start continuation phase, test sputum again at the end of treatment (6 months)
					+	Continue intensive phase for one more month, test sputum again at end of extended IP (3 months), and then at 2 months in CP (5 months) and at the end of treatment (7 months) #
II	Sputum smear-positive Relapse Sputum smear-positive Failure Sputum smear - positive Treatment after default Others***	2H ₃ R ₃ Z ₃ E ₃ S ₃ +1H ₃ R ₃ Z ₃ +4H ₃ R ₃ E ₃	+	3	-	Start continuation phase, test sputum again at 2 month in CP and at the end of treatment (8 months)
					+	Continue intensive phase for one more month, test sputum again at end of extended IP (3 months), end then at 2 months in CP (6 months) at the end of treatment (9 months)
III	New Sputum smear-negative, not seriously ill New extra-pulmonary, not seriously ill	2H ₃ R ₃ Z ₃ + 4H ₃ R ₃	-	2	-	Start continuation phase, test sputum again at the end of treatment (6 months)
					+	Re-register the patient and begin Category II treatment #

* The number before the letters refers to the number of months of treatment. The subscript after the letters refers to the number of doses per week. The dosage strengths are as follows: H : Isoniazid (600mg), R: Rifampicin (450mg), Z : Pyrazinamide (1500mg), E: Ethambutol (1200mg), S : Streptomycin (750mg), Patients who weigh 60 kg or more receive additional rifampicin 150 mg. Patients who are more than 50 years old receive streptomycin 500mg. Patients who weigh less than 30 kg, receive drugs as per body weight. Patients in Categories I and II who have a positive sputum smear at the end of the initial intensive phase receive an additional month of intensive phase treatment.

** Seriously ill also includes, any patient, pulmonary or extra pulmonary who is HIV positive and declares his sero-status to the categorizing/treating medical officer. For the purpose of categorization, HIV testing should not be done.

*** In rare and exceptional cases, patients who are sputum smear-negative or who have extra-pulmonary disease can have Relapse or Failure. This diagnosis in all such cases should always be made by an MO and should be supported by culture or histological evidence of current, active TB. In these cases, the patient should be categorized as 'others' and given Category II treatment.

Any patient treated with Category I who has a positive smear at 5 months or later should be considered a Failure and started on Category II treatment afresh. Any patient on Category III who has a positive smear anytime during the treatment is also considered as Failure and started on Category II treatment.

DOTS plus

DOTS-Plus is an integral component of RNTCP to manage MDR-TB and is being implemented through programme infrastructure (4). The first WHO endorsed DOTS-Plus programmes began in 2000. At that time, the Green Light Committee (GLC) was established to promote access to high quality second-line drugs for appropriate use in TB control programmes. DOTS-Plus pilot projects have demonstrated the feasibility and effectiveness of MDR-TB treatment in less affluent countries. In 2002, the Global Fund to fight AIDS, TB, and Malaria (GFATM) started financing TB control programmes, including MDR-TB, greatly reducing the economic barrier to MDR-TB control. Based on data and experience from these projects, practices and further scientific

evidence have emerged regarding services for MDR-TB. DOTS-Plus programmes can and should strengthen the basic DOTS strategy. XDR TB (extensive drug resistant tuberculosis) is defined as MDR TB with further resistance to 3 of 6 classes of second line drugs. DOTS plus which is handling MDR Tb has a serious threat from XDR TB.

Involvement of Private Practitioners in RNTCP

Private Practitioners (PPs) are generally the first point of contact for significant proportion of patients with tuberculosis (5). All PPs can support and encourage effective tuberculosis control by:

- Ensuring prompt referral of patients with cough for 3

Treatment received before interruption	Length of interruption	DO a sputum Smear examination	Result of sputum Smear examination	Outcome	Re-registration	Treatment
Less than 1 month	Less than 2 months	No	-	-	-	Resume Treatment and Complete All doses
	2 months or more	Yes	Neg	-	-	Resume Treatment
			Pos	Default	New	Begin CAT I afresh
Less than 2 month	No	-	-	-	Resume Treatment and Complete All does	
More than 1 month	More than 2 months	Yes	Neg	-	-	Resume Treatment and Complete All doses
			Pos	Default	Treatment After Default	Begin CAT II Treatment afresh

Treatment received before interruption	Length of interruption	DO a sputum Smear examination	Result of sputum Smear examination	Outcome	Re-registration	Treatment
Less than 1 month	Less than 2 Weeks	No	-	-	-	Continue CAT I*
	2-7 Weeks	No	-	-	-	Start again on CAT I *
	8 Weeks or more	Yes	Positive	Default	New	Start again on CAT I**
Negative			-	-	Continue CAT I *	
1-2 Months	Less than 2 weeks	No	-	-	-	Continue CAT I *
More than 2 months	2-7 Weeks	Yes	Positive	-	-	1 extra month of intensive phase of CAT I *
			Negative	-	-	Continue CAT I *
	8 Weeks or more	Yes	Positive	Default	Treatment after Default	Start on CAT II*
			Negative	-	-	Continue CAT I *
	2-7 Weeks	Yes	Positive	Default ***	Other	Start on CAT II*
			Negative	-	-	Continue CAT I *
8 Weeks or more	Yes	Positive	Default	Treatment After Default	Start on CAT II*	
		Negative	-	-	Continue CAT I *	

* A patient must complete all 24 doses of the initial intensive phase. For example, if a patient has to continue his previous treatment and he took 1 month of treatment and he took 1 month of treatment (12 doses) before interrupting. He will have to take 1 more month (12 doses) of the intensive treatment. The patient will then start the continuation phase of treatment.

** A patient who must start again will restart treatment from the beginning.

*** Although this patient does not strictly fit the definition of default. Default most closely describes the outcome of this patient, although at re-registration the patient should be categorized as 'Other'.

* Patients with extra-pulmonary TB should receive Category III treatment unless they are seriously ill, in which case they should receive Category I treatment.

** Examples of seriously ill patients are those suffering from meningitis, disseminated TB, tuberculous pericarditis, peritonitis, bilateral or extensive pleurisy, spinal TB with neurological complications, smearnegative pulmonary TB with extensive parenchymal involvement, intestinal, genito-urinary TB and co-infection with HIV. All forms of pediatric smear negative TB except primary complex and pediatric extrapulmonary lymph node TB and unilateral pleural effusion.

weeks or more for sputum smears.

- Providing reassurance that tuberculosis can be cured.
- Giving only RNTCP recommended drug regimens.
- Starting treatment with rifampicin-containing regimens only if it can be ensured that treatment can be completed under observation.

Involvement of NGOs in RNTCP

Involvement of Non-Governmental Organizations (NGOs) in RNTCP is of vital importance. NGOs have an active role in health promotion in the community and many patients seek treatment from/through them. Depending on the capacity of the NGOs, their possible areas of involvement can be health education, service delivery, planning, programming, implementation, training and evaluation(6).

Quality Assurance in RNTCP

Sputum examination is the mainstay for diagnosis of Tuberculosis under RNTCP. Poor quality microscopy services have serious implications for the programme, including the failure to detect persons with infectious TB who will continue to spread infection in the community, or leading to unnecessary treatment for “non-cases.” The quality assurance activities take place at the National reference laboratories, intermediate level reference laboratories and TB unit.

In addition, Internal Quality Assurance includes all means by which the laboratory personnel performing TB smear microscopy control the process, including checking of instrument, new lots of staining solutions smear preparation, grading etc. It is a systematic internal monitoring of working practices, technical procedures, equipment, and materials, including quality of stains.

RNTCP Tribal Action plan

Tribal constitute 8.08% of the country’s population, which makes India the second largest concentration of tribal communities in the world (8). There are 635 tribes in India located in five major tribal belts across the country. The RNTCP Tribal Action Plan has the following objectives (9) :

1. Encourage tribal populations to report early in the course of illness for diagnosis.
2. Enhance treatment outcomes amongst tribal populations
3. Promote closer supervision of tribal areas by RNTCP staff

IEC in RNTCP

Advocacy and communication is a central and integral part of the Phase II RNTCP (10). Communication plans are directed towards scaling up the current level of communication activities through good mass media campaigns to creating a supportive and enabling environment for grassroot level participatory processes and community empowerment.

TB and HIV

As per NACO sentinel surveillance report of 2006, the prevalence of HIV infection is estimated to be 0.36 % of the population, which translates to 2.5 million people living with HIV/AIDS in India. Tuberculosis (TB) continues to be a public health challenge in India and it is estimated that 1.8 million cases of TB occur in India annually. Active TB disease is the commonest opportunistic infection amongst HIV-infected individuals. A low cost and high quality cure for TB is provided

under RNTCP which is implementing the DOTS strategy of diagnosis and treatment for TB nationwide (11).In 2007-08, TB-HIV collaborative activities are to be extended to the entire country and have been included as an integral part of NACP III and RNTCP II.

The goal of the National framework is to further enhance collaboration between RNTCP and NACP, and reducing the burden of TB and HIV in India. The objectives are-

1. To establish mechanisms for coordination between RNTCP and NACP at National, State and District levels.
2. To decrease morbidity and mortality due to tuberculosis among persons living with HIV/AIDS.
3. To decrease the impact of HIV in tuberculosis patients and provide access to HIV related care and support to HIV-infected TB patients.

Conclusion

RNTCP is the second largest programme of the country and has strengthened the existing NTP structure and created TB unit at the sub district level. RNTCP has expanded in a systematic way covering the whole of country by March 2006. There has been intensified Public private mix in scaling up the initiatives to strengthen case detection and treatment. Political commitment is one of the main components of DOTS. DOTS have been made responsible for carrying out defaulter retrieval activity about the patients put on treatment. This ensures completion of treatment by the patients. Various NGOs are also playing useful role by providing man power or financial assistance (13).

Critical appraisal

There has been poor coverage due to gaps in primary health care infrastructure and manpower in difficult to assess areas. Quality of sputum examination is not up to the mark. The private practitioners at many places use non standard treatment regimens. The problem of drug resistant TB is emerging very fast which is virtually untreatable and spreading all over the world including India (12). Given the problems of number of drugs to be used, their cost, adverse effect, the duration of therapy and accessibility of treatment, this group is going to pose a big problem for the RNTCP in particular and the community at large. Direct supervision is the corner stone for the success of RNTCP but in our country, lot of stigma is still attached to TB. As a result, many patients, especially young females, who want to hide their ailment, do not go to DOTS-provider thrice or even once a week. Such patients often resort to influence the DOTS-provider and get medicines in bulk. In this process, direct supervision is lost.

Summary

National Tuberculosis Control Programme was launched in 1962 and suffered from weakness in the form of poor managerial control, inadequate funding, over-reliance on x-ray, non-standard treatment regimens, low rates of treatment completion, and lack of systematic information on treatment outcomes. The Revised National Tuberculosis Control Programme (RNTCP), based on the DOTS strategy, took its roots in India in 1993 with the goal of decreasing mortality and morbidity due to TB and cut transmission of infection until TB ceases to be a major public health problem in India. It progressed in a phased

manner and by 24th March 2006 entire country was covered by it and entered its second phase (2006-2010).

The objectives of the RNTCP are to achieve at least 85 percent cure rate of the newly diagnosed sputum smear-positive TB patients and to detect at least 70 percent of new sputum smear-positive patients after the first goal is met. Directly Observed Treatment Short course (DOTS) strategy has five components: Political and administrative commitment, Good quality drugs & an uninterrupted supply of good quality anti-TB drugs, Good quality diagnosis using sputum microscopy, Systematic monitoring and accountability and supervised treatment to ensure the right treatment. DOTS remain the core strategy of RNTCP II however few additional components in the form of DOTS expansion and enhancement, addressing TB-HIV, collaboration with other health programmes and general services and involvement of private practitioners have been emphasized.

The structure of RNTCP has The Central TB Division (CTD) at the top, State TB Cell (STC) at the state and District TB Centre (DTC) at the district level. The TB Units (TUs) at the subdistrict level is the lowest reporting unit under the RNTCP. The Tuberculosis unit (TU) consist of a designated Medical Officer-Tuberculosis Control (MO-TC) who does tuberculosis work in addition to his/her other responsibilities, as well as two full-time supervisory staff for tuberculosis work - a Senior Treatment Supervisor (STS) and a Senior Tuberculosis Laboratory Supervisor (STLS). The TU covers a population of approximately 500,000 (250,000 in tribal, desert, remote and hilly regions). The TU will have one Microscopy Centre for every 100,000 population (50,000 in tribal, desert, remote and hilly regions) referred to as the Designated Microscopy Centre (DMC).

Diagnosis of a case is based on sputum microscopy where three samples over two days are taken and ZN method of staining is used. For treatment the patient is classified into a category based on the definitions given in the programme and treatment of that particular category is started for the patient. The treatment is divided into two phases intensive phase and continuation phase. Antitubercular drugs being used in RNTCP are H : Isoniazid R : Rifampicin, Z : Pyrazinamide E : Ethambutol, S : Streptomycin. Household contacts of smear-positive TB cases, especially those below 6 years of age, must be screened for symptoms of tuberculosis. For asymptomatic children and those who are not found to be suffering from TB, chemoprophylaxis with isoniazid (5 mg per kg body wt) should be administered daily for a period of six months.

DOTS-Plus is an integral component of RNTCP to manage MDR-TB and is being implemented through programme infrastructure. XDR TB (extensive drug resistant tuberculosis) is defined as MDR TB with further resistance to 3 of 6 classes of second line drugs.

Another important aspect for success of RNTCP is involvement of private practitioners and NGOs in the programme. RNTCP also has a tribal action plan to Encourage tribal populations to report early in the course of illness for diagnosis, Enhance treatment outcomes amongst tribal populations, and Promote closer supervision of tribal areas by RNTCP staff. Tuberculosis is the commonest opportunistic infection in HIV cases. There is a strong collaboration between RNTCP and National AIDS Control Programme to decrease morbidity and mortality due to tuberculosis among persons living with HIV/AIDS and to decrease the impact of HIV in tuberculosis patients and provide access to HIV related care and support to HIV-infected TB patients.

Puja Dudeja & Ashok K. Jindal

NVBDCP is an umbrella programme for prevention and control of major vector borne diseases of public health importance namely Malaria, Filariasis, Japanese encephalitis (JE), Kala azar and Dengue/Dengue Hemorrhagic Fever (DHF) (1). The programme lays special focus on the vulnerable groups of the society namely, children, women, Scheduled Castes (SC) and Scheduled Tribes (ST). Under the programme, it is ensured that the disadvantaged and marginalized sections benefit from the delivery of services so that the desired National Health Policy and National Rural Health Mission (NRHM) goals are achieved.

Before 2003, various centrally sponsored schemes namely National Anti Malaria Programme, National Filariasis Control Programme and Kala Azar Control Programme were fighting with menace of malaria, filariasis and kala azar respectively on a cost sharing basis between center and state (2). There was no centrally sponsored programme for JE, dengue, chikungunya. The states were managing these with their own resources without any financial and technical assistance. From the year 2003-2004, Government of India decided to fight the peril of all vector borne diseases on a common platform as NVBDCP.

Mission Statement

Integrated accelerated action towards reducing mortality on account of malaria, dengue, Japanese Encephalitis by half and elimination of Kala-azar by year 2010 and elimination of Lymphatic Filariasis by 2015 (3).

Strategy

During the Tenth Plan (2002-2007), NVBDCP was planned to be implemented through the existing health care infrastructure and was planned to focus on improved training of health care workers, reporting and monitoring of VBDs, insecticide and drug resistance, involvement of Panchayati Raj Institutions (PRIs), improved IEC and community acceptance and availability of ITBNs (4). During the eleventh five year plan (2007-2012) the existing strategies of vector borne diseases would be further continued and further strengthened with special emphasis on surveillance, human resource development, behavior change communication, supervision and monitoring, quality assurance and quality control of diagnostics & drugs and operational research (5).

Implementation

The programme runs under the Union Ministry of Health and Family Welfare. The execution of the programme at various levels is given in Table 1.

There is also a strong link up between NVBDCP and NRHM (6). NRHM will focus on all diseases of NVBDCP. ASHA is envisaged to play a key role in the grass-root level implementation of NVBDCP. Actions to be taken under the NRHM are:

- ASHA and Village Health Team to be oriented to community based vector control strategies. Convergence with Water and Sanitation Mission will facilitate this process.
- ASHA to be able to give presumptive treatment for malaria
- Enhanced surveillance capacity (human resources and infrastructure) at PHC and CHC levels
- Enhancing laboratory capacity at CHC and PHC

Malaria

Malaria is major public health trepidation in our country. At the

Table - 1 : Organisational structure of NVBDCP

Level	Agency	Action
National	Directorate of National Vector Borne Diseases Control Programme	Framing technical guidelines & policies as to guide the states for implementation of Programme
		Budgeting and planning the logistics pertaining to central sector
		Monitoring of implementation through regular reports and returns
		Evaluation of Programme implementation
State	Regional Offices for Health and Family Welfare (ROH & FW) located at state HQ	Conduct the entomological studies in collaboration with zonal entomological setup of the state
		Drug resistance studies
		Cross checking of blood slides for quality control
		Capacity building of the states
	Directorate of Health Services	Responsible for implementation of Programme strategies and monitoring in accordance to Programme guidelines
		Development of infrastructure
		Coordination between the state and centre for effective implementation and monitoring
District	District Malaria Offices	Key unit for planning and monitoring of Programme under a technical officer
Village	Primary Health Centres	Passive surveillance for malaria

time of independence of the country, there were an estimated 75 million malaria cases and 0.8 million deaths annually. High malaria burden had adverse effects on agriculture, industrial development and national economy. Use of insecticides for malaria control became available in fifties and global experience in malaria control indicated then that malaria could be controlled or even eradicated within a short period, if available measures were implemented effectively.

Magnitude of the problem

Trend of Malaria Cases and Deaths Due to Malaria in India is depicted in Fig - 1a & 1b respectively.

As per the data from National Health Profile 2007, there were 1.78 million cases of malaria and 1704 deaths in the year 2006. The largest numbers of cases in the country were reported by Orissa, followed by Jharkhand, West Bengal, Assam, Chhattisgarh, Rajasthan, Gujarat & Uttar Pradesh and the largest numbers of deaths were reported by Assam followed by Orissa, West Bengal, Arunachal Pradesh, Meghalaya, Maharashtra, Mizoram, Gujarat and Karnataka.

Evolution of the Programme

The National Malaria Control Program (NMCP) was launched in 1953 and was redesignated as Eradication Program (NMEP) in 1958. The NMEP made an excellent progress till 1965, bringing down the malaria incidence to almost nil. However, thereafter setbacks started due to various operational, administrative and technical reasons. Against this background, in 1977, the Modified Plan of Operations (MPO) was started. The evolution is presented in Table - 2.

In 1995 the Malaria Action Plan (MAP) was launched. It envisaged decentralized planning (akin to RCH), covering a total of 199 million (20.6%) population living in high risk areas. The criteria for defining a high risk area are as follows:

(A) Rural / Tribal areas

1. Death due to malaria (Pf) - last 3 years
2. Doubling SPR in last 3 years
3. No doubling but average SPR in 3 years > 4%
4. *P. falciparum* > 30 % with SPR > 3 % in 3 years
5. Chloroquine resistant Pf.
6. Aggregation of labor in project areas.
7. New settlement in endemic/receptive and vulnerable area.

(B) Urban Areas

1. SPR > 10% during any of last 3 years
2. Population > 50000 & 5% with ration malaria: fever cases > 1/3

In 1997 the Enhanced Malaria Control Project (EMCP) was

S. No	Year	Programme	Remarks
1	1953	National Malaria Control Programme	Strategy - Residual insecticide spray; 75 million cases
2	1958	National Malaria Eradication Programme	Residual Spray+ Active search of cases & Radical Treatment following reduction of cases to 2 million Brought down annual malaria incidence to 0.1 million cases by 1965 Could not sustain for various technical, administrative and financial constraints
3	1965-66 1970's	Minimum no of cases 0.1million with no deaths. Resurgence of malaria with 6.47m cases in 1976	
4	1971	Urban Malaria Scheme (UMS)	Passive treatment of malaria cases, antilarval measures, minor engineering methods like closing ditches, biological control and awareness camps.
5	1977	Modified Plan of Operation (MPO) (also included <i>P. falciparum</i> containment programme)	The programme was integrated with primary health care delivery system in rural areas. Successfully brought down the annual incidence of malaria substantially, viz., reduction to a level of 2 million cases per annum by 1984 Strategies were selective insecticide spray API>2, Active Surveillance-Fortnightly visits- blood smear collection, antilarval operations in urban areas.

launched covering a total of 1045 PHCs in 100 districts of AP, Jharkhand, Gujarat, MP, Maharashtra, Orissa and Rajasthan through World Bank assistance. The components were Early detection and prompt treatment through a Link worker for every 2000 population and selective vector control using Temephos (Abate) for anti-larval and DDT / malathion for residual applications.

In 1998, World Health Organization and other partners initiated the “Roll Back Malaria” (RBM) plan. The key interventions were Vector Control through Insecticide Treated Nets (ITN) and Indoor Residual Spray (IRS); Intermittent Preventive Therapy during pregnancy (IPT); and prompt and effective case management, in particular Artemisinin based combination therapy.

In 2003, the NVBDCP was launched, integrating the various components of control strategies for common vector borne diseases. In 2005, the programme was made a important strategic part of NRHM.

Malaria control strategies in NVBDCP

1. Early case Detection and Prompt Treatment (EDPT)

- EDPT is the main strategy of malaria control - radical treatment is necessary for all the cases of malaria to prevent transmission of malaria.
- Chloroquine is the main anti-malaria drug for uncomplicated malaria.
- Drug Distribution Centres (DDCs) and Fever Treatment Depots (FTDs) have been established in the rural areas for providing easy access to anti-malarial drugs to the community.
- Alternative drugs for chloroquine resistant malaria are recommended as per the drug policy of malaria. NVBDCP drug policy recommends the use of combination therapy i.e Artesunate plus Sulfadoxine Pyrimethamine as a second line of treatment for *P. falciparum* cases in chloroquine resistant areas.
- All fever cases should preferably be investigated for malaria by microscopy or Rapid Diagnostic Kit (RDK). RDK is a immunochromatographic test. It detects *Plasmodium falciparum* histidine rich protein in blood.

2. Vector Control

(i) Chemical Control

- Use of Indoor Residual Spray (IRS) with insecticides recommended under the programme.
- Use of chemical larvicides like Abate in potable water
- Aerosol space spray during day time
- Malathion fogging during outbreaks

(ii) Biological Control

- Use of larvivorous fish in ornamental tanks, fountains etc.
- Use of biocides.

3. Personal Prophylactic Measures that individuals/communities can take up

- Use of mosquito repellent creams, liquids, coils, mats etc.
- Screening of the houses with wire mesh
- Use of bednets treated with insecticide
- Wearing clothes that cover maximum surface area of the body

4. Community Participation

- Sensitizing and involving the community for detection of Anopheles breeding places and their elimination
- NGO schemes involving them in programme strategies
- Collaboration with CII/ASSOCHAM/FICCI
- Observance of anti malaria month in June and intensify activities

5. Environmental Management & Source Reduction Methods

- Source reduction i.e. filling of the breeding places
- Proper covering of stored water
- Channelization of breeding source

6. Monitoring and Evaluation of the programme

- Monthly Computerized Management Information System (CMIS)
- Field visits by state by State National Programme Officers
- Field visits by Malaria Research Centres and other ICMR Institutes
- Feedback to states on field observations for corrective actions.

National Antimalaria Drug Policy

National antimalaria drug policy essentially provides a framework for the safe and effective treatment of uncomplicated and severe malaria as well as prevention of malaria in vulnerable groups, such as pregnant women and young children. The policy is as follows :

Presumptive Treatment (PT) - Low Risk Areas : PT comprises of a single dose of chloroquine phosphate 10 mg/kg. body weight to all fever / suspected malaria cases (Table - 3).

Age in Years	Chloroquine Phosphate	
	mg. Base	No. of Tablets (150 mg)
< 1	75	½
1-4	150	1
5-8	300	2
9-14	450	3
15 & above	600	4

Presumptive Treatment (PT) - High Risk Areas : As per revised policy of NVBDCP presumptive treatment of all suspected malaria cases, up to sub-centre level only, in “high risk areas” is as shown in Table - 4.

Drug	Day	Dose
Chloroquine Base	Day 1	10 mg/kg (600 mg adult)
Primaquine	Day 1	0.75 mg/kg (45 mg adult)
Chloroquine base	Day 2	10 mg/ kg (600 mg adult)
Chloroquine base	Day 3	5 mg/kg (300 mg adult)

Radical Treatment - Low Risk Areas

For *Plasmodium vivax* (Table - 5)

Age in year	Chloroquine Phosphate 150 mg base Single dose		Primaquine 2.5 mg base Daily dose for 5 days	
	mg base	No. of tablets	mg base	No. of tablets
< 1	75	1/2	Nil	Nil
1 - 4	150	1	2.5	1
5 - 8	300	2	5.0	2
9 -14	450	3	10.0	4
15 & above	600	4	15.0	6

For *Plasmodium falciparum* : In “Low Risk Areas” where presumptive treatment with 600 mg chloroquine alone (adult dose) has been given and later blood smear is found positive for Pf, the complete radical treatment should be given with a single dose of tablet chloroquine 10 mg/kg bw combined with 0.75 mg/kg bw of primaquine.

Radical Treatment - High Risk Areas

For *Plasmodium vivax* : In high risk areas where presumptive treatment with 1500 mg chloroquine base spread over three days and 45 mg primaquine (adult dose) has been given, chloroquine need not be administered again, but primaquine must be given for 5 days (Table - 6).

Age in year	Tablets Primaquine 2.5 mg base Daily dose for 5 days	
	mg base	No. of tablets
<1	Nil	Nil
1-4	2.5	1
5-8	5.0	2
9-14	10.0	4
15 & above	15.0	6

For *Plasmodium falciparum* : In “High Risk Areas”, fever cases are given presumptive treatment with 1500 mg Chloroquine (over 3 days) and 45 mg Primaquine (adult single dose). Therefore radical treatment with primaquine is not required if they are found positive for Pf microscopically.

Chloroquine resistant *P falciparum* cases : The radical treatment of Pf cases in chloroquine resistant areas, which are under alternate drug schedule, and in specific cases not responding to chloroquine, is by second line of treatment. Resistance should be suspected if in spite of full treatment and no history of vomiting, diarrhoea, patient does not respond within 72 hours parasitologically or deteriorate clinically. National Anti Malaria Drug Policy has recently recommended Artesunate + sulfadoxine/ sulfalene combination therapy (SP

-ACT) in confirmed chloroquine resistant cases. This must be followed with Primaquine (45 mg). The age-wise dosage is as shown in Table - 7.

Age in year	Artesunate (AS) Sulfadoxine+ pyrimethamine (SP)	I day (no. of tablets)	II day (no. of tablets)	III day (no. of tablets)
<1	AS	½	½	½
	SP	¼	Nil	Nil
1-4	AS	1	1	1
	SP	1	Nil	Nil
5-8	AS	2	2	2
	SP	1 ½	Nil	Nil
9-14	AS	3	3	3
	SP	2	Nil	Nil
15 & above	AS	4	4	4
	SP	3	Nil	Nil

- Dose of Artesunate is 4 mg /kg body weight for 3 days. Strength of the tablet is 50 mg.
- Dose of SP is 25 mg /kg body weight of sulfadoxine plus 1.25 mg /kg body weight of pyrimethamine single dose. The strength of SP tablet is 500 mg sulfadoxine and 25 mg of pyrimethamine.

Note: Sulfalene/ Sulphadoxine and Pyrimethamine combination does not take care of *P vivax* cases. Where SP - ACT is not available, SP alone should be given.

Chemoprophylaxis : In chloroquine sensitive areas chloroquine is to be given. In chloroquine resistant areas it is to be supplemented by proguanil.

Regimen

- Chemoprophylaxis is to be started a week before arriving at malarious area for visitors.
- For pregnant women in high risk area prophylaxis should be initiated from second trimester.
- Start with loading dose of 10 mg/kg bw and followed by a weekly dose of 5 mg/kg bw. This is to continue till 1 month after delivery in case of pregnancy and in travelers till one month after return from endemic area. The terminating dose should be 10 mg/kg bw along with 0.25 mg/kg bw of primaquine for five days.
- Chemoprophylaxis with chloroquine is not recommended beyond 3 years because of its cumulative toxicity.
- In chloroquine resistant areas chemoprophylaxis is recommended with chloroquine 5 mg/kg bw weekly and proguanil 100mg daily.

Vector control

In our country, control of vectors is actually control of *An. culicifacies* as 60-70% of new cases of malaria are due to it and rest 15-20%. by *An. fluviatilis*. Approx 70% of the allotted budget is spent for control of malaria in those areas where *An. culicifacies* is the vector species for malaria transmission.

Except for *An. stephensi* all other malaria vectors exist as species complexes comprising several sibling species that result in considerable impact on the transmission of malaria including susceptibility to commonly used insecticides in public health programme.

Insecticides : Wettable Powder (WP) formulations are used for indoor residual sprays and Emulsifiable Concentrate (EC) formulations are used for larval control. For Indoor Residual Spray (IRS) insecticides in use are DDT 50% WP, malathion 25% WP and synthetic Pyrethroid (WP). Synthetic Pyrethroids include deltamethrin 2.5% WP, Cyfluthrin 10% WP, lambda-cyhalothrin 10% WP, alphacypermethrin 5% WP, Etofenprox 10% WP and Bifenthrin 10% WP. Synthetic pyrethroid insecticides are also used for impregnation of bed nets.

Change of Insecticide : The change of insecticide is warranted after production of data on vector resistance studies and field observations on epidemiological impact of spray in respect of insecticide in use by State Govt. The change of insecticide will always be decided in mutual consultation between State Programme Officer for NVBDCP, ROH&FW and the Dte. of NVBDCP with concurrences of State and Central Govts.

Insecticide formulations used under NVBDCP : The formulations/compounds used under the NVBDCP for control of malaria are DDT; Malathion 25% WP (used under the programme in areas with DDT resistance); and, Synthetic Pyrethroids. As regards synthetic pyrethroids, the cost of these insecticides is much higher than the cost of DDT and Malathion. Currently there are five insecticides of this group registered with Central Insecticide Board for use in the programme. These are (i) Deltamethrin 2.5% WP, (ii) Cyfluthrin 10% WP, (iii) Alphacypermethrin 5% WP (iv) Lambda-cyhalothrin 10% WP and (v) Bifenthrin 10% WP.

Insecticide Resistance in Malaria vectors : Malaria vectors in India are resistant to DDT alone or double resistant to HCH or triple resistant to DDT, HCH, malathion and quadruple resistant to DDT, HCH, malathion and Deltamethrin (synthetic pyrethroid). HCH has been phased out in 1997. In the years to come development of resistance to synthetic pyrethroid warrants a caution of impending possibility of wide spread resistance to other compounds of this group that are introduced in public health programme for indoor residual spray as well as insecticide treated bed nets. Strategies for delaying / avoiding the onset of resistance include:

- Avoid indiscriminate use of insecticides
- Avoid use of insecticides that simultaneously select resistance to other chemically related insecticides.
- Avoid use of insecticides that induce development of more than one type of resistance mechanism of broad spectrum of resistance.
- Avoid use of the same insecticide for both against adults and larvae.
- Use of non chemical control methods, e.g. biopesticides, larvivorous fish.
- Use of synergist with insecticides to reduce physiological resistance.

Malaria Surveillance Under NVBDCP

The aim of surveillance is to detect changes in trends or distribution in malaria and other vector borne diseases in order to initiate investigative or control measures. Malaria surveillance presumes that every malaria case will present itself with symptoms of fever at some point of time during the course of infection. Surveillance activities are summarized in Table - 8.

Table - 8 : Surveillance activities under NVBDCP		
S.No	Component	Remarks
1	Fortnightly Domiciliary visits	Active case detection (ACD) is carried out by multipurpose health workers (male) under Primary Health Care System. He carries out search for a fever case or who had fever in between the visits of MPW, collects blood smear from such cases, administers appropriate anti-malarial(s). The rationale is that the "incubation interval" i.e., the full life cycle of malaria for the development of the parasite in the mosquito and that in the human being in case of <i>P. vivax</i> is approximately 22 days while for <i>P. falciparum</i> it is 35 days. Thus, surveillance cycle of less than one incubation interval will catch most of the secondary cases before the commencement of next cycle. Through this activity, the malaria surveillance can be measured.
2	Fever Treatment Depots (FTDs)	To avoid delay in detection of cases which occur in between visits of MPW, establishment of Fever Treatment Depots in villages especially in areas which are remote/ inaccessible and have low population density collection of blood smears, administration of presumptive treatment, impregnation of bed nets, promotion of larvivorous fish etc,
3	Passive Case Detection (PCD)	By Allopathic, Ayurvedic, Homeopathic, Siddha medicine dispensaries in the health sector, local residents or voluntary agencies operating locally, Anganwadi workers, private practitioners etc.
4	Rapid Fever Survey	In case of an epidemic outbreak, the suspected epidemic zone is covered in a short duration and all fever cases are screened by taking blood smears
5	Mass survey	Mass survey of the entire population may be carried out in the suspected epidemic zone. Here all the population irrespective of age, sex or fever status is screened by taking blood smear. Specially children must be included in survey.
6	Drug Distribution Centre (DDC)	The functions of DDCs are the same as those of FTDs, except that the DDCs do not take blood slides but administer drugs to fever cases.

Rationale behind surveillance : Malaria surveillance presumes that every malaria case will present itself with symptoms of fever at some point of time during the course of infection. Therefore, if all fever cases occurring in the community are kept under surveillance over a period of time and their blood smears are examined for malaria parasite, the total malaria parasite load can be examined. For accurate estimates of malaria endemicity, the blood smear examination rate specially the Monthly Blood Examination Rate (MBER) should be equal to fever rate of the month in the community. Therefore it is necessary to ensure that all persons having fever during malaria transmission months are included in the total blood slides examined during the year. The MBER norms of 0.8 percent during non-transmission season and 1.2 to 1.8 percent during transmission season (or approximately 1% per month) were laid down in the Malaria Eradication Programme. MBER should be monitored MPW-wise by the medical officer-in-charge during monthly meeting at the PHC in order to assess the surveillance operation in the PHC area. In both the cases i.e. ABER and MBER the denominator is common because the entire population is covered during each fortnightly domiciliary visit by MPW (male). ABER is the cumulative sum of monthly rates during the year. ABER/ MBER is an index of operational efficacy of the programme. The Annual Parasite Incidence (API) depends upon the ABER. A sufficient number of blood slides should be systematically obtained and examined for malaria parasite to work out accurate API.

As a rough guide, MBER should be 1% and ABER should be at least 10%. If it is less than this figure it indicates a poor surveillance coverage and in this situation, API may not remain a good index of malaria incidence. In such situations, SPR, rather than API should be considered. While collecting ABER or MBER, blood slides collected by all agencies are taken into account, i.e blood smears collected through ACD, PCD, FTD or any other voluntary agency during the same period. However, number of blood smears collected and examined during a mass survey and their results should not be included while calculating ABER or MBER.

$$\text{ABER} = \frac{\text{No. of blood smears collected during the year}}{\text{Population covered under surveillance}} \times 100$$

$$\text{MBER} = \frac{\text{No. of blood smears collected during the month}}{\text{Population covered under surveillance}} \times 100$$

$$\text{API} = \frac{\text{No. of blood smears found +ve during the Year}}{\text{Population covered under surveillance}} \times 1000$$

The *Slide Positivity Rate (SPR)* among the blood smears collected through both active and passive surveillance gives more accurate information on distribution of malaria infection in the community over a period of time. Monthly SPR can be calculated to find out the seasonal rise and fall in malaria prevalence in the community. SPR among children 2-9 years of age can be utilized for comparison with pre-control Child Parasite Rates to assess the impact of control measures on local malaria endemicity and transmission. SPR in the age group of less than one year (Infant Parasite Rate) can be

utilized for assessment of the impact of control operations. The SPR of blood slides collected from cases currently having fever will be higher than the SPR of the slides collected from cases with history of fever. Therefore, higher positivity rates are obtained in blood smears collected at the PCD. Trends in SPR can be utilized for predicting epidemic situations in the area. If monthly SPR exceeds by 2½ times of the standard deviation observed in SPR of the preceding 3 years or preceding 3 months of the same year, an epidemic build up in the area can be suspected. Monthly or yearly trends of SPR are utilized to study the impact of control operations.

SPR is measured as follows:

$$\text{SPR} = \frac{\text{No. of blood smears found +ve for MP}}{\text{No. of blood smears examined}} \times 100$$

Accelerated Urban Malaria Control Project

To address the malaria problem in urban areas, an Urban Malaria Scheme (UMS) was launched in 1971 with the objective to control malaria by reducing the vector population by way of recurrent anti-larval measures and detection and treatment of cases through the existing health services of the State/Urban Local Bodies. In this context, an "Accelerated Urban Malaria Control Project" is proposed in high endemic 28 towns/cities with GFATM support. The proposed project will be implemented by the Urban Local Self Govt, viz., Municipalities in collaboration with the local NGOs. The project goal is to reduce malaria morbidity and mortality in the project population (in 28 towns in 12 states) by 50% by 2015.

Project Objectives : Increasing the access to diagnosis and treatment in project areas, with particular focus on slums, construction sites/industrial estates/market areas with floating population. Majority of the population at risk at focused sites are poor and marginalized families, living below poverty line.

1. Malaria Transmission Risk Reduction through Integrated Vector Management mode (IVM).
2. Enhancing awareness towards behavioural impact about malaria prevention and control and promoting community, NGO and private sector participation.

Kala-azar

Kala-azar, a disease transmitted by sand fly vector is a cause of high morbidity and mortality in the 4 states of Bihar, Jharkhand, Uttar Pradesh and West Bengal, with 165.4 million population living in these endemic areas (7). A total of 48 districts are endemic, with sporadic cases being reported from few other districts. The burden of disease since 2004 is given in Table - 9.

S.No	Year	Cases	Deaths
1	2004	24340	156
2	2005	31217	157
3	2006	39178	187
4	2007(Provisional)	22751	101

Kala-azar Elimination Initiative : The National Health Policy (2002) has set the goal for elimination of Kala-azar by year 2010. Elimination Programme is 100 per cent Centrally Supported (except regular staff of State governments & infrastructure). In addition to kala-azar medicines and insecticides, cash assistance is being provided to endemic states since December 2003 to facilitate effective strategy implementation by states.

Strategy

- Interruption of transmission through vector control by undertaking residual indoor insecticide spraying in affected areas, with DDT up to 6 feet height from the ground twice annually.
- Early diagnosis and complete treatment (Table - 10).
- IEC and community mobilization.

Name of the Drug		Dosages
Injection SSG	Ist line drug for treatment	20 mg per kg. body weight daily for 20 days Maximum 8.5 ml per day
Injection Amphotericin-B	II nd line drug	1 mg. per kg. body weight alternate days 15 injections
Tablet Miltefosine		50 mg. bd below 12 years
		100 mg. bd above 12 years 2.5 mg/kg body weight bd
		(56 tablets) for 28 days (adult Dose)

Filariasis

Filariasis has been a major public health problem in India next only to malaria. India accounts for about 40% of the 120 million estimated cases globally with either disease or infection (Microfilaria cases). Cases of filariasis have been recorded from Andhra Pradesh, Assam, Bihar, Chattisgarh, Goa, Jharkhand, Karnataka, Gujarat, Kerala, Madhya Pradesh, Maharashtra, Orissa, Tamil Nadu, Uttar Pradesh, West Bengal, Pondicherry, Andaman & Nicobar Islands, Daman & Diu, Dadra & Nagar Haveli and Lakshadweep. It is a disabling & disfiguring disease and causes immense personalized trauma of the affected persons, even though it is not fatal. In 1955, the national filarial control programme was launched. The main control measures were mass DEC administration, antilarval measures in urban areas and indoor residual spray in rural areas.

The subsequent land marks in filarial control are given in Table - 11.

Strategy for Elimination of Lymphatic Filariasis : The strategy for achieving the goal of elimination is by annual mass drug administration of DEC for 5 years or more to the population excluding children below two years, pregnant women and seriously ill persons in affected areas to interrupt transmission of disease(8). Under the programme, Mass Drug Administration (MDA) campaign is organized and an annual single dose of Diethylcarbamazine citrate (DEC) tablets is administered to the eligible population in the affected areas on a single day designated as National Filaria Day. The drug distribution is made by door-to-door campaign. In addition, booths are established at health facilities, both in public and private sectors. Co-administration of DEC and Albendazole free of cost to be implemented in all the endemic districts by 2008 in a phased manner (Albendazole kills intestinal helminthic infections also).

The transmission of infection can be stopped by treating the entire eligible population living in filarial endemic areas with Mass Drug Administration (MDA) with DEC given once a year for 5-7 years i.e. during the life span of adult filarial worm which gives birth to millions of microfilariae. With every treatment there will be a heavy reduction in the circulating microfilariae. This will markedly reduce or stop the transmission of the infection by the mosquitoes to other healthy persons.

DEC is available as 50 mg or 100mg tablets. The drug has been in use in India for more than five decades. It is a safe drug at the recommended doses. The dose of DEC is 6 mg/kg body weight. The dose schedule which was being followed is shown in Table - 12.

Age (in year)	Dose of DEC
<2	Nil
2-3	50 mg
4-5	100 mg
6 - 11	150 mg
12 - 17	200 mg
> 18	300 mg

However, a simplified dose schedule was administered in Tamil Nadu for the mass drug administration campaigns. This was monitored by the state government and the Vector

S. No	Year	Activity	Remarks
1.	1996-97	Annual Mass Drug Administration	Covered 41m population, extended to 77m population in 2002 and 400m in 2004 Strategy is to be continued for 5 years or more to the population excluding children below two years, pregnant women and seriously ill persons in affected areas to interrupt transmission of disease.
2.	2002	National Health Policy	Elimination of Lymphatic Filariasis (ELF) by the year 2015
3.	2003	NVBDCP	Convergence with other vector borne diseases

Control Research Centre (VCRC), ICMR and found to be safe and effective. The results were discussed by the National Task Force on Lymphatic Filariasis and the following simplified schedule has been recommended for MDA in the country (Table - 13).

Age (in year)	DEC Dose	DEC (Tablet of 100 mg)
<2	Nil	Nil
2-5	100mg	1 tablet
6-14	200mg	2 tablets
15 & above	300mg	3 tablets

Side effects of DEC : DEC at the above doses is safe. Person with high mf density may experience general side effects in the form of headache, body ache, nausea and vomiting which result from the death of the Microfilariae. The side effects are temporary and subside in a day or two after symptomatic treatment. Rarely, localized reactions in the form swelling and tenderness of lymph nodes may occur. Temporary side effects that may occur in 1 to 10% of the population who may be carriers of microfilariae.

Contraindications of DEC : DEC is safe. However, as a matter of precaution, it should not be given to children under two years and to pregnant women. Severely ill patients may also avoid taking the drug.

The disease has been targeted for global elimination by 2020. Transmission control and disability alleviation are two pillars of the Global Elimination Strategy for Lymphatic Filariasis (GELF). Interruption of transmission can be achieved by mass annual drug administration of Diethylcarbamazine Citrate (DEC) to entire communities at risk of infection when community drug consumption rates are adequate. This is expected to result in reduction of transmission of lymphatic Filariasis to low levels and ultimately in the elimination of Filariasis, preventing new infections from occurring and protecting future generations from the disease.

Dengue

Dengue Fever (DF) is an acute viral infection with the potential of causing large outbreaks. Death can occur in dengue haemorrhagic fever (DHF), which is a severe form of the disease. The National Health Policy (2002) has set the goal of reduction of mortality on account of Dengue by 50% by year 2010.

Magnitude of the Problem

This is shown in the Fig. - 2.

Until June 2007 there were 256 cases and 2 deaths (9).

Strategy for Control

- Disease and vector surveillance
- Vector management through source reduction with community participation
- Case management
- IEC initiatives
- Epidemic preparedness and early response.

Guidelines for Integrated Vector Management for Control of Dengue / Dengue Haemorrhagic Fever under NVBDCP (10)

The key to control DF/DHF is adoption of a comprehensive approach by way of regular vector surveillance and integrated management of the Aedes mosquitoes through biological and chemical control that are safe, cost effective; and environmental management, legislations as well as action at household and community levels.

Vector Surveillance

Both larval and adult surveys to be carried out.

Larval surveys	Adult Surveys
i) House Index (HI)	i) Landing/biting collection
ii) Container Index (CI)	ii) Resting collection
iii) Breteau Index (BI)	iii) Oviposition traps
iv) Pupae Index (PI)	

Environmental Management : The major environmental management methods used for control of immature stages of dengue vector are:

(i) **Environmental modification:** Long lasting physical transformation of vector habitats. For example, improved water supply, mosquito proofing of overhead tanks, cisterns or underground reservoirs.

(ii) **Environmental manipulation:** Temporary changes to vector habitats that involve the management of essential and non-essential containers and management of or removal of natural breeding sites.

(iii) **Changes in human habitations:** Efforts are made to reduce man-virus contact by mosquito proofing of houses with screens on doors/windows.

Personal Protection : Insecticide treated mosquito nets have limited utility in dengue control, since the vector species bite during the day time. However, insecticide treated bed nets can be effectively used to protect infants and night workers while sleeping in daytime.

Biological Control

- Larvivorous fish are recommended for control of *Ae. aegypti* in large water bodies or large water containers.

(ii) Endotoxin-producing bacteria, *Bacillus thuringiensis* serotype H-14 (Bt H-14) has been found to be an effective mosquito control agent.

Chemical Control : Chemical control measures (larvicides, adulticides) are recommended in permanent big water containers where water has to be conserved or stored because of scarcity of water or irregular and unreliable water supply.

Larvicide : Since *Ae. aegypti* breeds in clean water, which is stored and used for household purposes, as such all the larvicides, which are safe, without any odour or colour, have residual effect with low mammalian toxicity and do not pose any health hazard should be used. Temephos, an organophosphate compound meets all the above mentioned requirements and this insecticide is being used under the public health programme. The recommended dose for application of Temephos (50 EC) is 1 ppm (1 mg per liter of water).

Adulticide : The following methods are recommended for the control of adult *Ae. aegypti* mosquitoes:

- a) Pyrethrum spray
- b) Malathion fogging or Ultra Low Volume (ULV) spray

Legislative Measures

Model civic byelaws : Under this act, fine/punishment is imparted, if breeding is detected. These measures are being strictly enforced by Mumbai, Navi Mumbai, Chandigarh and Delhi Municipal Corporations.

Building Construction Regulation Act : Building byelaws should be made for appropriate overhead / under ground tanks, mosquito proof buildings, designs of sunshades, porticos, etc for not allowing stagnation of water vis-à-vis breeding of mosquitoes. In Mumbai, prior to any construction activity, the owners/builders deposit a fee for controlling mosquitogenic conditions at site by the Municipal Corporation

Environmental Health Act : Suitable byelaws should be made for the proper disposal/storage of junk, discarded tins, old tyres and other debris, which can withhold rain water.

Behavior Change Communication (BCC) campaign : The community needs to be educated to prevent breeding of mosquitoes.

Chikungunya

Chikungunya is a relatively rare form of viral fever caused by an alpha virus that is spread by bite of *Aedes aegypti* mosquito. The name is derived from the Swahili word meaning 'that which bends up' in reference to the stopped posture developed as a result of the arthritic symptoms of the disease.

The preventive and control strategies are same as for dengue fever. Surveillance of fever cases with joint pains should be emphasized.

Japanese Encephalitis

Directorate of National Vector Borne Disease Control Programme (NVBDCP) is a nodal agency for control and prevention of Japanese Encephalitis (JE) in the country (12). Reduction of mortality on account of Japanese Encephalitis by 50% by year 2010 has been envisaged under the National Health Policy (2002).

Strategy

Early case detection and treatment : Early diagnosis & proper management of JE cases is of prime importance to reduce case fatality through strengthening of diagnostic and clinical management of JE cases, at PHCs/CHCs and District Hospitals. JE burden can be estimated satisfactorily if the facilities for JE confirmation are made available at least in referral hospitals. Considering the merits and demerits of each diagnostic test and the patients representing different clinical phases of infection, establishment of two diagnostic tests, one for detection of JE Reverse Transcriptase - Polymer Chain Reaction (RTPCR) and one for detection of virus antigen/virus genome is necessary.

Vector Control

Chemical control : Vector control is a serious challenge for JE control because of exophilic and exophagic behaviour of JE vectors, which limits effectiveness of conventional insecticides. *IRS is not recommended* for prevention and control for JE. However, in areas where vector is endophilic like *Mansonia annulifera*, IRS may be considered for vector control in high risk pockets. *Fogging is a very cost intensive vector control tool but with limited effect and therefore, not recommended* as a routine vector control measure. In case of JE outbreaks, since the vectors are mainly outdoor resting and outdoor feeding, peri-domestic fogging could be resorted to very carefully for containment of outbreaks. It has been suggested that most of the states *may resort to fogging whenever there is any JE outbreak* so that they can make their efforts visible in the community besides its impact on adult population of vector mosquitoes. Personnel protection methods and anti larval operations should also be taken.

Reduction of breeding sources for larvae : Two feasible methodologies have been demonstrated to control breeding of mosquitoes in rice fields. They are (i) water management system with intermittent irrigation system and (ii) incorporation of neem products in rice field. The water management is nothing but a strategy of alternate drying and wetting water management system in the rice fields. By using neem products as fertiliser in rice fields, they not only enhance the grain production but also suppress the breeding of culicine vector of JE.

Larvivorous fish : Introduction of composite fish culture for mosquito control in rice fields has been evaluated and proved to be successful. In other large and small water bodies release of larvivorous fish will prevent the JE vectors breeding.

Biolarvicides : Biocides like *Bacillus thuringiensis var. israelensis* and *Bacillus sphaericus* were promoted and anticipated to have great implications as biological larvicides against different mosquito species. Lack of suitable delivery system and short duration of larvicide effect restricted its use in vector control strategy.

Reduction in man-vector contact : Pyrethroid-impregnated bed nets and curtains have shown to reduce man-mosquito contact. However people may not prefer to use bed nets due to high temperature and humidity. In such areas, people do accept impregnated curtains instead of bednets. The limitation with this technology is the repeated impregnation of the curtains once in 6 to 9 months and periodic assessment of vectors for development of insecticide resistance to this product

Control of Pigs : Pigs constitute the amplifying host of JE and mosquitoes when bite pigs get infected that later infect humans. In JE endemic areas, pigs are found associated with human habitations. Control methods can include immunizing, slaughtering pigs, use of mosquito proof piggeries, etc. Segregating pigs at least 4-5 km away from human habitations can be used wherever it is possible by implementing some by-laws by local administration. Several studies conducted in Japan showed that pig immunization was effective in eliminating disease in pigs, which may reduce animal transmission and possibly lower human incidence. But it has not been used at the national level because pig immunization requires large number of newborn pigs to be immunized each year and because the period of vaccine effectiveness is limited.

Behaviour Change Communication (BCC) or (Information Education Communication) : Health Education should be imparted through all probable approaches on personal prophylaxis against vector, segregation of amplifier hosts by mosquito proofing and for early reporting of cases. Each endemic state should conduct a media advocacy and health education workshop a month prior to the expected season to educate media about the upcoming JE season and enlist their support in dissemination of messages on self protection methods and early case reporting at nearest medical facilities, etc., thereby avoiding any uninformed, adverse publicity.

Immunization against JE : There are three types of JE vaccine in widespread production and in worldwide use for control of JE. These are (i) inactivated mouse brain derived vaccine; (ii) inactivated primary hamster kidney cell-derived vaccine, and (iii) live attenuated vaccine. Under immunization protocol, immunization of pigs is to be considered which may reduce viral transmission by limiting or preventing viraemia in pigs. JE vaccines for pigs and equines have been used in various areas of China.

JE vaccine used in India is a formalin-inactivated product prepared from mouse brains infected with Nakayama JE virus manufactured at Central Research Institute, Kasauli, and Himachal Pradesh. The virus is purified with protamine sulphate treatment and ultra centrifugation. The final vaccine is supplied in a freeze dried form and reconstituted in 5.4 ml of sterile pyrogen free distilled water supplied by the laboratory. Pilot projects for JE vaccination have already started in few states in the country.

Critical Appraisal of NVBDCP

Technical manpower : There is shortage of MPWs in all the states. In some states the shortage may be as high as 60% or more of the sanctioned strength. For the timely and regular surveillance these field level functionaries are crucial.

Examination of blood smears : The blood smears collected by ACD & PCD are to be examined expeditiously. Under the current situation, in most of the places, there is considerable time lag between collection and examination of blood smears due to inadequate facilities. The laboratory for malaria microscopy should be decentralized and brought as near to the community as possible. All efforts should be made to reduce the time lag between blood smear collection and examination by utilizing

existing facilities available both in public & private sectors.

Urban Malaria : It is perceived as a major threat; no structured health care delivery system like the primary health care system as in rural areas has been established. Funds are also allocated for larvicides / adulticides only and the operational costs of malaria control activities are met by the State/Urban Local Bodies. The coverage by anti larval measures however, limited and do not extend to the entire towns/city limits. The source reduction drives in domestic areas are hampered by denial of entry to public health personnel on security reasons, limited community mobilization and multi-sectoral collaboration and absence of appropriate civic legislations.

Monitoring & Evaluation : Enactment and enforcement of legislatures to prevent mosquito breeding in domestic and peri-domestic areas or work places, government/commercial buildings, construction sites, etc. are the responsibility of multiple authorities and often not implemented in a coordinated manner. No proper resource allocation is also made for most of these components, even though these are extremely critical to achieve the desired health objectives of health and well-being in urban areas.

Use of insecticides for vector control : Using insecticides in improper dosage and schedule promotes vector resistance. There is shortage of insecticides due to which incorrect chemical is used as an alternative or the same is diluted to meet the requirement.

Community participation : It is inadequate.

Non Uniformity in treatment : No uniformity in medical practitioners regarding treatment of vector borne diseases.

Summary

NVBDCP is an umbrella programme for prevention and control of major vector borne diseases of public health importance namely Malaria, Filaria, Japanese encephalitis (JE), Kala azar and Dengue / Dengue Hemorrhagic Fever (DHF). It came into existence in 2003.

The Mission is to have Integrated accelerated action towards reducing mortality on account of malaria, dengue, Japanese Encephalitis by half and elimination of Kala-azar by year 2010 and elimination of Lymphatic Filariasis by 2015. The strategy lays emphasis on Training of health personnel in the diagnosis of vector-borne diseases and appropriate treatment including referral, Improved reporting, recording and monitoring of vector-borne diseases, Monitoring drug and insecticide resistance, Use of standardised protocol for the diagnosis and management of these diseases, Involvement of PRIs and research studies in vector borne diseases. The implementation at the national level is by Directorate of National Vector Borne Diseases Control Programme, at the state level by Regional Offices for Health and Family Welfare (ROH & FW) located at state HQ, district level by District Malaria Offices and Primary Health Centres at the village level. National Rural Health Mission will focus on all the diseases covered under NVBDCP.

The strategies for malaria control under the programme has been Early case Detection and Prompt Treatment (EDPT), Vector control (Chemical, Biological Control methods), Personal Prophylactic

Measures, Community Participation and Environmental Management & Source Reduction Methods. National antimalaria drug policy essentially provides a framework for the safe and effective treatment of uncomplicated and severe malaria as well as prevention of malaria in vulnerable groups, such as pregnant women and young children. All fever cases should preferably be investigated for malaria by microscopy or Rapid Diagnostic Kit (RDK). RDK is a immunochromatographic test. It detects *Plasmodium falciparum* histidine rich protein in blood. The first line of treatment is Chloroquine and the second line for *P. falciparum* is Artesunate combination therapy (ACT) consisting of Artesunate+ Sulphadoxine/Sulphalene+Pyrimethamine. In case of resistance to these formulations quinine would be the drug of choice. ACT is not to be used against treatment of *P. vivax* cases as it is not effective against it. Chemoprophylaxis for malaria: In chloroquine sensitive areas chloroquine is to be given and in Chloroquine resistant areas it is to be supplemented by proguanil.

Insecticides under NVBDCP for malaria control are DDT, Organophosphorous compounds (Malathion), Synthetic Pyrethroids (i) Deltamethrin 2.5% WP, (ii) Cyfluthrin 10% WP, (iii) Alphacypermethrin 5% WP (iv) Lambda cyhalothrin 10% WP and (v) Bifenthrin 10 WP) Wettable powder (WP) formulations are used for indoor residual sprays and emulsion concentrate (EC) formulations are used for larval control. Malaria vectors in India are resistant to DDT alone or double resistant to HCH or triple resistant to DDT, HCH, malathion and quadruple resistant to DDT, HCH, malathion and Deltamethrin (synthetic pyrethroid), however HCH has been phased out in 1997.

Malaria surveillance under NVBDCP is done through Fortnightly Domiciliary visits by MPW (male), Fever Treatment Depots (FTDs), Passive Case Detection (PCD), Rapid Fever Survey, Mass survey and Drug Distribution Centre (DDC). The National Health Policy (2002) has set the goal for elimination of Kala-azar by year 2010. Strategy under NVBDCP includes Interruption of transmission through vector control by undertaking residual indoor insecticide spraying in affected areas, with DDT up to 6 feet height from the ground twice annually, Early diagnosis & complete treatment and IEC & community mobilization.

The National Health Policy (2002) has set the goal for elimination of Lymphatic Filariasis (ELF) by the year 2015. The strategy for achieving the goal of elimination is by Annual Mass Drug Administration of DEC for 5 years or more to the population excluding children below two years, pregnant women and seriously ill persons in affected areas to interrupt transmission

of disease. The National Health Policy (2002) has set the goal of reduction of mortality on account of Dengue by 50% by year 2010. Strategy for dengue control comprise of Disease and Vector Surveillance, Vector management through source reduction with community participation, Case management, IEC initiatives and epidemic preparedness and early response.

Reduction of mortality on account of Japanese Encephalitis by 50% by year 2010 has been envisaged under the National Health Policy (2002). The strategy includes Early case detection and treatment, Vector Control (Reduction of breeding sources for larvae, use of Larvivorous fish, Biolarvicides), Reduction in man-vector contact and control of Pigs. JE vaccine used in India is a formalin-inactivated product prepared from mouse brains infected with Nakayama JE virus manufactured at Central Research Institute, Kasauli, and Himachal Pradesh.

“Leprosy work is not merely medical relief, it is transforming frustration in life into the joy of dedication, personal ambition into selfless service.” Mahatma Gandhi

The NLEP Emblem symbolizes beauty and purity in lotus. The Emblem captures the spirit of hope positive action in the eradication of Leprosy.

Evolution of Leprosy control in India

The details are given in Table - 1

The National Leprosy Control Programme (NLCP) was launched in 1954 (3). The strategy of NLEP was based on controlling the disease through reduction in the quantum of infection in the population, and reduction in infective source, thus breaking the chain of disease transmission. The program, therefore, had been planned on the following basic activities :

1. Survey and case detection.
2. Registration of cases for treatment.
3. Provision of continuous treatment with Dapsone to all cases, as close to their homes as possible.
4. Education of patients, their families and community at

large about leprosy.

5. Correction of deformities through deformity care programme.

Treatment with MDT was introduced under NLEP in phased manner in the year 1983 and programme was renamed as National Leprosy Eradication Programme. At the 44th World Health Assembly held in 1991, WHO and its Member States committed themselves to eliminate leprosy as a public health problem by the year 2000, elimination being defined as prevalence below one case per 10,000 population. The Government of India was also a signatory to this commitment. To enhance the process of elimination, the first World Bank supported project on NLEP was started in the year 1993-94 and MDT made available to all the registered cases. The Second World Bank supported National Leprosy Elimination Project was started for a period of 3 years and was implemented with the following objectives.

Objectives of NLEP II (2001 onwards)

1. To decentralize the NLEP responsibilities to the states/ UT: State level societies will be formed in 24 states and funding to the districts will be done by state societies. State societies will not be needed in the 8 smaller states/ Union Territories since the district societies there are adequate for channeling funds.

2. Integration of Leprosy Control Activities with the general health services : To accomplish integration of leprosy services with general health care system in 27 low endemic states and proceed with integration as rapidly as possible in the 27 low endemic states. In the 27 low endemic states/ UTs integration will be affected in all districts during the first project year

Table 1: Evolution of leprosy control in India

Year	Remarks
Pre independence	Initially Leprosy patients were isolated and segregated. Several statutory acts and laws were also enacted during this time against them. In India 'The Lepers Act 1898' was enacted, which discriminated against the Leprosy patients and segregated them socially. This act has since been repealed by Union Government & all the States & UTs.
1955	Government of India launched National Leprosy Control Programme with the objective of controlling leprosy with Dapsone.
1983	Launched National Leprosy Eradication Programme(NLEP) and introduced MDT for treatment
1991	WHO declaration to eliminate leprosy at global level by 2000
1993 - 2000	World Bank supported NLEP - I
1998 to 2003	After integration of leprosy services with GHC system in 2002-03, leprosy diagnosis and treatment services are available free of cost at all the Primary Health Centres (PHCs) in all the districts in India.
2002	National Health Policy had set the goal of elimination of leprosy (i.e., to reduce the number of cases to < 1/10,000 population) by the year 2005
2001 - 2004	World Bank supported NLEP - II
2005	National programme continues with GOI funds
2005	India achieved elimination of leprosy at National Level in December' 05, when the recorded Prevalence Rate (PR) in the country was 0.95/10,000 (<1/10,000) population.(1,2). By March 2007, the prevalence rate of leprosy in the country had declined to 0.72 per 10,000 population and 28 states/UTs have achieved the goal of leprosy elimination. The remaining 7 States/UTs viz. Bihar, Chhattisgarh, Jharkhand, West Bengal, Chandigarh, D&N Haveli and Delhi are having PR of >1 per 10,000 population and are progressing towards elimination. Out of 611 districts, 487 (79.71%) districts have achieved the elimination status

itself. In the 8 high endemic states a mixed approach has been followed from the first year onward with the general health service staff offering leprosy services that included case finding and treatment. The vertical staff is focusing on covering previously un-reached areas as well as providing support to general health service.

3. To achieve elimination at national level

Strategies

1. Special Action Project for Elimination of Leprosy (SAPEL) for rural and Leprosy Elimination campaigns for urban areas: It is an initiative aimed at providing MDT services in difficult to reach areas.

2. Modified Leprosy Elimination Campaign (MLEC): It is organizing camps which include a package of teaching, training, intensified IEC, case detection and prompt MDT. Wide publicity is given prior to camp. Five such nation wide campaigns have been carried out.

Activities

1. Early detection through active surveillance by the trained health workers
2. Regular treatment of cases by providing Multi-Drug Therapy (MDT) at fixed in or centers a nearby village of moderate to low endemic areas/district
3. Intensified health education and public awareness campaigns to remove social stigma attached to the disease.
4. Prevention of Disability & Medical Rehabilitation
5. Leprosy Training of General Health Services functionaries
6. Information Education and Communication (IEC) using Local & Mass Media for reduction of Stigma & Discrimination.
7. Monitoring & Evaluation
8. Inter-sectoral collaboration

Infrastructure

NLEP was implemented through the establishment of Leprosy control units (LCU), Survey Education and Treatment centers (SET) and urban leprosy centers. The leprosy control units were established in endemic areas with one medical officer, two non medical supervisors and twenty para medical workers. Each LCU covered a population of 4.5 lacs. The staff at SET center comprised of one paramedical worker for 20-25 thousand population and one non medical supervisor for 5 paramedical workers. The SET centers were attached to the PHCs and were under the medical officer in charge of PHC. Mobile leprosy treatment units provide services to leprosy patients in non endemic areas. Each mobile unit consisted of one medical officer, one non medical supervisor, two paramedical workers and a driver. There were two MLTU for moderately endemic and one for low endemic states.

At state level state leprosy officer was the chief coordinator and technical advisor to the concerned state govt. At the center, leprosy division of directorate general health services was responsible for planning, supervision and monitoring of the program. The division is under the control of Deputy Director General who advised govt on all anti leprosy activities. Presently NLEP has been integrated into the general health services system under NRHM. The program will run under the

same guidelines of GOI but will conform to Indian Public Health Standards as laid own under the mission. The minimum services available at the community health center should be diagnosis of leprosy, treatment of cases, management of reactions and advice to patients on disability prevention & care.

MDT : The details are given in Table - 2, 3 and 4

Type of leprosy/ Duration of treatment	Type of regimen	Characteristics
PB (Pauci - bacillary) Six pulses in 6-9 consecutive months	PB (Adult) / PB (child) Less severe type	1-5 patches &/ or involvement of one nerve
MB (Multi bacillary) Twelve pulses in 12-18 consecutive months	MB (Adult)/ MB (child)	More severe type 6 or more skin patches & or involvement of two or more nerves

Surveillance after treatment

- PB cases are clinically examined once a year for minimum two years after completion of treatment.
- MB cases are clinically examined once a year for a minimum period of five years after completion of treatment.

Multibacillary (Adult)	Rifampicin 600mg monthly given under supervision
	Dapsone 100mg daily self administered
	Clofazimine 300mg once monthly supervised; 50mg daily, self administered (When clofazimine is totally unacceptable owing to discoloration of skin, 250- 375mg of ethionamide or propionamide can be administered as daily dose).
Pauci bacillary (Adult)	Rifampicin 600 mg monthly given under supervision Dapsone 100mg daily self administered

Multibacillary (Child)	Rifampicin 450mg monthly given under supervision; Dapsone 50mg daily self administered; Clofazimine 150mg once monthly supervise and 50mg on alternate day, self administered
Pauci bacillary (Child)	Rifampicin 450mg monthly given under supervision; Dapsone 50mg daily self administered

Information, Education and Communication (IEC)

Objectives of IEC in moderately/low endemic states : This would be to encourage greater voluntary self-reporting, as the strategy for case detection in these states.

Objectives of IEC in high endemic states : In five high endemic states, where active search is conducted during MLEC, the objective of IEC is to create general awareness of MLEC and signs and symptoms of leprosy to provide support for and prepare the ground for MLEC. The targets are clients, influencers, and providers, particularly from general health services and private providers. Special client focus groups of IEC in the next phase are women, children, difficult to reach groups-urban remote areas, etc.

Training

All staff of the general health services in general health services in government hospitals, PHCs, CHCs, are expected to be trained to detect, treat, refer and to prevent and rehabilitate disability.

Monitoring and Evaluation of NLEP

NLEP has an inbuilt information system for monitoring and supervision of the programme activities at Central, State, District & Peripheral level.

Simplified Information System (SIS) : SIS was introduced in 2002 under which simplification of information system was done, so that the newly involved GHC service personnel can easily adapt to the system of record keeping, validation of records, reporting and monitoring of the programme at PHC/ Hospital, District and State level. This system has drastically improved recording, reporting and its transmission. The programme is monitored routinely at District, State and Central level through scrutiny of regular monthly reports. The system has been computerized for compilation of district reports at state level.

Leprosy Elimination Monitoring (LEM) : LEM exercise was undertaken with WHO support through the NIH&FW, New Delhi, to assess the programme achievement in identified indicators during the year 2002, 2003 and 2004(5). Immediate actions were initiated on the deficiencies observed.

Involvement of NGOs

NGOs are involved in leprosy elimination activities for many years and their contribution has been a positive impact in reducing the prevalence of leprosy. There are 285 NGOs working in the field of leprosy throughout the country and 54 NGOs are getting grant-in-aid from government of India for Survey, Education and Treatment (SET) scheme. Beside routine activities, some are also providing facilities for hospitalization and disability and ulcer care. Few NGOs are involved in conducting reconstruction surgeries. The NGOs serve in remote, inaccessible, uncovered, urban slums, industrial / labour population and other marginalized population groups. The various activities undertaken by the NGOs are, IEC, Prevention of Impairments and Deformities, Case Detection and MDT Delivery.

ILEP Agencies : International Federation of Anti-leprosy Association (ILEP) is actively involved as partner in NLEP. In India ILEP is constituted by 10 Agencies viz. The Leprosy Mission, Damien Foundation of India Trust, Netherland Leprosy Relief, German Leprosy Relief Association, Lepra India, ALES, AIFO, Fontilles - India, AERF - India and American Leprosy Mission. Activities carried out by ILEP are - capacity building of GHC staff, provision of technical support at various level

and providing re-constructive surgery services and support to various NGOs in the country carrying out leprosy related activities.

Leprosy Institutions : Four premier Leprosy Institutes are working under Directorate General of Health Services, Ministry of Health & F.W., Government of India viz. CLTRI, Chengalpattu, RLTRI, at Aska, Raipur and Gouripur are involved in research (basic and applied) in Leprosy and Training of different categories of staff involved for Leprosy elimination. These Institutes also play important role in management of referral patients, providing quality care to chronic ulcer and disabled patients with the help of Minor & Major Reconstructive Surgeries.

Urban Leprosy Control Programme

To address the complex problem like larger population size, migration, poor health infrastructure and increasing prevalence in urban areas, there was a need for Urban Leprosy Programme. Urban Leprosy Control Programme has been implemented since 2005 under which assistance is being provided by Govt. of India to urban areas having population size of more than 1 lakh. For the purpose of providing graded assistance, the urban areas are grouped in four categories i.e. Township-I, Medium Cities-I, Medium Cities-II, Mega Cities.

Post Elimination Period - NLEP

In the Post elimination period, NLEP needs to expand the scope of leprosy services provided to the patients, their families and community at large. The aims and objective under the 11th Plan (2007-2012) are as below. These objectives are also in conformity with the global strategy issued by WHO (2006-2010).

1. Further reducing the leprosy burden in the country.
2. Provide good quality leprosy services.
3. Enhance Disability Prevention and Medical Rehabilitation.
4. Increase advocacy towards reduction of stigma and stop discrimination and Strengthen monitoring and supervision.

New Paradigm : In view of the need to sustain leprosy services for many years to come, there has to be a shift from a campaign like elimination approach, towards the long term process of sustaining integrated high quality leprosy services, which in addition to case detection and treatment with Multi Drug Therapy, also include prevention of disability and rehabilitation. To get the programme move in the desired direction, the New Paradigms in NLEP have been detailed as below:

Burden of leprosy : The burden of leprosy can be looked at in three ways:

- Firstly, the most relevant epidemiological measure of the burden of leprosy is the incidence of disease, which is the number of people developing leprosy during a defined period usually one year. Because leprosy is an insidious disease, number of cases detected/ registered for treatment is generally lower than the actual number of incident cases for that time. Hence, incidence is difficult to measure directly and New Case Detection Rate (NCDR) is used as a proxy for incidence rate.
- Secondly, the burden may be related to the registered prevalence of disease, which is the number of people on

treatment at a certain point of time. Although registered prevalence was a useful indicator to achieve the leprosy elimination milestone, it is not adequate indicator to reflect changes in the epidemiological trend of leprosy.

- Thirdly, the burden of leprosy can be viewed as disability and deformity produced by leprosy.

Improving the quality of services : The quality of care depends on the quality of technical supervision provided by the program and availability of strong back up from an effective referral system. Quality leprosy services means treatment by MDT is available at all the health units without any geographical, economic or gender barriers. Services provided are patient-centred; observe patient's rights, including the rights to timely and appropriate treatment, privacy and confidentiality. The quality leprosy services addressing each aspect of case management, based on firm scientific evidence like diagnosis is carried out timely and accurate with supportive counselling, timely treatment with MDT, free of charge in a user friendly environment; appropriate disability prevention interventions; referral for complications and appropriate rehabilitation and maintaining simple records and encourage review and evaluation.

Prevention and management of impairments and disabilities: The current situation with regard to the number of persons living with leprosy - related disabilities and impairments may need reassessment, particularly at national level. In addition, programme should ensure that persons affected by leprosy have access to services by other programmes dealing with other disabling diseases or conditions. Interventions aimed at preventing disabilities / impairments from occurring and/or worsening include early detection and effective management of leprosy-related reactions and nerve damage, proper counselling on self care, participation of household members in home based care, development and use of locally produced and culturally and aesthetically acceptable footwear and other appliances.

Improving community awareness and involvement : The major theme of community awareness is to provide accurate information about the disease, its curability and availability of services at the nearest health facility. The objective of such IEC efforts should be to encourage self - reporting of new cases and to reduce stigma and discrimination. There are four key messages for the general public include early signs of leprosy, its curability, encourage people to support leprosy affected people to live a normal a life and no need to fear as disease can be managed just like any of other diseases; can be expressed in many different ways.

Support of National Rural Health Mission : ASHA could be utilized for early detection of suspected cases of leprosy, referral of such cases to nearest health centre for confirmation & completion of treatment. *Rogi Kalyan Samities* at PHC, CHC and district hospitals are autonomous registered bodies constituted at each level to facilitate in management of hospitals and delivery of quality care to patients. The NLEP will be benefited by working in coordination with other programs under the NRHM. District Health Mission which is chaired by the president of Zila Parishad may be helpful for advocacy of the program.

Critical Appraisal

Leprosy in present day scenario is still associated with social stigma. There are various myths related to the disease which interfere with health seeking behavior particularly early detection and treatment. Resistance to anti leprosy drugs i.e Dapsone, Rifampicin and Clofazimine has already been reported in few studies. No alternative regime is presently available for such cases. Achieving elimination will give a false sense of security against transmission of infection. Leprosy is a social disease however no efforts have been made for elimination of social factors related to the disease. There are many problems related to integration of program with general health services. Leprosy has always received low priority when compared to HIV/AIDS. Very little has been done in the area of rehabilitation of leprosy cases.

Summary

The National Leprosy control programme (NLCP) was launched in 1954. Treatment with MDT was introduced under NLEP in phased manner in the year 1983 and programme was renamed as National Leprosy Eradication Programme. The objectives of NLEP II (2001 onwards) have been To decentralize the NLEP responsibilities to the states/UT, Integration of Leprosy Control Activities with the general health services and To achieve elimination at national level. India achieved elimination of leprosy at National Level in December' 05, when the recorded Prevalence Rate (PR) in the country was 0.95/10,000 population.

The main activities are - Early detection through active surveillance by the trained health workers, Regular treatment of cases by providing Multi-Drug Therapy (MDT) at fixed in or centers a nearby village of moderate to low endemic areas/district, Intensified health education and public awareness campaigns to remove social stigma attached to the disease and Prevention of Disability & Medical Rehabilitation

The other strategies followed were Special Action Project for Elimination of Leprosy (SAPEL) for rural and Leprosy Elimination campaigns for urban areas: It is an initiative aimed at providing MDT services in difficult to reach areas. Modified Leprosy Elimination Campaign (MLEC): It is organizing camps which include a package of teaching, training, intensified IEC, case detection and prompt MDT Modified Leprosy Elimination Campaign (MLEC): It is organizing camps which include a package of teaching, training, intensified IEC, case detection and prompt MDT.

NLEP was implemented through the establishment of Leprosy control units (LCU), Survey education and Treatment centers (SET) and urban leprosy centers. Presently NLEP has been integrated into the general health services system under NRHM. The program will run under the same guidelines of GOI but will conform to Indian Public Health Standards as laid own under the mission. The minimum services available at the community health center should be diagnosis of leprosy, treatment of cases, management of reactions and advice to patients on disability prevention and care.

For Treatment leprosy cases are divided into Paucibacillary (Less severe type 1-5 patches &/or involvement of one nerve) and Multibacillary (More severe type 6 or more skin patches &

or involvement of two or more nerves). PB cases are clinically examined once a year for minimum two years after completion of treatment. MB cases are clinically examined once a year for a minimum period of five years after completion of treatment.

Monitoring and Evaluation of NLEP is through Simplified Information System (SIS) was introduced in 2002 under which simplification of information system was done, so that the newly involved GHC service personnel can easily adapt to the system of record keeping, validation of records, reporting and monitoring of the programme at PHC/ Hospital, District and State level. was introduced in 2002 under which simplification of information system was done, so that the newly involved GHC service personnel can easily adapt to the system of record keeping, validation of records, reporting and monitoring of the programme at PHC/ Hospital, District and State level.

In the Post elimination period, NLEP needs to expand the scope

of leprosy services provided to the patients, their families and community at large. The aims and objective under the 11th Plan (2007-2012) are to further reduce the leprosy burden in the country, Provide good quality leprosy services, Enhance Disability Prevention and Medical Rehabilitation, Increase advocacy towards reduction of stigma and stop discrimination and Strengthen monitoring and supervision.

Pilot Project On Prevention and Control Of Human Rabies Under 11th Five Year Plan

Puja Dudeja & Ashok K. Jindal

Rabies is an acute viral encephalomyelitis which is invariably fatal but can be easily prevented. Dog is the principal reservoir of Rabies in India. The goal of rabies control is to prevent human death and control dog rabies so that it no longer remains a major public health problem. This will reduce the socioeconomic losses from the disease. In India, cases of rabies occur throughout the year and in all parts of the country with the exception of Andaman and Nicobar Islands. It is estimated that about 20,000 people die of rabies every year. This figure may not be exact as there is on organized system of surveillance of rabies cases and hence lack of reliable data. There is at present no comprehensive National Rabies control Programme in India. Various organizations are currently involved in control activities without any intersectoral coordination. Existing rabies control activities are being carried out by Municipal Corporations/ Committees, Cantonments etc. in their respective areas.

Objectives : The broad objectives of the proposed pilot rabies control programme are firstly, prevention of Human deaths due to rabies and secondly, reducing the transmission of disease in animals.

Target : The specific target is reduction of rabies deaths in human beings by at least 50% by the end of Five year plan in the pilot project areas. For verification, the retrospective data will be collected from pilot project areas and continuous surveillance will be maintained till the end of XI five year plan.

Implementation : The programme will be implemented as a pilot project, with National Apex Committee for prevention and

control of rabies as the Nodal Agency. The committee will be chaired by DGHS with Animal husbandry Commissioner, Joint Commissioner, Live Stock and Health; Joint Commissioner, Ministry of Information and Broadcasting, Govt of India; Director NICD; Director IVRI Izzatnagar; Director PII, Coonor as members and HOD, Zoonosis Division NICD as member secretary. Initially the programme is proposed to be implemented on pilot basis in two major cities i.e. Delhi and Pune.

Components of the programme : There will be 2 components, as follows :

Human Component

1. Local Health Authorities will make available infrastructure and logistics in the pilot project area, areas for post exposure treatment.
2. Facilities of wound wash will be provided at anti rabies clinic by the local health authorities.
3. Surveillance system will be strengthened to generate reliable data. Attempts will be make to integrate surveillance under IDSP work.
4. Development of trained manpower.
5. Ensuring community participation in IEC activities.
6. Involvement of NGOs and private sector.
7. Strengthening the Nodal agency for human rabies control (NICD, Delhi) for monitoring and evaluation of human component.
8. Operational Research with focus on study of factors leading to rabies deaths and minimizing animal bites.

Animal Component

1. Vaccination of stray dogs
2. Sterlization of dogs and population management
3. Waste management
4. Dog movement restriction etc.

Puja Dudeja & Ashok K. Jindal

India is the first country in the world to establish the National Guinea Worm Eradication Programme in 1983-84 as a centrally sponsored scheme on 50-50 sharing between Centre and States with the objective of eradicating guinea worm disease from the country. The objective of the Guinea Worm Eradication Programme was to achieve zero guinea worm disease incidence in the country. The programme achieved zero guinea worm disease status in 1997, against 40,000 cases occurring annually in 1984. Banwari Lal, 25 years old, from Jodhpur in Rajasthan, was the last case in India in 1996 (1). "Zero" incidence has been maintained since August 1996 through active surveillance and intensified field monitoring in the endemic areas. In the Meeting of WHO in February 2000, India has been certified for the elimination of Guinea Worm Disease and on 15th February 2001, declared India as "Guinea Worm Disease Free (2)".

The important strategies adopted to eradicate the Guinea Worm (GW) were (2) :

1. GW case detection and continuous surveillance through active case search operations and regular monthly reporting.
2. GW case management.
3. Vector Control by the application of Tempos in unsafe water sources eight times a year and use of fine nylon mesh/ double layered cloth strainers by the community to filter Cyclops in all the affected villages.
4. Health education.
5. Trained manpower development.
6. Provision and maintenance of safe drinking water supply on priority in GW endemic villages.
7. Concurrent evaluation and operational research.

Puja Dudeja & Ashok K. Jindal

Due to rapid ecological changes, many zoonoses have emerged as epidemics. Leptospirosis causes significant morbidity and mortality in human beings especially in coastal region of the country. The objectives of the programme are to establish surveillance in the country and to reduce morbidity and mortality due to leptospirosis in India. The control programme will be implemented in a phased manner. In the first phase it will be conducted in Kottayam district of Kerala and South Gujrat. The reduction in Morbidity and Mortality would be an indicator of successful implementation of the programme.

Strategy : The strategy includes Development of Data Base through routine and IDSP system; Identifying vehicle of transmission; Identification of serovar in prevalent states;

Identifying the causes of upsurge; Strengthening diagnostic facilities; and, Improving management facilities.

Initiatives : The three major factors responsible for leptospirosis are salinity of soil, adequate moisture and presence of microorganisms in reservoir / carrier hosts. Intersectoral coordination among the departments of National Bureau of Soil Survey and Land Resource Management, Department of Meteorology, Rodent control Board of India and department of Animal Husbandry of endemic states will be taken. The areas from where the disease has not been reported but where similar ecological factors prevail will be separately earmarked as 'Leptospira Prone Areas'. A monitoring and evaluation system for above activities will be set up (1).

Puja Dudeja & Ashok K. Jindal

The **Red Ribbon** is an international symbol of AIDS awareness that is worn by people all year round and particularly on World AIDS Day (December 1) to demonstrate care and concern about people living with HIV/AIDS and to remind others of the need for their support and commitment. The concept of a World AIDS Day originated at the 1988 World Summit of Ministers of Health on programs for AIDS prevention. Since then, it has been taken up by Govts., International organisations and charities around the world.

Evolution : Evolution of National AIDS control programme is given in Table - 1.

Year	Remarks
1986	First HIV case reported in India
1987	AIDS control programme was launched
1992	Ministry of Health and Family Welfare set up a National AIDS Control Organization (NACO)
1986-1992	Surveillance launched in 55 cities in the three states and the programme activities were left to the states without a strong central guidance
1992-1997	National AIDS Control Project (Phase I), extended to 1999(1)
1999-2004	National AIDS Control Programme (Phase II), extended to 2007
2002	National AIDS Prevention & Control Policy (2)
2002	National Health Policy : Zero level growth of new HIV/AIDS by 2007
2007-2012	National AIDS Control Programme (Phase III)

National AIDS Control Programme Phase I (1992-99)

During this phase, the National AIDS Control Project was developed for prevention and control of AIDS in the country. The ultimate objective of the project was to slow the spread of HIV to reduce future morbidity, mortality, and the impact of AIDS by initiating a major effort in the prevention of HIV transmission. There was a nation wide capacity building in managerial and technical aspects of the programme. It also aimed at increasing awareness and condom usage in targeted high risk population.

National AIDS Control Programme Phase II (1999-2004)

The Phase II of the National AIDS Control Programme has become effective in 1999. It is a 100% Centrally sponsored scheme implemented in 32 States/UTs and 3 Municipal Corporations namely Ahmedabad, Chennai and Mumbai through AIDS Control Societies. The focus in this phase was to slow the spread of HIV infection, decrease the mortality and morbidity associated with HIV infection and minimize the socioeconomic impact resulting from HIV infection(3,4).

National AIDS Control Programme Phase III (2006-12)

NACP-III is based on the experiences and lessons drawn from NACP-I and II, and is built upon their strengths.

Goal : To halt and reverse the epidemic in India over the next five years by integrating programmes for *prevention, care and support and treatment*.

Objectives : To reduce the rate of incidence by 60 per cent in the first year of the programme in high prevalence states to obtain the reversal of the epidemic, and by 40 percent in the vulnerable states to stabilise the epidemic.

Strategy

- Prevent infections through saturation of coverage of high-risk groups with targeted interventions (TIs) and scaled up interventions in the general population.
- Provide greater care, support and treatment to larger number of People Living with HIV/AIDS (PLHA).
- Strengthen the infrastructure, systems and human resources in prevention, care, support and treatment programmes at district, state and national levels.
- Strengthen the nationwide Strategic Information Management System.

Programme Implementation

Intensive coverage of High Risk Groups through targeted interventions : Surveys conducted under NACP II indicated presence of high risk groups in all parts of the country and a focused strategy was launched to raise their awareness, motivating them to adopt safe behavior, improving their access to preventive services and tools such as condoms. NACP III will aim at increasing the coverage of such services especially for high risk groups, identified as sex workers and their clients, transgender population, men having sex with men (MSM) and IV drug users in urban and rural areas. The 'bridge population' identified as truck drivers, street children, prison inmates and migrant workers would also receive special attention under NACP III. The essential elements of target interventions proposed under NACP III are access to behaviours change communication, prevention services such as condoms, STI services, needles and syringes, treatment services in form of STI clinics, drug substitutions for IV drugs, antiretroviral therapy and creation of an enabling environment under all project sites.

Intensification of interventions among general populations: Although 99 % of Indian population is not infected, a high level of vulnerability exists, especially, among young people, women, migrant workers and marginalized populations. NACP

III aims at reducing risk, vulnerability and stigma through increased awareness and targeted behavior change. The program is considered to be effective when 99 % of population can recall three modes of HIV transmission and two methods of prevention. This is to be achieved through increased awareness through communication, social mobilization & advocacy and through integration and expansion of integrated HIV related services like HIV counseling, testing, STI treatment, Prevention of Parent To Child Transmission and Post Exposure Prophylaxis (PEP) at sub district hospital, community health centers and PHCs.

Sexually Transmitted Disease (STD) Control Program : Evidence suggests that likelihood of contracting HIV infection is 8-10 times higher in presence of other STDs, particularly genital ulcers. In view of the established relationship between HIV and STIs, Min of Health & Family welfare adopted a policy of integrating HIV/AIDS and STD control within the existing health care system. Under the program, emphasis is given to comprehensive treatment of STIs at primary health care level and integration of non-stigmatized services with greater accessibility and acceptability by patients and community, while maintaining confidentiality and privacy of the patients. NACO took over the STD control program (in operation since 1946) in 1992 and made it an integral component of AIDS control policy. After overcoming the shortcomings of the erstwhile STD control program (like poor accessibility, stigma), NACP III continues to provide STI services based on syndromic approach, with the aim to improve etiological management of STIs (5). The broad objective of STI control program under NACP III are to reduce STD infections, thereby controlling HIV transmission by minimizing a risk factor and to prevent short and long term morbidity & mortality due to STDs. This is to be achieved through the following strategies :

- (i) Development of adequate & effective program management by strengthening existing STD clinics, appointing STD program officers in State AIDS control societies and identification of district nodal officers who would supervise working of STD clinics.
- (ii) Promotion of IEC activities for prevention of transmission of STD & HIV infections in form of activities to educate people for responsible sexual behavior, safer sex and greater condom usage.
- (iii) Improving case management including diagnosis, treatment, counseling, partner notification and screening for other diseases, in form of two sets of guidelines for PHC level and for referral of STD specialists.
- (iv) Increasing access to health care for STD by strengthening existing STD clinics, increasing health seeking behavior through IEC & NGOs and establishing first Referral Units in collaboration with Dept of Family welfare.
- (v) Creating facilities for diagnosis & treatment of asymptomatic infections by providing trained lady medical officer and sensitizing community through family Health Awareness Campaigns for early detection and referral to PHCs.

(Details of syndromic approach to management of STDs is given in detail in the chapter on STDs).

Family Health Awareness Campaign (FHAC)

These are campaigns for 15 days, organized by the states to address the issue of RTIs/STDs and HIV/AIDS. The objectives of the campaign are :

1. To raise awareness levels regarding HIV/AIDS in rural and slum area and other vulnerable groups of the population.
2. To make people aware about the services available under the public sector for management of HIV/AIDS.
3. To facilitate early detection and prompt treatment of RTI/STD cases by utilizing the infrastructure available under primary health care system including provision of drugs.
4. To strengthen the capacity of medical and paramedical professionals working under health care system to respond to HIV/AIDS epidemic adequately.
5. To use safe blood from licensed blood banks and blood storage centers.
6. To be aware that HIV can be transmitted from the infected mother to her baby during pregnancy, delivery and breast feeding.

Voluntary Counseling and Testing (VCT) : VCT specifically involves increasing availability and demand for voluntary testing including joint testing of couples, training grassroots health workers in HIV counseling and providing counseling through blood banks and through STI clinics. Under NACP III, it is envisaged that at least one voluntary testing centre would be established in every district. Pretesting counseling (before HIV testing) essentially prepares an individual for undergoing HIV test, identifying high risk behavior. Post test counseling helps the client to understand the importance and meaning of negative or positive HIV test, benefits of changing the high risk behavior and constructively handling the marital and sexual needs.

HIV testing : Under the present HIV testing policy of Govt of India, there is no rationale for mandatory HIV testing of any individual. It is established that any form of mandatory testing usually drives 'underground' those who are at highest risk due to stigma & discrimination and is thus counter-productive in the long term. According to present HIV policy, HIV testing is carried out on voluntary basis with adequate pretest and post-test counseling. Govt of India has formulated a comprehensive HIV testing policy, in accordance to WHO guidelines, which states that :

- (i) No individual shall be made to undergo any form of mandatory HIV testing.
- (ii) HIV testing shall not be imposed as a precondition to employment or for providing health care facilities during employment.
- (iii) Adequate facilities for voluntary testing with pretest and post - test facilities will be made available throughout the country in a phased manner, so as to have at least one HIV testing centre in every district.
- (iv) Disclosure of HIV status to spouse of the person will depend entirely on willingness to part with such informations. However, all efforts should be made so that the individual voluntarily shares such information with family, to ensure proper home based care.
- (v) Different testing strategies are to be adopted under different circumstances, as under :

- **Mandatory testing** : Screening in blood banks for blood safety. However, testing in all blood banks will be undertaken on collected blood samples in an unlinked & anonymous manner so as to only identify the status of blood sample and not of the donor.
- **Unlinked and anonymous testing** : To be undertaken for epidemiological surveys and HIV surveillance to monitor the trend of HIV infection in community.
- **Voluntary and confidential testing** : To be undertaken as confirmatory testing for subclinical infections/clinical management and as voluntary testing.
- **Need based testing** : To be undertaken with explicit consent, for research purpose, after ensuring all ethical considerations.

For screening of donated blood, a single test by either Rapid or ELISA method is enough to eliminate possibility of HIV infected blood. For epidemiological surveys, the same procedure is adopted with one or two of Rapid/ELISA/Simple, which has high sensitivity. In such cases, testing is unlinked and anonymous and result is not given to the person. For clinical management and for confirmation of HIV status of individuals who voluntarily ask for it, testing using different antigen preparation. The result of HIV testing in such cases has to be disclosed only after proper pre-test and post-test counseling of the concerned individual.

Prevention of Parent To Child Transmission (PPTCT) : Various studies have indicated that chemoprophylaxis (in the form of Nevirapine) before delivery in case of HIV-infected pregnant woman significantly reduces mother-to-child transmission rate from 33 % to 8.4 % at birth or 10.1% at age of two months. The intervention cost has been worked out to Rs.175 per women, which is a very cost effective method to prevent perinatal HIV infection. NACP III envisages that antenatal clinics will be used for imparting HIV education to pregnant women through trained counselors. Special emphasis would also be given to drug prophylaxis linked with infant feeding, nutritional support and contraception. Drug regimes used for chemoprophylaxis would be modified according to emerging evidence of efficacy of the drugs.

Occupational Health and HIV/AIDS : NACP III has addressed the issue of expanding HIV/AIDS response at work place. Under NACP III, specific guidelines have been formulated in collaboration with employers, workers organizations, ministries and civil society, with the aim to strengthen response to HIV and mitigate the effect of the diseases at work place. The key areas for intervention at work place are prevention of HIV/AIDS, management & mitigation of impact at work place, care & support for infected workers and reducing stigma and discrimination at work place.

Universal Protection & Post Exposure Prophylaxis (PEP) : Under NACP III, health care worker will be provided specific protection against occupational exposure to HIV. NACP III recommends following measure after occupational exposure :

- Rapid testing facility for HIV testing.
- Exposure with HIV should be considered a medical emergency.
- Chemoprophylaxis should be started within 4 hours after exposure.

(iv) Chemoprophylaxis should be reviewed on 1, 3 and 6 months interval.

(v) Under NACP III, only following drugs are approved for post exposure prophylaxis :

- Zidovudine - 300 mg twice daily for 4 weeks
- Lamivudine - 150 mg twice daily for 4 weeks
- Indinavir - 800 mg thrice daily (only as part of expanded regime)
- Saquinavir - 600 mg thrice daily.

Blood Safety Program : In India, blood banking infrastructure is highly decentralized and there is acute shortage of trained manpower, equipment and financial resources necessary to provide the desired quality of blood. In addition, there is often shortage of blood which encourages private blood banks with inadequate infrastructure and quality control.

Blood safety has remained an integral part of NACP since its inception an NACP III has included the objectives of :

- Ensuring organized blood banking services at State/District level
- Educating & motivating community about importance of voluntary blood donation
- Enforcing quality control for all units of blood to be infused.

Condom Promotion Program : In India, heterosexual transmission constitutes the major transmission route of HIV and condom usage remains the single most effective and practical method to prevent HIV transmission. Accordingly, Condom Promotion program under NACP III proposed that there should be no moral, religious or ethical inhibition in promoting condom usage among sexually active individuals, especially those who practice high risk behavior(6). Under NACP III, it is envisaged to convince people to use condom not only for family planning but also as the best preventive measure against HIV, convince commercial sex workers and their clients to use condoms as means to prevent sexually transmitted diseases including HIV and to make available low cost, good quality condoms to people all over the country easily at the time and place where they will need them. The objective of Condom Promotion Program is to ensure easy access to acceptable, good quality and affordable condoms with the view to promote safe sex. The following are used as indicators for success of Condom Promotion Program under NACP III :

- Percentage of persons who report easy availability of condoms within 500 meters of the place where they need them.
- Percentage of persons reporting consistent use of condom in sexual encounters with non- regular partners in last 30 days.
- Percentage increase in number of non-traditional outlets for condoms, like post offices, shopping malls etc.

University Talk AIDS Project (UTA) : UTA Project began as early as Oct 1991 with partnership between National Service Scheme (NSS), Dept of Youth Affairs & Sports and NACO. The project aims to generate awareness among students on HIV related issues through seminars, talks workshops and written material. The program also deals with related issues pertinent to youth like drug abuse, relationship, courtships, marriage and thus aims to enhance life style skills among the youth.

Treatment for opportunistic infections : It was previously available at district level; would be now available at CHC and PHC levels. Drugs would be given free at all govt hospitals and few NGOs with good track record in providing HIV care would also be incorporated for treating HIV. NACP III also proposes close linkage between NACP and RNTCP since tuberculosis remains the most common and most lethal opportunistic infection among HIV infected individuals.

- (a) Anti retroviral therapy to as many infected individuals has been attempted under NACP III. NACP III proposes partnerships and through community partnership and ownership. Seropositive women who have participated in PPTCT program, children below 15 years with HIV/AIDS, PLHA referred under targeted interventions (such as for commercial sex workers, truck drivers or migrant workers) and AIDS patients getting treatment from govt ART centres will be given priority for ART. It is proposed that by 2010, as many as 1,84,000 individuals would be on ART.
- (b) NACP III also proposes to establish DNA PCR facility for diagnosis of HIV in children through selected national referral centres, to meet the requirement due to increasing number of infected children.

Capacity Building : Under NACP III, capacity building at national, state and district levels is envisaged through multiple strategies to meet the fast evolving challenges of HIV epidemic in the country. Possible centres for imparting training, identified by a multidisciplinary standing committee (including an epidemiologist, economist, microbiologist and public health, marketing, communication specialists among others), will identify training needs at various levels and also help states to plan their training. In addition, capacity building under NACP III will include issues of program management, finance and procurement of infrastructure human resource and medicines at various levels.

Monitoring & Evaluation

HIV Surveillance : Effective and accurate HIV surveillance is essential to monitor progress of the control program. NACP III undertakes HIV surveillance with the objective to estimate incidence, prevalence, morbidity and mortality due to HIV and also to identify behavioural and biological markers on progress of preventive program.

One of the significant achievements of NACP is a credible HIV sentinel surveillance system. Information gathered through HIV sentinel surveillance, behavioural sentinel surveillance and STD surveillance helps in tracking the epidemic and provides the direction to the programme. Under NACP-III, PPTCT surveillance and ANC surveillance system are planned to be included in the programme. Surveillance for HIV infection comprises of four broad areas : HIV Sentinel Surveillance, AIDS Case Surveillance, Behavioural Surveillance and Sexually Transmitted Infections (STI) Surveillance. HIV Surveillance closely monitors and tracks the level, spread and trends of the epidemic as well as the risk behaviours that predispose the growth of epidemic. Inputs from the robust sentinel surveillance system of India, routine AIDS Case reporting, and periodic behavioural surveillance surveys give direction to the programmatic efforts by showing the impact of the interventions and areas that need focus of different initiatives.

HIV Sentinel Surveillance : HIV Sentinel Surveillance is undertaken every year jointly by National AIDS Control Organisation (NACO) and Min of Health & Family Welfare since 1998, with the aim of updating HIV estimates for the country. Under this program, HIV prevalence in the country is estimated based on HIV prevalence recorded at designated sentinel surveillance sites (such as STD clinics, de-addiction centers and intervention centers for female sex workers) for different risk groups. Women attending antenatal clinics are taken to be representative of the general population. Blood samples collected (between 01 Aug - 31 Oct) by unlinked anonymous method are tested at regular intervals annually and the data is used for epidemiological analysis and estimation of HIV prevalence in the country. The HIV Sentinel Surveillance System of India has greatly evolved over time covering all the districts of the country as well as all the high risk population groups. Annual HIV Sentinel Surveillance is conducted among Pregnant women attending Antenatal clinics, Patients attending STI Clinics, Female Sex Workers, Injecting Drug Users, Men who have Sex with Men, Migrant Population, Long distance Truckers, Eunuchs and Fisher folk. Based on HIV Sentinel Surveillance data, all the districts in the country are categorised into four categories for priority attention in the programme.

Behaviour Surveillance Survey (BSS) : BSS throws light on the knowledge, awareness and behaviours related to HIV/AIDS among general population, youth as well as among different high risk group communities. It also provides rich inputs to understand the impact of the intervention efforts being undertaken through NACP (7). BSS is undertaken to provide behavioural measurement for recording trends of high risk behavior among selected population groups. A set of 9 indicators, as under were used on three occasions to assess the trends.

(a) *Knowledge indicators* : These include Proportion of respondents who know the following : 2 acceptable ways to prevent STDs; that condoms prevent STDs; 2 acceptable ways to prevent HIV; and, that condoms prevent HIV.

(b) *Behaviour Indicators* : These include proportion of respondents who report heterosexual intercourse with non-regular partner in the last year and proportion of respondents who report condom usage during last sexual intercourse with non regular partner in the last year

(c) *Prevalence of Urethritis* among male respondents who report symptoms of urethritis during last one year or proportion of male respondents who sought treatment from qualified medical practitioners for urethritis in the last year.

(d) *Appropriate perception of risk indicators* : This pertains to proportion of respondents with high risk behavior who perceive that they can get infected with HIV.

India's response to HIV epidemic is influenced by the available surveillance data, implementation capacities and political commitment at state and national level. Apart from the sentinel surveillance, nationwide Computerised Management Information System (CMIS) provides strategic information on programme monitoring and evaluation. However, in the planning of NACP-III it was felt that data from sentinel surveillance and CMIS are not sensitive enough to detect the

emerging hot spots of the epidemic. To overcome this, NACO, in its third HIV/AIDS programme introduced *Strategic Information Management System (SIMS)* at national and state levels to focus on strategic planning, monitoring, evaluation, surveillance and research. It is aimed to provide effective tracking and response to HIV epidemic. The system assigns clear responsibilities to all programme officers and facilitates data flow and feedback at various levels.

Core Services at District level

In packaging of services, care is taken for the special needs of the region and availability of complementary health care system. In high prevalence districts, the full spectrum of preventive, supportive and curative services are available in medical colleges or district hospitals. These hospitals provide HIV/AIDS prevention services including treatment and cure for sexually transmitted infections, psycho-social counselling and support for people infected or affected by HIV, management of opportunistic infections and anti-retroviral therapy for people living with HIV/AIDS, counselling and testing facility for prevention of parent to child transmission of HIV infection, specialised paediatric HIV care and treatment / referral for specialist needs such as surgery, ENT and ophthalmology etc.

Care and Support for Children : Approximately 50,000 children below 15 years are infected by HIV every year. So far, care and support response to these children was at a very minimal level. NACP-III plans to improve this through early diagnosis and treatment of HIV exposed children; comprehensive guidelines on paediatric HIV care for each level of the health system; special training to counsellors for counselling HIV positive children; linkages with social sector programmes for accessing social support for infected children; outreach and transportation subsidy to facilitate ART and follow up, nutritional, educational, recreational and skill development support, and by establishing and enforcing minimum standards of care and protection in institutional, foster care and community-based care systems.

Treatment : HIV infection is not the end of life. People can lead a healthy life for a long time with appropriate medical care. Anti-retroviral therapy (ART) effectively suppresses replication, if taken at the right time. Successful viral suppression restores the immune system and halts onset and progression of disease as well as reduces chances of getting opportunistic infections - this is how ART is aimed to work. Medication thus enhances both quality of life and longevity. Adherence to ART regimen is therefore very vital in this treatment. Any irregularity in following the prescribed regimen can lead to resistance to HIV drugs, and therefore can weaken or negate its effect. ART is now available free to all those who need it. Public health facilities are mandated to ensure that ART is provided to people living with HIV/AIDS (PLHA). Special emphasis is given to the treatment of sero-positive women and infected children. ART is initiated depending upon the stage of infection. PLHA with less than 200 CD4 (white blood cells/ mm³) require treatment irrespective of the clinical stage. For PLHA with 200-350 CD4, ART is offered to symptomatic patients. Among those with CD4 of more than 350, treatment is deferred for asymptomatic persons. There are 127 ART centres operating in the country as of June 2007. By 2012, 250 ART centres will become functional across the country in order to provide people living with HIV/

AIDS better access to treatment.

Paediatric Care and Support : The primary goal of paediatric prevention, care and treatment programme is to prevent HIV infection to newborns through Prevention of Parent To Child Transmission (PPTCT) and provide treatment and care to all children infected by HIV.

Research : Beginning NACP-III, NACO has positioned itself as the promoter and coordinator of research on HIV/AIDS not only in India, but the entire South Asia region through partnership and networking with national academic and other institutions in the region. This initiative will enhance NACO's knowledge and evidence base of the various aspects of the epidemic.

Strengthening decentralization and expanding health systems : Under the NACP-III, decentralization of HIV services and convergence of services with the Reproductive Child Health Programme is envisaged; with strengthening of the capacities of the districts to manage prevention, treatment, care and support programmes.

Prioritization of districts for programme implementation: National AIDS Control Programme - III envisages district level planning and implementation of all the programmatic initiatives. For the purpose of planning and implementation of NACP-III, all the districts in the country are classified into four categories based on HIV prevalence in the districts among different population groups for three consecutive years. The definitions of the four categories are as follows :

Category A : More than 1% ANC prevalence in district in any of the sites in the last 3 years.

Category B : Less than 1% ANC prevalence in all the sites during last 3 years with more than 5% prevalence in any High Risk Group (HRG) site (STD/FSW/MSM/IDU).

Category C : Less than 1% ANC prevalence in all sites during last 3 years with less than 5% in all HRG sites, with known hot spots (Migrants, truckers, large aggregation of factory workers, tourist etc).

Category D : Less than 1% ANC prevalence in all sites during last 3 years with less than 5% in all HRG sites with no known hot spots *or* no or poor HIV data.

Critical appraisal

Due to stigma attached with HIV/AIDS, people living with the disease face a lot of discrimination. The program does not lay much emphasis to this important issue. Rehabilitation of sex workers who are HIV positives has been neglected in the program and needs special budgetary allocation. When the program started no targets were fixed and the program could not be evaluated properly due to non existence of indicators. Provision of free ART may eat the budget of other important communicable diseases. NACP has been conspicuously silent on structural socioeconomic vulnerabilities and the root cause of continuing flow of subpopulation into situations involving high risk behavior. It offers nothing to address these vulnerabilities through creating viable, holistic alternatives for those presently entrapped. The concept of voluntary and confidential testing is not being implemented in true spirit. Many Indians are tested for HIV without their knowledge and consent especially for those undergoing surgeries.

Summary

The first HIV case was reported in 1986. National AIDS Control Programme was launched in 1987. The programme was in phase I from 1992-1997(extended to 1999), phase II (1999-2004) and is presently in phase III from 2007-2012. The Goal of NACP is to halt and reverse the epidemic in India over the next five years by integrating programmes for *prevention, care, support and treatment*. The Objectives are to To reduce the rate of incidence by 60 per cent in the first year of the programme in high prevalence states to obtain the reversal of the epidemic, and by 40 percent in the vulnerable states to stabilise the epidemic.

The Strategy in phase III has been to prevent infections through saturation of coverage of high-risk groups with targeted interventions (TIs) and scaled up interventions in the general population, Provide greater care, support and treatment to larger number of People Living with HIV/AIDS(PLHA), Strengthen the infrastructure, systems and human resources in prevention, care, support and treatment programmes at district, state and national levels and to Strengthen the nationwide *Strategic Information Management System*.

The activities which are included are - Intensive coverage of High Risk Groups through targeted interventions, Intensification of interventions among general populations, Sexually Transmitted Disease (STD) Control Program, Family Health Awareness Campaign (FHAC), Voluntary Counseling and Testing (VCT), Prevention of Parent to Child Transmission (PPTCT), Universal Protection & Post Exposure Prophylaxis (PEP), Blood Safety Program, Condom Promotion Program, University Talk AIDS Project (UTA), Treatment for opportunistic infections and Monitoring & Evaluation.

For HIV testing different strategies have been adopted for different situations such as (a) Mandatory testing : screening in blood banks for blood safety. However, testing in all blood banks will be undertaken on collected blood samples in an unlinked & anonymous manner so as to only identify the status of blood sample and not of the donor. (b) Unlinked and anonymous testing : To be undertaken for epidemiological surveys and HIV surveillance to monitor the trend of HIV infection in community. (c) Voluntary and confidential testing: To be undertaken as confirmatory testing for subclinical infections/clinical management and as voluntary testing. (d) Need based testing : To be undertaken with explicit consent, for research purpose, after ensuring all ethical considerations.

For care and support of children, NACP-III plan envisages early diagnosis and treatment of HIV exposed children; comprehensive guidelines on paediatric HIV care for each level of the health system; special training to counsellors for counselling HIV positive children; linkages with social sector programmes for accessing social support for infected children; outreach and transportation subsidy to facilitate ART and follow up.

ART is initiated depending upon the stage of infection. PLHA with less than 200 CD4 (white blood cells/ mm³) require treatment irrespective of the clinical stage. For PLHA with 200-350 CD4, ART is offered to symptomatic patients. Among those with CD4 of more than 350, treatment is deferred for asymptomatic persons.

National AIDS Control Programme - III envisages district level planning and implementation of all the programmatic initiatives. For the purpose of planning and implementation of NACP-III, all the districts in the country are classified into four categories based on HIV prevalence in the districts among different population groups for three consecutive years. The definitions of the four categories are as follows : *Category A* : More than 1% ANC prevalence in district in any of the sites in the last 3 years. *Category B* : Less than 1% ANC prevalence in all the sites during last 3 years with more than 5% prevalence in any HRG site (STD/FSW/MSM/IDU). *Category C* : Less than 1% ANC prevalence in all sites during last 3 years with less than 5% in all HRG sites, with known hot spots (Migrants, truckers, large aggregation of factory workers, tourist etc). *Category D*: Less than 1% ANC prevalence in all sites during last 3 years with less than 5% in all HRG sites with no known hot spots or no or poor HIV data.

Puja Dudeja & Ashok K. Jindal

In May 1988, the World Health Assembly committed the member nations of the World Health Organization (WHO) to achieving the goal of global eradication of poliomyelitis. This goal is defined as (1):

- No cases of clinical poliomyelitis associated with wild poliovirus, and
- No wild poliovirus found worldwide despite intensive efforts to do so.

WHO Regions that have been certified as polio-free are the Americas (last case in 1991, Peru; Region certified polio-free in 1994), the Western Pacific Region (last case in 1997, Cambodia; Region certified 2000), and the European Region (last case in 1998, Turkey; Region certified 2001).

Strategy

The primary strategies for achieving this goal are:

Attaining high routine immunization : By immunizing every child aged <1 year with at least 3 doses of oral poliovirus vaccine (OPV). Paralytic polio can be caused by any of 3 closely-related strains (serotypes) of poliovirus. Trivalent OPV (OPV3) provides immunity against all 3 types. Three routine OPV doses should be received by infants at ages 6, 10 and 14 weeks.

National Immunization Days (NIDs) : By conducting Pulse Polio Immunization (PPI) programme by providing additional OPV doses to every child aged <5 years at intervals of 4-6 weeks. The aim of NIDs/PPI is to “flood” the community with OPV within a very short period of time, thereby interrupting transmission of virus throughout the community. Intensification of the PPI programme is accomplished by the addition of extra immunization rounds, adding a house-to-house “search and vaccinate” component in addition to providing vaccine at a fixed post. The number of PPI rounds conducted during any particular year is determined by the extent of poliovirus transmission in the country. The modified IPPI (Intensified Pulse Polio Immunization) strategy included vaccination of children through fixed booth approach on first day, followed by extensive house-to-house search of missed children for vaccination.

Surveillance of Acute Flaccid Paralysis (AFP) : Identify all reservoirs of wild poliovirus transmission. This includes AFP case investigation and laboratory investigation of stool specimens collected from AFP cases, which are tested for polioviruses in specialized laboratories.

Mopping-up immunization : When poliovirus transmission has been reduced to well-defined and focal geographic areas, intensive house-to-house, child-to-child immunization campaigns are conducted over a period of days to break the final chains of virus transmission.

Evolution of Polio vaccination in India

This is presented in Table - 1

In 1999 - 2000, with a view to reach the global goal of reaching zero incidence of polio by 2000 AD, a strategy to intensify PPI

was adopted. The strategy consisted of four nation-wide PPI rounds in the months of October, November, December 2000 and January 2001; followed by two sub-national rounds in 8 States of Assam, Bihar, Gujarat, Madhya Pradesh, Orissa, Rajasthan, Uttar Pradesh and West Bengal and routine immunization, especially in the poor performing States. During 1999, Supplementary Immunisation Activities (SIAs) were intensified, with the addition of house-to-house vaccination after an initial day of fixed-site activity (2).

Table - 1

Year	Remarks
1978	Vaccination against polio was initiated under Expanded Programme on Immunization (EPI)
1984	Coverage achieved was around 40% of all infants with 3 doses of Oral Polio Vaccine (OPV)
1985	Universal Immunization Programme (UIP) was launched
1995	The number of reported cases of polio declined from 28757 during 1987 to 3265 in 1995. Pulse Polio Immunization (PPI) Programme was launched in 1995-96 to cover all children below the age of 3 years
1996-97	To accelerate the pace of polio eradication, the target age group was increased to all children under the age of 5 years
1997	National Polio Surveillance Project was launched by Govt. of India & World Health Organization

Summary of cases : Decadal trend of polio cases is given in Table - 2 (3).

Table - 2

Year	No. of cases
1998	1934
1999	1126
2000	265
2001	268
2002	1600
2003	225
2004	134
2005	66
2006	676
2007	874
2008	420 (P1:25, P3:325)

AFP Surveillance

The strategy to eradicate wild poliovirus is two-fold, viz., immunization and surveillance. The objective of AFP surveillance is to detect the exact geographic locations where wild polioviruses are circulating in the human population. All

cases of acute flaccid paralysis in children aged <15 years are rigorously investigated by a trained medical officer, with collection of stool specimens to determine if poliovirus is the cause of the paralysis. Analysis of the location of polioviruses isolated from AFP cases allows programme managers to plan immunization campaigns (Pulse Polio Immunization).

Case Definition : Acute flaccid paralysis is defined as any case of AFP in a child aged <15 years, or any case of paralytic illness in a person of any age when polio is suspected.

Acute : Rapid progression of paralysis from onset to maximum paralysis; *Flaccid* : Loss of muscle tone, “floppy” - as opposed to spastic or rigid; *Paralysis* : Weakness, loss of voluntary movement. Any case meeting this definition undergoes a thorough investigation to determine if the paralysis is caused by polio.

Components of AFP Surveillance

1. Case Notification
2. Case and laboratory investigation
3. Outbreak Response Immunization (ORI) and active search of cases in community
4. 60 days follow up, cross notification & tracking of cases

An AFP case detected by health workers is reported to local health authorities and to state and national bodies. Case investigators are sent to confirm the diagnosis and collect faecal samples that are transported to the nearest laboratory for virus culture. This is followed by Outbreak Response Immunization (ORI), wherein all children less than 59 months in the area are given an additional dose of OPV. At least 500 children are vaccinated under ORI. Along with ORI, an intensive search is carried out for more cases of AFP. The case definition includes any child less than 15 years with history of flaccid/floppy paralysis. The AFP cases are revisited after 60 days of onset of paralysis to check for residual weakness/neurological deficit. The confirmation of paralytic polio is based on the review after 60 days and the laboratory report of the stool specimen. The suspected stool samples are sent to WHO recognized National Laboratories where poliovirus culture and identification are carried out. If poliovirus is found, the samples are forwarded to one of the Regional Reference Laboratories where VDPV and wild poliovirus are differentiated.

National Polio Surveillance Project

The National Polio Surveillance Project is a collaborative project of Govt. of India & the World Health Organization and managed by the latter. Currently a team of more than 250 Surveillance Medical Officer (SMO), Sub-Regional Coordinator (SRC) and Regional Coordinator (RC) are spread across the country who comprise the field staff of project. They are supported by a network of 9 Polio National Laboratories, which undertake the Virological Investigation of AFP (Acute Flaccid Paralysis) cases. The central headquarter unit of the project - The National Polio Surveillance Unit (NPSU) provides logistical & technical backup to the field staff.

In October 1997, active surveillance of Acute Flaccid Paralysis was established to meet the demands of Polio Eradication. SMOs with Government counterparts established Reporting Units for reporting of occurrence of AFP cases to the District, State & National levels; timely case investigation & collection of stool

specimen from AFP cases and its shipment to laboratories. AFP Surveillance at the local level is institution based through a comprehensive network of reporting sites which includes health facility reporting units & informers.

Critical appraisal (4)

A critical juncture has been reached in eradication of poliomyelitis in India. The tools are available which are proven to be effective across the world. The large disparity in routine vaccine coverage among various regions of the country is hampering the eradication efforts. Compounding the problem is the social mobility from migrant labour moving to urban conglomerates. Eradication efforts need to be focused on these high risk groups, including mop-up activity for absentee and defaulter immunisation. Community participation remains the key to success and has to be ensured for better compliance. The importance of ensuring cold chain has to be stressed to maintain vaccine potency. Potency checking of OPV is hardly done after the inception of the Vaccine Vial Monitor (VVM) into IPPI. A review of this may be necessary to ensure that a potent vaccine is used. As we near the control of wild-virus transmission, Vaccine Associated Paralytic Polio (VAPP) is a real danger. The introduction of Injectable Polio Vaccine may be an option, at least in the better performing areas like Kerala and the North East. Combination of DPT with IPV in the UIP has been suggested and may have to be done in the near future.

Summary

Polio eradication is defined as - No cases of clinical poliomyelitis associated with wild poliovirus, and No wild poliovirus found worldwide despite intensive efforts to do so. The primary strategies for achieving this goal are attaining high routine immunization, National Immunization Days (NIDs), Surveillance of Acute Flaccid Paralysis (AFP) and Mopping-up immunization. On NID, OPV doses to every child aged <5 years at intervals of 4-6 weeks. The aim of NIDs/PPI is to “flood” the community with OPV within a very short period of time, thereby interrupting transmission of virus throughout the community.

AFP Surveillance: The objective of AFP surveillance is to detect the exact geographic locations where wild polioviruses are circulating in the human population. The Components of AFP Surveillance are Case Notification, Case and laboratory investigation, out break response immunization and active search of cases in community and 60 days follow up, cross notification and tracking of cases.

The National Polio Surveillance Project is a collaborative project of Govt. of India & the World Health Organization and managed by the later for active surveillance of Acute Flaccid Paralysis; was established to meet the demands of Polio Eradication.

Puja Dudeja & Ashok K. Jindal

Surveillance is essential for the early detection of emerging (new) or re-emerging (resurgent) infectious diseases. In the absence of surveillance, disease may spread unrecognized by those responsible for health care or public health agencies, because sick people would be seen in small numbers by many individual health care workers. By the time the outbreak is recognized, it may be too late for intervention measures. Continuous monitoring is essential for detecting the 'early signals' of outbreak of any epidemic of a new or resurgent disease. Surveillance data can be effectively used for the purpose of social mobilization to help the public participate actively in controlling important diseases. This will go a long way in reducing the burden of disease in the community.

IDSP is a decentralized; state based *Surveillance Project* (IDSP) which will be able to detect early warning signals of impending outbreaks and help initiate an effective response in a timely manner. It will also be expected to provide essential data to monitor progress of on-going disease control programs and help allocate health resources more optimally. IDSP will also facilitate the study of disease patterns in the country and identify new emerging diseases (1).

Aim & Objectives : The aim is to improve the information available to the government health services and private health care providers on a set of high-priority diseases and risk factors, with a view to improving the on-the-ground responses to such diseases and risk factors. The objectives are :

1. To establish a decentralized state based system of surveillance for communicable and non-communicable diseases, so that timely and effective public health actions can be initiated in response to health challenges in the country at the state and national level.
2. To improve the efficiency of the existing surveillance activities of disease control programs and facilitate sharing of relevant information with the health administration, community and other stakeholders so as to detect disease trends over time and evaluate control strategies.

Activities & Components

1. Establish and Operate a Central-level Disease Surveillance Unit.
2. Integrate and strengthen disease surveillance at the state and district levels.
3. Improve laboratory support.
4. Training for disease surveillance and action.

The details are shown in the Table - 1

Implementation : IDSP will monitor a limited number of conditions based on state perceptions including 13 core and 5 state priority conditions for which public health response is available. District, State & Central Surveillance units will be set up so that the program is able to respond in a timely manner to surveillance challenges in the country including emerging epidemics. It will integrate surveillance activities in the country under various programs and use existing infrastructure for its function. Private practitioners / Private hospitals / Private laboratories and medical colleges will be inducted into the program as sentinel units. Uniform high quality surveillance activities will be ensured at all levels. Following actions will be taken for successful implementation :

- (i) Limiting the total number of diseases under surveillance and reducing overload at the periphery.
- (ii) Developing standard case definitions.
- (iii) Developing formats for reporting.
- (iv) Developing user friendly manuals.
- (v) Providing training to all essential personnel.
- (vi) Setting a system of regular feed back to the participants on the quality of surveillance activity. District Public Health Laboratory will be strengthened to enhance capacity for diagnosis and investigations of epidemics and confirmation of disease conditions. Use of information technology will be done for communication, data entry, analysis, reporting, feedback and actions. A national level surveillance network will be established up to the district level.

Disease conditions under the surveillance program : Integration of Surveillance under various disease control programme : Under IDSP surveillance activities carried out under National Disease Control Programmes relating to Malaria, Tuberculosis, HIV/AIDS, Diseases under RCH (Measles, Polio, Acute Diarrhoeal Diseases) and state specific diseases would be integrated (See Table - 2).

Table - 1

Component	Activities
1.	Ministry of Health and Family Welfare (MOHFW) will establish a new Disease Surveillance Unit. It will give support to states surveillance units and help in coordination. It will also help in change of diseases in the system.
2.	It will integrate and strengthen disease surveillance at the state and district levels, and involve communities and other stakeholders, in particular, the private sector.
3.	This involves upgrading laboratories at the state level, in order to improve laboratory support for surveillance activities. Adequate laboratory support is essential for providing on-time and reliable confirmation of suspected cases; monitoring drug resistance; and monitoring changes in disease agents. It also includes introducing a quality assurance system for assessing and improving the quality of laboratory data.
4.	The first three components will require a large and coordinated training effort to reorient health staff to an integrated surveillance system and provide the new skills needed.

Table - 2 : Disease conditions under the IDSP		
Surveillance	Group of diseases	Examples
<i>Regular Surveillance</i>	Vector Borne Water Borne Respiratory Diseases Vaccine Preventable Diseases Diseases under eradication Others Other International commitments Unusual clinical syndromes	Malaria Acute Diarrhoeal Disease (Cholera), Typhoid Tuberculosis Measles Polio Road Traffic Accidents Plague Meningoencephalitis / Respiratory (Causing death / hospitalization) Distress Hemorrhagic fevers, other undiagnosed conditions
<i>Sentinel Surveillance</i>	Sexually transmitted diseases/Blood borne: Other Conditions	HIV/HBV, HCV Water Quality, Outdoor Air Quality (Large Urban Centers)
<i>Regular periodic surveys</i>	NCD Risk Factors	Anthropometry, Physical activity, Blood Pressure, Tobacco, Nutrition, Blindness
<i>Additional State Priorities</i>	Each state may identify up to five additional conditions for surveillance	

Response to the Surveillance Information at various levels (Fig. - 1)

1. **At Central Level** : The response functions at the central surveillance committee level will include Development of national guidelines for case definitions and disease control, compilation and analysis of SSU reports (quarterly), reporting to World Bank, coordinate external quality assurance activities. The CSU will also advise SSUs on disease control measures, Monitor situation and response (continuously), notify international public health agencies, seek and coordinate international assistance if necessary.

2. **At State Level** : The response functions at the state surveillance committee level will include : Advise to DSUs on disease control measures, monitor situation and response, notify CSU, and deployment of state rapid response team if necessary, Compilation of DSU reports (monthly), assess reporting performance of DSUs (monthly), reporting to CSU (monthly) and feedback to DSUs (monthly).

3. **At District Level** : The response functions at the District surveillance committee level will include : Initiation of outbreak investigation through Rapid Response Teams (RRT), provide coordination to Outbreak response activities involving CHCs, initiate disease control measures and treatment, notify SSU, facilitate private / public Partnership in outbreak response. It will also include Data entry of sentinel data from institutions not linked directly (weekly), analysis including calculation of case counts and descriptive epidemiology (weekly), monitoring and evaluation including assess accuracy and completeness of submitted reports (weekly), collection and trend analysis of water quality, air quality, and road accident data.

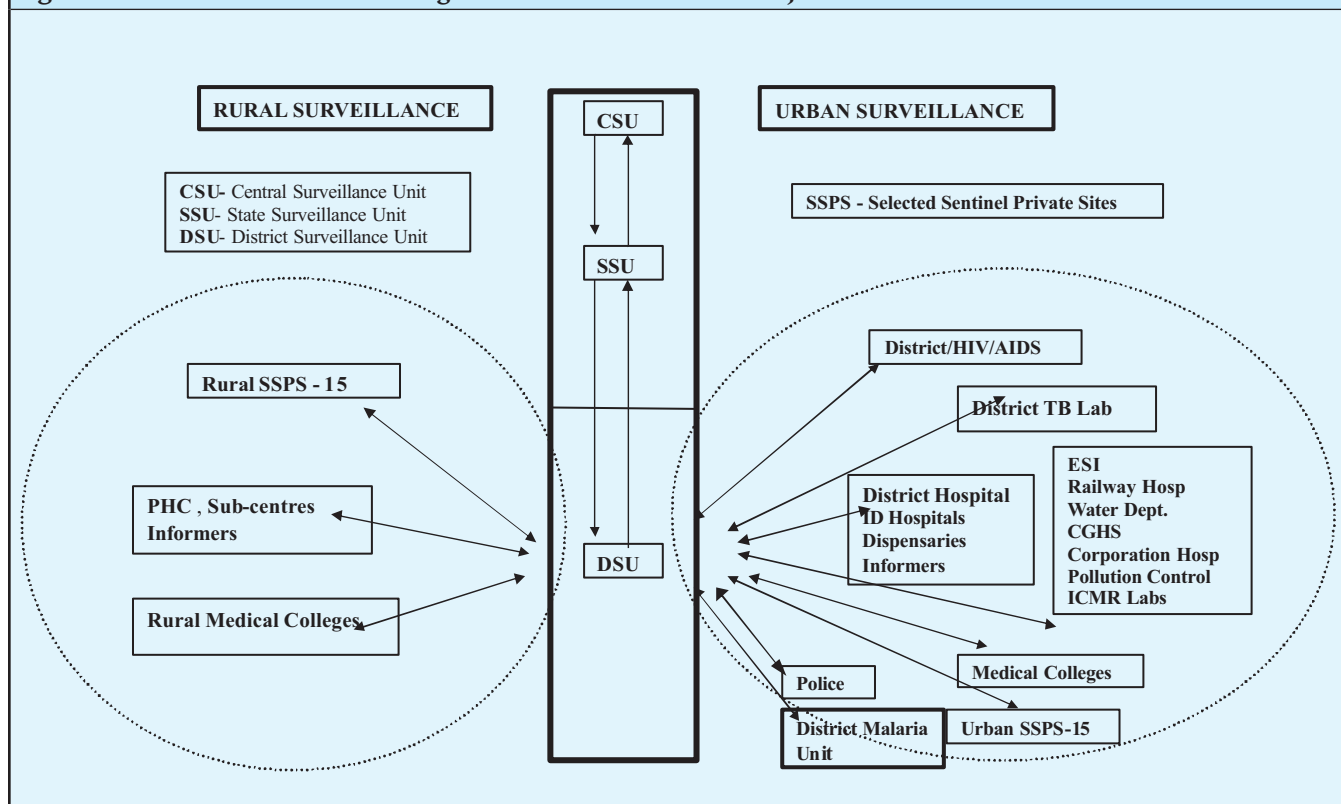

4. **At CHC / PHC Level** : The response functions at the MO i/c CHC and MO i/c PHC level will include Verification of reports of outbreaks from health worker (within 24 hours), verification of reports of Outbreaks in the rumor registry (within 48 hours), disease-specific control activities (immediately), collection and transport of biological samples to lab, reporting of suspected and confirmed cases to DSU (within 24 hours), IEC and integration with Village health committee, and outbreak investigation, under DSU directions. The actions will also include verification of local health worker case reports (weekly), verification of laboratory reports (weekly), and Feedback to local health workers (weekly).

5. **At Local Health Worker Level** : The response functions will include : Informing MO PHC/CHC, Active search for similar Cases, Collection and transport of biological samples to lab, and IEC activities. The actions will also include monitoring of illnesses and reporting to CHC, and to refer patients to PHC / CHC.

Phasing : IDSP will be implemented in three phases (2) as follows : Phase I (FY 2004-05), Phase II (FY 2005-06) and Phase III (FY 2006-07).

Conclusion : Surveillance is the essence of a disease control program. By setting up a decentralized, action oriented, integrated and responsive program, it is expected that IDSP will avert a sufficient number of disease outbreaks and epidemics and reduce human suffering and improve the efficiency of all existing health programs. Such a program will also allow monitoring of resource allocation and form a tool to enhance equity in health delivery.

Fig. -1 : Structural Framework Of Integrated Disease Surveillance Project

Summary

IDSP is a decentralized, state based *Surveillance Project* which will be able to detect early warning signals of impending outbreaks and help initiate an effective response in a timely manner. It will also be expected to provide essential data to monitor progress of on-going disease control programs and help allocate health resources more optimally.

The *aim* is to improve the information available to the government health services and private health care providers on a set of high-priority diseases and risk factors, with a view to improving the on-the-ground responses to such diseases and risk factors. The objectives are : To establish a decentralized state based system of surveillance for communicable and non-communicable diseases, so that timely and effective public health actions can be initiated in response to health challenges in the country at the state and national level; To improve the efficiency of the existing surveillance activities of disease control programs and facilitate sharing of relevant information with the health administration, community and other stakeholders so as to detect disease trends over time and evaluate control strategies.

The components are to Establish and Operate a Central-level Disease Surveillance Unit, Integrate and strengthen disease surveillance at the state and district levels, Improve laboratory support and Training for disease surveillance and action.

The implementation is through District, State & Central Surveillance units. There will be Regular Surveillance (Vector Borne, Water Borne, Respiratory Diseases, Vaccine Preventable Diseases and Diseases under eradication), Sentinel Surveillance (Sexually transmitted diseases/Blood borne conditions), Regular periodic surveys (NCD Risk Factors)and each state may identify up to five additional conditions for surveillance.

The flow of information will be from Local Health Worker to CHC MO / PHC MO, to District Surveillance Committee, to State Surveillance Committee and finally to Centre Surveillance Committee. IDSP will be implemented in three phases : Phase I (FY 2004-2005); Phase II (FY 2005-2006); and Phase III (FY 2006-2007).

Puja Dudeja & Ashok K. Jindal

Mental disorders form an important public health priority, both in terms of the numbers of people suffering from mental disorders and due to the burden of these disorders in the community (1, 2). These conditions include the severe forms of mental disorders like psychoses, substance abuse and mental retardation. Of the health conditions contributing to the disability adjusted life years (DALYs), of the top 10 conditions, four are mental disorders.

Objectives : NMHP was started in 1982 with the following objectives (3):

1. To ensure availability and accessibility of minimum mental health care for all in the near foreseeable future, particularly to the most vulnerable sections of the population.
2. To encourage mental health knowledge and skills in general health care and social development.
3. To promote community participation in mental health service development and to stimulate self-help in the community.

NMHP envisaged integration of mental health care with general health care and welfare (4).

Implementation : A model for delivery of community based mental health care at the level of district was evolved and field-tested in Bellary district of Karnataka by NIMHANS between 1986-1995. This model was adapted as the District Mental Health Programme (DMHP) and it was implemented in 27 Districts across 22 states/UTs in the 9th five year plan beginning in the year 1996.

Barriers to Implementation of the Programme:

1. Shortage of trained manpower in the field of mental health.
2. Social stigma & lack of knowledge of psychiatric patients & their families.
3. Negative attitude of general practitioners, primary care physicians & other specialists.
4. NGOs/Voluntary Organizations do not find this field attractive.
5. Inadequate staff & infrastructure of mental hospitals and psychiatric wings of medical colleges.
6. Uneven distribution of sparse resources limiting the availability of mental health care to those living in urban areas.

NMHP during the 10th Five Year Plan

An evaluation of the NMHP was undertaken in 2003 and the programme was re-strategised to incorporate the following changes and it became from single pronged to a multi-pronged programme for effective reach and impact on mental illnesses. Main strategies of NMHP during the 10th plan period are as follows:

1. Expansion of DMHP to 100 districts all over the country.
2. Strengthening and Modernization of Mental Hospitals.

3. Up gradation of Psychiatry wings in the General Hospitals/ Medical Colleges.
4. IEC Activities.
5. Research & Training in Mental Health for improving service delivery.

District Mental Health Programme

Its main objective is to provide basic mental health services to the community & to integrate these with other health services. The programme envisages a community based approach to the problem, which includes:

1. Training of mental health team at the identified nodal institutions.
2. Increase awareness about Mental Health problems.
3. Provide service for early detection & treatment of mental illnesses in the community (OPD/Indoor & follow up).
4. Provide valuable data & experience at the level of community at the state & center for future planning & improvement in service & research.
5. Strengthening and Modernization of Mental Hospitals.

Identified thrust areas based on experience gained during 10th Five Year Plan

1. To expand DMHP in an enlarged & more effective form.
2. Strengthening/modernization of remaining mental hospitals in order to modify from largely custodial role to therapeutic role.
3. Upgrading Departments of Psychiatry in Medical Colleges & enhancing the Psychiatric content of the medical curriculum at the UG/PG level.
4. Information, Education and Communication activities for creating awareness and reducing stigma.
5. Research & Training in Mental Health.
6. School Mental Health Programme.
7. Involvement of NGOs & Public Private Partnership in Community based care of mentally ill patients to fill the service gap in mental health delivery.

Revised Framework of 11th Five Year Plan

The revised approach for the programme in eleventh five year plan will recognize the importance of mental health care and will concentrate on providing counselling, medical services, and establishing helplines for all, especially people affected by calamities, riots and violence(5). The following actions are envisaged :

1. There is a need to empower the PHC doctor to offer care to mentally ill persons at the PHC.
2. There is a need to improve public awareness and facilitate community participation.
3. The psychiatric departments of Medical Colleges have to be upgraded to enhance better training opportunities.
4. Mental Hospitals that offer tertiary care to be improved to make treatment acceptable to the patients.

Indicators in 11th plan

1. No of districts that have successfully implemented DMHP
2. Improvement in service care in mental hospitals
3. Lowering of stigma attached to mental illnesses
4. Increased awareness of mental disorders

Strategies

1. Integrating mental health with primary health care through NMHP.
2. Providing of tertiary care institutions for treatment of mental disorders.
3. Eradicating stigmatization of mentally ill patients and protecting their rights through regulatory institutions like central and state mental health authorities.

Critical Appraisal

Successful implementation of mental health is a big challenge for all. With a large population of mentally ill in our country and very few psychiatrists being available, less than one psychiatrist is available for every 3 lacs population. The psychiatrist / population ratio in rural areas that account for 70% of country's population, could well be under one for every million. There is a need to strengthen district mental health programmes and enhance its visibility at the grass root level. The man power gaps in the field of psychiatry are required to be filled up. The NGOs have to join hands in this programme and help in Community Based care of mentally ill. Preventive and promotive aspects of the programme have to be focused and looked in addition to treatment of serious mental ailments. IEC activities have to be strengthened and training of general practitioners in mental health is required to be emphasized upon. Optimal mix of different mental health care services is given in Table 1(6,7). There is a need for integrating the mental health components in national level programmes like the ICDS, education system, and use of traditional systems like yoga, meditation, so that the mental health promotive activities become part of the programme.

Summary

NMHP was started in 1982 with the objective of ensuring availability and accessibility of minimum mental health care for all in the near foreseeable future, particularly to the most

vulnerable sections of the population, To encourage mental health knowledge and skills in general health care and social development, To promote community participation in mental health service development and to stimulate self-help in the community. NMHP envisaged integration of mental health care with general health care and welfare.

The objectives of the programme in the eleventh five year plan are to empower the PHC doctor to offer care to mentally ill persons at the PHC, improve public awareness and facilitate community participation, upgradation of psychiatric departments of Medical Colleges have to be upgraded to enhance better training opportunities.

The strategies in the eleventh plan include integrating mental health with primary health care through NMHP, Providing of tertiary care institutions for treatment of mental disorders and eradicating stigmatization of mentally ill patients and protecting their rights through regulatory institutions like central and state mental health authorities.

National Cancer Control Programme

Puja Dudeja & Ashok K. Jindal

Cancer is an important public health problem in India with nearly 7-9 lakh new cases occurring every year in the country. It is estimated that there are 20-25 lakh cases of cancer in the country at any given point of time. In India over 70% of the cases report for diagnostic and treatment services in advanced stages of the disease, resulting in poor survival and high mortality rates (1). With the objectives of prevention, early diagnosis and treatment, the National Cancer Control Programme (NCCP) was

launched in 1975-76. In view of the magnitude of the problem and the requirement to bridge the geographical gaps in the availability of cancer treatment facilities across the country; the programme was revised in 1984-85 and subsequently in December 2004.

Goals & Objectives : The goals and objectives are (2) :

1. Primary prevention of cancers by health education regarding hazards of tobacco consumption and necessity of genital hygiene for prevention of cervical cancer.
2. Secondary prevention i.e. early detection and diagnosis of cancers, for example, cancer of cervix, breast cancer and of the oro-pharyngeal cancer by screening methods and patients' education on self examination methods.

3. Strengthening of existing cancer treatment facilities, which were inadequate.
4. Palliative care in terminal stage cancer.

Global
<ul style="list-style-type: none"> ● Cancers cause 12 per cent of deaths ● Second leading cause of death in developed countries accounting 21 % (2.5m) of all deaths ● Second leading cause of death in developing countries accounting for 9.5% of all deaths (3.8m)
India
<ul style="list-style-type: none"> ● One of the ten leading causes of death ● There are 1.5-2 million cancer cases at any given point of time ● 7 lakh new cases of cancer and 3 lakh deaths occur annually due to cancer ● The common sites for cancer in India are oral cavity, lungs, oesophagus and stomach in males and cervix, breast and oral cavity among females

Existing Schemes under National Cancer Control Programme (3) : This is shown in Table - 1.

The programme was revised in December 2004. There are 5 schemes under the revised programme (4)

1. **Recognition of New Regional Cancer Centres (RCCs) :** In order to augment comprehensive cancer care facilities in regions of the country lacking them, new RCCs are being recognized.
2. **Strengthening of Existing RCCs :** A one-time grant of Rs. 3.00 crores is provided to the existing RCCs in order to further strengthen the cancer treatment facilities in the existing centres.
3. **Development of Oncology wing :** The scheme aims to correct the geographical imbalance by providing financial assistance to Government institutions (Medical Colleges as well as Government Hospitals) for enhancing the cancer care facilities.

4. **District Cancer Control Programme (DCCP) :** The DCCP will be implemented by the Nodal Agency, which may be an RCC or an Oncology Wing. The aim is to strengthen District Hospitals in 2-3 congruent districts for early detection and appropriate treatment or referral.

5. **Decentralized NGO Scheme :** This scheme has been devised to promote prevention and early detection of cancers. Non- Governmental Organizations (NGO) will implement these activities under the coordination of the Nodal Agency, which will be an RCC or an Oncology Wing.

District Cancer Control Programme

This programme was launched in 1990-91 and under this programme each state and union territory is advised to prepare their projects on health education, early detection, and pain relief measures. For this they can get up to Rs. 15 lakhs one time assistance and Rs. 10 lakhs for four years recurring assistance. The district programme has five elements:

1. Health education.
2. Early detection.
3. Training of medical & paramedical personnel.
4. Palliative treatment and pain relief.
5. Coordination and monitoring.

The District programmes are linked with Regional Cancer Centres/ Government Hospitals/ Medical Colleges. For effective functioning each district where programme has started to have one District Cancer Society that is chaired by local Collector/ Chief Medical Officer. Other members are Dean of medical college, Zila parishad representative, NGO representative etc.

National Cancer Registry Programme (NCRP)

National Cancer Registry Programme was launched in 1982 by Indian Council of Medical Research (ICMR) to provide true information on cancer prevalence and incidence. There are five population-based urban cancer registries in Mumbai, Bangalore, Chennai, Bhopal, Delhi and a rural registry at Barsi in Maharashtra and six hospital-based registries at Chandigarh, Dibrugarh, Thiruvananthapuram, Bangalore, Mumbai and Chennai. The NCRP provides data on regional difference and time

Scheme	Remarks
Financial Assistance to Voluntary Organisations	For IEC activities and early detection of cancer
District Cancer Control Scheme	District projects are given financial assistance to carry out health education, early detection and pain relief measures. Under this scheme one time financial assistance of Rs.15.00 lakhs is provided to the concerned State Government for each district project with a provision of Rs.10.00 lakhs every year for the remaining four years of the project period.
Cobalt Therapy Installation	To strengthen the cancer treatment facilities, the financial assistance of Rs. 1.0 crore is given to charitable organisations and 1.5 crores for government institutions is provided for procurement of teletherapy and brachytherapy equipments etc. This is one time grant as at present.
Development of Oncology Wings in Govt. Medical College Hospitals	The aim is to fill geographical gaps. One time financial assistance of Rs.2.00 crores is provided by the centre for purchase of equipment.
Regional cancer institutes	There are 25 Regional Cancer Research and Treatment Centres recognised by Government of India and recurring grant of Rs.75 lakhs is being given to these Regional Cancer Centres.

trends in cancer prevalence so that appropriate modifications in the ongoing programmes could be made.

Objectives of NCRP

1. To generate authentic data on the magnitude of cancer problem in India.
2. To undertake epidemiological investigations and advice control measures.
3. Promote human resource development in cancer epidemiology.

In the XI five year plan, the focus will be on community based cancer prevention and control strategies. We are in the process of establishing OncoNET India, a network connecting 25 Regional Cancer Centres and 100 peripheral centres thus facilitating telemedicine services and continued medical education.

Critical appraisal

The programme however has mainly contributed to the development of radiation oncology services rather than making any headway in the direction of prevention and early detection (5). There is no organised screening programme for any of the common cancers in the country. Most cancer centers provide only opportunistic screening services. Research and training was one of the objectives of the programme but was neglected during implementation of the programme.

Summary

National Cancer Control Programme (NCCP) was launched in 1975-76. The goals & objectives are primary prevention of cancers by health education regarding hazards of tobacco consumption and necessity of genital hygiene for prevention of cervical cancer; Secondary prevention i.e. early detection

and diagnosis of cancers, for example, cancer of cervix, breast cancer and of the oro-pharyngeal cancer by screening methods and patients' education on self examination methods, Strengthening of existing cancer treatment facilities and palliative care in terminal stage cancer.

Existing Schemes under National Cancer Control Programme are Financial Assistance to Voluntary Organisations, District Cancer Control Scheme, Cobalt Therapy Installation, Development of Oncology Wings in Govt. Medical College Hospitals and Recognition of New Regional Cancer Centres. The elements of district programme are Health education, Early detection, Training of medical & paramedical personnel, Palliative treatment and pain relief and coordination and monitoring.

National Cancer Registry Programme was launched in 1982 by Indian Council of Medical Research (ICMR) to provide true information on cancer prevalence and incidence. The NCRP provides data on regional difference and time trends in cancer prevalence so that appropriate modifications in the ongoing programmes could be made.

National Programme for Prevention & Control of Diabetes, Cardiovascular Diseases & Stroke

Puja Dudeja & Ashok K. Jindal

The World Health Report of 2002 states that Cardiovascular Diseases (CVD) will be the largest cause of death and disability in India by 2020. Non Communicable Diseases (NCDs), especially Cardiovascular Diseases (CVDs), Diabetes Mellitus, Cancer, Stroke and Chronic Lung Diseases have emerged as major public health problems in India, due to an ageing population and environmentally driven changes in behaviour. It is estimated that in 2005, NCDs accounted for 5,466,000 (53%) of all deaths (10,362,000) in India. The estimated burden of common NCDs are; 2.4 million Ischemic Heart Diseases, 37.8 million diabetes, 2.4 million cancers and 0.93 million stroke. Compared with all other countries, India suffers the highest loss in potentially productive years of life, due to deaths from

cardiovascular disease in people aged 35-64 years (9.2 million years lost in 2000). The common risk factors are Tobacco, Alcohol, Diet and Physical inactivity.

Rationale for Having a Common Programme for the Prevention and Control of Diabetes, CVD and Stroke

1. Diabetes is an important risk factor for both the major forms of cardiovascular disease (coronary heart disease and stroke).
2. CVD is the major cause of death and disability in persons with diabetes.
3. Common risk factors underlie CVD and diabetes: unhealthy diets, physical inactivity and over weight are common to both.
4. High blood pressure often precedes and predicts the onset of clinical diabetes by several years. This has led to 'hypertension' being regarded as a pre-diabetic condition.
5. Clinical trials have shown that, mortality reduction and increased survival are better achieved by blood pressure control than even by blood sugar control, in persons with diabetes.

- Persons with CVD or diabetes require similar lifestyle therapy and often similar drug therapy for prevention of complications (diet; physical activity; smoking cessation; cholesterol lowering drugs; aspirin; ACE inhibitors; other blood pressure lowering drugs).
- Persons with diabetes frequently need to be screened for CVD and risk factors of CVD.
- Proven lifestyle interventions which can prevent the onset of diabetes (diet and physical activity) are similar to those proven to reduce the risk of developing hypertension, coronary heart disease or stroke.

The strategic approaches and operational elements for prevention and control of CVD and diabetes are thus similar or closely interlinked, whether it is primordial prevention, primary prevention or secondary prevention (reducing the risk of complications after the onset of disease).

Implementation : The NPDCS will be implemented in a phased manner with a pilot being done in the Preparatory Phase 2006-07. Subsequently, the programme would be implemented across the country through select institutions over the XI Five Year Plan.

Aim of the Programme : Prevention and control of common NCD risk factors through an integrated approach and reduction of premature morbidity and mortality from DM, CVD and Stroke (1).

Long term objectives

- Reduce prevalence of risk factors of common NCDs.
- Reduce morbidity and mortality due to Diabetes, Cardiovascular diseases and Stroke.
- Building capacity of health systems to tackle NCDs and improvement of quality of care.

Immediate objectives

- Primary prevention of major Non Communicable Diseases through Health Promotion.
- Surveillance of NCDs and their risk factors in the population.
- Capacity enhancement of health professionals and health systems for diagnosis and appropriate management of NCDs and their risk factors.
- Reduction of risk factors of NCDs in the population.
- Establish National Guidelines for management of NCDs.
- Development of strategies/ policies for prevention of NCDs in the country through Inter ministerial collaborations/ coordination.
- Community empowerment for prevention of NCDs.

Summary

The NPDCS will be implemented in a phased manner with a pilot being done in the Preparatory Phase 2006-07. Subsequently, the programme would be implemented across the country through select institutions over the XI Five Year Plan. The aim of the Programme Prevention and control of common NCD risk factors through an integrated approach and reduction of premature morbidity and mortality from DM, CVD and Stroke. In the long term the programme envisages, reduction in prevalence of risk factors of common NCDs, reduction in morbidity and mortality due to Diabetes, Cardiovascular diseases and Stroke and building capacity of health systems to tackle NCDs and improvement of quality of care.

National Iodine Deficiency Diseases Control Programme

Puja Dudeja & Ashok K. Jindal

Iodine, an essential micronutrient with daily requirement of 100-150 mg, plays an important role in normal human growth and development. It has been widely recognized that deficiency of iodine not only contributes to goitre but also is an important risk factor for preventable mental retardation; it affects reproductive functions and impairs child's learning ability. The disorders produced as a result of nutritional iodine deficiency are classified as "Iodine Deficiency Disorders (IDD) or IDD syndromes" (1).

The History of Iodine Deficiency Control Programme in our country is given in Table 1.

S. No.	Year	Event
1.	1954-1962	Prospective study on iodine deficiency disorders in Kangra valley
2.	1962	National Goitre Control Programme (NGCP)
3.	1982	Technical goitre control review committee recommended to declare entire country goitre prone
4.	1983	Universal iodisation of salt in the country
5.	1992	NGCP was redesignated as National Iodine Deficiency Disorders Control Programme* (NIDDCP)

* The title has been changed in view of the wide spectrum of Iodine Deficiency Disorders like mental and physical retardation, deaf mutism, cretinism, high rates of abortion etc. and the Govt. commitment to overcome all other Iodine Deficiency Disorders apart from Goitre, through Universal Iodisation of salt.

Programme Implementation (2)

Responsibilities : It is a 100 percent centrally assisted programme. The Ministry of health and Family Welfare is the nodal ministry for policy decisions on NIDDCP. The central Nutrition and Iodine Deficiency Disorders Cell at the Directorate General of Health Services is responsible for the implementation of NIDDCP. The Salt Commissioner's office under the Ministry of Industry is responsible for licensing, production and distribution of iodated salt to States/UTs. This office is also responsible for monitoring the quality of iodated salt at production level and distribution of same in the country. The Salt Commissioner in consultation with the Ministry of Railways arranges for movement of iodated salt from production centres to the states/UTs on a priority basis. The best indicator for monitoring the impact of iodine Deficiency Disorders Control Programme is neonatal hypothyroidism.

The Government's goal of NIDDCP is to reduce the prevalence of iodine deficiency disorders below 10 percent in the entire country by 2012 AD.

The Objectives of NIDDCP are as under

1. Survey to assess the magnitude of the IDD
2. Supply of iodated salt in place of common salt
3. Resurvey after every 5 years to assess the magnitude of the IDD and the impact of iodated salt on it
4. Laboratory monitoring of iodated salt and urinary iodine excretion
5. Health education and publicity

Other components of the strategy are

- (i) Testing of salt at manufacturing level.
- (ii) Testing of salt at Consumption level.
- (iii) Testing of Urine samples at District/State level.
- (iv) Monitoring the Thyroid status of new borns through screening of cord Blood samples.
- (v) Strengthening of Central Iodine Deficiency Disorder Control Cell at the Headquarters.
- (vi) Strengthening of Training including establishment of Iodine Deficiency Disorder Training Programme.
- (vii) Information, Education and Communication.

IDD Control Cell : Each state has an IDD Control Cell which carries out periodic surveys regarding the prevalence of IDD and coordinates with central IDD cell. The functions of this cell are as under:

1. Checking iodine levels of the salt with wholesalers and retailers within the state and coordinating with food and civil supplies department.
2. The distribution of iodated salt within the state through open market and public distribution system.
3. Creating demand for iodated salt.
4. Monitoring consumption of iodated salt.
5. Conducting IDD surveys to identify the magnitude of IDD in various districts.
6. Conducting training.
7. Dissemination of information, education and communication.

Benefits of IDD control (3) : IDD is one of the three micronutrient deficiencies declared to be eliminated by WHO, the other two being vitamin A deficiency and iron deficiency. Apart from minimizing human misery, IDD control makes it possible to have better education to the children, high labour productivity and better quality of life. See Table - 2.

S. No.	Reduction	Benefits
1	Mental deficiency	Higher work output in school and work place
2	Autism	Reduced cost of custodial and medical care
3	Spastic diplegia	Reduced educational cost from reduced absenteeism and grade repetition and higher academic achievement by the student

Critical Appraisal : IDD control cells have not been established in all the states. The process of setting up iodine monitoring laboratory for estimation of iodine content of salt and urinary iodine excretion is slow. Lack of resources and trained manpower restricts the quality control of iodated salt at the consumer level. A lot needs to be done to create a felt need for the programme activities among the masses. Medical and para medical manpower needs to be trained on the subject.

Summary

The disorders produced as a result of nutritional iodine deficiency are classified as "Iodine Deficiency Disorders (IDD) or IDD syndromes". In 1962 National Goitre Control Programme was launched, however the title has been changed in 1992 to NIDDCP to cover the wide spectrum of Iodine Deficiency Disorders.

The goal of NIDDCP are to reduce the prevalence of iodine deficiency disorders below 10 percent in the entire country by 2012 AD. The Objectives of NIDDCP are to survey to assess the magnitude of the IDD, supply of iodated salt in place of common salt, resurvey after every 5 years to assess the magnitude of the IDD and the impact of iodated salt on it, laboratory monitoring of iodated salt and urinary iodine excretion and Health education and publicity. IDD Control Cell in each state has been established which carries out periodic surveys regarding the prevalence of IDD and coordinates with central IDD cell.

Hearing loss is the most common sensory deficit in humans today. As per WHO estimates in India, there are approximately 63 million people, who are suffering from significant auditory impairment; this places the estimated prevalence at 6.3% in Indian population; of these, a large percentage is children between the ages of 0 to 14 years. With such a large number of hearing impaired young Indians, it amounts to a severe loss of productivity, both physical and economic.

Objectives

1. To prevent the avoidable hearing loss on account of disease or injury.
2. Early identification, diagnosis and treatment of ear problems responsible for hearing loss and deafness.
3. To medically rehabilitate persons of all age groups, suffering with deafness.
4. To strengthen the existing inter-sectoral linkages for continuity of the rehabilitation programme, for persons with deafness.
5. To develop institutional capacity for ear care services by providing support for equipment & material and training personnel.

Long term objective : To prevent and control major causes of hearing impairment and deafness, so as to reduce the total disease burden by 25% of the existing burden by the end of eleventh five year plan.

Strategies

1. To strengthen the service delivery including rehabilitation.
2. To develop human resource for ear care.
3. To promote outreach activities and public awareness through appropriate and effective IEC strategies with special emphasis on prevention of deafness.
4. To develop institutional capacity of the district hospitals, community health centers and primary health centers, selected under the project.

Programme Execution & Expansion (1)

A pilot project, to be conducted in 25 districts derived from 10 states and one union territory, is already in the first phase of implementation. This will run from 2006 to 2008. In the remaining four years of the 11th Five year plan, it is proposed to expand this programme to include a total of 203 districts covering all the states and Union territories of India by 2012. The expansion will be done in a phased manner, with inclusion of 45 new districts each year. At the end of the plan, it is proposed to cover 50% of the districts in all the pilot states (except Uttar Pradesh) and 25% of the districts in all the other states/UTs.

Components of the Programme

1. Manpower training and development : For prevention, early identification and management of hearing impaired and deafness cases, training would be provided from medical college level specialists (ENT and Audiology) to grass root level

workers. The training of PHC doctors and health functionaries would be provided by Rehabilitation Council of India.

2. Capacity building : for the district hospital, community health centers and primary health center in respect of ENT/ Audiology infrastructure.

3. Service provision including rehabilitation : Screening camps for early detection of hearing impairment and deafness, management of hearing and speech impaired cases and rehabilitation (including provision of hearing aids), at different levels of health care delivery system.

4. Awareness generation through IEC activities : For early identification of hearing impaired, especially children so that timely management of such cases is possible and to remove the stigma attached to deafness.

Expected Benefits of the Programme

The programme is expected to generate the following benefits in the short as well as in the long run :

1. Large scale direct benefit of various services like prevention, early identification, treatment, referral, rehabilitation etc. for hearing impairment and deafness as the primary health center/community health centers/district hospitals largely cater to their need.
2. Decrease in the magnitude of hearing impaired persons.
3. Decrease in the severity/extent of ear morbidity or hearing impairment in large number of cases.
4. Improved service network for the persons with ear morbidity/hearing impairment in the states and districts covered under the project.
5. Awareness creation among the health workers/grassroot level workers through the primary health centre medical officers and district officers which will percolate to the lowest level as the lower level health workers function within the community.
6. Larger community participation to prevent hearing loss through panchyati raj institutions, *mahila mandals*, village bodies and also creation of a collective responsibility framework in the broad spectrum of the society.
7. Leadership building in the primary health centre medical officers to help create better sensitization in the grassroot level which will ultimately ensure better implementation of the programme.

Summary

The programme is a part of eleventh five year plan with the objective of preventing and controlling major causes of hearing impairment and deafness, so as to reduce the total disease burden by 25% of the existing burden by the end of eleventh five year plan. The Components of the Programme are Manpower training and development to grass root level workers, Capacity building - for the district hospital, community health centers and primary health center in respect of ENT/ Audiology infrastructure, Service provision including rehabilitation in the form of Screening camps, management of hearing and speech impaired cases and rehabilitation (including provision of hearing aids), at different levels of health care delivery system and awareness generation through IEC activities.

Puja Dudeja & Ashok K. Jindal

National Programme for Control of Blindness was launched in the year 1976 as a 100% centrally sponsored scheme with the goal to reduce the prevalence of blindness from 1.4% to 0.3%. India was the first country to launch the National Programme for Control of Blindness. Due to a large population base and increased life expectancy, the number of blind particularly due to senile disorders like Cataract, Glaucoma, Diabetic Retinopathy etc. is expected to increase. Among the emerging cause of blindness, diabetic retinopathy and glaucoma need special mention. 2 percent of India's population is expected to be diabetic. 20 percent of diabetics have diabetic retinopathy and this number is likely to grow in future. India is committed to reduce the burden of avoidable blindness by the year 2020 by adopting strategies advocated for Vision 2020: The Right to Sight. The prevalence and causes of blindness and future goals are given in Table - 1.

Objectives

The objectives of the programme are (1) :

1. To reduce the backlog of blindness through identification and treatment of blind.
2. To develop Eye Care facilities in every district.
3. To develop human resources for providing Eye Care Services.
4. To improve quality of service delivery.
5. To secure participation of Voluntary Organizations in eye care.

Table - 1 : Prevalence and causes of Blindness & Future Goals

Year	Population Prevalence (%)	Remarks
1971-74	1.38	Cataract was leading cause (75% of blindness)
1986-89	1.49	Cataract blindness increased to 80%. Trachoma and Vitamin A related blindness reduced.
2001-04	1.10	Cataract reduced to 63%. Refractive error second leading cause (20%). Glaucoma and diabetic retinopathy emerging causes.
2007	--	Goal for 10th plan : 0.8%
2010	--	Goal under "Vision 2020 Initiative": 0.5%

Programme Implementation

India is a vast country having 28 States and 7 Union Territories with 593 districts, with an average population of nearly two million per district. The programme implementation has

been decentralized up to the district level where District Blindness Control Societies (DBCS) have been set up as the nodal agencies. Members of the DBCS include officials from District Administration, Health, Education and Social Welfare Departments, media, community leaders and NGOs/Private Sectors involved in eye care. These societies directly receive funds from the Government. The concept is to establish a bottom up approach in dealing with blindness through multisectoral and coordinated efforts. These societies are responsible for identifying blind in every village, organize diagnostic screening camps at suitable locations, arrange transportation of patients to the designated facilities, and ensure follow up. The states have State ophthalmic cell under directorate of health services and state health societies. At the apex National institute of ophthalmology (Dr. Rajendra Prasad Centre for ophthalmic sciences in AIIMS, New Delhi) has been established. Various other regional institutes have been developed. Medical colleges have been upgraded under NPCB and few of them are providing training to ophthalmic assistants.

School Eye Screening Programme : Under this the children aged 10-14 years are being screened by trained teachers and those suspected to have refractory error are seen by ophthalmic assistants and corrective spectacles are prescribed.

Constraints

1. **Inequitable distribution of eye surgeons :** There are an estimated 12,000 eye surgeons in India with an average of 1 surgeon for 1,00,000 population. There is a wide disparity between urban and rural areas. This disparity has led to significant differences in services offered / sought by the public.
2. **Suboptimal utilization of human resources:** It is estimated that about 40 percent of eye surgeons in government section are non operating surgeons. They are either practicing medical ophthalmology/refraction services or providing general medical care.
3. **Inadequate number of paramedical eye personnel**
4. **Suboptimal coverage :** Govt. facilities, NGO and private sector are usually located in urban/ periurban areas. Geographically remote and socioeconomically backward population remains underserved.
5. **Over emphasis on cataract :** The problem of corneal blindness, Glaucoma and diabetic retinopathy has not been adequately addressed. Similarly pediatric ophthalmology and low vision has received low priority.
6. **Lack of public awareness :** Rural, illiterate and under privileged population are not fully aware about various interventions that are available to restore vision. Integration of the programme is limited and therefore rural health workers are also not motivating potential beneficiaries.

Major challenges ahead

1. In-depth study of epidemiology of blindness
2. Comprehensive eye care programme
3. Reaching the underserved population
4. Development of sustainable infrastructure
5. Technological advancement in eye care
6. Human resource development
7. Quality of care

Strategies during XI plan

1. Strengthening advocacy and motivation by involvement of village panchayat, local bodies, grass root NGOs, women group and formal and informal leaders.
2. Human resource development.
3. Infrastructure development.
4. Grant in aid to state blindness control societies and district blindness control societies.
5. Involvement of private practitioners.
6. Increased IEC activities.

Vision 2020 - The Right to Sight Initiative : The global initiative, "VISION 2020: The Right to Sight" is a collaborative response initiated by the World Health Organization (WHO) and the International Agency for the Prevention of Blindness (IAPB) to combat the gigantic problem of blindness in the world. It was launched in Geneva in 1999. The diseases covered under Vision 2020 are (2) :

1. Cataract
2. Trachoma
3. Onchocerciasis (not a problem in India)
4. Childhood blindness
5. Refractive Errors and Low Vision

These conditions have been chosen on the basis of their contribution to the burden of blindness and the feasibility and affordability of interventions to control them. Each country will decide on its priorities based on the magnitude of specific blinding conditions in that country. Under this initiative, five basic strategies to combat blindness are :

1. Disease prevention and control.
2. Training of personnel.
3. Strengthening the existing eye care infrastructure.
4. Use of appropriate and affordable technology.
5. Mobilization of resources.

Vision 2020 will serve as a common platform to facilitate a focused and coordinated functioning of all the partners in eliminating avoidable blindness by the year 2020. It will further develop and strengthen the primary health/eye care approach to the problem of avoidable blindness. Broad regional alliances will be sought to eventually develop a global partnership for eye health.

Cataract : Cataract is the major cause of blindness in the world. The aim is Elimination of cataract blindness (person with vision less than 3/60 in both eyes).

Trachoma : Trachoma is the second cause of blindness in sub-Saharan Africa, China and the Middle-Eastern countries. The aim is to eliminate blindness due to trachoma. Trachoma is to be controlled through the implementation of the SAFE strategy integrated within primary health care in all communities identified as having blinding trachoma within a country. This includes the following:

- i) Assessment to identify communities with blinding trachoma.
- ii) Delivery of community-based trichiasis Surgery by trained paramedical staff (S of SAFE).
- iii) Antibiotic treatment (either tetracycline eye ointment or oral azithromycin) for children with active disease (A of SAFE).
- iv) Promotion of Facial cleanliness (F of SAFE) and

Environmental improvement (E of SAFE), including personal hygiene and community sanitation as part of primary health care.

Childhood Blindness

Vitamin A deficiency : To achieve and sustain the elimination of blindness due to vitamin A deficiency.

Surgically avoidable causes : To control blindness in children from cataract, glaucoma and retinopathy of prematurity (ROP)

Refractive Errors and Low Vision : Spectacles are an essential part of the treatment of many eye patients. Their provision is therefore an integral part of eye care delivery. Elimination of visual impairment (vision less than 6/18) and blindness due to refractive errors or other causes of low vision. This aim goes beyond the elimination of blindness and also includes the provision of services for individuals with low vision.

Implementation : The proposed structure for implementation of Vision 2020 is vision centre at the primary level, Service centre at the secondary level and Training centre and centre of excellence at the tertiary level.

Summary

National Programme for Control of Blindness was launched in the year 1976. India was the first country to launch the National Programme for Control of Blindness. The objectives are to reduce the backlog of blindness through identification and treatment of blind, to develop Eye Care facilities in every district, to develop human resources for providing Eye Care Services, to improve quality of service delivery and to secure participation of Voluntary Organizations in eye care.

The programme implementation has been decentralized upto the district level where District Blindness Control Societies (DBCS) have been set up as the nodal agencies. These societies are responsible for identifying blind in every village, organize diagnostic screening camps at suitable locations, arrange transportation of patients to the designated facilities, and ensure follow up.

The Constraints for implementation are inequitable distribution of eye surgeons, suboptimal utilization of human resources, suboptimal coverage, over emphasis on cataract and lack of public awareness. The global initiative, "VISION 2020: The Right to Sight" is a collaborative response initiated by the World Health Organization (WHO) and the International Agency for the Prevention of Blindness (IAPB) to combat the gigantic problem of blindness in the world. It was launched in Geneva in 1999. The diseases covered under Vision 2020 are Cataract, Trachoma, Onchocerciasis, Childhood blindness and Refractive Errors and Low Vision.

Under this initiative, five basic strategies to combat blindness are disease prevention and control, training of personnel, strengthening the existing eye care infrastructure, use of appropriate and affordable technology and mobilization of resources.

Puja Dudeja & Ashok K. Jindal

(A) National Oral Health Programme

Oral diseases such as dental caries, periodontal diseases, malocclusion and oral cancers constitute an important public health problem in India today. Oral diseases have a great impact on systemic health and is now established that periodontal diseases has far reaching effects on various systemic diseases like low birth weight, Diabetes, Heart disease, Respiratory diseases, Stroke, Atherosclerosis etc. Oral cancer prevalence is highest in India, causing high morbidity and mortality. National oral health program is a pilot project on oral health started in the year 1999 by DGHS and the Ministry of Health and Family Welfare. Under this project, All India Institute of Medical Sciences has been made a nodal agency.

Programme targets : These are given in Table - 1.

Oral Diseases	Age Group	Prevalence (%) 2005	Status by 2012(%)
Dental Caries	All	40-50	<30
Periodontal diseases	15+	45	<35
Malocclusion	9-14	32.5	25
Oral cancer	35+	0.03	0.02
Fluorosis	All	5.5	4

Components

1. Oral Health Education by involving health workers, school children, teachers and mass media.
2. Production of IEC Material for awareness generation.
3. Formulation of modules for trainers (Dental surgeons), Health Workers and School Teachers.

The main focus of this project is on primary prevention which is the most cost effective, appropriate and desirable.

The project was reviewed by National Institute for Health and Family Welfare in 2004 and following recommendations were made:

1. The program to be divided into several implementation phases giving reasonable time frames and goals to be achieved in each phase.
2. Centre to provide technical support to the states by forming various committees and one time financial support.
3. The states to be responsible for implementation of the programme by involving the education department, school teachers, health workers and by developing adequate infrastructure and facilities.
4. Modification of the existing IEC material with respect to the local situation in the states and in consultation with agencies like Central Health Education Bureau, Indian

Institute of Mass communication, media division of MoHFW. The messages of oral and dental health should be merged with other IEC materials being developed by the centre and state governments.

Strategies for future

1. Oral Health Education : Use of primary health care approach: It is recommended to spread the messages of oral health care and strengthening of existing infrastructure. Health care workers to be an important part of the programme in spreading health awareness. Health care workers to be trained in providing pain relief and refer the case for further investigation and treatment.

- Development of IEC material and use of mass media in spreading awareness.
- Involvement of NGOs in delivery of oral health education.
- Networking with other departments like Dept. of Education and Social Welfare in imparting oral health education to the school children.

2. Manpower and infrastructure development for primary and secondary prevention of oral diseases : Mobile Dental Clinics to provide on the spot diagnostic, preventive, interceptive and curative services to the people and school children in far flung rural areas of the state, should be made available.

3. Strengthening school health services : Good oral habits and practices learnt early in life would help reduce the disease burden later in life.

Critical Appraisal

Oral health care has not been given sufficient importance in our country. Most of the district hospitals have the post of a dental surgeon but they lack in equipment, machinery and material. Even when the equipment exists, the maintenance is poor. Oral health has not been discussed in National Health Policy 2002 and National Rural Health Mission also does not have any mention of oral health services either. The treatment of Oro-dental diseases is enormously expensive and no Govt. across the globe can bear the cost for dental treatment for its entire population. It is suggested that Govt. should bear the cost for primary and secondary prevention completely and may impose cost to cost pricing for the treatment part at all levels.

(B) National Programme for Prevention of Fluorosis

Fluorosis, a public health problem, is caused by excess intake of fluorides through drinking water/food products/industrial pollutants, over a long period. It results in major health disorders like dental fluorosis, skeletal fluorosis and non skeletal fluorosis besides inducing ageing.

Level of fluoride : The fluoride content in drinking water in India is about 0.5mg/l but in fluorosis endemic areas, the natural water have been found to contain as much as 3-12 mg/l of fluoride. A concentration of 0.5 - 0.8 mg/l is considered safe limit in India. In temperate climate where intake of water is low, the optimum level of fluorine in drinking water is accepted as 1mg/l (2).

Problem statement : Fluoride endemicity has been reported in 196 districts of 19 states & UTs of the country. The affected

population with fluorosis is about 66 million in the country. Based on excess level of fluoride content in No. of district, the States/UTs have been classified as mild, moderate and severe endemic State/UTs of Fluorosis. States like Andhra Pradesh, Assam, Bihar, Chhattisgarh, Delhi, Gujarat, Haryana, Jharkhand, Karnataka, Kerala, Jammu & Kashmir, Madhya Pradesh, Maharashtra, Orissa, Punjab, Rajasthan, Uttar Pradesh, Tamil Nadu, West Bengal are affected from fluorosis. In all these states, the drinking water has high fluorine content.

Why a National Programme?

At present there is no National level Programme for Fluorosis Control. Data regarding prevalence of Fluorosis is based on studies conducted by different groups over a period of time. Surveys at a National level regarding prevalence have not been conducted so far. For provision of safe drinking water, Government of India supplements the efforts of State Government and UTs by providing funds under the Accelerated Rural Water Supply Programme (ARWSP). The chairman of National Human Rights Commission reviewed the fluorosis situation in the country and recommended a National Programme for the same in the XI plan(3).

Objectives

1. To assess the intake of fluoride by assessing its presence in all sources of drinking water, consumption of foods rich in fluoride and intake through industrial emissions at the district in the endemic states.
2. To coordinate the activities in relation to fluorosis being carried out in various departments/Ministries like M/o rural Development, D/o Drinking Water, RGNDWM, Education, Social Welfare, NICD, M/o H & FW.
3. To impart training to medical doctors and paramedicals of the districts for early diagnosis of Fluorosis.
4. To develop IEC material from Policy Level to the community personnel.

Strategies : The following strategies are to be adopted :

1. Conducting fluoride survey regarding fluoride level in all drinking water sources, food product sources, and industrial emissions if there is industry in the project district.
2. Launching of extensive Fluorosis prevention and control programme in coordination with Dept. of drinking water, Ministry of Environment, Ministry of Information and Broad casting, Ministry of Social Justice and Empowerment and Ministry of Health & Family Welfare.
3. Establishment of testing of fluoride facility in water, food and blood in each district of programme area.
4. Imparting training programme to medical and paramedicals of the programme districts to diagnose Fluorosis cases including deformity cases.
5. To develop extensive IEC material in relation of Fluorosis.
6. To implement the decision of Central Programme Implementation Committee under DGHS.

Project Area : In the beginning, the programme for prevention and control of Fluorosis, can be implemented in 5 districts selected from each of the following zones of the country based on prevalence of fluorosis, geographical distribution, weather,

etc. on a pilot basis.

- (a) Southern Zone (One district)
- (b) Western Zone (One district)
- (c) Northern zone (One district)
- (d) Eastern zone (One district)
- (e) Central zone (One district)

The Pilot Programme will be implemented in first two years time including impact evaluation of various strategies/components of the programme. Third year onwards, the Programme will be expanded to cover about 100 districts of 19 States depending on availability of funds.

(C) Programme for the Elderly

India, as the second most populous country, has 76.6 million people at or over the age of sixty (2001 Census) constituting about 7.7% of its total population. Life expectancy has increased from around 59 years in the 1970s to 63 years currently, and is expected to cross 70 years by the year 2020. The proportion of elderly in India is set to rise dramatically in the next few decades.

Care of elderly : The Health of the elderly requires comprehensive care with preventive, curative & rehabilitative services. Unlike the developed countries, India does not have a well structured Geriatric Health services, thus leading to a relatively ad hoc system of health care delivery for the elderly. In this scenario, there is a need for a specialized geriatric health service, which recognizes the elderly as being a vulnerable population.

Programme Vision : A society where persons aged 60 years and above will have the peace of mind and sense of security that arises from the knowledge that they have access to quality health care at all times.

Programme Mission : A community based holistic care system, which offers every citizen above the age of 60 years the opportunity to participate in a health care programme, which includes preventive, curative and emergency health care services of high quality.

Goal : To improve the access to promotive, preventive, curative and emergency health care among elderly persons.

Objectives

1. Provide comprehensive health care to the elderly by preventive, curative and rehabilitative services.
2. Train Health professionals in Geriatrics, including supportive care and Rehabilitation.
3. Develop scientific solutions to specific elderly health problems by research into Geriatric and Gerontology.

Programme Implementation : The national program for health care of the elderly will be a centrally funded program. The entire Geriatric population will be covered by the 2 national institutes of Ageing, one in North India and the other in south India, eight identified regional centres (each implementing Geriatric Health Care in about 3 to 4 states). Under the control of these two institutes, one teaching medical college/Tertiary level hospital in each state to develop the Geriatric Unit which will include the Outpatient services, Acute care, Subacute Care and Long term care units. The health professionals trained here will be sent to the district level centres for Geriatric Health Care delivery.

(D) Nutritional Programmes & Integrated Child Development Services (ICDS)

Details of various National Nutritional Programmes and ICDS programme are discussed in an exclusive chapter in the section on nutrition.

(E) Water Supply and Sanitation Programme

Evolution : The Ministry of Rural Development has been taking initiatives to provide safe drinking water in all rural habitations. The National Water Supply and Sanitation Programme was initiated in 1954 with the objective of providing safe water supply and adequate drainage facilities to the entire urban and rural population of the country. In 1972 a special programme known as Accelerated Rural Water Supply Programme (ARWSP) was started to supplement the national water supply and sanitation programme. The Govt of India launched International Drinking water Supply and Sanitation Decade Programme in 1981. Other programmes like Prime Minister's Gramodaya Yojana - Rural Drinking Water (PMGY-RDW), have been implemented to resolve drinking water crisis in rural habitations. These programmes also give importance to rainwater harvesting, sustainability of sources and community participation.

Accelerated Rural Water Supply Programme (ARWSP)

Objectives

1. To ensure coverage of all rural habitations and especially reach the unreached with access to safe drinking water;
2. To ensure sustainability of the systems and sources;
3. To tackle the problems of water quality in affected habitations;
4. To institutionalize the sector reform initiative in rural water supply sector.

Programme Implementation

Rural water supply is a State subject. States have been taking up projects and schemes from their own resources for the provision of safe drinking water. State Governments decide the implementing agencies for the programme. The agencies may be the Public Health and Engineering Department (PHED), Rural Development Department or the Panchayati Raj Department. Implementation is also taken up by the Government Boards / Nigams / Agencies in a few States. All projects and schemes proposed under ARWSP are approved by the State Level Scheme Sanctioning Committee.

Role of Panchayats : As per the 73rd Amendment to the Constitution of India, the subject of rural water supply is vested with the Panchayati Raj Institutions (PRIs). The Panchayats are to play a major role in providing safe drinking water and managing the systems and sources in their respective areas. They can be involved in the implementation of schemes, particularly in selecting the location of handpumps, standposts and spot sources.

Sub-Mission : Sub-Mission programmes of the Government of India were launched with the objective to provide safe drinking water facilities in rural habitations affected by water quality problems like fluorosis, arsenic, brackishness, excess iron, nitrate etc. The States undertake these projects. For ensuring source sustainability through rainwater harvesting,

artificial recharge etc. State Governments also use funds under Sub-Mission. Powers have been delegated to the States for sanctioning Sub-Mission projects.

Prime Minister's Gramodaya Yojana (Rural Drinking Water)

Prime Minister's Gramodaya Yojana (PMGY) was launched by the Prime Minister in 2000-01.

Goal : To provide basic necessities to the people in rural areas for improvement of the physical quality of life.

Components : Primary education, Primary health, Rural shelter, Rural drinking water, nutrition and rural electrification are the six components of PMGY. 10 per cent of the PMGY funds have been earmarked for rural water supply.

Objectives

1. Emphasize on taking up projects and schemes for water conservation, rainwater harvesting, water recharge and sustainability of drinking water sources in areas under Drought Prone Areas Programme (DPAP) and Desert Development Programme (DDP); overexploited dark and grey Blocks and other water stress and drought affected areas
2. Take up projects/schemes to tackle quality related problems and for providing safe drinking water to uncovered and partially covered habitations.

Swajaldhara : It is a community led participatory programme launched in 2002, aimed at providing safe drinking water in rural areas. It also includes building awareness among the village community on the management of drinking water projects, including better hygiene practices and encouraging water conservation practices along with rain water harvesting. It has two components. The first is for a gram panchayat or a group of panchayats at the block/tehsil level and the second at the district level.

(F) Rural Sanitation

The concept of sanitation connotes a comprehensive definition, which includes liquid and solid waste disposal, food hygiene, personal, domestic and environmental hygiene. Although the concept of sanitation has undergone qualitative changes during the years, there has been a very limited change in the sanitation condition of rural India.

Central Rural Sanitation Programme (CRSP)

CRSP was launched in 1986 and aims at improving the quality of life of the rural people and to provide privacy and dignity to women in particular.

Objectives

1. Improving the general quality of life in rural areas.
2. Accelerating coverage in rural areas.
3. Generating demand through awareness creation and health education.
4. Controlling incidence of water and sanitation related diseases.

Programme components

1. To construct individual sanitary latrines for households Below Poverty Line (BPL) with subsidy, where demand exists.

2. To encourage other households to buy facilities through markets including sanitary marts.
3. To assist in setting up of sanitary marts.
4. To launch awareness campaigns in selected areas.
5. To establish sanitary complex for women.
6. To encourage locally suitable and acceptable models of latrines.
7. To promote total sanitation in villages through construction of drains, soakage pits for liquid and solid waste disposal.

Subsidy for household latrines : Subsidy is given for simple and less expensive latrines. A duly completed household sanitary latrine comprises only a Basic Low Cost Unit (BLCU) without any super structure.

Strategy for School Sanitation : School Sanitation is a vital component of sanitation. It is proposed to construct toilets in all rural schools (separate complex for boys and girls) by the end Government machinery, NGO participation and IEC campaigns, provision for an alternate delivery system and more flexible demand-oriented construction norms are also stressed.

(G) Minimum Needs Programme

It started in 1975 with the objective of providing certain basic minimum needs and improve the living standards of the people. Its bigger objective is social and economic development of the community, particularly the underprivileged and under-served population. The programme includes the following components.

- (a) Rural Health
- (b) Rural Water Supply
- (c) Rural Electrification
- (d) Elementary Education
- (e) Adult Education
- (f) Nutrition
- (g) Environmental improvement of Urban Slums
- (h) Houses for landless labourers

It laid emphasis on establishment of PHC, subcentres to improve rural health. To improve the nutritional status, it aimed at providing nutritional support to eligible persons, to expand "Special nutrition programme" to all the ICDS projects, and to consolidate the mid-day meal programme and link it to health, potable water and sanitation.

(H) 20 - Point Programme

It is an *agenda* for national action to promote social justice and economic growth. It was restructured in 1986 with the objective of "eradication of poverty, raising productivity, reducing inequalities, removing social and economic disparities and improving the quality of life". At least 8 of the 20 points are related, directly or indirectly, to health. These are: Point 1 - Attack on rural poverty; Point 7 - Clean drinking water; Point 8 - Health for all; Point 9 - Two - child norm; Point 10 - Expansion of education; Point 14 - Housing for the people; Point 15 - Improvement of slums; and Point 17 - Protection of the environment.

Study Exercises

MCQs & Exercises on National Health Programmes

Puja Dudeja & Ashok K Jindal

1. Which of the following is true with respect to goals of RCH - II? (a) IMR < 45/1000 (b) MMR < 100/100000 (c) Both of above (d) None of above
2. The long term objective of RCH - II is to achieve a stable population by (a) 2045 (b) 2050 (c) 2015 (d) 2055
3. Centchroman (non steroidal contraceptive) has been developed by (a) Indian Institute of Population Sciences (b) National Institute of Health and Family Welfare (c) All India Institute of Medical Sciences (d) Central Drug Research Laboratory, Lucknow
4. Reducing MMR < 200/100000 is a goal of (a) National Health Policy 2002 (b) National Population Policy (c) Tenth five year plan (d) RCH II
5. Home visits for postnatal care for mother and new born under RCH II are done on (a) Day 2 and 5 (b) Day 3 and 7 (c) Day 1 and 3 (d) Day 3 and 5
6. Which of the following is not a critical element of First Referral Unit in RCH II? (a) Availability of surgical interventions (b) Newborn care (c) Blood storage facility on a 24 hr basis (d) Easy accessibility
7. A total number of _____ tablets of iron with folic acid are given to a pregnant woman by health worker (a) 100 (b) 70 (c) 150 (d) 200
8. Under National Nutritional Anemia Prophylaxis Program the strength of iron and folic acid in tablets is (a) 60 mg elemental iron and 0.5 mg folic acid (b) 100 mg of elemental iron and 0.5 mg folic acid (c) 100 mg of elemental iron and 0.1mg folic acid (d) 60 mg elemental iron and 0.1 mg folic acid
9. *Janani Suraksha Yojana* (JSY) aims at reducing maternal and neonatal mortality rate by (a) Promoting institutional delivery (b) Health education (c) Distribution of iron and folic acid tablets to the mothers (d) All of the above
10. Under IMNCI the pink colour chart refers to a treatment at (a) Out patient facility (b) Home management (c) Give injection/oral drops (d) Urgent referral
11. The objective of national programme for prophylaxis against blindness in children due to vitamin A deficiency is to decrease the prevalence of Vitamin A deficiency to (a) 0.1 % (b) 0.2 % (c) 0.3 % (d) 0.001%
12. The objective of national programme for prophylaxis against blindness in children due to vitamin A deficiency is being implemented through (a) RCH programme (b) National programme for control of blindness (c) UIP (d) None of above
13. Goal of National tuberculosis control programme is

- (a) To eradicate TB (b) To decrease the transmission of TB (c) To treat all sputum +ve patients (d) To decrease the incidence of TB to such a low level that is no longer a major public health problem (e) BCG vaccination of all infants
14. Which of the following is an objective of RNTCP? (a) To achieve at least 70 percent cure rate of the newly diagnosed sputum smear-positive TB patients (b) To detect at least 85 percent of new sputum smear-positive patients after the first goal is met (c) To achieve at least 85 percent cure rate of the newly diagnosed sputum smear-positive TB patients (d) Both A & B
 15. Which of the following is not a component of DOTS ? (a) Political and administrative commitment (b) Systematic monitoring and accountability (c) Supervised treatment to ensure the right treatment (d) Health education
 16. Which of the following statement is false? (a) Duration of Intensive phase of Category I is 8 weeks (b) Duration of Continuation phase of Category II is 22 weeks (c) Duration of Intensive phase of Category II is 12 weeks (d) None of the above
 17. The total number of doses in category II is (a) 78 doses (b) 102 doses (c) 108 doses (d) 76 doses
 18. Which of the following Anti tubercular drug is bacteriostatic? (a) Streptomycin (b) Ethambutol (c) INH (d) Rifampicin
 19. DOTS plus strategy is for treatment of (a) HIV with TB (b) Malaria with TB (c) MDR TB (d) All the above
 20. Drug used in chemoprophylaxis of TB is (a) INH (b) Rifampicin (c) Both of above (d) None of above
 21. Under NAMP, radical treatment of falciparum malaria is given for (a) 1 day (b) 5 days (c) 7 days (d) 14 days
 22. All of the following statements about NAMP are true except: (a) MBER should be equal to fever rate of the month in the community (b) Trends in SPR can be utilized for predicting epidemic situations in the area (c) Annual blood examination rate is calculated from the number of slides examined per 100 cases of fever (d) For calculating ABER and MBER the denominator is common
 23. Function of FTD is best denoted by: (a) Diagnosis of cases + spraying (b) Collection of slides + treatment of fever (c) Only treating fever cases (d) Treatment + slide collection + spraying
 24. Which of the following diseases are not included under NVBDCP ? (a) Malaria (b) Japanese Encephalitis (c) Viral encephalitis (d) Dengue
 25. Choice of insecticide for Kala Azar elimination under NVBDCP is (a) Malathion (b) DDT (c) Malathion+ DDT (d) DDT
 26. A person wants to visit a malaria endemic area of low level chlorquine resistant falciparum malaria The best chemoprophylaxis is : (a) Chloroquine (b) Proguanil+ Chloroquine (c) Sulphadoxin + pyrimethamine (d) Mefloquine
 27. A malaria survey is conducted in 50 villages having a population of one lakh. Out of 20000 slides examined, 500 turned out to be MP positive. The SPR is (a) 20% (b) 5% (c) 25% (d) 0.4%
 28. Which of the following is an indicator for operational efficacy? (a) API (b) ABER (c) AFI (d) SPR
 29. Anti- malarial month is (a) April (b) May (c) September (d) June
 30. Which of the following statements is false? (a) Lymphatic filariasis has been targeted for elimination in 2015 (b) Strategy for elimination is by Annual Mass Drug Administration of DEC for 5 years or more (c) Children less than 2 ys are not included in Annual Mass Drug Administration (d) DEC is safe in Pregnancy
 31. Which one of the following strategies is aimed at AIDS control in India ? (a) Detection and treatment of AIDS cases in the community (b) Detection and isolation of HIV infected persons in the community (c) Immune-prophylaxis of the risk groups (d) Community education behavioral change
 32. AIDS was first detected in India in the year (a) 1975 (b) 1981 (c) 1986 (d) 1991
 33. Which of the following is not true about National AIDS control Programme? (a) Sentinel surveillance methodology have adopted (b) Community based screening for prevalence of HIV taken up (c) Early diagnosis and treatment of STD is a major strategy to control spread of HIV (d) Formulating guidelines for blood banks donors & dialysis units
 34. National Leprosy Eradication programme was started in (a) 1949 (b) 1955 (c) 1973 (d) 1983
 35. Elimination in leprosy stands for (a) Reduce the number of cases to < 1/10,000 population (b) Reduce the number of cases to < 1/1000 population (c) No case of leprosy in a region for 5 years (d) 100 percent treatment of all cases
 36. Which one of the following statements is not correct regarding National Leprosy Eradication Programme (NLEP) (a) Multibacillary leprosy treatment is recommended for one year (b) Skin smear examination is done for classification into paucibacillary and multibacillary (c) Special Action Project for Elimination of leprosy is for rural areas (d) Surveillance for two years for a treated case of paucibacillary leprosy to be carried out
 37. India was declared 'Guinea Worm disease free' in the year (a) 1996 (b) 2000 (c) 2001 (d) 2002
 38. National Mental Health programme was started in (a) 1992 (b) 1983 (c) 1994 (d) 1985
 39. Which of the following is not a component of AFP SURVEILLANCE? (a) Case notification (b) Case in Laboratory investigation (c) Out break response and active search in community (d) Attaining high routine immunization
 40. Which of the following is not a strategy for achieving Polio Eradication? (a) Attaining high routine immunization (b) National Immunization Days (NIDs) (c) Surveillance of Acute Flaccid Paralysis (AFP) (d) Mopping-up immunization (e) None of the above
 41. National Mental Health Programme is (a) Vertical programme (b) Integrated Programme (c) None of the above
 42. National Cancer Control Programme was started in (a) 1976 (b) 1986 (c) 1970 (d) 1992
 43. Under National Cancer Control Programme, oncology wings were sanctioned to - (a) Regional Cancer Institutes (b) District Hospital (c) Medical College Hospitals (d) Voluntary Agencies treating cancer patients
 44. National Cancer Registry Programme (NCRP) was started by (a) Ministry of Health and Family Welfare (b) Indian

- Council of Medical Research (c) Collaboration of (a) and (b) (d) None of the above
45. The goal of NIDDCP is (a) To reduce the prevalence of iodine deficiency disorders below 10 percent in the entire country by 2012 AD (b) To reduce the prevalence of iodine deficiency disorders below 5 percent in the entire country by 2012 AD (c) To reduce the prevalence of iodine deficiency disorders below 10 percent in the entire country by 2010 AD (d) None of the above
46. The best indicator for monitoring the impact of Iodine Deficiency Disorders Control Programme is (a) Prevalence of goiter among school children (b) Urinary iodine levels among pregnant women (c) Neonatal hypothyroidism (d) Iodine level in soil
47. Which one of the following is not a target disease under 'Vision 2020: The Right to Sight' (a) Refractive error (b) Trachoma (c) Corneal blindness (d) Diabetic retinopathy
48. SAFE strategy in vision 2020 is for which eye condition (a) Trachoma (b) Cataract (c) Onchocerciasis (d) Childhood blindness
49. Vision 2020 'The right to sight' includes all except (a) Trachoma (b) Epidemic conjunctivitis (c) Cataract (d) Onchocerciasis
50. ICDS is running under (a) Ministry of health and Family Welfare (b) Ministry of Women and child development (c) Collaboration of both of above (d) None of above

Answers : (1) b; (2) a; (3) d; (4) c; (5) b; (6) d; (7) a; (8) b; (9) a; (10) d; (11) c; (12) a; (13) d; (14) c; (15) d; (16) b; (17) b; (18) b; (19) c; (20) a; (21) b; (22) c; (23) b; (24) c; (25) d; (26) b; (27) c; (28) b; (29) d; (30) d; (31) d; (32) c; (33) b; (34) d; (35) a; (36) b; (37) c; (38) a; (39) d; (40) e; (41) b; (42) a; (43) c; (44) c; (45) a; (46) c; (47) d; (48) a; (49) b; (50) b.

Sunil Agrawal

An important aspect of Preventive Medicine and Public Health is legislative control or legislative power. These laws protect public health at large but it should maintain the balance between individual autonomy and community protection and its actions should be directed to improve the health status in the community. The characteristics of public health laws are:

1. Responsibility of government as a right to provide adequate health and health services to all citizens.
2. Public health laws protect community health rather than individual's health.
3. Public Health contemplates the relationship between the state and the population.
4. Public health laws deals with the delivery of public services based on scientific methodologies e.g. Purification of water.
5. The laws acts as important guidelines for the state, community and individuals.

To achieve the fundamental goals of our constitution various acts and rules are enacted.

Act : Act means statutes or laws adopted (enacted) by a national or state legislative assembly or other governing body.

Rules: Rules are explicit statements that tell an individual what he or she ought to do or ought not to do.

Important legislations in India pertaining to public health and its protection are grouped in the following categories for the

purpose of better understanding:

1. Health Facilities and Services
2. Disease Control and Medical Care
3. Human Resources
4. Ethics and Patients Rights
5. Pharmaceutical and Medical Devices
6. Radiation Protection
7. Hazardous Substances
8. Occupational Health and Accident Prevention
9. Health of the Elderly, Disabled, Rehabilitation and Mental Health
10. Families, Women and Children
11. Smoking, Alcoholism and Drug Abuse
12. Social Security and Health Insurance
13. Environmental Protection
14. Nutrition and Food Safety
15. Health Information and Statistics
16. Intellectual Property Rights
17. Custody, Civil and Human Rights
18. Other Aspects not covered by any heading above

Under the constitutional provisions, the government of India owes its population social security, health services, safety, environmental protection, equal opportunity and justice. The methods adopted by the government to deliver these services are through framing policies, execution of legislation and implementation of programs. The provision of an act is further explained in detail in rules and regulations. Public health officials enforce rules through following ways:

- a) Permits, licenses and registrations
- b) Administrative orders
- c) Civil penalties
- d) Injunctions

Legislations are not an end in themselves. They have to be executed in letter and spirit by a responsible society and the officials responsible for their implementation. Often these legislations may not be able to bring about the desired result. There are many factors responsible for lack of effectiveness of these legislations, viz., Lack of awareness, Lack of implementation, Corruption, Lack of infrastructure, Inconsistency and, Inadequacy. To overcome these problems Government of India has initiated *National Legal Literacy Mission in 2005* to impart knowledge and education on various legal aspects including those related to Public Health. This programme seeks to sensitise, and create awareness among people about their legal rights, acts and regulations and interpretation of legal jargon.

Laws in relation to Health Facilities and Services

- Indian Red Cross Society Act, 1920
- All India Institute of Medical Sciences Act, 1956
- Post Graduate Institute of Medical Education and Research, Chandigarh, Act, 1966
- Bureau of Indian Standards Act and Rules, 1986, 1987
- National Institute of Pharmaceutical Education and Research Act, 1998
- Clinical Establishment Acts
 - a. Nursing Homes Registration Acts
 - b. State Clinical Establishment Acts and Rules

Laws in relation to Disease Control and Medical Care

- Epidemic Diseases Act, 1897
- Indian Aircraft Act and Rules, 1934, 1954
- Indian Port Health Rules, 1955
- Medical Termination of Pregnancy Act, 1971, 1975
- Transplantation of Human Organs Act and Rules, 1994, 1995, 2002
- Prenatal Diagnostic Techniques (Regulation and Prevention of Misuse) Act and Rules, 1994, 1996, 2002, 2003

Laws in relation to Human Health Care Resources

The professional ethics, quality control of education programmes, standards etc. are important for all the systems of medicine, hence there are acts and regulations which are enumerated below:

Allopathy

- Indian Medical Council Act and Rules, 1956, 1957, 1965, 1993, 2001, 2002.
- Medical Council of India 1994, 1998, 2000, 2001
- Establishment of New Medical Colleges, Higher Course Regulations, 1993.
- Eligibility Requirement for Taking Admission in Undergraduate Medical Course in a Foreign Medical Institution Regulations, 2002.

Indian System of Medicine and Homeopathy

- Indian Medicine Central Council Act and Regulations, 1970, 1989, 2005
- Homeopathy Central Council Act, 1973, 2002
- Homeopathy Education Courses, Standards, 1983
- Homeopathy Practitioners (Professional Conduct, Etiquettes and Code of Ethics) Regulations, 1982

Dentistry

- Dentist Act, 1948, 1993

- Dental Council of India Regulations, 1955, 1956, 1984, 2006
- Dental Council (Election) Regulations, 1952
- BDS, MDS Course Regulations, 1983
- Establishment of Dental Colleges, 1993

Pharmacy

- Pharmacy Act, 1948
- Pharmacy Council of India - Regulations

Nursing

- Indian Nursing Council Act, 1947
- Indian Nursing Council Regulations

Rehabilitation

- Rehabilitation Council of India Act and Regulations, 1992, 1997, 1998

Laws in relation to Ethics and Patients Rights

- Consumer Protection Act and Rules, 1986, 1987, 2002
- Ethical Guidelines for Biomedical Research on Human Subjects, 2000
- Right to Information Act and Rules, 2005
- Central Information Commission (Appeal Procedure) Rules, 2005

Laws in relation to Pharmaceutical and Medical Devices

- Drugs and Cosmetics Act, 1940, 2005, 2006
- Drugs Control Act, 1950
- Drug and Magic Remedies (Objectionable Advertisement) Act, 1954
- Department of Ayurveda, Yoga and Naturopathy, Unani, Siddha and Homeopathy (Ayush) Orders, 2005

Laws in relation to Radiation Protection

- Atomic Energy Act and Rules, 1962, 1984
- Radiation Protection Rules, 1971
- Radiation Surveillance Procedures for Medical Application of Radiation, 1980, 1989
- Atomic Energy (Working of the Mines, Minerals and Handling of Prescribed Substance) Rules, 1984, 1987
- Safety Code for Medical Diagnostic X-Ray Equipment and Installations

Laws in relation to Hazardous Substances

- Narcotic Drugs and Psychotropic Substances Act and Rules, 1985
- Prevention of Illicit Traffic in Narcotic Drugs and Psychotropic Substances Act, 1988
- Hazardous Wastes (Management and Handling) Rules, 1989, 2002

Laws in relation to Occupational Health and Accident Prevention

India is signatory to many International treatise and ILOs convention on occupational health. To bridge the large gap in health status of workers and provide a safe and secure work place certain legislations are required to be enacted to ensure health and safety of the workers, these legislations are as under:

- Workmen's Compensation Act, 1923
- Factories Act 1948, 1987
- Mines Act, 1952, 1957

- Motor Transport Workers Act, 1961
- Personal Injuries (Emergency Provisions) Act, 1962, 1963
- Beedi and Cigar Workers Act, 1966
- Child Labour (Prohibition and Regulation) Act, 1986
- Dock Workers (Safety, Health and Welfare) Rules, 1990
- Public Liability Insurance Act and Rules, 1991
- Building and Other Construction Workers Act, 1996
- Fatal Accidents Act, 1855
- Contract Labour (Regulation and Abolition) Central Rules, 1971

Laws in relation to Elderly, Disabled, Rehabilitation and Mental Health

- Mental Health Act, 1987
- Central and State Mental Health Rules, 1990
- Persons with Disabilities (Equal Opportunities, Protection of Rights and Full Participation) Act, 1995, 1996
- National Trust for Welfare of Persons with Autism, Cerebral Palsy, Mental Retardation and Multiple Disabilities Act, 1999, 2000

Laws in relation to Family, Women and Children

- Special Marriage Act, 1954
- Hindu Marriage Act, 1955
- Children Act, 1960
- Dowry Prohibition Act, 1961
- Suppression of Traffic in Women and Girls Act, 1956
- National Commission for Women Act, 1990
- Juvenile Justice (Care and Protection of Children) Act, 2000

Laws in relation to Smoking, Alcoholism and Drug Abuse

- Cigarettes (Regulation of Production, Supply and Distribution) Act, 1975
- Cigarettes and Other Tobacco Products (Prohibition of Advertisement and Regulation of Trade and Commerce, Production, Supply and Distribution) Act and Rules, 2003, 2004
- Cigarettes and Other Tobacco Products (Prohibition of Sale on Cigarettes and Other Tobacco Products around Educational Institutions) Rules, 2004

Laws in relation to Social Security and Health Insurance

- Minimum Wages Act, 1948
- Employees State Insurance Act and Rules, 1948, 1950
- Life Insurance Corporation Act, 1956
- Maternity Benefit Act, 1961, 1963
- Insurance Regulatory and Development Authority Act, 1999, 2000, 2001, 2002

Laws in relation to Environmental Protection

Environmental protection is one of the most important global requirements of today. There are many provisions in the constitution of India to safeguard the environment and state is made responsible for this. There are many Acts in the country to protect the environment and mankind. These are as under:

- Insecticides Act and Rules, 1968, 1971, 1993, 2000
- Water (Prevention and Control of Pollution) Act and Rules, 1974, 1975, 1977, 1978, 2003

- Air (Prevention and Control of Pollution) Act and Rules, 1981, 1982, 1983
- Environment (Protection) Act, 1986, 2002
- Bhopal Gas Leak Disaster Act, 1985, 1992
- Central Board for the Prevention and Control of Water Pollution (Procedure for Transaction of Business) Rules, 1975

Laws in relation to Nutrition and Food Safety

- Prevention of Food Adulteration Act and Rules, 1954, 1955, 2001, 2002
- Infant Milk Substitutes, Feeding Bottles and Infant Foods Act and Rules, 1992, 1993, 2003
- Atomic Energy (Control of Irradiation of Food) Rules, 1996
- Food Safety and Standards Act, 2006

Laws in relation to Health Information and Statistics

- Births, Deaths and Marriages Registration Act, 1886
- Registration of Births and Deaths Act, 1969
- Collection of Statistics Act and Rules, 1953, 1959
- Census Act, 1948, 1993

Laws in relation to Intellectual Property Rights

- Patents Act and Rules, 1970, 1972, 2005
- Arbitration and Conciliation Act, 1996
- Trade Marks Act, 1999
- Laws in relation to Custody, Civil and Human Rights
- Indian Penal Code, 1860
- Unlawful Activities (Prevention) Act, 1967
- Protection of Human Rights Act, 1993

Laws in relation to Other (Miscellaneous) Issues

- Essential Commodities Act, 1955
- Standards and Weights Measures Act, 1976

The Consumer Protection Act (CPA), 1986

The CPA is a comprehensive legislation in which consumers can approach with complaints to Commissions at the District, state and central level without any lawyers and there is no court fee.

The CPA protects following consumer rights

1. Right to safety
2. Right to be informed
3. Right to choose
4. Right to be heard
5. Right to seek redressal
6. Right to consumer education

Under this Act a complainant can file any allegation in writing about:

- a) A loss or damage suffered as a result of any unfair trade practice adopted by the trader
- b) The goods / service suffers from one or more defects
- c) An excess price is charged than the one displayed for the goods or service

The Supreme Court declared that like other service providers under contract, doctors who offer services for the price offered are also under the same obligation to compensate the purchaser (patient) for any deficiency in the quality of their services. Doctors in government service, charitable clinics providing free service are exempted from CPA. If the cost of the

services or goods and compensation is less than 5 lakhs then the complaint can be filed in the district forum. If the cost is up to 10 lakhs then the complaint is filed with State Commission and for higher amounts the case is registered with National Commission at New Delhi.

The punishment for the guilty under the Act is imprisonment for minimum one month extendable up to three years or fine not less than Rs 2000/- extendable up to Rs 10,000/- or both.

Negligence means that, 'a person who holds himself ready to give medical advice and treatment implied undertakes that he possesses the skills and knowledge for that purpose. Such person when consulted by a patient owes him certain duties namely a duty of care in deciding what treatment to give or a duty of care in the administration of that treatment. A breach of any of those duties gives a right of action for negligence to the patient'.

Registration of Births and Deaths Act, 1969

In India, vital statistics are generated through Civil Registration System (Registration of births and deaths), sample registration system, decennial population census, rural survey of cause of death, medical certification of causes of death from hospitals and health centres and adhoc surveys conducted by national and international research organizations.

The Registration of Births and Deaths Act was implemented in 1969 with the aim to collect and compile vital statistics which is necessary for planning and administration. The Act has given statutory authority to the Registrar General, India to coordinate the work of civil registration throughout the country. In rural areas, the local registrars are mainly drawn from panchayat, police, health or revenue departments. In urban areas, health officers of the municipalities or corporations or the executive officers are the Registrars.

Every registrar has to register births and deaths, occurring within his/her administrative areas. The information regarding occurrence is to be given within 21 days in both the events of births and deaths. Delayed registration requires late fee and affidavit from notary public. Every registering authority sends periodical returns to the Chief Registrar who in turn sends it to Registrar General of India. Registrar General brings out every year annual report called 'Vital Statistics of India'.

The Act also provides for medical certification of cause of death. A medical officer has to certify free of cost in the prescribed format, the cause of death if he/she is attending the deceased during his last breath or illness.

Epidemic Diseases Act, 1897

The Act provides power to exercise for the control and to prevent any epidemic or spread of epidemic in the States or Country. The states may authorise any of its officers or agency to take such measures if the state feels that the public at large is threatened with an outbreak of any dangerous epidemic (Sec. 2). Person who is inspecting, is empowered to determine about the process and authority to take responsibility of all expenses incurred in compensation, travelling, temporary accommodation, segregation of infected person, etc. The State Government can authorise the Dist. Magistrate or other officials to utilise any resources in terms of man, money and material

to mobilise infected persons or community to prevent spread of epidemic. State or Central Government can inspect any ship or vessel leaving or arriving at any port in the territories and take appropriate action as prescribed. Violation of this Act is punishable under sec 188 of the IPC.

The Drugs and Cosmetics Act, 1940 (Amended in 1964, 1983, 1995)

The Drugs and Cosmetics Act is mainly aimed to regulate the import, manufacture, distribution and sale of Drugs and Cosmetics, presumably for maintaining high standards of medical treatment. Substandard medicines / drugs may cause severe damage to lives of people.

The Act extends to the whole of India. In this Act the drug is defined as, 'All Medicines (Ayurveda, Siddha, and Unani) for internal or external use of human being or animals and all substances (other than food) intended to be used for or in the diagnosis, treatment, mitigation or prevention of any disease or disorder in human beings or animals including preparation applied on human body or to destroy insects'.

The Central or State government have power to make rules and appoint inspector to control or inspect any drug or cosmetic for its standardization and safety which can be tested in the Central or State Drug laboratory. The Government can prohibit manufacturing, importing or selling of any drug or cosmetic. Violation of law by any person or corporate manager or owner is liable for punishment for a term which may extend to 3-10 years and shall also be liable to fine which could be five hundred or ten thousand rupees or with both.

Drugs and Cosmetic Rules 1995 contains the list of drugs for which license is required by manufacturer, importers, and exporters. Recently 'in vitro' blood groups, sera and in vitro diagnostic devices for HIV, HBsAg, and HCV are also included in schedule CI. All imported drugs in indigenous manufacturers have to register to control over the quality of imported as well as locally manufacturing kits.

The Medical Termination of Pregnancy Act, 1971

(It extends to the whole of India except the State of Jammu and Kashmir.)

Registered Medical Practitioners who may terminate Pregnancies : A pregnancy may be terminated by a Registered Medical Practitioner (RMP) registered under the MCI Act, and those who have undergone 6 months housemanship or 3 years post graduate training in obstetrics and gynaecology or any registered medical practitioner who have conducted 25 cases of MTP in approved institution. Where the length of the pregnancy does not exceed twelve weeks, then one RMP can conduct MTP and if the length of the pregnancy exceeds twelve weeks but does not exceed twenty weeks, opinion of not less than two registered medical practitioners are required to certify the valid reasons as per the law for discontinuation of pregnancy.

Conditions under which MTP can be carried out :

(i) Therapeutic : The continuance of the pregnancy would involve a risk to the life of the pregnant woman or of grave injury to physical or mental health.

(ii) **Eugenic** : There is a substantial risk that if the child were born, it would suffer from such physical or mental abnormalities as to be seriously handicapped.

(iii) **Social** : When economic and social environment is not suitable for continuation of pregnancy or due to failure of any method used by couple for the purpose of limitation of children.

(iv) **Humanitarian** : It involves pregnancy due to rape.

(v) **Lunatic** : When pregnant woman is mentally not sound or lunatic.

Note : No pregnancy shall be terminated except with the consent of the pregnant woman.

Place where pregnancy may be terminated : No termination of pregnancy shall be made in accordance with this Act at any place other than :

- (a) a hospital established or maintained by Government, or
- (b) a place for the time being approved for the purpose of this Act by Government.

Punishment : Termination of pregnancy not falling under the purview of MTP Act is an offence punishable with rigorous imprisonment for a term which shall not be less than 2 years up to maximum 7 years.

The Workmen's Compensation Act, 1923, 1984, 2000

As per the Workmen's Compensation Act, any worker employed in wide varieties of hazardous occupations by an employer, if suffers an injury, he/she is eligible for compensation. If he dies then legal dependents can claim the benefits provided by the Act. The 'employer' includes any body of persons whether incorporated or not and any managing agent of an employer and the legal representative of a deceased employer and when the services of a workman are temporarily lent or let on hire to another person by the person with whom the workman has entered into a contract of service or apprenticeship means such other person while the workman is working for him;

The disablement means the loss in the earning capacity of a workman in every employment which he was capable of doing at the time of accident. Its effect may be temporary or permanent. To enter into contract of Workmen's Compensation Act, and claim for an occupational disease, he or she should have been employed in the specified occupation for at least 6 months.

The compensation is paid to the workers according to the damage:

1. In case of death, compensation is paid to the dependents; 40 percent of the monthly wage, multiplied by factor or Rs 20,000/- whichever is more.
2. In case of permanent disablement; 50 percent of the monthly wage, multiplied by factor, or Rs.24,000/- whichever is more.
3. In case of partial permanent disablement; the compensation is percentage of that payable in case of total permanent disability as given in schedule I.
4. In case of total or partial temporary disablement; a sum equal to 25 percent of the monthly wages of the workman shall be paid half yearly.

Further details of Workmen Compensation Act and other laws in relation to industrial health are discussed in detail in the section on Occupational health in this book.

The Water (Prevention and Control of Pollution) Act 1974

This Act was passed by the Parliament in 1974 to counter and contain ever growing pollution of natural water resources. This Act is comprehensive in providing the legal basis for prevention and control of water pollution, maintenance and restoration of wholesomeness of water sources in the country.

Definitions

Under the Act important definitions are:

a) Pollution : Pollution means contamination of water or such alteration of the physical, chemical or biological properties of water or such discharge of any sewage or trade effluent or of any other liquid, gaseous or solid substance into water as may, or is likely to create a nuisance or render such water harmful or injurious to public health or safety, or to domestic, commercial, industrial, agricultural or other legitimate uses, or to the life and health of animals or plants or of aquatic organisms.

b) Sewage Effluent : Sewage Effluent means effluent from any sewerage system or sewage disposal works and includes sullage from open drains.

c) Trade Effluent : Trade Effluent includes any liquid, gaseous or solid substance which is discharged from any premises used for carrying on any industry, operation or process, or treatment and disposal system, other than domestic sewage.

To execute the aforesaid purposes, the Act provides for the constitution of Central, State and Joint Boards having prescribed powers and functions. These boards are to be called Pollution Control Boards. The main function of the Central Board shall be to promote cleanliness of watercourses in different areas of the States. The Board has been conferred the power to perform several functions i. e., advisory to the Central Govt; co-ordinating the activities of the State Boards; provide technical assistance and guidance to the state board, carry out and sponsor investigations and research relating to problems of water pollution and their abatement; plan and organize training of persons engaged or to be engaged in programmes for prevention and control; collect, compile and publish technical and statistical data related to the subject; to lay down, modify or annul the standards for a water course; plan and cause to be executed, nationwide programmes and so on.

The Board may establish or recognize laboratories to enable it to perform its functions including the analysis of samples of water, sewage or trade effluents. The State Boards, under the guidance of Central Board, are similarly responsible to plan and execute comprehensive programmes in their respective territories. They have also been conferred the powers of entry into any premises after giving due notice to the owner and collect samples of water, sewage and trade effluents for analysis and recommend necessary legal steps. The State Governments, under advice from the Board, are also authorised to take emergency measures when pollutants have entered or threatened to enter the watercourse due to accidental or unforeseen event or act of omission or commission. A joint Board is set up on subjects of

common interest by mutual agreement either between adjacent states or between the states(s) and the Central Govt. when the latter has been appointed as the executing agency for the Union Territories.

Punishments : Any person or organisations which fail to comply with regulations of this Act can be convicted and punished with imprisonment of 3 months or fine up to Rs 10,000/ or with both. If offender repeats the offence then additional fine up to Rs 5,000/ for everyday, during which such failure continues after the conviction for the first such failure.

If the failure continues beyond a period of 1 year after the date of conviction, the offender shall, on conviction, is punishable with imprisonment for a term which shall not be less than 2 years but which may extend to 7 years and with fine.

Air (Prevention and Control of Pollution) Act, 1981

The Air (Prevention and Control of Pollution) Act, 1981 is an Act to provide for prevention, control and abatement of air pollution. The Act is an outcome of the United Nations Conference on the Human Environment held in Stockholm in June, 1972. The Act extends to whole of India.

Definitions

In this Act, important definitions are -

(a) Air Pollution : Air Pollution means any solid, liquid or gaseous substance (including noise) present in the atmosphere in such concentration as may be or tend to be injurious to human beings or other living creatures or plants or property or environment.

(b) Automobile : Automobile means any vehicle powered either by internal combustion engine or by any method of generating power to drive such vehicle by burning fuel.

(c) Control Equipment : Control Equipment means any apparatus, device, equipment or system to control the quality and manner of emission of any air pollutant and includes any device used for securing the efficient operation of any industrial plant.

(d) Emission : Emission means any solid or liquid or gaseous substance coming out of any chimney, duct or fuel or any other outlet.

(e) Industrial Plant : Industrial Plant means any plant used for any industrial or trade purposes and emitting any air pollutant into the atmosphere.

(f) Occupier : Occupier, in relation to any factory or premises, means the person who has control over the affairs of the factory or the premises, and includes, in relation to any substance, the person in possession of the substance.

Central Pollution Control Board (CPCB)

The Central Pollution Control Board constituted under Section 3 of the Water (Prevention and Control of Pollution) Act, 1974 (6 of 1974), shall, without prejudice to the exercise and performance of its powers and functions under that Act, exercise the powers and perform the functions of the Central Pollution Control Board for the prevention and control of air pollution under this Act.

Functions of Central Board

- (1) To improve the quality of air and to prevent, control or abate air pollution in the country.
- (2) To advise the Central Government on any matter concerning the improvement of the quality of air and the prevention, control or abatement of air pollution.
- (3) Plan and cause to be executed a nationwide programme for the prevention, control or abatement of air pollution.
- (4) Co-ordinate the activities of the State Boards and resolve disputes among them.
- (5) Provide technical assistance and guidance to the State Boards, carry out and sponsor investigations and research relating to problems of air-pollution and prevention, control or abatement of air pollution.
- (6) Plan and organise the training of persons engaged or to be engaged in programmes for the prevention, control or abatement of air pollution on such terms and conditions as the Central Board may specify.
- (7) Organise through mass media a comprehensive programme regarding the prevention, control or abatement of air pollution.
- (8) Collect, compile and publish technical and statistical data relating to air pollution and the measures devised for its effective prevention, control or abatement and prepare manuals, codes or guides relating to prevention, control or abatement of air pollution.
- (9) Lay down standards for the quality of air.
- (10) The Central Board may establish or recognise a laboratory or laboratories to enable the Central Board to perform its functions under this section efficiently.
- (11) The Central Board may delegate any of its functions under this Act generally or specially to any of the committees appointed by it.

CPCB has power to restrict use of any area, automobile, or industry having or causing air pollution. Any person empowered by pollution control boards shall have right to enter, at all reasonable times as he considers necessary, any place for seizing or examining and testing any control equipment, air sampling, industrial plant, record, register, document or any other material object or for conducting a search of any place in which he has reason to believe that an offence under this Act or the rules has been made.

Punishment

Whoever fails to comply with the provisions shall be punished with imprisonment for a term which shall not be less than one year and six months but which may extend to six years and with fine, and in case failure to comply continues, an additional fine may be imposed which may extend to Rs 5,000/- for every day during which such failure continues after the conviction for the first such failure.

If the failure continues beyond a period of 1 year after the date of conviction, the offender shall, on conviction, is punishable with imprisonment for a term which shall not be less than 2 years but which may extend to 7 years and with fine.

The Transplantation of Human Organs Act, 1994

An Act to provide for the regulation of removal, storage and transplantation of human organs for therapeutic purposes and for the prevention of commercial dealings in human organs.

Definitions

In this Act, some important definitions are :

(a) Brain-stem death : Brain-stem death means the stage at which all functions of the brain-stem have permanently and irreversibly ceased.

(b) Deceased Person : Deceased Person means a person in whom permanent disappearance of all evidence of life occurs, by reason of brain-stem death or in a cardio-pulmonary sense, at any time after live birth has taken place.

(c) Donor : Donor means any person, not less than eighteen years of age, who voluntarily authorises the removal of any of his human organs for therapeutic purposes.

(d) Human Organ : Human Organ means any part of a human body consisting of a structured arrangement of tissues which, if wholly removed, cannot be replicated by the body.

(e) Near Relative : Near Relative means spouse, son, daughter, father, mother, brother or sister.

(f) Transplantation : Transplantation means the grafting of any human organ from any living person or deceased person to some other living person for therapeutic purposes.

Authority for Removal of Human Organs

Any donor may, in such manner and subject to such conditions as may be prescribed, authorise the removal, before his death, of any human organ of his body for therapeutic purposes in writing and in the presence of two or more witnesses use for therapeutic purposes. And no such removal shall be made by any person other than the registered medical practitioner.

Authority for Removal of Human Organs in Case of Unclaimed Bodies in Hospital or Prison

In the case of a dead body lying in a hospital or prison and not claimed by any of the near relatives of the deceased person within forty-eight hours from the time of the death of the concerned person, the authority for the removal of any human organ from the dead body which so remains unclaimed may be given, in the prescribed form, by the person in-charge, for the time being, of the management or control of the hospital or prison, or by an employee of such hospital or prison authorised in this behalf by the person in charge of the management or control thereof.

Restrictions on Removal and Transplantation of Human Organs

No human organ removed from the body of a donor before his death shall be transplanted into a recipient unless the donor is a near relative of the recipient.

Registration of Hospitals Engaged in Removal, Storage or Transportation of Human Organs.

No hospital shall commence any activity relating to the removal, storage or transplantation of any human organs for

therapeutic after the commencement of this Act unless such hospital is duly registered under this Act.

Punishment for Removal of Human Organ without Authority

- (1) Any person who renders his services to or any hospital and who, for purposes of transplantation, conducts, associates with, or help in any manner in, the removal of any human organ without authority, shall be punishable with imprisonment for a term which may extend to five years and with fine which may extend to ten thousand rupees.
- (2) Where any person convicted under *sub-section (1)* is a registered medical practitioner, his name shall be reported by the Appropriate Authority to the respective State Medical Council for taking necessary action including the removal of his name from the register of the Council for a period of two years for the first offence and permanently for the subsequent offence.

Punishment for Commercial Dealings in Human Organs

Whoever

(a) makes or receives any payment for the supply of, or for an offer to supply, any human organ; (b) seeks to find a person willing to supply for payment any human organ; (c) offers to supply any human organ for payment; (d) initiates or negotiates any arrangement involving the making of any payment for the supply of, or for an offer to supply, any human organ; (e) takes part in the management or control of a body of persons, whether a society, firm or company, whose activities consist of or include the initiation or negotiation of any arrangement referred to in clause (d); or (f) publishes or distributes or causes to be published or distributed any advertisement.

Shall be

Punishable with imprisonment for a term which shall not be less than two years but which may extend to seven years and shall be liable to fine which shall not be less than ten thousand rupees but may extend to twenty thousand rupees.

Punishment for Contravention of any other Provision of this Act.

Whoever contravenes any provision of this Act or any rule made, or any condition of the registration granted, thereunder for which no punishment is separately provided in this Act, *shall be* punishable with imprisonment for a term which may extend to three years or with fine which may extend to five thousand rupees.

The Immoral Traffic (Prevention) Act, 1956

An Act to provide in pursuance of the International Convention signed at New York on the 9th day of May, 1950, for the prevention of immoral traffic. Any person who keeps or maintains or acts or assists in the keeping and management or a brothel, is liable to be punished under this section.

Definitions

Some of the definitions in this Act are :

(a) Brothel : Brothel includes any house, room, conveyance or place, or any portion of any house, room, conveyance or place,

which is used for purposes of sexual exploitation or abuse for the gain of another person or for the mutual gain of two or more prostitutes.

(b) Prostitution : Prostitution means the sexual exploitation or abuse of persons for commercial purposes or for consideration in money or in any other kind, and the expression “prostitute” shall be construed accordingly.

(c) Child : Child means a person who has not completed the age of 16 years.

(d) Major : Major means a person who has completed the age of 18 years.

(e) Minor : Minor means a person who has completed the age of 16 years but has not completed the age of 18 years.

Offences and Punishments in this Act are:

1. Any person who keeps, or manages, or acts or assists in the keeping or management of, a brothel, shall be liable to be punished with -
 - (a) rigorous imprisonment for not less than 1 year but upto 3 years and also fine upto Rs.2,000/-, on first conviction; and
 - (b) rigorous imprisonment for not less than 2 years but upto 5 years and also fine upto Rs. 2000/-
2. Any person who procures or induces any person for the purpose of prostitution; or takes, causes or induces any person to carry on prostitution, shall be punishable with -
 - (a) rigorous imprisonment for not less than 3 years but upto 7 years; and
 - (b) fine upto Rs. 2,000/-
3. Any person over the age of 18 years who knowingly lives on the earnings of the prostitution of any other person, shall be liable to be punished with imprisonment upto 2 years, or fine upto Rs. 1,000/-, or both.
But, where such earnings relate to the prostitution of a child or a minor, the offender shall be liable to be punished with imprisonment for a term of not less than 7 years and not more than 14 years.
4. Any person who detains any other person in any brothel, or in or upon any premises, for the purpose of prostitution, shall be liable to be punished with imprisonment for not less than 7 years but upto for life; or imprisonment upto 10 years and also fine.
5. Any person who carries on prostitution in or in the vicinity of public places which are within a distance of two hundred metres of any place of public religious worship, educational institution, hostel, hospital, nursing home or such other public place of any kind as may be notified in this behalf by the Commissioner of Police or Magistrate in the manner prescribed. Any person who commits an offence shall be punishable with -
 - (a) imprisonment for not less than 7 years but for life; or
 - (b) imprisonment upto 10 years and also fine.
6. Any woman who tempts, or attracts, or endeavours to tempt or attract the attention of, any person for the purpose of prostitution; or solicits or molests any person, or loiters or acts to cause obstruction or annoyance to persons or to offend against public decency, for the purpose of prostitution, shall be punishable with -

(a) imprisonment upto 6 months or fine upto Rs. 500/- or both, on first conviction; and (b) imprisonment upto 1 year and fine upto Rs. 500/-, in the event of a second or subsequent conviction.

But, a man who commits any of offences under this section, shall be punishable with imprisonment for not less than 7 days but upto 3 months.

Prostitution is a social evil and indicates poverty, weak social fabric, alcoholism and lower status of women. Immoral traffic will not only lead to lower social morals but also spread of certain killer diseases like STIs, HIV/AIDS etc. There is an increasing prevalence of HIV/AIDS noticed in commercial sex workers.

The Child Marriage Restraint Act, 1929

The Act extends to whole of India except state of J & K. the Act is expedient to restrain the solemnisation of child marriages.

Definitions

Under this Act some definitions are :

(a) Child : Child means a person who, if a male, has not completed twenty one years of age, and if a female, has not completed eighteen years of age.

(b) Child Marriage : Child Marriage means a marriage to which either of the contracting parties is a child.

(c) Minor : Minor means a person of either sex who is under eighteen years of age.

Punishments

- a) Any male above eighteen years of age and below 21 years, contracts a child marriage shall be punishable with simple imprisonment which may extend to 15 days, or with fine which may extend to Rs 1,000/- or with both.
- b) Any male above 21 years of age contracts a child marriage shall be punishable with simple imprisonment, which may extend to 3 months and shall also be liable to fine.
- c) Where a minor contracts a child marriage, any person having charge of the minor, whether as parent or guardian or in any other capacity, lawful or unlawful, who does not act to promote the marriage or permits it to be solemnised shall be punishable with simple imprisonment up to 3 months and shall also be liable to fine. It is a cognisable offence and person can be arrested without the warrant or without the orders of a Magistrate.

Bio Medical Waste (Management and Handling) Rules 1998

This is dealt in detail in an exclusive chapter in this book.

Municipal Solid Waste (Management and Handling) Rules, 2000

The solid waste generated in urban areas is increasing everyday. The characteristics of the waste generation are changing with more disposable plastic items being wasted along with other non decomposable low combustible items. On an average 0.2-0.5 kg of solid waste per capita per day is generated in the Indian cities and the civic authorities collect about 35 million tons of municipal solid waste every year. There are various reasons for poor management of solid waste in urban areas

such as lack of fund, lack of technology, lack of awareness and people's participation, inadequate staff etc. Under the EPA 1986 to safeguard the environment and human health government of India has laid down Municipal solid waste management rules.

These rules lay down the responsibility of management of solid waste disposal and various standards for disposal of treated leachate. The management of solid waste has been made the responsibility of municipal authority. The district magistrate / deputy commissioner shall have the over all responsibility for the enforcement of the provisions under these rules. Refuse based fuel technology has been advocated by the government and wastes like plastic generate energy but also emits carcinogens such as dioxins into air. By 2020, it is decided that 50 percent of municipal solid waste and 70 percent of the other waste must be recycled.

Cantonments Act 1924

An Act to consolidate and amend the law relating to the administration of cantonments.

It extends to the whole of India. The important definitions in this Act are:-

Definitions

(a) Assistant Health Officer : Assistant Health Officer means the medical officer appointed by the officer Commanding-in-Chief to be the Assistant Health Officer for a cantonment.

(b) Board : Board means a Cantonment Board constituted under this Act.

(c) Civil Area : Civil Area means an area declared to be a civil area by the Central Government.

(d) Executive Officer : Executive Officer means the person appointed under this Act to be the Executive Officer of a cantonment.

(e) Health Officer : Health Officer means the senior executive medical officer in military employed on duty in a cantonment.

Constitution of Cantonment Boards

In Class I cantonments (population exceeding 10,000) & class II Cantonments (population > 2500 but not exceeding 10,000), the Board shall consist of (a) The Officer Commanding the station or such other military officer as may be nominated in his place by the Officer Commanding-in-Chief, the Command; (b) an executive Magistrate nominated by the District Magistrate; (c) the Health Officer; (d) the Executive Engineer; (e) 1, 2 or 3 military officers (depending on the population), nominated by name by the Officer Commanding the station by order in writing.

In Class III Cantonments (population upto 2,500), the Board shall consist of (a) The Officer Commanding the station, or such other military officer as may be nominated in his place by the Officer Commanding-in-Chief, the Command; (b) one military officer nominated by name by the Officer Commanding the station in writing; (c) one member elected under this Act. The Officer Commanding the station, if a member of the Board shall be the President of the Board; moreover, in every Board in which there is more than one elected member, there shall be a Vice-President elected by the elected members only.

Executive Officer : For every cantonment there shall be an Executive Officer appointed by the Central Government or by such person as the Central Government may authorise in this behalf. The Executive Officer shall have the following duties :- (a) exercise all the powers and perform all the duties conferred or imposed upon him by or under this Act or any other law for the time being in force; (b) prescribe the duties of, and exercise supervision and control over the acts and proceedings of, officers and other employees of the Board, other than medical officer in charge of the cantonment general hospital or dispensary; (c) be responsible for the custody of all records of the Board; (d) arrange for the performance of such duties relative to the proceedings of the Board or of any Committee of the Board or of any Committee of Arbitration constituted under this Act, as those bodies may respectively impose on him; (e) comply with every requisition of the Board on any matter pertaining to the administration of the cantonment.

Summary

The Public Health Legislations aims to improve the health status of the community by maintaining the balance between individual autonomy and community protection. Government of India has initiated, National Legal Literacy Mission in 2005 to impart knowledge and education on various legal aspects.

The CPA is a comprehensive legislation in which consumers can approach with complaints to Commissions at the District, state and central level without any lawyers and court fee. Doctors in government service, charitable clinics providing free service are exempted from CPA.

The Registration of Births and Deaths Act was implemented in 1969 with the aim to collect and compile vital statistics which is necessary for planning and administration. The Act has given statutory authority to the Registrar General, India to coordinate the work of civil registration throughout the country. Every registrar has to register births and deaths, occurring within his/her administrative areas. The information regarding occurrence is to be given within 21 days in both the events of births and deaths. The Act also provides for medical certification of cause of death.

The Epidemic Diseases Act, 1897 provides power to exercise for the control and to prevent any epidemic or spread of epidemic in the States or Country.

The Drugs and Cosmetics Act aims to regulate the import, manufacture, distribution and sale of Drugs and Cosmetics for maintaining high standards of medical treatment.

As per the Workmen's Compensation Act, any worker employed in wide varieties of hazardous occupations by an employer, if suffers an injury, he/she is eligible for compensation, provided he is employed for at least 6 months. If he dies then legal dependents can claim the benefits provided by the Act.

The Water (Prevention and Control of Pollution) Act 1974 was passed by the Parliament in 1974 to provide legal basis for prevention and control of water pollution, maintenance and restoration of wholesomeness of water sources in the country. The State Boards, under the guidance of Central Board, are responsible to plan and execute comprehensive programmes in their respective territories.

The Air (Prevention and Control of Pollution) Act, 1981 is to provide for prevention, control and abatement of air pollution. The Central Pollution Control Board constituted under Section 3 of the Water (Prevention and Control of Pollution) Act, 1974 (6 of 1974), exercise the powers and perform for the prevention and control of air pollution.

The Immoral Traffic (Prevention) Act, 1956 provides for the prevention of immoral traffic. Any person who keeps or maintains or acts or assists in the keeping and management or a brothel, is liable to be punished under this section. Immoral traffic not only leads to lower social morals but also spread of certain killer diseases like STIs, HIV/AIDS etc.

The Child Marriage Restraint Act, 1929 extends to whole of India except state of J & K. The Act is expedient to restrain the solemnisation of child marriages.

Municipal Solid Waste (Management & Handling) Rules, 2000 was laid down under the EPA 1986 to safeguard the environment and human health. The district magistrate / deputy commissioner shall have the over all responsibility for the enforcement of the provisions under these rules

The Cantonments Act 1924 consolidates and amends the law relating to the administration of cantonments.

Study Exercises

MCQs & Exercises

- Following are the ways & means in which public health officials enforce rules: (a) Permits, licenses and registrations (b) Administrative orders (c) Civil penalties Injunctions (d) All of the above
- The factors responsible for lack of effectiveness of public health legislations are (a) Lack of awareness (b) Lack of implementation (c) Corruption (d) all
- CPA protects all of the following consumer rights except: (a) Right to safety (b) Right to be informed (c) Right to seek redressal (d) Right to consumer education (e) Right to follow religion
- Who all are covered under CPA?
- Define 'Drug' as in Drugs and Cosmetics Act, 1940?

Fill in the blanks

- Public Health laws protect _____ rather than individual's health.
- Govt of India initiated National Legal Literacy Mission in 2005 to _____.
- The Registration of Births and Deaths Act was implemented in _____.
- The information regarding occurrence of birth and death event is to be given within _____ in _____ the events. Delayed registration requires _____.
- Violation of Epidemic Diseases Act, 1897 is punishable under sec _____ of the IPC.
- Recently under the Drugs and Cosmetics Act _____ and _____ are also included in schedule CI.
- As per the Workmen's Compensation Act, disablement means _____ and employer' includes _____.

- The Water (Prevention and Control of Pollution) Act 1974 states that term 'Pollution' means _____ and term 'Trade effluent' includes _____.
- Name the Act which is an outcome of the United Nations Conference on the Human Environment held in Stockholm in June, 1972 _____.
- "Brain-stem death" under the Transplantation of Human Organs Act, means _____.
- Under the Immoral Traffic (Prevention) Act, 1956 "Minor" means a person who has completed the age of _____ but has not completed the age of _____.
- The Immoral Traffic (Prevention) Act, 1956 defines 'Child' as a person who has not completed the age of _____ while under the Child Marriage Restraint Act, 1929 'Child' means a person who, if a male, has not completed _____ years of age, and if a female, has not completed _____ years of age.
- On an average _____ kg of solid waste per capita per day is generated in the Indian cities
- As per the Cantonments Act 1924 in Class I cantonments are with population exceeding _____ & class II Cantonments has population _____ but not exceeding _____. The Class III Cantonments has only population up to _____.

Answers : MCQs : (1) d; (2) d; (3) e; (4) The Supreme Court declared that like other service providers under contract, doctors who offer services for the price offered are also under the same obligation to compensate the purchaser (patient) for any deficiency in the quality of their services. (5) Under the Drugs and Cosmetics Act, 1940 defines drug as, 'all Medicines (Ayurvedic, Siddha, and Unani) for internal or external use of human being or animals and all substances (other than food) intended to be used for or in the diagnosis, treatment, mitigation or prevention of any disease or disorder in human beings or animals including preparation applied on human body or to destroy insects'.

Fill in the blanks : (1) community health; (2) to impart knowledge and education on various legal aspects including those related to Public Health; (3) 1969; (4) 21 days, both; (5) 188; (6) 'in vitro' blood groups, sera and in vitro diagnostic devices for HIV, HBsAg, and HCV; (7) disablement means the loss in the earning capacity of a workman in every employment which he was capable of doing at the time of accident, includes any body of persons whether incorporated or not and any managing agent of an employer; (8) 'Pollution' means contamination of water or such alteration of the physical, chemical or biological properties of water or such discharge of any sewage or trade effluent or of any other liquid, gaseous or solid substance into water, any liquid, gaseous or solid substance which is discharged from any premises used for carrying on any industry, operation or process, or treatment and disposal system, other than domestic sewage; (9) Air (Prevention and Control of Pollution) Act, 1981; (10) "brain-stem death" means the stage at which all functions of the brain-stem have permanently and irreversibly ceased; (11) 16yrs, 18yrs; (12) 16yrs, 21yrs, 18yrs; (13) 0.2-0.5kg; (14) 10000, 10000, 2500, 2500.

Sunil Agrawal

A disability can be defined as 'an existing difficulty in performing one or more activities which in accordance with the subject's age, sex and normative social role are generally accepted as essential basic components of daily living'. There seems to be lack of reliable data regarding the incidence and prevalence of various disabilities. National Survey Sample Organisation conducted a sample survey in 1991 which estimated that 1.9% of India's population had disability, and 3% of children had delayed development and likely to be Mentally Retarded. Various studies have shown that 4% of India's population has visual impairment and 6-15% children have learning disability. Overall 10% of our child population has special educational needs.

The highest prevalence of disaster in India is seen in Assam and Arunachal Pradesh states with prevalence more than 20 per 1000 population.

The Government of India has been very concerned regarding the problem and has taken a number of steps in this direction. The Ministry of Social Justice & Empowerment (previously welfare) has been identified as the nodal ministry by the government for the welfare of the disabled. The major legal initiatives towards the field of rehabilitation are described below.

Rehabilitation Council of India Act (RCI Act), 1992

The Government of India set up a Rehabilitation Council, as a registered society under the Societies Registration Act, 1860. Thereafter, this was converted to a statutory body under the Rehabilitation Council of India Act, 1992. It came into force from 31st July, 1993. This is under the administrative control of Ministry of Social Justice and Empowerment. RCI has been established to regulate training programmes in the field of rehabilitation and maintenance of central rehabilitation register, with the following objectives :

- To regulate the training policies and programmes in the field of rehabilitation of people with disabilities.
- To prescribe minimum standards of education and training of various categories of professionals dealing with people with disabilities.
- To regulate these standards in all training institutions uniformly throughout the country.
- To recognise institutions/universities running degree/diploma/certificate courses in the field of rehabilitation of persons with disabilities
- To recognise foreign degree/diploma/certificate awarded by universities/institutions on reciprocal basis;
- To maintain central rehabilitation register of persons possessing the recognised rehabilitation qualification; and
- To encourage continuing rehabilitation education in collaboration with organisations working in the field of disability.

Persons with Disabilities (Equal opportunities, protection of rights and full participation) Act (PWD), 1995

The legislation called Persons with Disabilities Act, was enacted in 1995 to protect the rights of persons with disabilities, to provide educational opportunities and full participation. The Act enshrines a multisectoral response to rehabilitation of persons with disabilities.

Visual Impairment

Blind persons are defined as those who suffer from either of the following conditions :

Total absence of sight; Visual acuity not exceeding 6/ 60 or 20/ 200 (Snellen) in the better eye with correcting lenses; Limitation of the field of vision subtending an angle of 20 degrees or worse.

Different reports and studies, world wide shows that 35-45 million people are blind and an additional 110 - 135 million (Table-1) suffer from low vision conditions. As per the global statistics on Blindness 1998, India has approximately 10 million blind persons requiring services. The estimated incidence of blindness in India is 2.13 million per year (1). The common causes of blindness and visual impairment in India are : Cataract, Glaucoma, Corneal ulcer, Xerophthalmia and other forms of vitamin A deficiency, Conjunctivitis, Retinal detachment, Albinism, Astigmatism, Nystagmus, Optic atrophy, Retinitis pigmentosa and Trachoma. The percentage wise distribution of causes of visual impairment in India is cataract (81%), refractive errors (7%), corneal opacity (3%), glaucoma (2%), trachoma (0.2%), malnutrition related blindness (0.04%) and other causes put together (6.76%). The magnitude of blindness in India has multifarious dimensions with most of them having preventable background.

Category	Prevalence per 1000 popn
Male	10.2
Female	12.2
All ages	11.2

National Efforts

In India, efforts to control blindness were taken by the government during the seventies. The National Programme for Control of Blindness (NPCB) was launched in 1976 with the goal to bring down the prevalence rate of blindness from 1.4% to 0.3% by the end of twentieth century. Since its launch, considerable progress has been made in building up of infrastructure at Primary Health Centres (PHCs), district hospitals, and medical colleges, and in setting up of central and district mobile units for preventive and curative aspects of visual disability. The major work under the programme has been the effective tackling of cataract through large scale involvement of voluntary organizations and the private sector.

Collaborative Efforts

The WHO and a consortium of International Non-Governmental Development Organizations (INGDOs) have launched a massive scheme called Vision 2020 which states that the avoidable blindness in the developing countries must be prevented by the year 2020. The Danish International Development Agency (DANIDA) entered into bilateral agreement with the Government of India in 1987 with the objective of preventing blindness and also in capacity building in executing prevention related services. The Sight First Programme of the Lions Club International is also targeting many regions in India to prevent avoidable blindness. Similarly World Bank is assisting blindness control projects in India since 1994-95.

Vocational Rehabilitation

In the process of rehabilitation, employment should aim at normalization, sensitization and advocacy on the abilities of persons with visual impairment. The Persons with Disabilities Act 1995 states that government shall identify posts which can be reserved for persons with disabilities. The employment of persons with visual impairment in India may be classified into following :

Types of Employment	
•	Employment opportunity in government jobs through open competition
•	Employment in government sector through reservation
•	Employment opportunity through special drive
•	Employment exchange guided employment in private companies
•	Employment through placement services
•	Employment in special industries for the disabled
•	Employment in vocational / production centres for the blind
•	Family supported employment
•	Self employment

Schemes and Concessions for Persons with Visual Impairment

Travel Concession for the Disabled : A blind person traveling alone or with an escort, by rail, on production of a certificate from Government doctor or a registered medical practitioner, is eligible to get the concession as below. The concession certificate may be issued by the Station Master and blind person may not be present at the station for purchase of the ticket.

Class	First Class	Second Class	Sleeper
% of concession	75	75	75

Similarly, The Indian Airlines Corporation allows 50% concessional fare to Blind persons on all domestic flights. To avail this facility (for blind persons) they have to produce a certificate from a medical practitioner. Air Hostess/Steward will look after the Blind Persons not accompanied by escorts in flight. The Public Relation Officer or the Traffic Officer Incharge at the airport will render necessary assistance to such infirm passengers at the airport of the departure and arrival. Escorts are to pay full fare.

Communication : Blind literature packets are exempted from payment of postage. Blind persons are given concessional and on priority telephone connections.

Customs Concession : The central government exempts goods like vocational aids or specific equipments which are essential for management, when imported in India by a handicapped or disabled person for his personal use.

Conveyance Allowance : In terms of GoI order vide OM 19029/1/78-E.IV (B) dated 31.8.78, as amended from time to time, conveyance allowance is admissible to such of the Central Government employees borne or regular establishment (including work-charged staff) as are Blind or are Orthopaedically Handicapped with disability of lower extremities. Consequent upon coming into force of these orders, such conveyance allowance shall be abolished and instead all such employees may now be paid transport allowance at double the normal rates prescribed under these orders. The allowance shall not be admissible in case such employees have been provided with the facility of Government transport.

Scheme for Integrated Education for the Disabled Children: This is a centrally sponsored scheme and was launched in 1974 by the then Department of Social welfare and now with Department of Education since 1982. 100 percent assistance is provided to the states/UTs for education of the child suffering from certain mild handicaps in common schools with the help of necessary aids, incentives and specially trained teachers. The handicapped children are provided with the books and stationary allowance, uniform allowance, transport allowance, reader allowance, escort allowance and subsidized equipments.

Hearing Impairment

The first school for the deaf in India was started in Bombay Presidency in 1884. By the time India became independent in 1947, there were 38 schools for the deaf. In 1964, Kothari commission recommended the establishment of special schools in every district. All India Institute of Speech and Hearing (AIISH) was established in 1965 at Mysore. In 1983, Ali Yavar Jung National Institute for the hearing handicapped was started at Bombay under the Ministry of welfare, GOI as an apex body for the hearing handicapped.

The Deaf are defined as those in whom the sense of hearing is non-functional for ordinary purposes of life. They do not hear and understand sounds at all events with amplified speech. The cases included in this category will be those having hearing loss less than 90 decibels in the better ear (profound impairment) or total loss of hearing in both ears.

Worldwide there are about 123 million persons with hearing loss majority of them are living in South Asian Countries. In 1991, NSSO estimated that there are 3 million persons with hearing impairment in India. The age wise distribution per 1000 persons with hearing impairment is as shown in Table-2.

Hearing is one of the important factors which determines the 'quality' of life we lead. Irrespective of the age of onset of hearing impairment, it comes in the way of the individual utilizing his potentials to the maximum, be it in terms of speech and language acquisition, education, vocational placement, if

not attended to on time. WHO in 1980 summarised the main causes of hearing impairment in India as infections, neglect and ignorance

Table - 2 : Age wise distribution of hearing impaired

Age Group (years)	Hearing Impairment	
	Rural	Urban
0-4	NA	NA
5-14	85	80
15-59	387	377
60 & above	526	541

National Efforts

National Information Centre of Disability and Rehabilitation (NICDR) was established in 1987. This is a nodal agency for creation of awareness regarding the causes and prevention of disabilities, services available for such disabilities etc. In addition to this National Institutes for hearing handicapped and District Rehabilitation Centre mainly for surveys, research and training were established. The setting up of Vocational Rehabilitation Centres (VRCs) by the government has formalized vocational training and rehabilitation. There are currently 17 VRCs that are working towards training of persons with disabilities, while the Training Centre for Adult Deaf (TCAD) at Hyderabad works exclusively for the hearing impaired.

Other Facilities Available

- Government of India set up the National Advisory Council for the education of the handicapped in 1955.
- All India Federation of the Deaf (AIFD), a voluntary organization was established in 1955.
- Special employment exchanges were started since 1959.
- AIFD established a multi purpose training centre in Delhi in 1960.
- Government started central scheme of assistance and awards scholarships.
- Training centre for the adult deaf was established by Madras Association of the Deaf in Madras, in 1973.
- A school for the partially hearing impaired started in Hyderabad by the Ministry of Welfare.
- Ministry of welfare launched a centrally sponsored Integrated Education scheme, in 1974.
- NCERT developed a department for special education.
- There are 200 medical colleges and hospitals in the country where special medical facilities are provided for ENT problems.

Travel : A deaf and dumb person traveling alone (both afflictions together in the same person) on production of a certificate from a government doctor is eligible for rail concession as follows :

Class	First Class	Second Class	Sleeper
% of concession	50	50	50

A deaf & dumb person is permitted to travel by 2-tier A.C. on payment of concessional fare for first class and full surcharge for 2-tier A.C. Sleeper.

Locomotor Impairment

Today it is estimated, 1.6 percent of the Indians - the figure comes to around 16 million in absolute terms are inflicted with locomotor disabilities. In India's below 14 yr child population, approximately 3 million were inflicted with locomotor disability - the most common cause of which is poliomyelitis, cerebral palsy etc.

The orthopaedically handicapped are those who have a physical defect or deformity which causes an interference with the normal functioning of the bones, muscles and joints. In above definition if inability resulting from afflictions of nervous system is added then it is called locomotor disability. It can be classified as :

- 1. Congenital** - cerebral palsy, CTEV, meningocele, meningo myelocele, phocomelias, congenital dislocation of hip etc.
- 2. Acquired.**
 - (a) Infective - Tuberculosis of spine or joints, poliomyelitis, septic arthritis, chronic osteomyelitis etc.
 - (b) Traumatic - Road traffic accidents, domestic accidents, industrial accidents etc
 - (c) Vascular - Cerebro-vascular disease, peripheral vascular disease, Perthe's disease etc.
 - (d) Others : These include metabolic, neoplastic and degenerative diseases

National Efforts

An All India Institute of Physical Medicine and Rehabilitation (AIIPMR) came up at Mumbai under the aegis of the central health ministry. The centre's main occupation is to provide rehabilitative services to the locomotor disabled and few non governmental organization also started contributing for locomotor disabled. The Medical Council of India (MCI) sent a directive to all medical colleges to start a department of physical medicine and rehabilitation so that students are exposed to principles of rehabilitation medicine.

The institutions engaged in rehabilitation of the locomotor disabled are National Institute for Rehabilitation Training and Research (NIRTAR), Olatpur in Orissa, National Institute for Orthopaedically Handicapped (NIOH), Calcutta, Institute for the Physically Handicapped (IPH), New delhi.

The Artificial Limbs Manufacturing Corporation of India (ALIMCO), set up at Kanpur as a Government undertaking, mainly for social services and not for profits, started production in October 1976.

The District Rehabilitation Centre (DRC) Scheme was initiated in 1985 by the Ministry of Welfare in collaboration with the National Institute of Disability and Rehabilitation Research (NIDRR) and Department of Education and UNICEF. The services provided by these centres are :

1. Prevention and early detection
2. Medical intervention and surgical correction
3. Fitment of artificial aids and appliances
4. Therapeutic services such as Physiotherapy, occupational therapy and speech therapy
5. Provision of training for acquisition of skills through vocational training
6. Job placement in local industries.

Facilities and Concessions

Travel : State governments offer either full concession or 50 percent concession for traveling in state run buses. As regards rail travel, the Orthopaedically Handicapped person traveling with an escort, on production of a certificate from a Government doctor to the effect that the person concerned is orthopaedically handicapped and cannot travel without the assistance of an escort, is eligible for getting rail concession at the same rates/as mentioned for locomotor handicapped persons. Locomotor Disabled persons (80% and above) are also allowed 50% Concession in Indian Airlines.

Mental Retardation

During the 1950s, children with moderate mental retardation emerged as focus of concern, largely through the efforts of increasingly well organized parent advocacy groups. This led to formation of National Association for Retarded Children (NARC) in 1950, now known as the Association for Retarded Citizens (ARC). Self advocacy and consumer awareness, that have empowered people with disabilities globally, have made human services to recognize and restructure their programmes and strategies.

Mental Retardation (MR) is prevalent in all societies and cultures and the prevalence is estimated to be around 30 per thousand worldwide. Nearly 75 percent of people diagnosed to have mental retardation fall in the category of mild mental retardation, while the remaining 25 percent have IQ of 50 or below are classified as moderately, severely or profoundly retarded. Nearly 10 percent have associated medical conditions like epilepsy, hyperkinesias or mental illness. Nearly 4 percent of all children with MR have multiple handicaps. In India the prevalence varies from 0.22 to 32.8 per thousand population. Family history and retardation had high association and in rural areas incidence of retardation is more.

Classification

The DSM-IV classifies four different degrees of mental retardation : mild, moderate, severe, and profound. These categories are based on the functioning level of the individual.

Mild mental retardation : Approximately 85% of the mentally retarded population is in the mildly retarded category. Their IQ score ranges from 50-75, and they can often acquire academic skills up to the 6th grade level.

Moderate mental retardation : About 10% of the mentally retarded population is considered moderately retarded. Moderately retarded individuals have IQ scores ranging from 35-55. They can carry out work and self-care tasks with moderate supervision.

Severe mental retardation : About 3-4% of the mentally retarded population is severely retarded. Severely retarded individuals have IQ scores of 20-40. They may master very basic self-care skills and some communication skills. Many severely retarded individuals are able to live in a group home.

Profound mental retardation : Only 1-2% of the mentally retarded population is classified as profoundly retarded. Profoundly retarded individuals have IQ scores under 20-25. They may be able to develop basic self-care and communication skills with appropriate support and training.

National Efforts

The development of education for the disabled and particularly mentally retarded took a different progressive turn after 1964-66 when the education commission, following the constitutional directives, suggested with emphasis that education for handicapped has to be organized not merely on humanitarian grounds but on grounds of utility by making them useful citizens. The National Policy for Children (1974) came in and measures were intended to cover all children including those who came from weaker sections of society and those who were handicapped. Integrated Education for the Disabled commenced with central funding in 1974.

To make programme planning more realistic, working groups on the education of disabled child were set up in 1981 by the Ministry of Welfare and Ministry of Education and culture, Government of India. The committee suggested special day schools, residential schools, resource teacher programme and partial integration over 20 year time span.

The National Institute for the Mentally Handicapped (NIMH) was established in Secunderabad in 1985. The Early Childhood Care and Education (ECCE) scheme through ICDS, preschool programme, and District Primary Education Programme (DPEP) have included disability education including mental retardation since 1999. From July 1999, RCI started a national level programme, training programme for PHC doctors, to train them in disability management. This national level programme named, "National Programme on Orientation of Medical Officers working in Primary Health Centres to Disability Management", which will train 30,000 medical officers through a three day orientation module. Thakur Hari Prasad Institute of Research and Rehabilitation for the mentally handicapped (THPI), Hyderabad is a NGO run organization. It was established in the year 1968 and made significant contribution in the field of manpower development. The Mental Health Act, 1987 is an act to consolidate and amend the laws relating to the treatment and care of mentally ill persons, to make better provisions with respect to their property and affairs and for connected matters.

Facilities and Concessions

A mentally retarded person, accompanied by an escort, on production of a certificate in the prescribed form, from a government doctor, is eligible to get the same rate of railway concession as entitled for locomotor handicapped persons.

Vocational Training

With modern training procedures retarded children can engage in some occupations and achieve at least partial economic independence. Vocational training is therefore of great importance and about 200 institutions in this country offer vocational training. On completion of training, the adult MR person move towards four possible employment :

1. Open employment
2. Supported open employment
3. Sheltered employment
4. Self employment.

Placement services : About 10 percent of vocational institutions have taken up this task of not only providing vocational training but placing the adult mentally retarded

person in open employment with little support. Home based self employment in our Indian context are *Agarbatti* making, candle making, running photo copier, chalk making, telephone booths etc.

Parental Counseling

Several voluntary organizations are engaged in parents counseling through their multidisciplinary approach. The counseling of parents is very important because :

1. They have to deal with the normal development and interpersonal crisis in the MR child.
2. They have to cope with the complications introduced by the reality of child's disability of which they have little knowledge or experience.

Sports and Recreation

Sports Olympics India was founded in 1988 to provide opportunity for persons with Mental Handicap to participate in National and International sports and games. Sports Olympics India organizes national games to select appropriate candidates for the International special Olympics.

Foster Care Home

Foster care home is a home away from home, specially mentioned home for children with mental retardation, who require accommodation and special care. Many voluntary organizations and NGOs are running such homes. Here with the help of foster care mothers who impart systematic training and guidance they learn daily routine of home, activities of daily living.

Others

1. Allotment of public telephone booths on priority to handicapped persons.
2. A scheme of scholarship for pursuing education in special schools run by NGOs.
3. Government servant is eligible to draw Children's Educational Allowance when his MR child goes to school away from the station of his/her posting.
4. Housing boards and urban development authorities have scheme of preferential allotment of plots and housing sites to individuals with disability.
5. The GOI, Department of Personnel and Training in 1991, makes a provision for a choice in the place of posting of parents in government service having a child with MR.

Facilities and Concessions given by the Central and State Governments for the Disabled

1. Employment Opportunity Schemes

3 percent Reservations in Gr 'C' & 'D' Posts : As per the order of Government of India reservation of 3% in jobs have been made in Gr.'C' & Gr.'D' posts for the PH persons. The category of handicapped persons benefited are the blind, the deaf and the O.H. Persons with disability will be given preference at the time of recruitment in the identified Gr.'A' and 'B' posts.

Age Concession : As per the Government order it has been decided to extend the age concession of 10 years in favour of handicapped persons to recruitment to posts filled through the SSC

and through Employment Exchange in Gr.'C' & Gr.'D' posts.

Apart from other employment schemes/reservation in jobs as mentioned earlier for disabled persons, they are also provided relaxation in

Age : Upper age limit has been relaxed upto 10 years and if physically handicapped is SC/ST then further 5 years are relaxed in the age criteria.

Physical fitness : Physically handicapped persons are not subjected to the usual medical examination by the appointing authorities.

Qualifications : Relaxation is also given on various qualifications for different posts. e.g. exemption of typing for appointment to clerical posts.

Another scheme is being developed with the objective of providing assistance to disabled persons in getting gainful employment either through Special Cells in normal Employment Exchanges or through Special Employment Exchanges for physically handicapped persons. The scheme is implemented through Labour Department of State Governments/UT Administrations. Up to 100% financial assistance is provided in the case of Special Cells and 80% in case of Special Employment Exchanges to State Govts./Union Territory Administrations.

2. Income Tax Concessions

The following rebates are available. These rebates are available not only to a handicapped person but also to any normal person who has a handicapped person as his / her dependant.

a) 80DD (Deductions in respect of medical treatment, etc., of handicapped persons) : When an assessee is suffering from a permanent physical disability (including blindness) or is subject to mental retardation, being a permanent physical disability or mental retardation specified in the rules made in this behalf by the Board, which is certified by a physician, a surgeon, an oculist or a psychiatrist, as the case be, working in a government hospital, and which has the effect of reducing considerably such person's capacity for normal work or engaging in a gainful employment or occupation. The assessee shall, be allowed a deduction of a sum of fifteen thousand rupees only (Rs.15,000/-) in respect of the previous year.

b) 80 DDA (Deduction in respect of deposit made for maintenance of handicapped dependent) : In computing the total income of an assessee the amount can be deducted not exceeding twenty thousand rupees (Rs.20,000) paid or deposited by him in the previous year out of his income chargeable to tax, under any scheme framed in this behalf by the Life Insurance Corporation or the Unit Trust of India.

c) 80 DDB (Deduction in respect of medical treatment etc.): Where an assessee who is resident in India has, incurred any expenditure for the medical treatment of such disease or ailment for himself or a dependent relative, the assessee shall be allowed a deduction of a sum of fifteen thousand rupees only (Rs.15,000) in respect of that previous year in which such expenditure was incurred.

d) 80U (Deduction in respect of permanent disability (including blindness)) : In computing the total income of an individual, who is suffering from a permanent physical disability or mental retardation shall be allowed a deduction of

a sum of seventy five thousand rupees (Rs.75,000).

3. Financial Assistance to Persons with Disabilities

(a) National Handicapped Finance & Development Corporation (NHFDc) : The “National Handicapped Finance and Development Corporation” has been incorporated by Ministry of Social Justice & Empowerment, Govt.of India on 24th Jan, 1997 under section 25 of the Companies Act, 1956 as a company not for profit. It is wholly owned by Govt. of India and has an authorized share capital of Rs. 400 crores (Rupees Four Hundred Crores only). The objectives of this corporation are :

- Promote economic developmental activities for the benefit of persons with disabilities.
- Promote self-employment and other ventures for the benefit/ economic rehabilitation of persons with disabilities.
- Extend loans to person with disability for pursuing general/ professional/ technical education for training at graduate and higher level.
- Assist in the upgradation of technical and entrepreneurial skills of persons with disability for proper and efficient management of production units.
- Assist self-employed individuals/ group of individuals of registered factories/ companies/ co-operatives of disabled persons in marketing their finished goods and assist in procurement of raw materials.

Any Indian Citizen with 40% or more disability and age between 18 and 55 years and annual Income below Rs.60,000/- for urban areas (less than Rs.55,000/-p.a. for rural areas) is eligible for the scheme.

NHFDc Schemes : These include loans for setting up small business (Loan upto Rs.20.00 Lakhs), for higher studies, for agricultural activities (Loan upto Rs.5.00 Lakhs), for manufacturing/ production of assistive Devices for disabled persons (Loan upto Rs.25.00 Lakhs), for self employment amongst persons with mental Retardation, Cerebral Palsy and Autism (Loan upto Rs.2.50 Lakhs).

(b) National Trust for Welfare of Persons with Autism, Cerebral Palsy, Mental Retardation and Multiple Disabilities: The National Trust for welfare of Persons with Autism, Cerebral Palsy, Mental Retardation and Multiple Disabilities Act, 1999 came into force w.e.f. 30th December,1999. The National Trust supports programmes which promote independence, facilitate guardianship where necessary and address the concerns of those special persons who do not have their family support. The Trust also seeks to strengthen families and protect the interest of persons with autism, cerebral palsy, mental retardation and multiple disabilities after the death of their parents. The Trust is empowered to receive grants, donations, benefactions, bequests and transfers. It is exempted from income tax.

4. Central Government Schemes for the Rehabilitation of Persons with Disabilities

Ministry of Social Justice and Empowerment

a) Scheme to promote Voluntary Action for Persons with Disabilities (Umbrella Scheme)

The enactment of the people with disabilities, equal opportunities and protection of Right Act of 1995 is landmark

legislation and an expression of India's commitment of social justice. The Disability Division of the Ministry of Social Justice and Empowerment has so far been administering the following five grant-in-aid schemes which are being implemented through NGOs :

- Scheme of Assistance to organizations for the disabled.
- Scheme of Assistance to Disabled Persons for Purchase/ Fitting of Aids/Appliances.
- Scheme of Assistance of Voluntary Organization for the Rehabilitation of Leprosy Cured Persons.
- Scheme of Assistance to voluntary Organizations for Special School for Handicapped Children.
- Scheme of Assistance of Organizations for Persons with Cerebral Palsy and Mental Retardation.

b) Scheme of Assistance to Disabled Persons for Purchase/ Fitting of Aids & Appliances (ADIP)

Ministry of Rural Areas & Employment : Convergence of Poverty Alleviation Programme of the Ministry of Rural Areas and Employment with the ADIP Scheme of Ministry of Social Justice and Empowerment.

- TRYSEM training to disabled.
- Financial assistance to group of persons with disability in rural areas.
- Revision/Modification of Jawahar Rozgar Yojana guidelines, earmarking of funds for persons with disability.
- 3% reservation to persons with disability in the Rural Sanitation programme.
- Earmarking of 3% of funds for the benefits of persons with disability under Indira Awas Yojana.

5. Pension and Unemployment Allowance

Some of the state governments have introduced disability pension and unemployment allowance schemes.

6. Educational Assistance Schemes

- Ministry of Welfare covers scholarships for general education from class IX onwards and for technical training at certificate, diploma and degree levels.
- Department of Social Welfare provides scholarships to pursue education from class I to class VIII

7. Fellowships

The University Grants Commission has reserved 1 percent of the fellowships allocated to the Universities for the handicapped.

8. Reservations in Higher Educational Institutions.

A number of State Governments have reserved 3 percent seats in Industrial Training Institutes / Engineering and management Colleges (usually it is 1% each for Visual, Hearing and Locomotor handicapped persons).

9. District Rehabilitation Centres

The Government of India launched the District Rehabilitation Centre Scheme in early 1995, to provide comprehensive rehabilitation services to the rural disabled right at their door steps. The scheme, at present, is operational at 11 different districts of the 10 states of our country. These are -

Bhubaneshwar (Orissa); Bilaspur (Madhya Pradesh); Kharagpur (West Bengal); Mysore (Karnataka); Chengalpattu (Tamil Nadu); Sitapur (Uttar Pradesh); Vijaywada (Andhra Pradesh);

Bhiwani (Haryana); Kota (Rajasthan) and Virar (Maharashtra), Jagdishpur (Uttar Pradesh).

The services provided in the scheme includes -

- Prevention and Early Detection
- Medical Intervention and Surgical Correction
- Fitment of Artificial Limbs, Aids and Appliances
- Therapeutic Services
- Training for acquiring Vocational Training, Job Placement etc.

10. Regional Rehabilitation Training Centres (RRTCs)

Four Regional Rehabilitation Training Centres (RRTCs), also been set up at Chennai, Cuttack, Lucknow and Mumbai for training and manpower development in the field of rehabilitation particularly for the DRCs. The RRTCs also have been conducting training programmes for Communities, Parents and even for Persons with Disabilities themselves.

11. Science and Technology Project in Mission Mode on Application of Technology for the Welfare and Rehabilitation of the Handicapped

The objective of the scheme is to coordinate and fund the research projects for generation of new technology in terms of development of assistive devices for large scale use by the disabled. The focus of S&T Mission Mode scheme is to design, develop and standardize new and innovative assistive devices of better materials, design and technology for fabricating high quality modern state of the art assistive devices.

Several products have been successfully developed, to name a few such as plastic aspheric lenses for the low vision persons, B.K. Prosthesis, inter-pointing Braille writing frame, PU Foam foot, multifunctional wheelchair, feeding aid for spastic etc. developed under the Mission Mode. The implementation of this scheme is through 100% funding to the research/scientific institutions through Rehabilitation Technology Centre.

12. Scheme for Setting up of Composite Regional Centre for Persons with Disabilities

It has been approved to set up Composite regional Centres for persons with disabilities in different parts of country. The basic objective of setting up Composite Resource Centres (CRCs) is to create the infrastructure required for training and manpower development, research and providing services to persons with disabilities, particularly in those parts of the country where much infrastructure is lacking at present. The Centres would be expected to function as the Outreach Centres of National / Apex Institutes, presently functioning under the Ministry and will facilitate the process of capacity building at local levels, in regions, in which these are being set up. The proposed centers would also carry out the following objectives.

- To serve as Resource Centre for rehabilitation and special education of persons with disabilities. To start with, short term and orientation courses will be taken up.
- To establish linkages with existing medical, educational and employment services, following the principles of community-based rehabilitation and offer extension services in the rural areas.
- To develop strategies for delivery of rehabilitation services suitable to the socio-cultural background of the region.

- To undertake designing, fabrication and fitment of aids and appliances.
- To undertake services of education and skill development leading to enhancement of opportunities for employment, rehabilitation, mobility communication, recreation and integration in society.

First such Composite Regional Centre has started functioning at Srinagar and the second Composite Regional Centre has started functioning at Lucknow since 2000.

13. Scheme for Setting up Regional Rehabilitation Centres for Persons With Spinal Injuries and other Orthopaedic disabilities

It has been approved to establish four Regional Rehabilitation Centres for Persons with Spinal Injuries and other Orthopedics Disabilities in the country, as a Centrally Sponsored Scheme on 90 : 10 Centre : State sharing basis. These Centres would provide facilities for treatment and rehabilitation services to the spinally injured and persons with other orthopaedic disabilities. The Indian Spinal Injuries Centre, New Delhi, a Centre of Excellence will provide the required technical support for setting up of these centres and will also function as Referral Centre.

Various services to be provided by the Centre will include :

- Diagnostic Facilities
- Equipped Physio-Occupational Therapy
- In patient beds facility
- Minor Operation Theatre
- Artificial Limbs and appliances fitting centre
- Vocational Training
- Teaching and Training to health personnel & community workers.

14. National Awards for People with Disabilities

The Ministry of Social Justice & Empowerment has been giving National Awards since 1969 on the International Day of Disabled Persons on 3rd December every year. The Awards are given in different categories, namely best employer of disabled, outstanding employee, placement officer, best individual, institution, barrier-free environment, creative disabled person and National Technology Awards involved in the rehabilitation and welfare of persons with disabilities.

Institution of Awards has created awareness amongst the disabled persons both in public and private sector and brought them in the mainstream.

15. Others

- (a) Handicapped persons are exempted from payment of application and examination fee as prescribed by UPSC/SSC
- (b) Assistance to Disabled persons for purchase / fitting of aids/appliances to procure durable, sophisticated and scientifically manufactured aids and appliances to promote their physical, social and psychological rehabilitation.
- (c) Assistance to voluntary organizations working for the disabled welfare. Financial support is given up to maximum limit of 90 percent of the total project cost.
- (d) Assistance to voluntary organizations working for the rehabilitation of leprosy cured persons both in rural and

urban areas. Financial support is given up to maximum limit of 90 percent of the total project cost. Programmes like awareness generation, early intervention, educational and vocational training, economic rehabilitation, social integration etc are undertaken in the schemes.

- (e) Physically handicapped owners of motorized vehicles are granted exemption from the payment of road tax by the state government and are eligible to claim refund upto 50 percent of the expenditure incurred by them on purchase of petrol/diesel from recognized dealers subject to certain ceilings. The scheme is operative through District Social Welfare Officers or Tehsildars or any other equivalent authority.

Important Organisations and Centres

National Level Rehabilitation Institutes

- Ali Yavar Jung National Institute for the Hearing Handicapped (AYJNIHH), Mumbai
- National Institute of Mentally Handicapped (NIMH), Secunderabad
- National Institute of Visually Handicapped (NIVH), Dehradun
- National Institute for the Orthopaedically Handicapped (NIOH) rechristened as Dr. Shyama Prasad Mukherjee National Institute for Orthopaedically Handicapped, Kolkata
- National Institute for Rehabilitation Training & Research, Cuttack.
- The Institute for the Physically Handicapped, Delhi.

Associated Organisations

- Artificial Limbs Manufacturing Corporation of India (ALIMCO)
- Dr. Ambedkar Foundation
- Institute for the Physically Handicapped (IPH), rechristened as Deen Dayal Upadhyay Institute of Physically Handicapped
- National Handicapped Finance and Development Corporation (NHFDC)
- National Trust for the Welfare of Persons with Autism, Cerebral Palsy, Mental Retardation and Multiple Disabilities
- National Institute of Social Defence (NISD)
- Office of the Chief Commissioner for Disabilities
- Swami Vivekanand National Institute of Rehabilitation, Training and Research (SVNIRTAR).

Summary

WHO has defined rehabilitation as “the combined and coordinated use of medical, social, educational and vocational measures for training and retraining the individual to the highest possible level of functional ability”. The GOI has set up a Rehabilitation Council in 1860, converted to a statutory body under the Rehabilitation Council of India Act, 1992 to regulate training programmes in the field of rehabilitation, under the aegis of the Ministry of Social Justice & Empowerment. The Persons with Disabilities Act was enacted in 1995 to protect the rights of persons with disabilities, to provide educational opportunities and full participation.

The National Programme for Control of Blindness (NPCB) was

launched in 1976 with the goal to bring down the prevalence rate of blindness from 1.4% to 0.3% by the end of twentieth century and considerable progress has been made since its launch. The WHO and a consortium of international non governmental development organizations (INGDOs) have launched Vision 2020 with aim to prevent the avoidable blindness in the developing countries by the year 2020. DANIDA in 1987 and World Bank since 1994-95 are in agreement with GOI for assisting in control projects and capacity building.

The first school for the deaf in India was started in Bombay Presidency as back as 1884. Following recommendation of Kothari Commission, All India Institute of Speech and Hearing (AIISH) was established in 1965 at Mysore and Ali Yavar Jung National Institute for the hearing handicapped was started at Bombay in 1983. WHO in 1980 summarized the main causes of hearing impairment in India as infections, neglect and ignorance. National Information Centre of Disability and Rehabilitation (NICDR) was established in 1987 for creation of awareness regarding the causes and prevention of disabilities, services available for such disabilities etc. In 1991, NSSO estimated that there are 3 million persons with hearing impairment in India. Currently 17 VRCs that are working towards training of persons with disabilities, while the Training Centre for Adult Deaf (TCAD) at Hyderabad works exclusively for the hearing impaired.

In India around 16 million are inflicted with locomotor disabilities of which around 3 million are below 14 yr child population- the most common cause of which is poliomyelitis, cerebral palsy etc. The institutions engaged in rehabilitation of the locomotor disabled are All India Institute of Physical Medicine and Rehabilitation (AIIPMR), Mumbai; National Institute for Rehabilitation Training and Research (NIRTAR), Olatpur in Orissa; National Institute for Orthopaedically Handicapped (NIOH), Kolkata; Institute for the Physically Handicapped (IPH), New Delhi; and the Artificial Limbs Manufacturing Corporation of India (ALIMCO), Kanpur. The District Rehabilitation Centre (DRC) Scheme was initiated in 1985 by the Ministry of Welfare in collaboration with the National Institute of Disability and Rehabilitation Research (NIDRR) and Department of Education and UNICEF.

Mental Retardation (MR) is prevalent in all societies and cultures and in India the prevalence varies from 0.22 to 32.8 per thousand. National Association for Retarded Children (NARC) formed in 1950 is now known as the Association for Retarded Citizens (ARC) focusing on children with moderate mental retardation. Integrated Education for the Disabled commenced with central funding in 1974 and working groups on the education of disabled child were set up in 1981 to make it more realistic. National Institute for the Mentally Handicapped (NIMH) was established in Secunderabad in 1985. The Early Childhood Care and Education (ECCE) scheme and District Primary Education Programme (DPEP) have included disability education since 1999. From July 1999, RCI started “National Programme on Orientation of Medical Officers working in Primary Health Centres to Disability Management”, which will train 30,000 medical officers through a three day orientation module. The Mental Health Act, passed in 1987 to consolidate and amend the laws relating to the treatment and care of

mentally ill persons, to make better provisions with respect to their property and affairs and for connected matters.

Facilities and Concessions given by the Central and State Governments for the Disabled

1. Employment Opportunity Schemes
 - 3 percent Reservations in Gr 'C' & 'D' Posts
 - Age Concession of 10 years in favor of handicap persons to recruitment to posts filled through the SSC and through Employment Exchange in Gr.'C' & 'D' posts.
 - Physically handicapped persons are not subjected to the usual medical examination by the appointing authorities.
 - Relaxation is also given on various qualifications for different posts. Eg exemption of typing for appointment to clerical posts.
 - Getting gainful employment either through Special Cells in normal Employment Exchanges or through Special Employment Exchanges for physically handicapped persons.
2. Income Tax Concessions are applicable to not only to a handicapped person but also to any normal person who has a handicapped person as his / her dependant :
 - 80DD -Deductions in respect of medical treatment, etc., of handicapped persons
 - 80 DDA -Deduction in respect of deposit made for maintenance of handicapped dependent
 - 80 DDB -Deduction in respect of medical treatment etc.
 - 80U -Deduction in respect of permanent disability including blindness
3. Financial Assistance to Persons with Disabilities is available through :
 - National Handicapped Finance & Development Corporation (NHFD)C
 - National Trust for Welfare of Persons with Autism, Cerebral Palsy, Mental Retardation and Multiple Disabilities
4. Central Government Schemes for the Rehabilitation of Persons with Disabilities :
 - Scheme to promote Voluntary Action for Persons with Disabilities (Umbrella Scheme)
 - Scheme of Assistance to disabled persons for purchase/ fitting of aids & appliances (ADIP).
 - Convergence of Poverty Alleviation Programme of the Ministry of Rural Areas and Employment with the ADIP Scheme of Ministry of Social Justice and Empowerment
 - Revision/Modification of Jawahar Rozgar Yojana guidelines
 - Earmarking of 3% of funds for the benefits of persons with disability under Indira Awas Yojana.
5. Pension and Unemployment Allowance
6. Educational Assistance Schemes
7. Fellowships
8. Reservations in Higher educational Institutions
9. District Rehabilitation Centres
10. Regional Rehabilitation Training Centres (RRTCs)
11. Science and Technology Project in Mission Mode on Application of Technology for the Welfare and Rehabilitation of the Handicapped
12. Scheme for Setting up of Composite Regional Centre for Persons with Disabilities
13. Scheme for Setting up Regional Rehabilitation Centres

for Persons With Spinal Injuries and other Orthopaedic disabilities

14. National Awards for People with Disabilities.

Study Exercises

Long Question : Discuss the various Facilities and Concessions given by the Central and State Governments for the Disabled

MCQs

1. Which ministry has been made responsible by the government for the welfare of the disabled ? (a) Ministry of Social Justice & Empowerment (b) Ministry of Health and Family Welfare (c) Ministry of Labour (d) None
2. Blindness as per WHO classification is includes all except: (a) 3/60 (finger counting at 3 meters) to 1/60 (finger counting at 1 meter) (b) 1/60 to light perception (c) No light perception (d) 6/60 to 3/60
3. WHO in 1980 summarized; the main causes of hearing impairment in India as : (a) Infections (b) Neglect (c) Ignorance (d) All
4. The most common cause of locomotor disability in India among below 14 yr child population : (a) poliomyelitis (b) cerebral palsy (c) both of above (d) congenital causes
5. AIIPMR, Mumbai established under the aegis of : (a) Ministry of Social Justice & Empowerment (b) Ministry of Health and Family Welfare (c) Ministry of Labour (d) None
6. Integrated Education for the Disabled commenced in : (a) 1977 (b) 1974 (c) 1983 (d) 1965
7. National Institute for the Mentally Handicapped (NIMH) was established in 1985 at : (a) Bangalore (b) Secunderabad (c) Mysore (d) Mumbai
8. Possible employment for a mentally handicapped individual are : (a) Supported open employment (b) Sheltered employment (c) Self employment (d) All
9. In India Regional Rehabilitation Training Centers is not located at (a) Chennai, (b) Cuttack, (c) Lucknow (d) Secunderabad
10. Who all amongst the international agencies are providing collaborative support to GOI in prevention and control of Blindness : (a) DANIDA (b) World Bank (c) WHO (d) all of above

Fill in the Blanks

1. National Survey Sample Organisation in 1991 estimated that _____ of India's population had disability, and _____ of children had delayed development and likely to be Mentally Retarded.
2. Rehabilitation Council of India Act was passed in _____ and came into force from _____.
3. Commonest causes of blindness and visual impairment in India are : _____, _____ & _____.
4. National Programme for Control of Blindness (NPCB) was launched in _____ with the goal to bring down the prevalence rate of blindness from _____ to _____ by the end of twentieth century.
5. _____ commission recommended the establishment of special schools for hearing impaired in every district.
6. The Deaf are defined as those having hearing loss more than _____.

- _____ in the _____ ear (profound impairment) or _____ loss of hearing in both ears.
- Currently _____ VRCs are working towards training of persons with disabilities.
 - Training Centre for Adult Deaf (TCAD) at _____ works exclusively for the hearing impaired.
 - Artificial Limbs Manufacturing Corporation of India (ALIMCO) set up at _____ as a Government undertaking, mainly for social services and not for profits, started in _____.
 - Examples of Home based self employment for mentally retarded are _____, _____ & _____ etc.
 - District Rehabilitation Centre (DRC) Scheme was initiated in 1985 by the Ministry of _____ in collaboration with Department of _____ and _____.
 - National Association for Retarded Children (NARC) in 1950, now known as the _____.
 - Sports Olympics India was founded in _____ to provide opportunity for persons with Mental Handicap to participate in National and International sports and games.
 - Upper age limit for physically handicapped has been

- relaxed upto _____ years & if physically handicapped is SC/ST then further _____ years are relaxed in the age criteria.
- Any Indian Citizen with _____ or more disability and age between 18 and 55 years and annual Income below Rs. _____ for urban areas and less than Rs. _____ for rural areas is eligible for the NHFDC scheme

Answers : MCQs : (1) a; (2) d; (3) d; (4) c; (5) d; (6) b; (7) b; (8) d; (9) d; (10) d.

Fill in the Blanks : (1) 1.9%, 3%; (2) 1992, jul1993; (3) Cataract, glaucoma & xerophthalmia; (4) 1976, 1.4% to 0.3%; (5) Kothari; (6) 90-dB, better, total; (7) 17; (8) Hyderabad; (9) Kanpur,1976; (10) *Agarbatti* making, running Photo copier, telephone booths etc; (11) Welfare, Education & UNICEF; (12) Association for retarded citizens; (13) 1988; (14) 10, 5; (15) 40%, 60,000, 55,000.

Human Manpower Resources in India (Including AYUSH)

Anagha Khot

Human resources are the most precious resource of a country. Globally national health systems are finding it challenging to train, sustain and retain their health workers. While India is being propelled to a position of international eminence, it faces three main groups of challenges: *first*, dealing effectively with unfinished agendas of communicable diseases, maternal and child health, and health systems strengthening; *second*, dealing with new emerging challenges such as premature burden of non-communicable diseases; and *third*, dealing with globalization related issues while contributing to the management and shaping of the global policy environment. In addressing these challenges, the health workforce is confronted by shortages, migration, issues of quality, accountability, public-private coordination, and the complexity of service provision to large and diverse populations.

Concepts and Definitions(1)

Human resources for health (HRH) : HRH (*Used synonymously with 'health manpower, health personnel, or health workforce'*) refers to "people engaged in actions whose primary intent is to enhance health" (World Health Report, 2006). This includes both private and public sectors and different domains of health systems, such as personal curative and preventive care, non-

personal public health interventions, disease prevention, health promotion services, research, management and support services (Fig. - 1).

HRH encompass "all individuals engaged in the promotion, protection, or improvement of population health, including clinical and non-clinical workers." The persons are engaged in any capacity in the production and delivery of health services. These persons may be paid or volunteer, with or without formal training for their functions, and in the public or private sector. (JLI, 2004)

Health Human Power System : Health human manpower consists of a system composed of the following inter-related elements :

- Human resources development (HRD), as applied to human resources for health (HRH), includes the planning, production, and management of health personnel.
- Human resources planning "...is the process of estimating the number of persons and the kinds of knowledge, skills, and attitudes they need to achieve predetermined health targets and ultimately health status objectives" (WHO, 1978). Over the years this function has been broadened to include that of formulating human resources policy, in which the word 'policy' refers to statements made by relevant authorities that are intended to guide the allocation of resources and effort.
- Human resources production refers to "...all aspects related to the basic and post-basic education and training of the health labour force. Although it is one of the central aspects of the health manpower (development) process,

it is not under the health system's sole control" (WHO, 1978). The production system includes all the educational and training institutions, which are increasingly a joint responsibility of service and educational institutions.

- Human resources management has been defined as the "mobilization, motivation, development, and fulfilment of human beings in and through work" (WHO, 1978). It "...covers all matters related to the employment, use, deployment and motivation of all categories of health workers, and largely determines the productivity, and therefore the coverage, of the health services system and its capacity to retain staff." Management also encompasses programmes for in-service and continuing professional education, as well as evaluation.

AYUSH : An extremely important national initiative in India for ensuring appropriate utilization of technology and manpower of available indigenous systems of health in the country, viz. Ayurved, Yoga & naturopathy, Unani, Siddha, and Homeopathy, which fits very well with the ethos of the community and is quite acceptable by the people.

Dimensions of the performance of the health work force (2)

- Coverage refers to the extent to which the work force provides services to the various sub-groups of the population and supplies the whole range of services corresponding to their health needs.
- Productivity corresponds to the output extracted from personnel, such as patients seen per doctor, number of procedures per provider.
- Technical quality is the degree to which providers produce services which (1) respect the accepted technical norms, usually defined by professional associations, and (2) have a positive impact on the health status of users.
- Socio-cultural or service quality refers to the degree to

which providers produce services which are culturally and ethically acceptable to users, meet their expectations, and are organized in a way that makes them accessible.

- Organizational sustainability is the degree to which the work force is utilized in a way that ensures (1) the maintenance of the capacity to provide needed services over time, both in quantitative and qualitative terms, and (2) the adaptation of services to changing needs and circumstances.

Each of these dimensions, individually or in combination, has an impact on health outcomes, responsiveness, even financial protection

Global & Regional Scenario

The WHO estimates that there are a total of 59.2 million full-time paid health workers worldwide (World Health Report 2006). Of these, there are about 39.5 million health service providers and over 19.5 million management and support workers. It is estimated that there is a global shortage of more than 4 million doctors, midwives, nurses, pharmacists, dentists and support workers.

There exist considerable inter-regional as well inter-country variations in terms of availability of human resources. While the WHO South East Asia Region (South East Asia Region herein includes Bangladesh, Bhutan, DPR Korea, India, Indonesia, Maldives, Myanmar, Nepal, Sri Lanka, Timor- Leste and Thailand) has a quarter of the world's population, it has only 12 per cent of the global health workforce. On the regional average, there are 29 essential health service providers per 10,000 population. This figure is well below the global average of 62 (See Fig. - 2 & 3). In addition, the Region also faces the imbalance in their distribution of these health workers, mainly between rural and urban areas as well as across the public and private sector.

Fig. - 1 : Health Workers in All Sectors

Source: World Health Report 2006

Some of the critical issues that countries are grappling to address include :

- Addressing issues of shortages of human resources
- Numerical and distributional imbalances of human resources that are not only wasteful but contribute to poor coverage of health services
- Poor training and technical skills of health personnel that impede the effective delivery of health care
- Inefficient skills- mix of health personnel
- Over-burdened district staff
- Personnel management issues involving non-existent career structures
- Inadequate staff supervision
- Lack of support and poor working environment
- Lack of opportunities for personal development and several other factors that lead to inefficient delivery of health care
- Migration of health personnel

Health Workforce in India

The state of human resources for health in India is diverse and multifaceted. They range from rigorously trained biomedical specialists and super-specialists at one end to an assortment of community and household based healers at the other. One half of this continuum is abounding with trained and qualified doctors of allopathic or modern biomedicine, psychiatrists, dentists, radiographers, a range of paramedical professionals - nurses, pharmacists, laboratory technicians, and a number of allied personnel - policy makers, health planners and managers, social workers, psychologists, researchers, health educators and promoters, and health technologists. While the other half is replete with the richness of India's traditional healing systems. Here one finds professionally trained and University qualified practitioners of Ayurvedic, Unani, Homeopathic, Siddha and Naturopathic medical traditions. One also comes across informally trained providers through apprenticeships, traditional and household birth attendants, a variety of healers and community or household elders learned in the art of traditional healing and indigenous remedies. These human resources can also be categorized into a public sector & a private sector.

A brief profile of main categories of health workforce is given below:

1. Doctors

As of 2007, a total of 6,96,747 allopathic medical practitioners practicing in the different states in India and, are registered with the different State Councils.

Alongside, as on 2006, about 78096 dental surgeons were registered with different State Dental Councils. Table - 1 provides a state-wise overview of government allopathic doctors and dentists and average population covered. Moreover, around 26,252 allopathic doctors are part of the government's network of rural Primary Health Centres (PHC) and Community Health Centres (CHC) across the country (See Table - 2 & 3). However, a comparison of these public sector doctors in the public system reveals sharp contrasts. Also, over 80% of the qualified private health care providers are concentrated in cities, towns and urban areas. In terms of the public health sector, a total of 22,608 doctors are located in PHCs and 5,117 specialists are posted at CHCs. Despite this there is a shortfall of about 1,410 doctors at the PHC and about 9,455 specialists at the CHC. A look at the data relating to specialists at CHC shows that in spite of around 10,615 positions being sanctioned, there are around 50% vacant positions.

Alongside, around 72,5338 AYUSH doctors are practicing in the different states in India and, are registered with the different State Councils Table 4 and 5 provide an overview of AYUSH (traditional medicine) infrastructure and human resources.

All this data, clearly indicates the rural-urban divide in distribution of health personnel in the country. Various States have designed and implemented innovative measures to address these shortages of manpower in rural areas. Compulsory rural postings, incentives for rural posting and hiring of private specialists for providing essential services are some of the initiatives undertaken by the States. Integrating of AYUSH practitioners into general health service delivery system is yet another measure to enhance the reach of health

Fig. - 3 : Number of Health Service Providers (per 10000 Population) for selected categories in countries of the SEA Region, 2005

services in the community. Anesthetists and obstetricians are essential if CHCs are to function as FRUs. In order to meet these demands, the National Board of Examinations has expanded its post graduate equivalent courses and most states have also started training in-service MBBS doctors in short-term courses of anesthesia and emergency obstetric care.

2. Nurses and Midwives

The auxiliary staff is the backbone of the health system as they are the first point of contact between the health system and community. As of 2007, a total of 150,9196 nurses (ANM, GNM and LHV) are registered in India (See Table - 6) The number of nurse midwives positioned in PHCs and CHCs is about 29,776 and the shortfall is 17,262 (See Table - 7).

Migration of nurses (in-country and out-country) is one of the critical areas of concern.

Right from the Bhole Committee, different committees have emphasized the need to develop a huge pool of auxiliary health personnel to enhance the service delivery especially primary health care. The National Rural Health Mission (NRHM) has provided for additional ANM in high priority states as well as filling up of existing vacancies. Under RCH-II programme, some of the States too have experimented with additional ANM in sub-centers to boost the reach of RCH services.

3. Pharmacists

Pharmacists are an important source of health care provision, in rural as well as urban areas (Ray and Bhaduri, 2001). Even though they may not be perceived as doctors, households are known to procure modern medicines directly from pharmacists without going through a medical consultation. As of December 2007, around 681,692 pharmacists are registered in India (See Table - 6). At the level of PHCs and CHCs, 17,919 pharmacists

are in place, while there exist a shortfall of around 4,910 pharmacists (See Table - 8).

4. Paramedical and other health workers

There exists a gamut of other health workers - male health workers, health assistants, block extension educators, laboratory technicians, radiographers, Accredited Social Health Activist (ASHA) amongst others across various levels of the health system. Besides nurses and pharmacists, there are around 12,101 laboratory technicians, around 4,068 block extension educators, 20,234 male health assistants and 62,881 male health workers, currently in position at different levels of the health system (Rural Health Statistics, 2007). Even out of the sanctioned posts, a significant percentage of posts are vacant at all the levels (See Tables - 9 & 10). There is a need to develop this category of

health staff both to increase the reach of primary health care delivery as well as to allow trained professionals to deliver specialized services to a larger population.

Education and Training

Standardization and quality of education and training imparted in colleges is of utmost importance for development of human resources in health. The various statutory councils like the Medical Council of India (MCI), the Dental Council of India (DCI), Indian Nursing Council (INC), Central Council of Indian Medicine (CCIM), Central Council of Homeopathy (CCH), Pharmacy Council of India (PCI) and Rehabilitation council of India (RCI) are the appointed authorities establish uniform standards of higher qualifications in medicine; granting permission/recognition to educational institutions/ practitioners; registration of doctors with recognized medical qualifications and address issues of ethics and standards of practice amongst others.

In India, the number of allopathic medical colleges had increased steadily during the years after Independence. There was a rapid growth of medical colleges from 25 in 1947 to 106 in 1981 and now to 289 (encompassing 31298 seats at the MBBS level). Also, the colleges are not evenly distributed with the poorer states having a lesser number and the growth of medical colleges in the private sector has been tremendous. The report of the NCMH shows that there are 7,700 undergraduate seats in the north compared to 18,000 in the south: a total admission capacity of 25,500 seats per year. There are 55% seats in the public sector, a fall from 99% in 1950. This shows a rapid privatization of medical education, particularly in the Southern and richer states. For example in the states of Kerala, Karnataka, Tamil Nadu, Andhra Pradesh, Gujarat, Punjab, Haryana and Gujarat medical seats increased from

about 60 in 1950 to over 9,500 in 2004. In contrast, in the states of Bihar, Jharkhand, Orissa, UP, Uttaranchal, Assam, North Eastern states, Rajasthan etc. seats increased from 0 in 1950 to less than 1000 in 2004 (NCMH, 2005). Some of this growth has been attributed to India's liberalized economy post 1990 which saw investments in medical education increase as a response to favourable market conditions. This development has the potential to further widen educational disparities between the states. The high educational expenses involved are also one key factor that compels graduate doctors to look for better financial opportunities rather than practice in rural and primary care settings. There is at present an acute shortage of good teaching faculty in medical colleges, particularly acute in pre and para clinical subjects like anatomy, physiology, biochemistry, pathology microbiology, pharmacology, forensic medicine and community medicine (NCMH, 2005).

Training of ANMs and multipurpose workers is conducted through an elaborate network of State Institutes of Health and Family Welfare (SIHFW), Health and Family Welfare Training Centers (HFWTC), District Training Centers (DTCs) and ANM Training Centres (ANMTCs). As of March 2006, there are 336 ANM/MPW(F) Schools funded by Govt of India, 42 LHV promotional schools established by Govt of India and 56 MPW(M) training centres in the country. However, several of these suffer from shortages of good faculty and adequate budgets. Inadequate faculty implies poor quality of education. This is also true of nursing education, which has also witnessed shortfalls in the quality of education due to inadequate infrastructure, insufficient budgets, non-adherence to student-teacher norms, lack of commitment and accountability in educators for clinical supervision and guidance and insufficient hands-on training for students. In 2004, 61.2% of the 635 nursing schools and 165 nursing colleges were found unsuitable for teaching. De-recognition by the Indian Nursing Council has no impact as they continue to function with the permission of the State Nursing Councils (NCMH, 2005). There are also no specialized nursing disciplines in India like nurse anaesthetists or nurse practitioners as no formal system exists for the training of nurses and midwives to keep them abreast with the latest developments in the field.

The Pharmacy Council of India governs the education and functioning of the pharmacists in India. The minimum qualification required for registration is a D. Pharm. - a 2-year Diploma in Pharmacy. Higher qualifications include a 4 year Bachelor's degree (B.Pharm.), a 2-year Masters' degree (M.Pharm.) or a doctorate in pharmacy. Despite the presence of the Pharmacy Council, there are numerous unregulated and unauthorized pharmacy training centers that produce diploma trained pharmacists, whose skills are likely to be short of the required standards of registered pharmacists. Around 2% pharmacists were unaccounted for in the pharmacy workforce study in India (International Pharmaceutical Federation, 2006). In the case of paramedical professions too, like pharmacy and Laboratory technology, there is considerable diversity and dilution of standards of education. Pharmacy education is guided by a pharmacy council but in absence of enforcement of regulations, many unlicensed institutions provide diploma courses in pharmacy. There is no separate council to guide the

training of laboratory technicians.

Recommendations concerning regulation of education, curriculum reforms and reorganization of statutory councils to maintain standards and quality of education have been provided by different expert committees. Continuing education was recognized as an important measure to update the knowledge and skills of health personnel. Towards this objective, CME programmes were initiated in the 6th Plan period with National Academy of Medical Sciences as the nodal agency. While CME of medical personnel has received attention, CME of other categories of health personnel and their in-service training opportunities have had not been discussed adequately.

During the past few years, there has been an increase in dialogue and discussions on strengthening and reforming public health among the national, regional and state-wide public health associations. Public health education in India is provided at undergraduate level for medical, dental, veterinary, nursing and other allied health sciences by departments of preventive and social (P&S) medicine. There are about 210 departments of P&S medicine, which include 90 private institutions. The postgraduate programme at MD level is conducted in more than 60 institutes, while the Diploma in Public Health is provided in more than 13 institutes. Several postgraduate courses are provided as Diplomas, Masters, MD and Doctoral levels, in various public health disciplines. Alongside, several institutes of public health are being strengthened or are in the process of being established.

Selected Key Challenges of Human Resources in India

There exist various advantages as well as human resource related challenges in India. The advantages include availability of skilled work force; existence of an established system of training and educational institutions for medical and paramedical education; commitment by government to rural and population health. While some challenges are specific to the public and / or private sector, others are more cross cutting in nature.

1. Information about Human Resources : The exists lack of complete and current empirical data on different categories of medical, paramedical and allied human resources, required for efficient planning and forecasting, especially in the private sector. There is no adequate information about the private sector. Available data is primarily limited to the public sector. Furthermore, whatever data exists, it is not regularly updated and also, tends to concentrate on doctors and nurses. Moreover, available data shows large inter-state variations.

The existing registration systems of professional councils do not have robust processes for renewing registration; thus, data do not reflect attrition and dropouts. For instance, the Medical Council of India (MCI) gives comprehensive information on the total number of doctors in the country registered with various State Medical Councils. The data is available both State wise and year wise. However, the MCI data is cumulative and does not take into consideration attrition due to death, retirement, out of practice or migration within or outside the country. The MCI register does not give specific information regarding the

specialty or distribution of doctors. While, information of the number of specialists can be obtained from the membership of various professional bodies/associations, such information is limited as it gives information about the members alone. The Northeastern states except Assam and Sikkim do not have their own State councils and doctors passing out from these States are registered elsewhere. Further, a doctor may be registered with more than one State council in cases where one is practicing in a State other than the one where s/he is first registered. This may lead to duplication of registration of doctors. Also, the total available figures may represent an inflated version of the numbers of workers that are currently available for the health system. Attrition, migration is not reflected in any of this data. Similar issues affect the functioning of other existing Councils. No separate councils/registers exist for paramedical personnel like laboratory technicians, radiographers, opticians, speech therapists, physiotherapists etc; and in case of nurses and pharmacists information of their location and distribution is not available.

2. Management of Human Resources in Health : The performance of health system depends to a large extent on the development of its human resources. This includes framing policies for human resource development and management. Some of the areas which need attention include- recruitment, posting, transfer, clear job functions, match between the skills and functions, living and working conditions, professional development opportunities, transfer guidelines, performance based incentives, motivation, management & information and technology use for HR development. While meeting its own needs, the health system should also be able to match the aspirations of health personnel and provide opportunities for their personal as well as professional growth.

The public health system in India is plagued by issues of low motivation amongst its staff, high attrition rate, low productivity amongst others. The existing management policies and practices are out dated and ineffective - there is sharp public- private wage differential; unattractive incentive systems; unclear work roles, lack of recognition for good work; inadequate opportunities for career advancement and personal development; the recruitment, promotion and retirement policies are outdated; transfer policies tend to be unclear, further complicated by excessive political interference in transfers; there is a mismatch between functions and skills of staff; there is a lack of career development opportunities and of in-service training opportunities, poor working and living conditions for staff, and lack of systematic performance appraisals and monitoring and supportive supervision. Last, but not the least, private practice by government doctors is also common, thereby impact delivery of health services.

3. Shortage of human resources : Issues exist around numeric inadequacy of human resources. For instance, there is acute shortage of specialists (obstetricians, paediatricians, & anaesthetists, and of women doctors in rural areas). There are insufficient trained personnel for meeting the country's needs and demands for curative, preventive and promotive health. In part, this could be attributed to insufficient institutional capacity for production of health professionals, in particular, specialists; women doctors; public health workers and health

managers; paramedical personnel. Moreover, large vacancies exist for key cadres in public sector across levels of health care system. This in turn, could be due to low / no incentives; poor working conditions etc. Irregular staff attendance or absenteeism aggravates the shortages. Overseas and in-country migration of personnel (doctors, nurses and paramedical) is also common leading to further shortages.

4. Inequitable distribution of human resources : Human resources are inequitably distributed between the public and private sectors, across states and regions, between rural and urban areas. For instance, 80-90% of all qualified and trained resources are present in the private sector (including AYUSH) and in urban "better off" areas. In part this could be attributed to a lack of deployment policies.

5. Skill Mix Issues : In order to cater to the health needs of the community and deliver promotive, preventive and curative health care, it is essential to have the right skill mix at all levels of health care. The skill mix is to be planned in a way to optimally utilize the available resources (including human resources) as well as to deliver the required services. Staffing of health facilities has to be directed towards providing personnel with the right skills. At the same time, it is also pertinent to enhance the skills of health personnel to function in situations demanding application of two or more skills.

Orientation of medical personnel especially those exclusively dealing with clinical services to preventive & promotive aspects, public health management and epidemiology has been recognized as important way to train medical personnel meeting the needs of our country. Having built huge infrastructure and health personnel, it is essential to review the skill mix of personnel at different levels of care and carefully plan the staffing and delivery pattern. There is a distinct shortage of managerial and public health skills, especially at senior levels of the system.

6. Inadequate institutional infrastructure and capacity for education and training of all categories of HR : The need for trained human resources is enormous in India. For instance, under the National Rural Health Mission (NRHM) 6000 Block Mission Team and Block Resource Groups; 600 District level Mission Teams and Resource Groups; 35 State/UT level Mission Teams and Resource Centres; 1.75 lakh ANMs, 26000 LHV's, 26000 Staff Nurses; 26000 Medical Officers into Skilled Birth Attendants and 2 lakh ANMs, Nurses, etc at induction level need to be trained and supported. In spite of large scaling up initiatives, the existing institutional infrastructure is not adequate to meet the health requirements of the country.

Furthermore, the education and training of human resources is affected due to low funding, lack of quality faculty, lack of effective regulation of the private sector, persisting and unchanged legacy of conventional educational models; sub-optimal technical standards in medical and paramedical education amongst others.

7. Competency of health workforce : In terms of competency of health workforce, pre-service training is not adequately geared to capture the challenges of service delivery; need-based, job oriented training is not yet practiced widely; there is an inadequacy of infrastructure and training equipment ;

several training centres still use outdated teaching methods and materials; quality assurance mechanisms are often lacking and few opportunities exist for continuing education.

Possible Strategic Directions for Addressing the Challenges of Human Health Resources in India

Notwithstanding the various challenges of human resources, attempts are underway to address these critical issues. The launch of the National Rural Health Mission (NRHM) is a laudable step in this regard. Several initiatives for human resource development, manpower augmentation and strengthening of health management are already underway, both at the Centre and in the States/UTs. Some possible strategic directions that could be considered are :

Policy Making & Management

- Improve evidence base: Understand the health needs and demands of local populations.
- Systematically forecast and plan human resources to maximize responsiveness. The first step would be to set evidence based rather than population based norms; assessment of current workforce and future requirements with respect to the needs and demands of the population and the health system (A variety of diagnostic and planning tools are available and have been used in developing countries that use simulation models and scenario planning for forecasting, projecting and planning human resource. (Starkiene et al 2005). The WPRO/RTC health workforce planning workbook is one such tool that provides steps for developing an HR plan and includes a simple computer based planning model (Dewdney, 2001).
- Need for human resources policy to be integral component of the health policy / policy documents.
- States to be persuaded to sanction posts for human resources especially for key public health cadres.
- Increase age of retirement for specialists from 60 to 62, Specialists could be allowed to continue upto 65 years provided willing to serve in underserved areas.
- Improve information systems: Professional councils could streamline and enforce periodic renewal of registration.
- Decentralizing human resource planning to local bodies and to district level.
- Public private partnerships-for curative and preventive/promotive and non-clinical, especially for urban areas.
- Need for better understanding of the impact of migration on health care delivery, financial implications and health outcomes. Presently there is lack of adequate data on the nature of migration of health personnel in India.

Education & Training

- Increase training institutions for all types of health workers
- Relaxed norms for new medical colleges, especially in states without medical colleges
- Establishment of medical colleges in the public sector
- Existing manpower may have to be given short term course in public health
- Wherever possible PG seats in medical colleges to be increased on priority
- Explore possibility of a certificate course for accrediting informal providers including AYUSH practitioners

Enhancing Coverage

- Systematic forecasting and planning: based on needs rather than universal population size based norms
- Pool and optimize all available resources - allopathic & AYUSH; formal & informal
- Changing skill-mixes: allopathic & non-allopathic, formal & informal, doctors, nurses & paramedics to meet local health needs & demands
- Use of technology: computers, telemedicine, mobile phone technology, etc. to maximize reach and efficiency of all available health workers
- Innovations in medical education: reintroducing the shorter licentiate courses, recruiting students from rural educational backgrounds, incentives for rural service
- Innovative public private partnerships for increasing access to curative as well as preventive and promotive health care

Addressing Motivation

- Clear job roles and performance appraisals. Some States have develop job descriptions for various categories of staff
- Opportunities for in-service training and continuous professional development
- Financial and non-financial incentives for good work: linking promotions with qualifications/training and abilities rather than with seniority, and reducing political interference in transfers and promotions
- Better working conditions and safety from occupational hazards

Competence Building

- Create a cadre of community based providers who will be willing and able to live and work in rural areas, may be through revival of licentiate courses
- Improving standards of health education: improving technical skills as well as ration use of medicines and technologies
- Multi- skilling : e.g. an AYUSH practitioner trained in some essential allopathic treatments, training nurses as nurse anesthetists and as skilled birth attendants and training PHC doctors in emergency obstetric care and psychiatry
- Increase cadre of health providers who are trained in public health

Regulation

- Strengthening existing legislation and regulatory bodies to foster quality assurance for all categories of human resources.
- Innovative regulation - self regulation/peer regulation (e.g. accreditation); social franchising for informal sector.
- Licensing to ensure minimum standards.
- Decentralization of regulatory functions with strengthening of management capacity at all levels, including panchayati raj institutions.

To conclude, the health sector in India is at cross roads with having to deal with communicable diseases on one hand and rapidly increasing incidence of non-communicable lifestyle diseases on the other. This together with strengthening of health systems to deliver affordable, accessible and equitable services has been the thrust area of planning in recent years. One of the

key challenges in programme planning is the development and management of human resources.

In course-plotting the map for development of health sector, successive Five Year Plans have addressed various issues related to human resources and have recommended measures for building up this critical resource pool. From time to time, the Government has set up expert Committees to examine the existing health systems and provide recommendations on specific issues. Health workforce has featured prominently in these recommendations. Presently, various initiatives are underway to address these human resource challenges, both

by the government across levels as well as other stakeholders. Adopting a multi-stakeholder approach with strong impetus on capacity building, addressing of systemic issues such as governance and stewardship, evidence based action and developing implementable initiatives would help address these human resource challenges.

Amit Sengupta

The promotion of Health needs to address a large number of areas, such as nutrition, environment, economic and social well being etc. Within this larger framework, access to essential medicines is a major determinant of health outcomes and an integral, and often crucial, component of health care. It has been estimated by different sources that 50% to 80% of the Indian population are not able to access all the medicines that they need. The World Medicine Report (2004) of World Health Organization finds that India is the country with largest number of people (649 million) without having access to essential medicines. Given that India today is the 4th largest producer of drugs in the world and exports medicines to over 200 countries, this is clearly an unacceptable situation.

In an ideal situation all medicines that are researched and marketed should enhance therapeutic goals. Unfortunately the actual situation in the medicines market is much more complex. There are several issues that need to be addressed in order to pursue the broad goal of ensuring access to all medicines that a population may need.

The first issue relates to the price of medicines. Medicine prices often become a major determinant of access, especially in a country such as India where the income poor constitute a majority of the population. Studies indicate that poorer populations spend a larger proportion of health care expenditure in buying medicines. A World Bank Study suggests that out-of-pocket medical costs alone may push 2.2% of the population below the poverty line in one year (India - Raising the Sights: Better Health Systems for India's Poor, World Bank, May, 2001). The situation is compounded by the fact that, in India, the proportion of private expenditure, of the total expenditure on health is one of the highest in the world - 84% as compared to just 16% public expenditure.

The Concept of Essential Drugs

We shall turn later to one obvious way of addressing this problem, which is to do with mechanisms designed to control medicine prices. Another approach to ensuring access has been promoted by the World Health Organisation since 1978. It is called the "Essential Drugs" Policy. The policy starts from an understanding that it is necessary for countries to prioritise which medicines should be made available to all its population(1). Each country would need to develop its priorities based on the country's existing demographic profile and disease prevalence rates. The WHO defines "Essential Drugs" as those "that satisfy the health care needs of the majority of the population". The WHO further suggests that "they should therefore be available at all times in adequate amounts and in the appropriate dosage forms, and at a price that individuals and the community can afford".

The WHO, periodically, publishes a "Model" list of essential drugs (the first model list was published in 1978), but countries are encouraged to develop their own model lists, based on local

conditions. The use of such lists have led to the improvement in the quality of health care and the reduction of costs. The broad criteria (2) that are recommended for selection of drugs for inclusion in such a model list include the following:

1. The disease burden in a particular country and data on the efficacy, safety and comparative cost-effectiveness of available treatments. The evaluation process bases itself on a comparison between various drug products and on cost/benefit considerations. The advantage of a new treatment over the existing one is then compared to its extra cost. Such information has proved very helpful in taking informed decisions about the selection of essential drugs. When adequate scientific evidence is not available on current treatment of a priority disease, choice of certain drugs may either be deferred until more evidence becomes available, or a choice can be made based on expert opinion and experience.
2. Stability of medicines in various conditions (temperature, humidity etc.), the need for special diagnostic or treatment facilities (i.e. if the use of a drug requires facilities for monitoring biochemical or other parameters in the patient) and pharmacokinetic properties are also considered if appropriate.
3. It is recommended that most essential medicines should be formulated as single compounds. Fixed-ratio combination products are selected only when the combination has a proven advantage in therapeutic effect, safety or compliance over single compounds administered separately, viz. combinations to treat Tuberculosis and Malaria.
4. As cost is an important factor that determines access, the ability of populations to afford a drug (or of the public health system to be able to procure it) is an important consideration. In cost comparisons between medicines, the cost of the total treatment, and not only the unit cost of the medicine, is considered. Cost and cost-effectiveness comparisons are made among alternative treatments within the same therapeutic group. However, the absolute cost of treatment does not constitute a reason to exclude a medicine from the Model List if other selection criteria are met (i.e. if medicines required to treat a disease of major public health importance are expensive, but no cheaper alternatives that are safe and effective are available, then the medicines should be included in the list).
5. As the list is aimed at facilitating availability, countries are also encouraged to factor in issues such as local manufacturing capability and availability.

It needs to be underlined that the formulation of a national essential drugs list is only the *first* step towards the realisation of a policy to promote access to essential medicines. For the list to be useful, its application needs to be integrated in the formulation of a national medicines policy. This would mean that the national policy should include measures to ensure that the medicines in the national list are available to all who need them, are affordable and of good quality, and ideally are locally manufactured so that a reliable and constant supply is ensured.

Second, the national policy on use of medicines should promote the use of medicines on the list as a matter of first choice, both

in the public and private sector. This requires constant updating of the knowledge of prescribers, so that prescription practices are tailored to the essential list. Further, the essential drugs list should be accompanied by the development of evidence-based standard treatment guidelines. If prescribers are trained to use the essential drugs list as a guide, they also become more familiar with a relatively small set of medicines and are better able to recognise and report adverse events related to medicines use. Moreover, a limited range of drugs in the supply system may lead to economies of scale and competition between manufacturers, further reducing the costs.

An Essential Drugs Policy has been critiqued in certain quarters as one that restricts the freedom of practitioners to prescribe according to their choice. To the contrary a well designed Essential Drugs Policy is geared towards assisting prescribers in making a choice based on the best available evidence. An Essential Drugs list, ideally, should include all medicines that are necessary to treat more than 95% of illnesses that a physician is likely to encounter. This means that a policy based on the Essential Drugs List does not preclude the use of medicines outside the list, when it is so warranted.

An Essential Drugs List also needs to be dynamic, that is it needs to be updated periodically (every 2-3 years) in order to be able to capture recent advances in therapeutics and changes in disease prevalence scenarios. The WHO's model list is also a graded list of essential drugs, and countries are encouraged to do the same. A graded list indicates at which level of care (primary, secondary, tertiary) a certain medicine should be recommended. So while some medicines may be needed for all levels of care (e.g. an antipyretic like paracetamol), others may be needed at the secondary and tertiary levels only, or at the tertiary level only. The grading that is built into an essential drugs list is also a helpful planning tool, as it helps public health authorities to decide which medicines should be made available at appropriate levels.

Rational Use of Medicines

As we have seen above, an Essential Drugs Policy is a prerequisite for ensuring that physicians prescribe medicines based on sound scientific evidence. An ideal situation would be one where the only medicines that are available for prescribing, are those that are scientifically validated and are recommended in standard text books that students read in medical college. Unfortunately the real situation is very different, and students fresh out of college are suddenly confronted with a plethora of medicines that they have read little or nothing about. This happens because rational treatment goals and the goals of commerce that are pursued by drug manufacturers, are largely at variance. Drug manufacturers are driven by the need to maximise profits, not by the need to optimise therapeutic goals.

In India, an average family spends Rs.2,000 in buying medicines and on diagnostics. It has been estimated that at least 50% of this expenditure is incurred on irrational or unnecessary drugs and diagnostic tests. This adds up to a colossal waste of Rs.15,000 - 20,000 crores every year, and amounts to an average unnecessary drain of Rs.1,000 per year for every family. The first, and best known, part of irrational practices in

health care is related to irrational prescription of drugs. WHO has defined irrational prescribing as use of a therapeutic agent when the expected benefit is negligible or nil or when its usage is not worth the potential harm or the cost.

Irrational drug prescribing : It can occur when the medication prescribed is incorrect, inappropriate, excessive, unnecessary or inadequate. Accordingly, the types of Irrational Prescribing are:

- 1. Incorrect prescribing:** This means the use of wrong medicines to treat a disease or the use of medicines when no medicines are required.
- 2. Inappropriate prescribing:** This pertains to use of medicines that are not suitable for the particular patient, viz. use of medicines that may be harmful in pregnancy, in children, in older people, etc.
- 3. Over prescribing:** This is related to use of too many different kinds of drugs to treat a disease, when fewer (or just one) drugs would have sufficed. It also includes use of drugs for long periods, when a shorter course of treatment is adequate.
- 4. Multiple prescribing:** This means the prescription of more than one drug of the same kind (i.e. drugs which have the same effect) to treat a disease
- 5. Under prescribing:** This has to do with prescribing medicines for too short a duration or in inadequate dosage.

All these irrational practices are rampant in India. The reasons are manifold. One is to do with the proliferation of a large number of drugs in the Indian market that are either irrational or useless. With rapid developments in Science and Technology there has been an explosion in the number of drugs which are available in the market. Unfortunately only a small minority of drugs entering the market offer an advantage over existing drugs. A study in the U.S. showed that of the 348 new drugs introduced from the 25 largest US drug companies between 1981 and 1988 : 3% made an "important potential contribution to existing therapies"; 13% made a "modest potential contribution; and 84% made "little or no potential contribution". A more recent study by the French journal, *Prescrire International*, estimated that out of 2257 medicines introduced in the global market between 1981 and 2000, 0.31% were a major therapeutic innovation and 2.96% were an "important" therapeutic innovation, while 63.23% "does not add to existing clinical possibilities". The situation in India is no different and probably worse, given the fact that our Drug Control mechanisms are much more lax than in developed countries. The only reason why Indian studies are not available is because there is virtually no mechanism in India to monitor the use of irrational and hazardous drugs.

As a consequence there are an estimated 60,000 to 80,000 brands of various drugs available in the Indian market. On the other hand the WHO lists a little over 350 drugs which can take care of an overwhelming majority (over 95%) of the health problems of a country. In this situation of extreme anarchy the task of an already overstretched Drug Control Authority becomes almost impossible to cope with. A majority of the estimated 80,000 products in the market are either hazardous, or irrational or useless.

The pharmaceutical companies and the government regulatory bodies need to share the blame for allowing such a situation to develop. But all this would not be possible without the active involvement of the medical profession, who contribute by prescribing such irrational and useless drugs. One reason for this is the fact that there is almost no source of regular unbiased, authentic information on drugs available in the country. Given the rapid changes in treatment procedures and introduction of a large array of new drugs, medical practitioners need to update their knowledge regularly. Such a system of continuing medical education is largely absent in this country, and most doctors do not find the need to take time out from their busy practice to update their knowledge by reading the most recent books and journals. Thus we have the sad practice of a bulk of medical practitioners depending on promotional material supplied by Pharmaceutical companies. Obviously such promotional material only provides information to doctors, with a view to maximising the sale of the products being promoted. It thus makes it possible to sell a large number of useless and irrational drugs.

The problem is not limited to just a question of irrational or useless or harmful drugs. Rational, or even life saving drugs can be used in an irrational manner. The commonest problem is the unnecessary use of drugs. Thus, often we see expensive antibiotics being used for trivial infections. Moreover this is often accompanied by wrong dosage schedules. Another problem is the prescription of a large number of drugs for a simple ailment, when one or few drugs would have sufficed. Doctors, in many cases, when they are not sure of the diagnosis prescribe a large no. of drugs to cover for all the possibilities. Thus a patient coming with fever may be given some antibiotic, a drug to treat malaria, a drug to treat typhoid, etc. It may turn out that the patient was just suffering from a viral fever, which could have been treated with some paracetamol tablets, only. Such prescription practices increase the cost to the patient, unnecessarily exposes the patient to potential side effects, and in the case of antibiotics leads to drug resistance, i.e. a situation when these antibiotics become useless when they are really required.

Patients must also realise that if a Doctor advises no drugs, he is giving as valuable (or in some cases more) advice as someone who prescribes a large number of drugs. All illnesses do not require drugs -- in fact a large number of illnesses are "self limiting", i.e. the body cures itself without the use of drugs.

While the costs of individual drugs is very important, what affects patients is the total cost of treatment. Irrational drug use increases treatment costs, at times enormously, by promoting use of drugs when they are not indicated. Such use has implications for health outcomes too, and at the same time add unnecessarily to treatment costs. While a lot of anecdotal references are available that indicate this, unfortunately there are few systematic studies that quantify the impact of irrational drug use on costs. A single District study (3) done in Satara, Maharashtra, in the 1990s, provides some indication of the massive costs of irrational drug use. The study showed that due to irrational prescribing, 69% and 55% of the money spent on prescriptions in the private and public sector respectively, was a waste. Projected to the whole district, this wastage amounts

to Rs.17.7 crores out of the total drug supply of Rs.22 crores. It concluded that if all the patients in Satara district were to be adequately and rationally treated, the drug-expenditure would have been less than the amount actually spent on drugs in the District (both public and private included) - Rs.20.61 crores, compared to the total drug expenditure of Rs. 21.84 crores. If we extrapolate the results of this study to the national level, it would mean that the present expenditure on drugs in the country is adequate to treat all patients, if rational prescribing norms were adhered to.

Promotion of Medicines by Medicine Companies

Irrational prescribing and aggressive promotion of medicines by drug companies go hand in hand. Companies spend large amounts to promote medicines, and this is particularly so when they need to promote medicines that are irrational and their use is contrary to scientific evidence. There is insufficient data in India to quantify the impact on drug prices. An indication may however be found from a recent study in the US (4), that examined the quantum spent on promotion by US drug companies in the US market. The study concluded that the drug industry spent around US\$61,000 in promotion per physician in 2004, and further that as a percentage of US domestic sales promotion consumed 24.4% of the sales.

Effective medicines have an obvious marketability and demands are self-generating. But any drug that is therapeutically not valid needs artificial generation of demands and contributes to unethical marketing practices. Irrational prescribing practices are often initiated and maintained by marketing techniques of the drug industry. The industry spends 20% of its annual sale or about Rs. 3,000 crores in advertising; this works out to about Rs. 50,000 per doctor per annum and each doctor prescribes drugs worth Rs. 250,000 per annum.

Drug companies have been known to use incomplete or misleading evidence to promote irrational medicines. Physicians are sought to be influenced by a variety of inducements and sponsorships. Such a practice gets perpetuated also because prescribers depend on information provided by drug companies, as there is scant availability of unbiased information on the rational use of medicines.

Unlike in India, many countries control the promotion of medicines through ethical guidelines, such as the model guidelines authored by the WHO (5). Policies in India need to consider the fact that large investments made by drug companies push up medicine costs and promote irrational prescription practices.

Prescribing of Medicines by Generic (non-proprietary) Names

A fresh medical graduate is often confronted with a situation that medical college seldom prepares them for - the need to make sense of a huge variety of brand names of medicines. While medical education relies almost entirely on familiarising students with the scientific names of medicines (i.e. generic or non-proprietary), an overwhelming bulk of prescribing is done by the use of Brand (proprietary) names. The promotion of generic prescription has always been seen as a primary requirement for ensuring of rational use of medicines. It is globally acknowledged that aggressive promotion of Branded

medicines by pharmaceutical companies, much of which is unethical, leads to irrational prescription practices. Prescriptions based on Brand names also allow commonly prescribed branded drugs to be priced much higher than generic equivalents. In India the situation is further compounded by a lack of avenues and requirements for continuing medical education - thereby leaving doctors at the mercy of pharmaceutical companies to update their knowledge about newly introduced medicines. This opens the door for prescription practices that are driven, on many occasions, not by therapeutic needs but by promotion of specific brands.

For efforts aimed at encouraging prescription of medicines by their generic names to be successful, there are some crucial areas that need to be addressed. Critiques of the mandatory introduction of generic prescription argue that prescriptions based on generic names compromises the ability of doctors to prescribe quality medicines. The argument is premised on the belief that there is a major variation in the quality of medicines in the Indian market, thereby requiring brand names to identify quality drugs. While the concern for quality is not incorrect, it is also true that substandard drugs are also produced or marketed by large companies with big reputations - both Indian and Foreign. It is also a common practice today for big companies to get their drugs manufactured in the small scale sector. Thus the issue is really one of implementing quality control measures at all levels - which if not done will always compromise attempts to promote prescriptions by generic names. If issues about quality remain doctors could well just shift to prescribing by the generic name and identify the company as well. This would defeat the whole purpose of introducing generics to foil monopoly pricing based on brand images.

The other issue is the necessity to have qualified pharmacists at retail outlets for medicines. This is a requirement if Chemists are to have the authority to substitute generic versions of the same drug. Today there are not enough pharmacists to service all medicine shops and the issue needs to be addressed. What also needs to be ensured is that pharmaceutical companies do not start targeting Chemists more aggressively to promote their drugs once generic names are introduced.

Pricing of Medicines

Finally, the big issue that determines the access to medicines for poor people, relates to how medicines are priced. The WHO states (6) : "In 1975, less than half the world's population were estimated to have regular access to essential medicines. New estimates from the 1999 World Medicines Survey show that this fraction has fallen to around one third. However absolute number of people without access has remained unchanged, at about 1.7 billion. Getting the right medicines to the people who need them at the time they need them remains a major challenge."

Studies indicate that poorer populations spend a larger proportion of health care expenditure in buying medicines. Given, that a very large portion of this cost is borne by patients themselves, there is clear evidence that the cost of medicines is a major barrier to access to health care. A World Bank Study(7) suggests that out-of-pocket medical costs alone may push 2.2% of the population below the poverty line in one year.

The situation is compounded by the fact that the proportion of private expenditure, of the total expenditure on health is one of the highest in the world - 84% as compared to just 16% public expenditure. The NSS (National Sample Survey) 55th round on consumer expenditure shows that 77% of health expenses in rural areas and 70% in urban areas is on medicines alone. Poorer the people, larger the share of expenses on medicines.

Clearly the situation requires attention from regulatory agencies in the form of controls on the prices of medicines. Price control is a form of market regulation that limits the capacity of the supplier to set the price of a product. Price control usually takes the form of a maximum price (ceiling), which means that the supplier is allowed to set a lower price. The mechanics of price control usually differ from country to country, but the end result is normally the same: the pharmaceutical companies are prohibited from charging a market-based price for the products they manufacture. Interestingly, most developed countries implement price regulation for pharmaceuticals that cover the majority of their population. The methods of regulating prices vary. In stark contrast, the majority of developing countries do not regulate pharmaceutical prices.

India introduced a very stringent regime of price control on medicines in 1978, whereby the prices of 378 medicines were controlled. However, in the last thirty years the price control regime, that is administered by the Drug Price Control Order (DPCO) has been significantly relaxed. Today only 74 medicines are under price control, and as the last time the list of medicines under control was drawn up was in 1995, many of the medicines under price control have ceased to be of importance.

The decontrol of medicine prices in India in the last 30 years have been premised on the argument that drug prices do not need to be controlled if there is competition in the market, i.e. if there are several companies who market the same medicine under different brand names. However the experience has been that this assumption is largely false. This is shown to be so by the fact that most top-selling brands are more expensive than brands of other companies making the same medicine, and in some cases the most expensive among all competitors.

The reason why competition in the market does not depress medicine prices is manifold. First, in the pharmaceutical market the decision to buy a drug is not taken by the consumer but is based on a Doctor's prescription or a pharmacist's choice. Prescription practices of doctors are prone to being influenced by marketing strategies of drug companies, and chemists are also influenced by inducements provided by companies. Second, unlike in the case of consumer goods, patients do not have the choice not to buy if they are in need of medicines. Third, in India over 80% of medicines are bought by patients from their own finances. This is the reverse of the situation in most developed and many developing countries, where public health insurance or the public health services provide for over 80% of medicines consumed. Thus patients in India, especially poor patients bear the brunt of high medicine prices.

The shift in policies in India, that has led to most medicines being outside price control today, have been increasingly questioned. The Government is believed to be actively considering the imposition of price controls on a much larger number of medicines.

Drug Policy Formulation in India

Drug policies in India are formulated by the Ministry of Chemicals and Fertilizers. In addition, in 1997, the National Pharmaceutical Pricing Authority (NPPA) was instituted as an independent body to take decisions on pricing. The Ministry of Health and Family Welfare looks into the issues of quality, manufacturing, sales and distribution of drugs. These two functions are performed in isolation and there is minimal co-ordination between the two major areas of policy making in the pharmaceutical sector.

As a consequence the drug policy focuses only in the areas of production and pricing. Drug policies, thus formulated, have not incorporated a focus on health. In successive policies, the emphasis has shifted to addressing the viability of the private pharmaceutical industry. In the absence of a coherent link between health needs and the policies on drug pricing, issues of equity have been generally ignored.

In addition there are other Acts that regulate the use of medicines. The prominent ones are the Drugs and Cosmetics Act that deals with manufacturing and quality norms, prescribing norms etc. and the Magic Remedies Act that deals with the promotion and advertising of medicinal products. The Drug price Control Order (DPCO) lays down regulations for controls over drug prices. The Magic Remedies Act, especially is outdated, and requires a major overhaul as it contains provisions that are of little or no relevance in today's context.

According to guidelines formulated by the WHO (8), a national drug policy is a commitment to a goal and a guide for action. It expresses and prioritizes medium- to long-term goals set by the government for the pharmaceutical sector, and identifies the main strategies for attaining them. It provides a framework within which the activities of the pharmaceutical sector can be coordinated. It covers both the public and the private sectors and involves all the main actors in the pharmaceutical field. In the broadest sense, a national drug policy should promote equity and sustainability of the pharmaceutical sector. The present practice in of drug policy making in India is thus at variance of such accepted norms.

There is thus, the need to formulate a National Pharmaceutical Policy that addresses the critical issue of universal access to essential medicines. Such a policy needs also to harmonise different aspects of the Drugs and Cosmetics act and the Magic Remedies Act. This policy should be prepared by an intersectoral committee of the Ministry of Health & Family Welfare and Ministry of Chemicals & Fertilizers after discussions with all sections that have a stake in the pharmaceutical sector. The two should jointly constitute a National Drugs and Therapeutic Authority, which should be a statutory body with powers to regulate all aspects of the National Pharmaceutical Policy.

Summary

Access to essential medicines is a major determinant of health outcomes and an integral, and often crucial, component of health care. An approach to ensuring access has been promoted by the World Health Organisation since 1978 called the "Essential Drugs" Policy. It defines "Essential Drugs" as those "that satisfy the health care needs of the majority of the population". The

WHO further suggests that "they should therefore be available at all times in adequate amounts and in the appropriate dosage forms, and at a price that individuals and the community can afford". The WHO, periodically, publishes a "Model" list of essential drugs but countries are encouraged to develop their own model lists, based on local conditions. The national policy should include measures to ensure that the medicines in the national list are available to all who need them, are affordable and of good quality, and ideally are locally manufactured so that a reliable and constant supply is ensured. An Essential Drugs List also needs to be dynamic, that is it needs to be updated periodically.

WHO has defined irrational prescribing as use of a therapeutic agent when the expected benefit is negligible or nil or when its usage is not worth the potential harm or the cost. Irrational drug prescribing can occur when the medication prescribed is incorrect, inappropriate, excessive, unnecessary or inadequate. Irrational prescribing and aggressive promotion of medicines by drug companies go hand in hand. Policies in India need to consider the fact that large investments made by drug companies push up medicine costs and promote irrational prescription practices. The promotion of generic prescription has always been seen as a primary requirement for ensuring of rational use of medicines.

Finally, the big issue that determines the access to medicines for poor people relates to how medicines are priced. Clearly the situation requires attention from regulatory agencies in the form of controls on the prices of medicines. Price control is a form of market regulation that limits the capacity of the supplier to set the price of a product. In India the price control regime, administered by the Drug Price Control Order (DPCO) needs to be more stringent.

Drug policies in India are formulated by the Ministry of Chemicals and Fertilizers. In addition, in 1997, the National Pharmaceutical Pricing Authority (NPPA) was instituted as an independent body to take decisions on pricing. The Ministry of Health and Family Welfare looks into the issues of quality, manufacturing, sales and distribution of drugs. These two functions are performed in isolation and there is minimal co-ordination between the two major areas of policy making in the pharmaceutical sector. In addition there are other Acts like Drugs and Cosmetics Act, the Magic Remedies Act, Drug price Control Order (DPCO) that regulate the use of medicines. There is thus, the need to formulate a National Pharmaceutical Policy that addresses the critical issue of universal access to essential medicines and need for joint constitution of ministries to form a National Drugs and Therapeutic Authority, which should be a statutory body with powers to regulate all aspects of the National Pharmaceutical Policy.

Study Exercises

Long Question : What are the possible approaches/policies to ensure universal accessibility and availability of Drugs? Describe Essential drug policy in India.

Short Notes : (1) Essential Drug policy (2) Rational prescribing of drugs

MCQs

1. It is recommended that essential drug list in any country is to be updated at least every (a) 1-2 yrs (b) 2-3 yrs (c) 6 months (d) 3 months
2. Irrational drug prescribing can occur when the medication prescribed is (a) Incorrect (b) Inappropriate (c) Excessive (d) All the above
3. In India Drug policies are formulated by the Ministry of (a) Chemicals and Fertilizers (b) National Pharmaceutical Pricing Authority (c) Ministry of Health and Family Welfare (d) None of the above
4. An Essential Drugs list, ideally, should include all medicines that are necessary to treat more than ___% of illnesses that a physician is likely to encounter. (a) 100 (b) 95 (c) 90 (d) 50

Answers : (1) b; (2) d; (3) a; (4) b.

110 Medical Education in India

There were 30 medical colleges in India at the time of independence which have expanded to 262 medical colleges now. The annual turn out is of about 24000 medical graduates every year. The system of medical education in India is basically westernized and hospital oriented since its origin about 150 years ago. This has not undergone much change over all these years. There is still lack in the production of basic doctors, competent enough to provide primary health care and meet the requirements at the grass root level. Health related education and training has become more urban oriented, doctor-centric and technology-driven; the quality, quantity and distribution of the health oriented human resources being produced leaves much to be desired. Over the years, the bulk of the growth in medical education institutions has occurred in the richer states, potentially leading to increased regional inequity in access.

Aim of medical education

The aim of medical education is to:

1. Impart theoretical knowledge about patient care and health needs.
2. Teach practical procedures for diagnosis, treatment, communication and management.
3. Create competence and motivation to serve the health needs of the country and its people.

Current Scenario

The medical education system in India is a heterogeneous system. It is broadly classified into:

- Allopathy, or Non Indian System of Medicine (NISM)
- Indian Systems of Medicine and Homeopathy (ISMH)

There are at present, the following number of recognized

medical, dental and nursing colleges in the country, with the respective number of seats:

1. Medical: Colleges = 262; Seats = 30558
2. Dental: Colleges = 204; Seats = 11850
3. Nursing: Colleges = 116; Seats = 2845

Higher Organisation

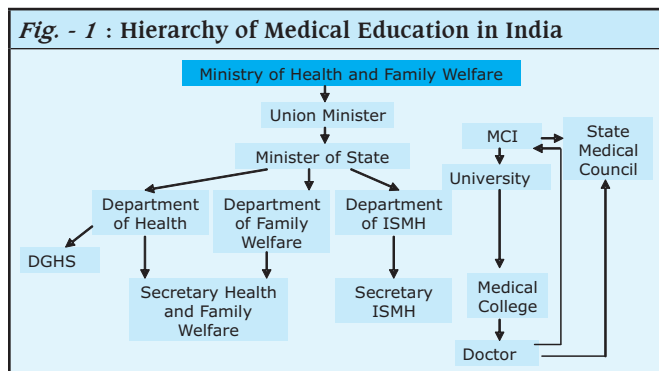

The medical education system in India comes under the Ministry of Health and Family Welfare which has the Department of Health, the Department of Family Welfare and the Department of ISMH. It is headed by the Union Minister. There is also a Minister of State for Health and Family Welfare. The Health Secretary is an IAS officer who looks after the affairs related to the Department of Health and the Department of Family Welfare, whereas the Department of ISMH has its own Secretary. The Director General of Health Services is associated with the Department of Health. Besides, there are various technical officers in the department. The flow chart is shown in figure-1.

The Medical Council of India : The Medical Council of India was established as a statutory body under the provisions of the Indian Medical Council Act, 1933 which was later repealed by the Indian Medical Council Act, 1956. A major amendment in the Indian Medical Council Act, 1956 was made in 1993 to stop the mushroom growth of medical colleges, increase of seats and starting of new courses without prior approval of the Central Government in the Ministry of Health and Family Welfare. The main functions of the Council are:

1. Maintenance of uniform standards of medical education at undergraduate and post-graduate level
2. Maintenance of Indian Medical Register
3. Provisional/permanent registration of doctors with recognised medical qualifications and registration of additional qualifications

- 4 Reciprocity with foreign countries in the matter of mutual recognition of medical qualifications.

Fig. - 1 : Hierarchy of Medical Education in India

Universities and Deemed Universities : The function of the universities is to ensure proper and systematic instruction, teaching, training and research in the institutions affiliated to them. They ensure balanced growth in the various fields of medical sciences and also maintain uniformity in various courses offered by the institutions affiliated to them. A doctor passes out of a medical college affiliated to a university and gets registered with the MCI and/or the State Medical Council in order to practice medicine.

Structure of Medical Education in India

Most of the medical colleges in the country are located in urban areas. There is a geographic mal-distribution of the medical colleges all over the country. The six states of Maharashtra, Karnataka, Andhra Pradesh, Tamil Nadu, Kerala and Gujarat have a total of 63% of the medical colleges and 67% of total medical seats in the whole country. The North Eastern states, on the contrary, have only 3% of medical colleges. Almost 50% medical colleges in the country are in the private sector. This number has more than doubled from 60 in 2000 to 131 in 2006. The number of seats at the undergraduate level has increased by nearly 5 times while the number of institutions has increased by eight times during 1970 to 2004.

ISMH : The developments in ISMH education parallel these trends. The number of ISMH institutions increased by nearly 70 percent over the last two decades. Nearly 82 percent of all ISMH enrollment capacity in training and 76 percent of all ISMH training institutions are in the private sector. Almost all of the increase in ISMH institutions during the last two decades has occurred in states with the richest of the population. The Department of Ayurveda, Yoga & Naturopathy, Unani, Siddha and Homoeopathy (AYUSH) was established as Department of Indian Systems of Medicines and Homoeopathy (ISM & H) in Ministry of Health & Family Welfare in March, 1995, to oversee the educational process in this system.

Process of Medical Education

Selection of Students : The selection of students is based on the marks obtained by students on the basis of a MCQs test. The test is usually directed towards testing of mere recall of facts. The humanistic approach, attitudes and communication skills are hardly assessed. Merit in the board examinations or

competitive tests is not combined with any aptitude test (except in few institutions that have their own entrance exam) to form the criteria for selection tests. However, there is also non-availability of appropriate objective instruments for testing aptitude in large number of students at present. Besides, the private medical colleges offer subsidized “merit seats”, based on a common entrance exam. Remaining seats are offered through “management” quota, apparently on considerations of merit, but do require substantial fees.

Teachers : Criteria are laid down explicitly by the MCI in terms of the basic University or equivalent qualification, the experience, the number of papers published (in national and international journals), as well as the number of teachers authorized to a particular type of medical institution.

Courses : For the undergraduate, the course is for a period of 5 1/2 years. The pattern of curriculum is split up as follows:

- 1 year: basic sciences
- 1 1/2 years: para-clinical sciences
- 2 years: clinical subjects

Compulsory rotatory internship has to be there for a period of 1 yr after completing the final year. Recent recommendation has been of a compulsory rural phase for all graduates before they can be awarded the bachelor's degree. For the post-graduate, there are three main types of “post-graduate” training opportunities:

- 3 year residency programs i.e. MD or MS
- 1 or 2 year long diploma training programs and DNB

For super specialization, there are super-specialty residency programs in medical and surgical specialties for those who have completed the MD/MS or the DNB.

Curriculum : The curriculum is well laid out. Horizontal and vertical integration of the subjects is advocated e.g. anatomy with physiology and anatomy with surgery, respectively. The division into theory classes and practicals for all subjects as well as topics is well laid out.

Assessment : Periodic assessment is advocated, both objective and subjective. But actually, it is the textual knowledge that is mainly assessed.

Internship : Compulsory rotatory internship for a period of one year is there, following the completion of the undergraduate course. 3 months each is laid down in the field of medicine (and allied subjects), surgery (and allied subjects), obstetrics and gynaecology and preventive and social medicine.

Specialisation : All medical graduates are eligible for specialization after completion of internship. Seats for the same are available through an all India exam, state PG medical entrance exams and PG medical entrance exams of private institutions.

Issues

Current Scenario : The medical education system in India is more westernized. The western model has not been adapted well to Indian realities. The settings for training are different than the ground realities. Doctors are usually not competent enough to provide primary health care. Medicine used to be a highly sought after profession earlier. But it is minus the “nobleness” now. The status is falling now and it is losing the

luster. Over the years, there has been a disproportionate growth of institutions which has been more in richer states. This has led to increased regional inequity.

Higher Organisations : The higher organizations tend to have a dictatorial approach. The MCI wants at least a particular number of teachers in a medical institution, at the same time itself being the body which has a documented deficiency of many at all levels. It is ironical when the MCI itself fails to understand such problems and derecognises institutions for lack of teaching faculty. Often there are politically motivated decisions as well as vested interests, with many politicians owning medical colleges. At the top positions in the government, there are bureaucrats instead of technocrats who handle the affairs related to medical education. The former can hardly be trusted for their knowledge of technical matters as the latter can be.

ISMH : It is not clear as to where do these doctors practice. Many are in competition with allopaths. Many more actually are practicing allopathy. This is happening especially in the private nursing homes and clinics where they are employed at lesser salary and allowed to practice allopathy. Also, we do not know of any regulatory body for them like the MCI.

Issues with Process of Education

Selection of Students : The selection of students is by MCQs tests. This involves a mere recall of facts. There is no subjective assessment of aptitude of the students. At the same time, it is actually difficult to do an aptitude test on such a large scale, as lakhs of students appear in the medical entrance exams every year. In assessing the students by a MCQs test alone, the approach, attitudes and communication skills are hardly assessed.

Selection of Teachers : While selecting teachers, aptitude to teach is hardly assessed. A good student may not be a good teacher since there is a difference in acquiring knowledge and being able to impart the same. Adequate training in the techniques of teaching is rarely imparted to them. Teachers are not held accountable to the students. The teacher's performance is taken for granted and his or her competence in teaching is never questioned. There isn't much accountability and monitoring of the teaching faculty towards fulfillment of their teaching responsibilities. Besides this, it is observed that research is taking precedence these days over patient care, in the clinical specialities.

The last inspection conducted by the MCI showed that a large number of doctors are claiming employment as medical teachers in more than one medical college at the same time. It was being observed that the names of the doctors shown as medical teachers in a particular medical college were getting repeated in the inspection reports of certain other medical colleges, in the same proximity of time. Apparently, the medical colleges and the medical teachers were indulging in such activities only to show to the inspection team of the Council that the colleges concerned are fulfilling the minimum requirement for the teaching staff for seeking permissions/renewals. The pathetic state can be gauged by the fact that there are reports that even in government medical colleges, teachers are transferred from one college in the state to another, just before an anticipated

MCI inspection, so as to show to the inspecting team that there is no shortage of teaching staff !

Continuing Medical Education : The concept of Continuing Medical Education (CME) is a good one that helps keep the professionals abreast of the latest knowledge. But a resistance to change has been observed on the part of doctors. Most lack motivation to attend CMEs. These days, CMEs have been reduced more to pharmaceutical industry driven activities only. Many doctors utilize this opportunity for furthering their own careers.

Curriculum : The pattern of curriculum is fragmented. Subjects are taught in isolation. There is little or no integration of the basic sciences with the clinical disciplines. Often there is neglect of realities of rural and remote areas. The medical graduate, after passing out, finds himself more at home in better developed countries, than in the villages of India since he has been trained at an institute akin to a tertiary care set-up. There is over-burdening with theoretical knowledge. Due attention is not given to subjects like medical ethics, behavioral sciences, communication skills and managerial skills. This puts the medical graduate at a disadvantage when after passing out he/she gets posted to a PHC and has to manage the men, materials and money all alone.

Over the years, there has been a tendency to increase the number of subjects in which the student is to be independently assessed. For instance, fifty years back, medical curriculum had 10 subjects which were to be studied in 5 years; today a medical student has to cope up with 13 subjects in 4 ½ years; the number of subjects may further increase in the next couple of years to come.

Assessment : It is common knowledge that learning is driven by the method of assessment. Examinations are knowledge dominated rather than skill oriented. Performance of students is assessed in comparison to other students (peer-referenced), or norm-referenced rather than a standard criterion (criterion-referenced). This is what happens in practice, since most of the examinations in medicine do not have a clear criteria laid down beforehand for the purpose of assessment. Regular feedback is not provided to students during the training. There is dilution of the requisite standards of teaching and the transparency in examinations and results are also doubtful in most institutions.

A senior faculty of a premier medical college in India says, "We accept racehorses and turn out asses", meaning thereby that we accept the best students into the college after an entrance exam, but do not teach them as they should be taught, before they pass out as doctors.

Clinical Skills : Investigative medicine has largely taken over these days. This is likely to increase the cost of medical care and learning. Learning on the part of the students is inadequate to make a sound clinical judgement. Skills of traditional clinical bedside history taking, physical examination, formulation of differential diagnosis, and planning a diagnostic and management plan for various problems are not well inculcated.

Internship : The period of internship is not effectively utilised to develop and refine clinical skills. More often it is utilised

for preparation of postgraduate entrance examinations. Irregularities in attendance have been observed, especially during rural attachments. Lack of interest has been noticed in case of medical officers under whom the interns get attached. Rural works, preventive activities are not attractive to interns who are not motivated at the end of their undergraduate days. Moreover they feel that 6 months period of rural internship is too long a period which deprives them of the clinical experience in hospitals that they value more. Internship is more about completion in paper at most places and less to do with acquiring skills. Ground realities observed in studies conducted showed that 30% students had not performed simple procedures like recording the weight of mother and infant, 30-40% had never given any immunization while 70% had never prescribed common contraceptive methods like condom or oral pill.

Specialisation : There is inadequate training for service in rural areas. There is a lack of production of “basic” doctors who are able to deliver primary health care at the community level. Medicine, surgery and their super specialties are more popular among the fresh graduates. Less importance is given to community based education compared to institution or hospital-based education.

Privatisation of Medical Education : Measures are required to ensure proper regulation of medical education in these institutions by the medical council. Growing merchandisation of medical education has been observed in certain private institutions. Certain such institutions have been found to be substandard. Improper admission practices under the management quota have been observed. There is compelling evidence that many private medical colleges are short of staff and infrastructure, including hospital beds.

Recommendations

In view of the above mentioned problems, following recommendations are put forward:

- 1 Increase in the number of human resources at all levels should be done
- 2 Shortage of experienced teachers should be met
- 3 Performance of teachers should be assessed from time to time
- 4 Teachers should be made more accountable
- 5 There should be revamping of the teacher training at all levels and promotion of development of teaching aids to retain student attention in classrooms
- 6 Academic recognition should be given to the teachers for their contribution
- 7 It is important to encourage and reward teachers who show a flair for teaching and adopt innovative teaching methods
- 8 Career prospects of teachers need to be enhanced, by giving promotions more frequently, rather than stagnation at certain appointments
- 9 There is a need to shift from knowledge dominated examinations to more skill oriented examinations for the students
- 10 Assessment should predominantly be based on the core curriculum and should be criterion referenced, i.e. the performance of students is assessed against a standard

- 11 criterion and not just in comparison to others
- 11 Radical changes are required in the evaluation system to encourage scientific thinking and promote better understanding of basic science concepts
- 12 Objective and subjective feedback to students should be given to help them improve their deficiencies, instead of a mere verbal input on their performance
- 13 Thrust is needed during the training in the basic skills in human resource management, leadership qualities (ability to lead a health care team) and providing cost effective care in rural/non-hospital settings
- 14 Internship training should be revamped so that it is not just a repeat learning of the skills but should be aimed at delivery of health services
- 15 A formal assessment at the end of internship can ensure proper utilisation of this period for development of skills
- 16 Greater importance needs to be given to community based education rather than institution or hospital-based education
- 17 PG entrance examinations should be made more suitable for testing higher level of knowledge and skills rather than mere recall of facts
- 18 There is a need to urge medical students to look at specialising in disciplines on considerations other than their market value
- 19 The profession should be made financially more gainful
- 20 At the top positions in the government, in addition to the bureaucrats, there is a need for more technocrats to handle the affairs related to medical education
- 21 The state-wise skewed distribution of doctors should be corrected by providing adequate and as far as possible, equal facilities in all states
- 22 Rural health services need to be made more attractive - by improvements in position, pay, facilities and job satisfaction
- 23 New institutions need to be raised in rural and backward areas (In the 11th Five Year Plan: 2007-12, the government plans to set up six institutions like the All India Institute of Medical Sciences and upgrade 13 existing medical institutions)

There is a need to revamp the medical education system in our country. The aim of professional education in health must be production of a cadre of professionals who would have competence as well as motivation to serve the health needs of the country and its people as a whole. The number and type of medical training institutions in India is entirely disproportionate to the actual needs of the vast majority of people. We must train professionally competent doctors and bring back the nobleness in the profession. Concurrent concepts and modalities of implementation are not conducive to our achieving the aims of medical education in India. And although India is, no doubt, still producing good doctors, the standards vary to an alarming extent. That most young doctors - irrespective of their ability, emerge with a jaundiced view of the integrity of the medical system is probably no bad thing. It prepares them for the future; they have to be politically aware. Being bright and highly motivated is simply not enough. Therefore, there is a need to change.

Summary

At the time of independence, there were 30 medical colleges in India, which have expanded to 262 medical colleges now. The annual turn out is of about 24000 medical graduates every year. The system of medical education in India is basically westernized and hospital oriented since its origin about 150 years ago. There is still lack in the production of basic doctors, competent enough to provide primary health care and meet the requirements at the grass roots level. Most of the medical colleges in the country are located in urban areas. There is a geographic mal-distribution of the medical colleges all over the country. Currently, the medical education system in India is broadly classified into Allopathy, or Non Indian System of Medicine (NISM) and Indian Systems of Medicine and Homeopathy (ISMH). It comes under the Ministry of Health and Family Welfare which has the Department of Health, the Department of Family Welfare and the Department of ISMH. It is headed by the Union Minister. There is also a Minister of State for Health and Family Welfare. The Director General of Health Services is associated with the Department of Health. The Medical Council of India is the apex body that regulates the medical education in India. The selection of students is on the basis of a MCQ test that tests mere recall of facts. For the undergraduates, the course is for a period of 5 1/2 years whereas for the post-graduates it is for 3 years (MD/ MS) and 1 or 2 years (Diploma). The curriculum is well laid out. Horizontal and vertical integration of the subjects is advocated. But actually the pattern of curriculum is fragmented and the subjects are taught in isolation. Both objective and subjective periodic assessment is advocated. Besides, the concept of CME is advocated that have been reduced merely to pharmaceutical industry driven activities these days. Many doctors utilize this opportunity for furthering their own careers. Irregularities in the placement of teaching faculty were observed during the last MCI inspection. Investigative medicine has largely taken over these days. This is likely to increase the cost of medical care and learning. Skills of traditional clinical bedside history taking, physical examination, formulation of differential diagnosis, and planning a diagnostic and management plan for various problems are not well inculcated. The period of internship is not effectively utilised to develop and refine clinical skills. More often it is utilised for preparation of postgraduate entrance examinations. Irregularities in attendance have also been observed. Measures are required to ensure proper regulation of medical education in private institutions by the MCI as well as similar regulation of the ISMH colleges. The aim of professional education in health must be production of

a cadre of professionals who would have competence as well as motivation to serve the health needs of the country and its people as a whole. Therefore, there is a need to revamp the medical education system in our country.

Study Exercises

Long Question : Critically review the current medical education system in India.

MCQs:

1. A medical graduate needs to get his degree registered with the following: (a) Ministry of Health and Family Welfare (b) MCI (c) State Medical Council (d) MCI and/ or State Medical Council
2. The Ministry of Health and Family Welfare has the following departments: (a) Dept. of Health and Dept. of Family Welfare (b) Dept. of Health, Dept. of Family Welfare and the Dept. of ISMH (c) Dept. of Family Welfare (d) Dept. of Health
3. The various departments under the ministry are headed by: (a) Secretary, Dept. of Health and Family Welfare (b) Secretary, Dept. of Health (c) Secretary, Dept. of Health, Family Welfare and ISMH (d) Secretary, Dept. of Health & Family Welfare and the Secretary, Dept. of ISMH
4. ISMH comprises of: (a) Ayurveda, Yoga, Unani, Siddha and Homoeopathy (b) Allopathy, Yoga, Unani, Siddha and Homoeopathy (c) Ayurveda, Yoga & Naturopathy, Unani, Siddha and Homoeopathy (d) Allopathy, Yoga & Naturopathy, Unani, Siddha and Homoeopathy
5. The Indian Medical Register is maintained by: (a) Ministry of Health and Family Welfare (b) MCI (c) State Medical Council (d) Both the MCI and State Medical Council

Answers: (1) d; (2) b; (3) d; (4) c; (5) b.

*Kunal Chatterjee***Urban Slums**

The growth of slums in the cities has accompanied the pace of their industrialisation. Migration of people from rural to urban areas has compounded the housing problem in the latter and these people settle in shanty towns and slums in the fringes of the cities. Majority of them are economically backward, less educated and poorly paid workers prone to ill health due to overcrowding, poor housing, unsanitary environment and poverty. As per the 2001 census in the country, in cities with population of over one million, nearly one-fourth of the population reside in slums. Slum areas include the recognised and unrecognised slums, temporary settlements and pavement dwellers of whom the latter two are the poorest and the most needy.

Problems in urban slums

Change in the environment : The necessities enjoyed freely by slum dwellers while residing in rural areas, become commodities in the urban areas such as drinking water, cooking fuel, housing space etc. Marginal increase in income for the urban poor does not by itself assure better living conditions. Relative difference in income and wealth with the rich in the cities drives up the prices of food, health care goods and essential commodities, making them unaffordable to the poor. The change in environment for the people who have migrated to slums from rural areas has strong impact on their livelihood.

Social support : Consumption of public goods such as water, infrastructure and electricity is higher by the richer people, who also enjoy the subsidies provided by the government for these goods. The urban laws look upon migration as the root cause of all problems in the cities, as a result the migrants are denied the right to housing, their infrastructure is neglected and they are not provided easy access to basic health care. This aggravates the economic dependency already prevalent in the urban poor.

Access to water supply : Water supply in urban slums is usually not satisfactory. Per capita consumption of water in slums is less than in non-slum areas in a city. Water is supplied in common water points in slums. Overcrowding reduces the quantity available per head and subsoil water through borewells also does not prove sufficient. At times contamination of ground water table due to proximity to industries affects its quality thereby reducing the available water supply even further.

Sanitation in surroundings : As a result of higher population density in the slums, the total quantity of garbage and other wastes generated is higher, though the per capita solid waste is lower as compared to the non-slum areas. Solid wastes in slum areas are not appropriately disposed due to various reasons such as low awareness among the dwellers regarding waste hazards, segregation of wastes is not attempted, high rate of recycle of any material which has a perceived use, waste

bins are not kept in sufficient numbers, waste carriage to final disposal site is infrequent, streets are narrow inhibiting access to lorries/ vans and stray animals / birds have easy access to the bins thereby dispersing the wastes in the surrounding area.

Sewage disposal : Disposal of sewage in slums is inadequate or at times rudimentary. The public toilets installed for this purpose are insufficient in number and not cleaned properly. The slum dwellers resort to open air defecation in nearby areas. Storm water drains and *nullahs* flowing near the settlements are frequently used for this purpose, creating filth and insanitation. The most vulnerable in this community are young children, elderly and women who also suffer the most due to improper toilet facilities. Lack of adequate water for cleaning or bathing increases their vulnerability and diarrhoeal diseases are highly endemic in this population.

Care in illness : Slum dwellers are subjected to various diseases brought about by interplay of factors such as poverty, ignorance and poor health infrastructure. Numerous studies have found high levels of malnutrition among the under 5 years old residing in these areas. The children below 5 years show high levels of stunting suggesting chronic malnutrition equal to that seen in the remote areas of the country. A study has also revealed that approximately 27% of infants in slums had a low birth weight as compared to 18% of those born in non-slum areas. Anaemia among the pregnant women is a major cause of maternal and perinatal mortality. Urban poor also spend substantially on childhood illnesses such as respiratory infections, diarrhoeal diseases as well as on tuberculosis, HIV/AIDS etc. The latter two have shown rising trends in the slum population.

Level of health care : There are consistent differences seen in the health care between slums and the non-slum areas in the cities. This is marked in the reproductive and child health care with studies revealing only about 55% women in slums having received three or more antenatal check ups compared to 74% of the non-slum population. The levels of institutional delivery and awareness of safe delivery practices also differ between the slum and non-slum areas. Immunisation coverage among children in urban slums is poor and so is the health care service available to residents. Besides, the treatment seeking behaviour in these areas is influenced by the negative-gender attitudes, which compounds the discrimination against the women and young & vulnerable group.

Social issues : Violence against vulnerable people in the slums is widely prevalent. The most affected are the women. Alcoholism and drug abuse envelop the slum youth who are uneducated or unemployed and this results in their getting involved in anti-social activities.

Strategies for health care of the slum dwellers

Comprehensive health policy : There is a need for a comprehensive policy to focus on the health needs of the slum population. Governments in different countries need to focus on the requirements of the urban poor and the strategies for improvement of their health care need to be adopted accordingly. The various aspects covered under this policy could be:

- Involvement of the community in all aspects of health care delivery. This should be encouraged by the local/ municipal bodies

- Generate the demand for health services including the preventive and curative services
- Involvement of the local non governmental organisations, medical practitioners and practitioners of traditional medicine in the community
- Create a secure economic environment in which the dwellers do not feel a threat due to illnesses or hospitalisations
- Special funds could be created in the State government health plans to cater to the health care in slum areas and disadvantaged groups.

Provision of the basic necessities : The policy should enunciate the means and the method to provide basic necessities to the slum dwellers, including nutritious diet with the locally and seasonally available food, safe and wholesome drinking water in adequate quantities for the family, system of hygienic disposal of excreta and the availability of healthy housing conditions.

Network of services : There is a need to generate a network of health care services such that the facilities are easily accessible to all the sections of population. Special emphasis should be given to the most vulnerable sections of slum dwellers as described above and also the pavement dwellers and temporary settlers who are not ordinarily included in the slum rehabilitation schemes. These networks could include the following:

Free health care should be available on-site, adequate to the local needs, functional and non-discriminatory in nature such that it is universally acceptable in the spirit of health for all.

Outreach services which are able to provide for the most peripheral of populations and also able to empathise with and understand their health care needs.

Referral services should be integrated with the health care and outreach services such that comprehensive health care is available to the slum inhabitants.

Curative services : The health infrastructure in the urban slum areas needs to be strengthened at all the tiers to cover the entire slum area. A health care centre could be created as a first tier to cater to primary health care requirement of community. Similar attempt has been made in the Urban health care model by the Government of India by creating Urban Health Posts. The health care centre should be equipped to provide basic health facilities and reach the most vulnerable population. It should have necessary manpower to function the centre. The services provided should be OPD based including Reproductive & Child Health (RCH), first aid, treatment for common ailments, basic laboratory service, counselling, ancillary services and facility for referral to second tier of health care. The second tier of facility should be appropriately identified for referral such as hospitals, maternity homes and nursing homes. Private partners should be identified at each level of care to improve the coverage and quality of services.

Preventive services : Primary care should be integrated with preventive health care services. Immunisation of children and pregnant women should be carried out on priority as per laid down schedule. The immunisation days at the health centres should be communicated to all people. The workers at the health centres should teach the community to adopt safe and

healthy family planning practices. Active and passive disease surveillance should be established at the first tier, which could integrate with the state/central surveillance network. Voluntary workers could be identified and involved in conduct of preventive care activities in the slum community.

Involvement of NGOs and self-help groups : Aim of provision of urban health care is to be able to reach each and every person or group with these services. Involvement of community in identifying their health needs and improving their health awareness could be achieved with the help of these organisations. Volunteers could be identified from the community, who could spare 3-4 hours a day to provide outreach services. They would also be integrated with other slum development activities.

Income generating activities : The volunteer groups, NGOs and State health authorities could motivate the community members to be involved in income generating activities especially the ones where the youth could be addressed. Community leaders could be asked to lead in this regard. Slum development activities could help in diverting the youth from anti-social activities to more productive work.

Public-private partnerships : Partnerships between the urban local bodies, family welfare organisations and State government will improve the chance of success of the urban health schemes for the slums. Coordination between various State departments such as engineering, health and education would help in making the schemes sustainable and improve overall sanitation services in slum areas.

Monitoring : Health Management Information Systems should be established in slums to measure health data in the population, for future policy planning. At present this data is inadequately received at the State level. Baseline indicators should be determined from health surveys. These could include morbidity, mortality indicators, immunisation coverage, infant and neonatal care, safe delivery/abortion practices and so on. Periodic review of the implementation of these schemes could be carried out by establishing programme management units at district and State levels.

Tribal Health and Health Care of Population in Remote Areas

Tribal people inhabit various geographic and climatic zones in different countries in the World. Their vocations range from hunting, gathering, nomadic living to living in societies with settled culture in harmony with nature. In India majority of the tribal population live in remote areas and their problems depend on their remoteness from the rest of the communities as well as their indigenous customs and traditions. Tribal communities in the country belong to more than 400 linguistic and cultural groups, with some states having almost fifty percent tribal population.

Nature of problems

Urbanisation and industrialisation : The rich heritage of knowledge, expertise and age old wisdom passed over generations in the traditional communities have been endangered by urbanisation and industrial growth. Oppression, land exploitation and degradation of environment have dented their simple ways of cohabitation with nature.

Diseases and deficiencies : Tribal communities are more prone to communicable diseases and nutritional deficiencies. Major health problems include respiratory infections, malaria, diarrhoeal diseases and skin infections. Women are more affected by anaemia, complications during pregnancy such as toxaeemias, prolonged labour, abnormal foetal presentations etc. The maternal, perinatal and infant mortality rates are quite high. Some tribal communities are also exposed to environmental pollutants and effects of progressive land/forest degradation severely depleting their habitat.

Social issues : Tribal communities and those living in remote areas depict a higher rate of alcohol intake and substance abuse. The harmonious living with nature is disturbed; lack of employment and awareness, availability of cheap or spurious liquor, trading in opium and narcotic drugs increases their vulnerability to these behaviours.

Awareness and utilisation of health facilities : The level of awareness regarding health facilities among the tribal community is fairly low. In a study carried out in Bastar district of Madhya Pradesh, it was found that only 40% population knew about subcentres and PHCs. Where services are available, indigenous people are often reluctant to use them because of insensitive staff at the health centres. Most communities still rely on the traditional systems of medicines to address their health problems.

Availability of infrastructure : Government health care facilities are usually inadequately available in tribal and remote areas. Buildings, equipments, drugs and other supplies and health personnel are insufficient in these places. NGOs and self help groups therefore take up the cause of providing health care and social mobilisation of tribals.

Strategies to improve health care

Identifying the objectives : To assess the unmet needs in tribal communities, stimulate the demand for health care services, improve service coverage, and ensure accessibility and acceptability of these services by the community.

Strengthen health infrastructure : Government health infrastructure should be upgraded. Policies should be made to relax qualifications for personnel to suit local requirements, effective remuneration and turnover of health personnel in these areas ensured. Institutions such as the Panchayati Raj Institutions should be encouraged to help communities in various health care activities, besides the socio-economic development of the community. Referral services should be made organised and effective.

Promote community participation : Involve people to map inaccessible areas, community based organisations could participate in outreach services, volunteers could be involved in improving awareness and education of community. Existing health functionaries such as Anganwadi workers under in Indian villages could create demand for services for women and children.

Involvement of Non Governmental Organisations : NGOs with good track records should be encouraged to take responsibility for managing MCH services as well as support the public health facilities in tribal communities and remote areas. Practitioners of traditional systems of medicine should also be involved in

health care.

Behaviour Change Communication strategies : Local area specific IEC activities should be planned. The tribal leaders and persons of prominence in the community should be taken into confidence for developing such communication strategies, which should be based on values, beliefs and practices locally prevalent.

Development of human resources : Promoting training in midwifery for the community volunteers and local married women in supporting the health care activities in these communities.

Summary

Urban Slums : The Migration of people from rural to urban areas has compounded the housing problem in the latter and these people settle in shanty towns and slums in the fringes of the cities. There are some unique problems faced by the people in urban slums. High prices of food, health care goods and essential commodities are making them unaffordable. They are denied the right to housing, their infrastructure is neglected and they are not provided easy access to basic health care; Scarcity of water supply and overcrowding reduce the quantity available per head. Solid wastes in slum areas are not appropriately disposed due to various reasons and disposal of sewage in slums is inadequate or at times rudimentary. Slum dwellers are subjected to various diseases brought about by interplay of factors such as poverty, ignorance and poor health infrastructure. Malnutrition among the under 5 years old, Low birth weight, Anaemia among the pregnant women and childhood illnesses such as respiratory infections, diarrhoeal diseases as well as on tuberculosis, HIV/AIDS etc. have shown rising trends in the slum population. Violence against vulnerable people in the slums is widely prevalent. Alcoholism and drug abuse envelop the slum youth who are uneducated or unemployed and this results in their getting involved in anti-social activities.

There is a need for a comprehensive policy to focus on the health needs of the slum population. Governments in different countries need to focus on the requirements of the urban poor and the strategies for improvement of their health care need to adopt accordingly. The policy should enunciate the means and the method to provide basic necessities to the slum dwellers, including nutritious diet with the locally and seasonally available food, safe and wholesome drinking water in adequate quantities for the family, system of hygienic disposal of excreta and the availability of healthy housing conditions. Health Management Information Systems should be established in slums to measure health data in the population, for future policy planning.

Tribal Health : In India majority of the tribal population live in remote areas and their problems depend on their remoteness from the rest of the communities as well as their indigenous customs and traditions. Urbanisation, industrialisation, Oppression, land exploitation and degradation of environment have dented their simple ways of cohabitation with nature. Tribal communities are more prone to communicable diseases and nutritional deficiencies. Major health problems include respiratory infections, malaria, diarrhoeal diseases and skin

infections. Women are more affected by anaemia, complications during pregnancy such as toxaeemias, prolonged labour, abnormal foetal presentations etc. The maternal, perinatal and infant mortality rates are quite high. Some tribal communities are also exposed to environmental pollutants and effects of progressive land/forest degradation severely depleting their habitat. Strategies to improve health care in Tribal areas are to Identifying the objectives, Strengthen the health infrastructure, Promote community participation, Involvement of Non Governmental Organisations and Behaviour Change Communication strategies.

Study Exercises

Long Questions : (1) Discuss the Health problems faced by people in Urban Slums and Suggest measures for the same (2) Discuss the Health problems existing in people in Tribal

areas and Suggest measures for the same.

Short Notes : (1) Urban Slums (2) Tribal Health (3) Strategies for health care of the slum dwellers.

MCQs

1. As per the 2001 census in the country, in cities with population of over one million, the percentage of the population residing in slums is (a) 10 (b) 15 (c) 25 (d) 30
2. The percentage of infants in slums having low birth weight as compared to 18% of those born in non-slum areas is (a) 7% (b) 27% (c) 37% (d) 42%
3. The percentage of women in slums having received three or more antenatal check ups compared to 74% of the non-slum population is (a) 35% (b) 55% (c) 70% (d) 10%

Answers : (1) c; (2) b; (3) b.

RajVir Bhalwar

In our vast country, a number of extremely important, scientifically appropriate and acceptable systems of indigenous medicine are available. These include the Ayurved system, which is popular mostly in the States of Kerala, Himachal Pradesh, Gujarat, Karnataka, Madhya Pradesh, Rajasthan, Uttar Pradesh and Orissa. The Unani system is particularly popular in Andhra Pradesh, Karnataka, Tamil Nadu, Bihar, Maharashtra, Madhya Pradesh, Uttar Pradesh, Delhi and Rajasthan. The Siddha system is widely acceptable in Tamil Nadu and Kerala. Homoeopathy is practised all over the country and is especially popular in Uttar Pradesh, Kerala, West Bengal, Orissa, Andhra Pradesh, Maharashtra, Punjab, Tamil Nadu, Bihar, Gujarat and North-Eastern States. These Indian Systems of Medicine and Homoeopathy (ISM&H) were given an independent identity in the Ministry of Health and Family Welfare in 1995 by creating a separate department, which was renamed as Department of Ayurveda, Yoga and Naturopathy, Unani, Siddha and Homoeopathy (AYUSH) in November 2003. The department is entrusted with the responsibility of developing and propagating the above-mentioned officially recognised Indian systems of medicine and Homoeopathy.

Organization

The department is a part of the Ministry of Health and Family welfare, Govt of India and is administratively headed by the Secretary, Dept of AYUSH, assisted by various administrative and technical officials. The Department has two subordinate offices, one public sector undertaking, two statutory organisations, four research councils, eight educational institutions and a national Medicinal plant board (with 35 State/ UT level boards)

under its administrative fold, as per following details :-

Subordinate Offices : These include the *Pharmacopoeial Laboratory for Indian Medicine (PLIM)*, located at Ghaziabad, which is the Standard Setting-cum-Drug-Testing Laboratory for Indian Medicine (Ayurveda, Unani and Siddha System) at the National level and the *Homoeopathic Pharmacopoeial Laboratory (HPL)* which is also located at Ghaziabad for the purpose of laying down standards and testing for identity, purity and quality of Homoeopathic Medicines.

Public Sector Undertaking : There is one PSU, viz., the *Indian Medicine Pharmaceutical Corporation (IMPCL)*, located in Almora, Uttaranchal, with the prime objective of manufacturing authentic Ayurvedic and Unani medicines according to classical texts, for catering to the needs of dispensaries of Central Government Health Scheme (CGHS), Units of Central Research Councils of Ayurveda and Unani, and state government institutions.

Statutory Regulatory Councils: The Central Council of Indian Medicine (CCIM) and the Central Council for Homoeopathy (CCH) were set up under the Acts of Parliament. Ayurveda, Siddha and Unani systems are within the ambit of the Central Council of Indian Medicine, and Homoeopathy is under the Central Council for Homoeopathy. These councils prescribe course curricula, evolve and maintain standards of education and maintain central registers of practitioners of Ayurveda, Siddha, Unani and Homoeopathy respectively. Their main responsibilities are to regulate education and practice of respective systems of medicine and advice the Government regarding education.

Research Councils: There are four apex research councils, all located in New Delhi, namely, Central Council for Research in Ayurveda and Siddha (CCRAS), Central Council for Research in Unani Medicines (CCRUM), Central Council for Research in Homoeopathy (CCRH) and Central Council for Research in Yoga and Naturopathy (CCRYN).

National Apex Institutes: Eight apex educational institutions are established to promote excellence in Indian Systems of Medicine and Homoeopathy education. For each system there is a national institute, viz.- National Institute of Ayurveda, Jaipur; National Institute of Siddha, Chennai; National Institute of Unani Medicines, Bangalore; Morarji Desai National Institute of Yoga, New Delhi; National Institute of Naturopathy, Pune and National Institute of Homoeopathy, Kolkata. The Rashtriya Ayurveda Vidyapeeth has been established at New Delhi.

Broad Goal, Strategies and Activities

Broad Goal of the Programme: Mainstreaming of AYUSH in the health care service delivery system, with a view to strengthen the existing public health system.

Strategies : Mainstreaming of AYUSH is one of the key strategies under the National Rural Health Mission (NRHM) under which it is envisaged that all PHCs/CHCs would be provided AYUSH facilities under the same roof. AYUSH manpower would be arranged either by relocation of AYUSH doctors from existing dispensaries or from contractual hiring of AYUSH doctors under NRHM funds. The other infrastructure and supply of medicines to PHCs/CHCs would be done through the Centrally Sponsored Scheme of Hospitals and Dispensaries which has received a very good response from States in the last two years of the 10th five year Plan. The following are the main strategies of this programme:

- Integrate and mainstream ISM&H in health care delivery system including National Programmes.
- Encourage and facilitate in setting up of specialty centres and ISM clinics.
- Facilitate and Strengthen Quality Control Laboratory.
- Strengthening the Drug Standardization and Research Activities on AYUSH.
- Develop Advocacy for AYUSH.
- Establish Sectoral linkages for AYUSH activities

Main Activities

(a) Improving the availability of AYUSH treatment facilities and integrating it with the existing Health Care Service Delivery System

- Integration of AYUSH services in various CHC / Block PHC with appointment of contractual AYUSH Doctors.
- Appointment of paramedics where AYUSH Doctors shall be posted.
- Appointment of a Data assistant to support the ISM&H Directorate.
- Strengthening of AYUSH Dispensaries with provision of storage equipments.
- Making provision for AYUSH Drugs at all levels.
- Establishment of specialized therapy centers in District Headquarters Hospitals and Medical Colleges.
- AYUSH doctors to be involved in all National Health Care programmes, especially in the priority areas like IMR, MMR, Control of Malaria, Filariasis, and other communicable diseases etc.
- Training of AYUSH doctors in Primary Health Care.
- All AYUSH institutions will be strengthened with necessary infrastructure like building, equipment, manpower etc.
- One Yoga Therapy Centre will be opened in district Headquarters Hospitals to provide Yogic therapy for

specific diseases and also as a synergistic therapy to all other systems of treatment.

- Block level School Health Programmes to be conducted twice in a year in two groups consisting of 100 students in each group to improve the physical and mental health of the school children.
- It is proposed to create necessary Managerial post in the State and District level for effective supervision and implementation of different activities.
- Necessary vehicles with supporting manpower has also been proposed to strengthen the supervisory Joint monitoring visits to health centres to be undertaken by both AYUSH and Health Care Officials at the District level's/State level.

(b) Integration of AYUSH with ASHA.

- Training module for ASHA and ANMs have to be updated to incorporate information of AYUSH.
- Training & capacity building to be undertaken by the Director, SIHFW, Bhubaneswar and necessary training material for the purpose to be modified and provided accordingly.
- Drug kit that will be provided to ASHA will contain one AYUSH preparation in the form of iron supplement. But other drugs which are used in the treatment of common diseases, control of communicable diseases as well as drugs promoting the maternal and child health as well as improving quality of life could be included subsequently.

(c) Drug Management:

- Priority will be given to manufacture of drugs in Govt. Sector Pharmacies, as per their capacity. In case of any surplus funds, drugs will be procured from the market observing all financial formalities of the Govt.
- Provision of Rs. 25,000/- to supply drugs per AYUSH dispensary has been projected as per NRHM norm.
- Provisions of medicines for District AYUSH wings and Specialty Therapy Centres proposed to be operated in the State.

(d) Special Initiatives for Development of AYUSH Drugs.

(i) Strengthening the Quality Control Laboratory

- The quantum of Ayurvedic and Homoeopathic medicines used / procured in both public and private health sectors is huge. There has been wide ranging concern about spurious, counterfeit and sub standard drugs. In order to prevent the spread of sub-standard drugs and to ensure that the drugs manufactured or sold or distributed throughout the state are of standard quality, drug regulation and enforcement unit has to be established in the state.
- The drug regulatory mechanism to be strengthened at the state level to improve the quality of drugs used in AYUSH and ensure proper standardization. The existing State Drug Testing and Research Laboratory (ISM) at Bhubaneswar shall also be modernised and strengthened for the purpose.

(ii) Strengthening the Drug Standardisation and Research Activities on AYUSH : Standardisation and research is an important activity in the process of development of a drug used for preventive and curative purpose. The major drawback in the development of AYUSH is lack of research and development activity on the drugs used for the System. The

following activities will be undertaken to strengthen the drug standardisation and research activities on AYUSH:

- It has been proposed to evaluate the chemical, pharmacological and clinical efficacy of the plant drugs.
- The phytochemical entities responsible for the therapeutic activity of the plant drugs used in AYUSH system will be evaluated through intensive R & D activity.
- The pharmacologically viable drugs will be screened clinically under WHO guidelines to establish the therapeutic activity.
- Clinical trials on different diseases like Psoriasis, Liver disorders, Diabetes, Asthma will be conducted to establish the effect of various drugs used for such diseases.
- It has also been proposed to conduct literary research like translation of manuscripts and its publications.
- Re-vitalisation of the local health traditions and the knowledge of traditional drugs used by experienced local health practitioners will be gathered and documented.

(iii) Development of Herbariums and crude drug museums:

- Herbarium will be developed in collaboration with the Forest departments in 15 selected Districts of the State.
- The existing Herbal gardens will be strengthened with necessary infrastructure.
- One State Herbarium at Bhubaneswar shall be developed. This shall enable greater research and study on development and innovation in AYUSH Drugs.
- 10 selected centres will be developed for extraction and preservation of the plants for medicinal use.

Modalities of Delivery

- For mainstreaming of AYUSH in NRHM, the personnel of AYUSH may work under the same roof of the Health Infrastructure, i.e. PHC, CHC; however, separate space should be allocated exclusively for them in the same building.
- The Doctors under the Systems of AYUSH are required to practice as per the terms & conditions laid down for them by the appropriate Regulatory Authorities.
- Provision of one Doctor of any of the AYUSH systems as per the local acceptability assisted by a Pharmacist in PHC.
- Provision of one Specialist of any of the AYUSH systems as per the local acceptability assisted by a Pharmacist in CHC.
- Supply of appropriate medicines pertaining of AYUSH systems.
- The already existing AYUSH infrastructure should be mobilized. AYUSH dispensaries that are not functioning well should be merged with the PHC or CHC barring which, displacement of AYUSH clinic is not advised.
- Cross referral between allopathic and AYUSH streams should be encouraged based on the need for the same.
- The specific choice of AYUSH system that should be set up in each state should be decided by the State depending on the local preference.
- AYUSH Doctors shall be involved in IEC, health promotion and also supervisory activities.
- The Indian Public Health Standards (IPHS) pertaining to AYUSH will be developed and also the detailed manpower and other requirements and financial projections for the same will be provided by the Department of AYUSH for further consideration.

Regulatory Measures

The Central Acts are in place to regulate education and practice, manufacture of drugs for sale and enforcement mechanism. Ayurveda, Siddha, Unani and Homoeopathy drugs are covered under the purview of Drugs and Cosmetics Act, 1940. Since most of the medicines of AYUSH sector are made from medicinal plant materials, the Department has set up a National Medicinal Plants Board to promote cultivation of medicinal plants and ensure sustained availability of quality raw material. A separate National Policy on Indian Systems of Medicine and Homoeopathy is in place since 2002.

Infrastructure

The infrastructure under AYUSH sector consists of 1355 hospitals with 53296 bed capacity, 22635 dispensaries, 450 Undergraduate colleges, 99 colleges having Post Graduate Departments, 9,493 licensed manufacturing units and 7.18 lakh registered practitioners of Indian Systems of Medicine and Homoeopathy in the country. 7 Ayurvedic and 5 Unani drugs have been supplied to 9 States and 4 Cities respectively as part of the on-going National Reproductive & Child Health Programme (RCH) for the treatment of common ailments of pregnant, women and children. As regards mainstreaming of AYUSH in the activities of NRHM, the following was the status as on 30 April 2008 is given in Table - 1.

The details of AYUSH manpower have also been described in detail, earlier, in the chapter on health manpower resources.

Parameter	Total
No. of PHCs where AYUSH practitioners have been co-located	3793
No. of AYUSH doctors posted on contractual appointments in CHCs	2199
No. of AYUSH doctors posted on contractual appointments in PHCs	1683
No. of AYUSH paramedics posted on contractual appointments in CHCs	17
No. of AYUSH paramedics posted on contractual appointments in PHCs	629
CHCs where AYUSH facilities are co-located	973
PHCs where AYUSH facilities are co-located	2012

Budget

There has been a three fold increase in the Plan budget of the Department in the 10th as compared as 9th Plan, most of which was on account of scaling up of the budget provision in the last two years of the 10th Five Year Plan i.e. 2004 - 2005 and 2005 - 2006 in line with the declared policy of the Central Government to increase the budgetary provision for AYUSH sector for mainstreaming it in the national health care delivery network. The Plan allocation for 2006-07 is Rs. 381.60 crore. It is proposed to scale up Plan provision for Department of AYUSH from Rs.1057.26 crore in the 10th Plan to Rs.2486.45 crore in the 11th Plan

Future Course

It has been proposed to further step up the activities under AYUSH during the 11th five year plan. The following special steps are contemplated :

1. Development and Upgradation of AYUSH Institutes/Colleges : This is one of the Centrally Sponsored Schemes being implemented by the Department for Development of AYUSH Institutions. This Scheme has been in operation since last three plan periods and the present plan period. The scheme has following components:-

- (i) Development of UG colleges.
- (ii) Assistance to P.G. Medical Education
- (iii) Re-orientation Training Programme for AYUSH Personnel.
- (iv) Renovation and strengthening of Hospital wards of Govt./ Govt. aided teaching
- (v) Establishment of computer laboratory.
- (vi) Up-gradation of academy institutes to the status model Institutes of AYUSH.

2. Strengthening of Hospitals & Dispensaries : The scheme has the following components

- (i) Setting up of Speciality Therapy Centres and Speciality Clinics of ISM&H
- (ii) Setting up of ISM&H Wings in District Allopathic Hospitals
- (iii) Strengthening of existing AYUSH health care facilities
- (iv) Supply of essential medicines

3. Quality Control of AYUSH Drugs

- (i) To establish/strengthen the State Drug Testing Laboratories for ASU&H drugs.
- (ii) To establish /strengthen the State Pharmacies of ASU&H drugs.
- (iii) To strengthen state Drug Controllers on ASU&H enforcement mechanism.
- (iv) To assist AS&U drug manufacturing unit to improve their infrastructure.

Summary

All the Indian Systems of Medicine and Homoeopathy (ISM&H) were given an independent identity in the Ministry of Health and Family Welfare in 1995 by creating a separate department, which was renamed as Department of Ayurveda, Yoga and Naturopathy, Unani, Siddha and Homoeopathy (AYUSH) in November 2003. The Department has two subordinate offices, one public sector undertaking, two statutory organisations, four research councils, eight educational institutions and a national Medicinal plant board (with 35 State/ UT level boards) under its administrative fold.

The broad Goal of the Program is to mainstream the AYUSH in the health care service delivery system, with a view to strengthen the existing public health system. Mainstreaming of AYUSH is one of the key strategies under the National Rural Health Mission (NRHM) under which it is envisaged that all PHCs/CHCs would be provided AYUSH facilities under the same roof.

The main activities are (a) improving the availability of AYUSH treatment facilities and integrating it with the existing Health Care Service Delivery System (b) Integration of AYUSH with ASHA. (c) Drug Management / Provisions of medicines

(d) Special Initiatives for Development of AYUSH Drugs. For mainstreaming of AYUSH in NRHM, the personnel of AYUSH may work under the same roof of the Health Infrastructure and the Doctors under the Systems of AYUSH are required to practice as per the terms & conditions laid down for them by the appropriate Regulatory Authorities. The already existing AYUSH infrastructure should be mobilized. AYUSH dispensaries that are not functioning well should be merged with the PHC or CHC barring which, displacement of AYUSH clinic is not advised. AYUSH Doctors shall be involved in IEC, health promotion and also supervisory activities. The Indian Public Health Standards (IPHS) pertaining to AYUSH will be developed.

The Central Acts are in place to regulate education and practice, manufacture of drugs for sale and enforcement mechanism. Ayurveda, Siddha Unani and Homoeopathy drugs are covered under the purview of Drugs and Cosmetics Act, 1940. A separate National Policy on Indian Systems of Medicine and Homoeopathy is in place since 2002.

The infrastructure under AYUSH sector consists of 1355 hospitals with 53296 bed capacity, 22635 dispensaries, 450 Undergraduate colleges, 99 colleges having Post Graduate Departments, 9,493 licensed manufacturing units and 7.18 lakh registered practitioners of Indian Systems of Medicine and Homoeopathy in the country. It is proposed to scale up Plan provision for Department of AYUSH from Rs.1057.26 crore in the 10th Plan to Rs.2486.45 crore in the 11th Plan.

It has been proposed to further step up the activities under AYUSH during the 11th five year plan. Some of them are Development & Upgradation of AYUSH Institutes/Colleges, Strengthening of Hospitals & Dispensaries and Quality Control of AYUSH Drugs.

Study Exercises

Long Question : Mainstreaming of AYUSH is one of the key strategies under the National Rural Health Mission (NRHM). Comment and discuss the activities and modalities of delivery of AYUSH

Short Notes : (1) Mainstreaming of AYUSH (2) Activities proposed under AYUSH during the 11th five year plan (3) AYUSH Organisation

MCQs

1. Indian Systems of Medicine and Homoeopathy (ISM&H) was renamed as Department of Ayurveda, Yoga and Naturopathy, Unani, Siddha and Homoeopathy (AYUSH) in (a) 2003 (b)2000 (c)2005 (d)2007
2. As per NRHM norm, the amount projected for supply of drugs per AYUSH dispensary is (a) 20000 (b) 25000 (c) 30000 (d)35000
3. Which of the following is a subordinate office under Dept of AYUSH,MOHFW (a) Pharmacopoeial Laboratory for Indian Medicine b) Homoeopathic Pharmacopoeial Laboratory c)Indian Medicine Pharmaceutical Corporation d)all the above

Answers : (1) a; (2) b; (3) d.

Social, cultural, psychological and behavioural factors are important variables in the etiology, prevalence and distribution of disease. The way the people live, their habits, beliefs, values and customs are significant determinants of individual and collective health. The behavioural sciences (sociology, social psychology, cultural anthropology) have made significant role in developing better understanding about the social etiology of health problems. It is recognized that causation and spread of a disease does not depend entirely upon biological organism. The cultural and social factors which govern human behaviour also have dominant role to play in the disease process. Any behaviour is determined by a combination of cultural, psychological, social and economical variables. Hence the study of health embraces the totality of life and ways of living.

Sociology : Sociology is the science concerned with the organization of structure of social groups. It studies the kinds and cause of variation in social structure, and the processes by which intactness of social structure is maintained. Sociology deals with the study of society. Society is a group of individuals who have organized themselves and follow a given way of life. The behaviour of man depends very much upon his relationship with other fellow beings. Man is a subunit of a small group; the family, while the family is the basic unit of society. Man's behaviour is affected not only by his physical and biological environment but also, to a larger extent by social environments represented by his family.

Community : In the simplest terms, a community can be defined as a group of people who have some common characteristics and are bound together by "WE" feeling. This sense of 'we' feeling (i.e., shared togetherness) may be due to a place where they all stay or due to some other common interest.

Accordingly, communities can be either "structural" or else, "functional" communities. Functional communities are non-geographical aggregates which are bound together by some common factor other than geographical place of residence or work; e.g., religion (as, Hindu community), occupation (as medical community), special interest (as cricket lovers) or need (as socially backward communities). Structural communities are organised by geographical or political boundaries. It could be as small as an "indoor patient's community in a hospital" or increasingly larger, according to a "Mohalla", village, slum, city, district, state or even a nation. Community affiliations often provide a source of support for individuals and group. The sense of group identity eases the growth of motivation. For this reason the community is ideal for focal point of programme.

Culture : Culture is defined as learned behaviour which has been socially acquired. Culture includes all that man acquired in the mental and intellectual sphere of his individual and social life. It is a product of human societies.

Culture is necessary for human being; it makes life worth

living and socializes man. A culture denotes total way of life. It is recognized that cultural factors are deeply involved in all the affairs of man including health and sickness. The cultural factors such as customs, beliefs, values and religious taboos create an environment that helps in the spread or control of certain diseases and affect health of the community. The cultural factors are deeply involved in matters of personal hygiene, nutritional and breast feeding habits, weaning and rearing practices, family planning, immunization and seeking early medical care.

Family : "The Family is a group defined by a sex relationship precise and enduring to provide for the procreation and upbringing of children" (MacIver). The family is a primary unit of all societies. As a cultural unit, the family reflects the culture of wider society of which it forms a part and determines the behaviour and attitudes of its members. The family is an epidemiological unit, and a unit for providing social services as well as comprehensive medical care.

Family life cycle stages : A family passes through the following stages in its evolution :

- Married couple - beginning of family
- Child bearing family
- Family with pre- school children
- Family with school age children
- Family with teenage children
- Middle age
- Aging family members/ retirement

Role of Family in Health and Disease

Family is the reproductive nucleus of society, a fundamental and social institution whose primary and essential task is to socialize the new born so that they may be placed in life as mature and independent. From the time the child is born, the course of his physical and mental development is determined by his initial experiences with the family. Every society from nomads to city- dwellers has its institution of marriage and stable family life. Through the family, human beings maintain physical continuity by reproduction, maintain social and cultural continuity through training and education.

The health of the child is bound up with the family's internal and external environment even before it is born, and the foetus in the womb can be harmed by the health, nutrition and behaviour of the mother. Undernutrition of mother can give rise to infants born prematurely and of low birth weight with attendant high risks of mortality or damage to the nervous system. Her unborn child can be damaged by familial infections like rubella and syphilis. Subsequent experiences in infancy, in the quality of feeding and method of training for instance may further influence development, physique, stature and personality.

The members of family share a pool of genes and a common environment as well as common modes of thoughts and behaviour and family material and social environment which includes housing, sanitation and diet. A damp overcrowded house encourages streptococcal infections (Rheumatic fever and nephritis). Tuberculosis flourishes in poor and over crowded homes. It is not only infective agents that pass between the members of a family; parents may transmit distorted cultural

perceptions & behavioural norms to their children; thus creating deviant behaviour and failures of adaptation among them.

Familial beliefs and attitudes go a long way in shaping the reasons for health and disease. The various causes for sickness, as understood, may be classified in two categories : Supernatural causes and Physical causes. Supernatural causes include diseases caused by (a) breach of taboos e.g. leprosy, sexually transmitted diseases; (b) wrath of god and goddesses e.g. small pox & chicken pox; (c) spirit intrusion, ghost intrusion and evil eye. The physical causes include excessive heat or cold, wrong combination of foods and impurity of blood etc. Prevention of disease and bringing improvements in the health conditions in any society is dependent upon our ability to understand and improve the social or environmental factors.

As families enter each new developmental stage, transition occurs. Events such as marriage, childbirth, releasing members as adolescents and young adults, and continuing as a couple or single person and aging years move families through new stages. Each new developmental stage requires adaptation and new responsibilities. Each new stage presents opportunities for health promotion and intervention. There are certain functions which are relevant to health behaviour, and are important from the medical sociology point of view.

- **Upbringing of children** : One of the important functions of the family with which medical and health workers are concerned, is the physical care of the dependent young in order that they may survive to adulthood and perpetuate the family. It is important to note that child care (e.g. feeding, nutrition, hygiene, sleep, clothing, discipline, habit training) are passed on from one generation to another. The ideas people have about nutrition exercise; sleep and clothing have a large social component which varies from society to society.
- **Socialization in the family** : By socializing is meant teaching the values of society and transmitting information, culture, beliefs, general codes of conduct, by example and precept, in order to make them fit for membership in the wider society of the family is a part. The family plays the most dominant role in the individual's socialization. The child finds much to learn in the behaviour of his family members, parents, relatives and friends. He imitates them in their mannerisms, behaviour etc. He tries to avoid such activities which are considered bad in the family. It is the family environment which forms his good habits. It is in the family that the child acquires such important qualities as sincerity, sympathy, self submission and realizing responsibilities. The child's first school is his home and family. It is the family which imparts practical education to children concerning the customs in society, preservation of health, love, sympathy, cooperation etc. Learning about health promotion and disease prevention begins at birth, with the family providing the environment for incorporating health in the value system of its members.
- **Influence of family on personality** : The environment of home has a comprehensive influence on the development of personality. In the family the relation of the child with the parents is the most intimate. The cultural development of the child is very much influenced by the behaviour of

the parents. The capacity of an individual to withstand stress and strain and the way in which he interacts with other people is to a large extent determined by his early experience on the family. The families acts as a placenta excluding various influences, modifying others and pass through it and contributes some of its own in laying foundation of physical, mental and social health of the child.

- **Care during sickness** : The family is expected to provide care during sickness and injury of adults and dependents from the public health point of view. Care of women during pregnancy and childbirth is an important function of the family. The joint family provides support, security and encouragement to the aged and handicapped.
- **Family as strength in crisis** : The family is understood as shock absorber. The family is an important source of support. During times of illness and crisis the family is there for the individual. The family provides an opportunity, both for adults and children, for release of tension so that the individual can attain mental equilibrium and strive to maintain a stable relationship with other people. The family has an important function in stabilization of the personality of both adults and children, and in meeting their emotional needs.
- **Problems in families** : The factors in most problem families are usually those of personality and of relationship, backwardness, poverty, illness, mental and emotional instability character defects and marital disharmony. These families are recognized as problems in social pathology. There is a need to render useful service in rehabilitating such families in a community.

The family therefore plays an important part both in health and disease - in prevention and treatment of individual illness, in the care of children and dependent adults, and in the stabilization of the personality of both adults and children.

Crowd : In common usage any large number of people gathered in one place is called a crowd. A crowd is potential medium for arousing emotion and for encouraging its expression. Large gathering people provide congenial conditions for emotional contagion. Simulation and suggestions are heightened. The presence of others gives a sense of security and approval and crowds convey a feeling of anonymity. By their very nature casual crowds and mobs are not part of organised system of social relations.

Mob : The term refers to one crowd that is fairly unified and single minded in its aggressive intent. Mob action is not usually destructive but tends to be focused on some one target or identity. Mob activity is the most goal oriented and the most dependent upon leadership for its direction

Sick role : 'Being Sick ' is not simply a state of fact or condition, it is a specifically patterned social role. To be ill is more than a medical condition. The patient has a customary part to play in relation to his doctor and to his family members of his society & in turn they expect him to behave in certain prescribed ways.

Rights

- The Sick person temporarily is exempt from normal social roles. The more severe the sickness, the greater the exemption.

- The sick person generally is not held responsible for his condition. Illness considered beyond individuals control therefore not simply curable by willpower.
- The sick person has a right to be taken care of.

Duties / obligations

The sick person has an obligation to try to get well. In this context exemption from normal responsibilities is temporary and conditional upon wanting and trying to get better.

The sick person has an obligation to seek technically competent help from a suitably qualified professional and to cooperate in trying to recover.

Social Pathology : Social pathology is the systematic study of human disease in relation to social conditions and disease process outside the human body. The cause is to be found in the society. These include Social Problems (namely, poverty and destitution, illiteracy and ignorance, migration, lower status of women,, child neglect and child abuse, child labour, drug abuse, juvenile delinquency); social conditions (as housing, environmental sanitation, crime and corruption, stress, suicide) and social circumstances (Viz., stigma, social isolation, vulnerable populations). The causes of social problems, conditions which affect the health of the people are to be understood and actions are to be taken to prevent such problems through health education and rehabilitation.

Social Diagnosis : This is made by socio- medical surveys and by study of domestic and social conditions of individuals.

Social Therapy : Social therapy offers holistic development centered therapeutic and support services. The approach addresses and supports the total social, emotional and educational needs of young and the entire family. Clinical treatment of any disease with drug should be supplemented with social therapy as far as possible. The Social security measures link between hospital and community, health education, legislation serve as supportive measures.

Knowledge : Education is a process of learning undergone by individuals for gaining knowledge, developing attitudes and acquiring skills. Knowledge is the basis of health education where a person gets of information by many modes which become his knowledge. Some apply the term knowledge to what are held to be certainties. Knowledge is intellectual and passive. Awareness can be created through imparting knowledge on a particular topic. e.g. receiving information about harmful effects of smoking.

Attitudes : Attitudes are mental habits acquired from social experiences that predispose us to react to specific objects, persons or situations in a definite way. They are the crystallized habits of thoughts that we develop relative to social situations and that set us to respond in a certain manner. An attitude is an enduring system that includes a cognitive component, an emotional (feeling) component and an action tendency. They are manifested in conscious experience, verbal reports, gross behaviour and physiological symptoms. The people are motivated to change attitudes to adopt new health behaviour. e.g. the individuals are motivated to stop smoking through various methods of health education and individuals are ready to change behaviour.

Practices : Practices are application to particular and personal situation. Practices are guided by principles under the light of intellect. The individuals modify their behaviour and maintain the change for the rest of their life. e.g. the individual stops smoking after changing attitude.

Community's social support systems : In medical practice the ability of a family to provide social support and material aid to dependent members is obvious importance. When patients who are disabled by sickness are reintroduced to normal social life, for example their family relationships and attitudes help to determine the outcome. Support comprises a network of family, friends, co-workers and professionals.

Social assistance implies provision of relief to individuals at critical times without having received any contribution from them. Social assistance is a non-contributory benefit extended to vulnerable groups including women, children and the aged. The community's participation in health programmes and programmes which are developed locally is to be found through situational analysis. The programmes such as aid to families with dependent children, medical aid, family counseling services, crisis support (food, shelter, clothing, fuel), referrals to appropriate medical services, drug de-addiction services, treatment services for alcoholics, delinquency prevention, services for the retarded and emotionally disturbed, income generation, vocational training services are provided by the community through appropriate groups, organizations and agencies. The philosophy behind tertiary prevention of chronic diseases is that it is often possible to live with and die with disease rather than dying from the disease. It is possible to prolong time period of optimal physical functioning and social activity by providing social support and self management services.

Social Environment : The social environment includes all those things which arise out of social relationships such as customs, traditions, institutions social conduct, rituals, diet, way of life and economic status. Health is profoundly influenced by the social environment which acts in many ways to shape the contours of disease, in populations as well as individuals. For promotion and protection of health and prevention and control of disease, social environment should be free from harmful agents. Important measures for providing healthy social environment are :

- Social security against fear and want (ESI scheme, old age pension, life insurance, provident fund and health and medical facilities).
- Fair distribution of food and other amenities of life such as housing
- Facilities for exercise and leisure
- Facilities for education for all
- Propagation of healthy customs, freedom of expression and thought
- Protection of property, life and honour
- Safe work place which involves establishing a stimulating work environment and making sure that the work place creates social contacts which do not interrupt the family networks.

Non-Governmental Organizations (NGOs), Voluntary Organizations : NGOs form a bridge between the government and community and provide platform for people participation. NGOs are many and diverse. Their scale may be large, medium, and small. Their support may come from external sources, from their own fund raising or from Government. Their principle activity may be direct service to those in need in the community, health education or research. Voluntary organizations could be defined as those organizations which are non- governmental and non profit making in character and not fully funded whether directly or indirectly only by government. Most voluntary organizations have four primary purposes (i) raise money to fund research and programmes (ii) provide education to both professional and the public (iii) provide services to individuals and families affected by the disease and health problem (iv) to advocate for beneficial policies, laws and regulations. (e.g. VHAI, Indian Red Cross Society, Hind Kusht Nivaran sangh, Tuberculosis Association of India etc.)

Social Security : Social security means public programmes designed to protect individuals and their families from income losses due to unemployment, old age, sickness or death and to improve their welfare through public services (e.g. medical care) and economic assistance. The term may include social insurance programmes, health and welfare services and various income maintenance programmes.

Social class and Socio-Economic Status : Socio-economic standard of people is conventionally expressed in terms of various social classes in which people are distributed which are referred to as social stratification. Social stratification is a horizontal division of society in to several socio-economic layers : each layer or social class has a comparable standard of living, status and life style. Social class is determined on the basis of three parameters of development, namely education, occupation and income. Education determines the knowledge, attitude, and value system of individuals and their socio-economic growth potential. Occupation determines the income generating capacity of individuals and their status. Income determines the purchasing power of individuals and their socio-economic status. On the basis of these parameters populations are divided in to social classes - upper, upper middle, middle, upper lower and lower. These social class gradients have helped to provide a deeper understanding of clinical phenomena. The poor had a higher incidence of some diseases, the rich of others. Health practices too, like the use of health services, welfare and maternity clinics, and methods of infant feeding were found to

be correlated with social class.

Kuppuswamy's scale : The socio-economic status scale (urban) developed by Kuppuswamy attempts to measure the socio-economic class of family in urban community. It is based on three variables - education, occupation, and income. A weightage is assigned to each variable according to seven point predefined scale. The total of three weightages gives the socio-economic status score which is graded to indicate the five classes, as per details in Table - 1. To get current income group, a conversion factor based on current All India Consumer Price Index (AICPI) is used, which is given later.

For income, the conversion factor can be obtained by dividing AICPI by 60.04. The income group in the Kuppuswamy's scale are multiplied with the conversion factor to get the appropriate income group (Indian Journal of Pediatrics, volume 70, March 2003). Now, since AICPI in June 2008 was approximately 650, hence 650 divided by 60.04 = 10.83. Thus all the income groups in the Kuppuswamy scale in the above table are multiplied with the conversion factor to get the appropriate income group. Thus, the conversion factor 10.83 is multiplied by Rs. 2000 which comes to Rs 21,660/- and rest income groups would be as given in Table - 2.

Income Original	Modified by using conversion factor (multiplied by 10.83)	Score
> 2000	>21660	12
1000-1999	10830-21659	10
750-999	8122-10829	6
500-749	5415-8121	4
300-499	3249-5414	3
101-299	1093-3248	2
<100	<1093	1

The Total score in Kuppuswamy's classification is calculated as the sum total of the three scores, i.e., Education (A)+ Occupation (B)+ Income (C) Depending on the total score so computed, the five socio-economic classes are as given in Table-3.

Education of head of family	Score	Occupation	Score	Family Income per month	Score
Professional Degree	7	Professional	10	Rs.2000and above	12
Graduate	6	Semi-profession	6	Rs1000-1999	10
Intermediate/Diploma	5	Clerical/shop/farm	5	Rs 750-999	6
High school	4	Skilled worker	4	Rs 500-749	4
Middle school	3	Semiskilled	3	Rs 300-499	3
Primary school	2	Unskilled	2	Rs 101-299	2
Illiterate	1	Unemployed	1	Rs <100	1

Total Score	Class	Description
26 - 29	I	Upper class
16 - 25	II	Upper middle
11 - 15	III	Lower middle
5 - 10	IV	Upper lower
Below 5	V	Lower

Prasad's Scale : Dr. B G Prasad's social classification was developed in 1961 and is based on per capita per month income. There are five classes, as follows Upper class (per capita per month income Rs 100 and above); Upper middle (50-99); Lower middle (30-49); Upper lower (15-29); and Lower (below 15). The income group can be recalculated by multiplying the above mentioned income as mentioned in Prasad's classification with P Kumar's conversion factor i.e.

Conversion factor = (Value of CPI X 4.93) ÷ 100

For example, the AICPI for June 2008 was 650. Thus the conversion factor will be

$(4.93 \times 650) \div 100 = 32.04$, or roughly, 32. Thus the ranges of per capita per month income of this classification for 2008 will be >Rs 3200; 1600 - 3199; 960 - 1599; 480 - 959; and, < 480.

Pareek's Scale : The Socio-Economic Scale (rural) developed by Pareek attempts to measure socio-economic status of a rural family. It is based on the nine items as follows : Caste; Occupation of head of family; Education; Levels of social participation; Land holding; Farm power (prestige animals); Housing; Material possessions; and, Family type. The combined score for the nine items is graded to indicate socio-economic class categories.

Summary

Sociology deals with the study of society. Society is a group of individuals who have organized themselves and follow a given way of life. Man is a subunit of a small group; the family, while the family is the basic unit of society. Man's behaviour is affected not only by his physical and biological environment but also, to a larger extent by social environments represented by his family. A *community* can be defined as a group of people who have some common characteristics and are bound together by "WE" feeling. This sense of 'we' feeling (i.e., shared togetherness) may be due to a place where they all stay or due to some other common interest. Accordingly, communities can be either "structural" or else, "functional" communities. Community affiliations often provide a source of support for individuals and groups. *Culture* is defined as learned behaviour which has been socially acquired. The cultural factors such as customs, beliefs, values and religious taboos create an environment that helps in the spread or control of certain diseases and affect health of the community. The *Family* is a group defined by a sex relationship precise and enduring to provide for the procreation and upbringing of children. The family is a cultural unit, an epidemiological unit, and a unit for providing social

services as well as comprehensive medical care. The Family has an important role to play in Health and Disease. The health of the child is bound up with the family's internal and external environment even before it is born. The members of family share a pool of genes and a common environment as well as common modes of thoughts and behaviour and family material and social environment which includes housing, sanitation and diet. For health promotion and intervention, every family has certain important functions like Upbringing of children; Socialization in the family; laying foundation of physical, mental and social health of the child; Care during sickness especially pregnant women, children, aged and handicapped; providing support in crisis and problems.

Any large number of people gathered in one place is called a *crowd*. A crowd is potential medium for arousing emotion and for encouraging its expression. The term *mob* refers to one crowd that is fairly unified and single minded in its aggressive intent. Mob action is not usually destructive but tends to be focused on some one target or identity. *Social Pathology* is the systematic study of human disease in relation to social conditions and disease process outside the human body. *Social Diagnosis* is made by socio-medical surveys and by study of domestic and social conditions of individuals. *Social Therapy* offers holistic development-centered therapeutic and support services. The approach addresses and supports the total social, emotional and educational needs of young and the entire family.

Education is a process of learning undergone by individuals for gaining *knowledge*, developing attitudes and acquiring skills. *Attitudes* are mental habits acquired from social experiences that predispose us to react to specific objects, persons or situations in a definite way. *Practices* are application to particular and personal situation. *Community's Social Support Systems* comprise a network of family, friends, co-workers and professionals. *Social Assistance* implies provision of relief to individuals at critical times without having received any contribution from them. *Social Environment* includes all those things which arise out of social relationships such as customs, traditions, institutions, social conduct, rituals, diet, way of life and economic status. Health is profoundly influenced by the social environment. Important measures for providing healthy social environment are : Social Security against fear and want, Good Housing with all important facilities, Protection of property, life and honour and Safe work place. *Social Security* : Social security means public programmes designed to protect individuals and their families from income losses due to unemployment, old age, sickness or death. Social stratification is a horizontal division of society in to several socio-economic layers : Each layer or social class has a comparable standard of living, status and life style. Social class is determined on the basis of various scales like Kuppuswamy's scale for Urban and Prasad's scale and Pareek's scale for Rural.

Study Exercises

Long Questions : (1) Describe the role of Family in Health and Disease. (2) Describe the role of Cultural factors in Health and Disease. (3) What is Social environment? How does it affect the health and disease? Enumerate important measures for providing healthy social environment.

Short Notes : (1) Social pathology (2) Social Security measures (3) Kuppuswamy's scale.

MCQs :

1. Kuppuswamy's scale is based on the following variables except (a) Education (b) Occupation (c) Income (d) Housing
2. According to Kuppuswamy's scale, total score for upper middle class is (a) 11-15 (b) 16-25 (c) 26-29 (d) 29-31
3. According to Kuppuswamy's scale, total score for upper

lower class is (a) 11-15 (b) 16-25 (c) 26-29 (d) 5-10

4. The Socio-Economic Scale developed for rural setup is (a) Kuppuswamy (b) Pareek (c) Prasad (d) None of the above
5. The following are Social security measures against fear and want except (a) ESI scheme (b) Old age pension (c) Housing (d) Life insurance

Answers : (1) d; (2) b; (3) d; (4) b; (5) c.

Family Health History & Individual Medico - Social History - Taking

RajVir Bhalwar & SSL Parashar

It is abundantly clear by now that every disease has a tremendous social component. The various components of sociology, as described in previous chapter, decide whether a given human being will be exposed to the disease process or not; if exposed, whether disease process will perpetuate or not; and finally, what will be the outcome of the disease process. It is therefore extremely important that every Doctor should work up the psycho-social and behavioural components of a patient and not simply the clinical findings / laboratory investigative results, to effectively treat the patient and to prevent recurrence of the disease. For example, going simply by the clinical picture, we may treat a child with dehydration, with i.v. fluids and supportive therapy, and discharge her after a few days as "cured". However, if we did not work up the details of environmental sanitation and water supply at the child's house, the knowledge attitudes and health related practices of the mother, the family size, and so on, for certain the child will keep coming to us. Thus, for having a totalistic or holistic overview of our patient and to really treat the disease effectively, "from the root causes", we must take a proper medico-social history, work out the various sociological parameters and treat, not only the clinical disease, but also the social causes.

Medico-social history taking is, therefore, also an essential requirement at the undergraduate and postgraduate level of medical curriculum, with a view to prepare the general and specialist Doctors to function effectively as Community physicians.

In addition to recording a detailed medico-social history from an individual patient, it is also very important for the public health manager to consider the "family" as a unit of action for her various health care activities. In the previous chapter, we have already emphasized regarding the tremendous impact

that the family has on the health and disease of individual members of the family.

In fact, it would be highly desirable that every Public Health Programme Manager and Medical Officers in-charge of a Primary Health Centre (PHC) / Community Health Centre (CHC) should develop "Family Health Folders" for each and every family in his / her area of health care, on the same lines as Departments of Community Medicine in Medical Colleges; maintain and regularly update such folders in their respective Rural Health Training Centres (RHTCs) and Urban Health Centres (UHCs). The contents of these family folders should be regularly updated by regular visits to the households by medical / paramedical staff, preferably once in six months and definitely once in a year. It would be a further good work if the contents of these folders be entered into a computer database, so as to help in quick retrieval and analysis of data, which would greatly assist in planning and evaluation of public health programmes.

In the present chapter, we shall be dealing with the details of firstly, the 'family health folder' and secondly, regarding medico-social history taking and how to draw conclusions from such history.

The Family Health Folder & Family Health Records

As said above, it should be an endeavour of all health care providers to ensure that they have a detailed family health folder for each and every family in their area of health care jurisdiction, and these folders should be updated very regularly.

General description : The family health folder should be generally 12 inches X 10 inches and preferably having a hard cover to ensure durability. It should have a system so that various cards / papers can be filed in the folder. Having a "multiple leaflet" folder may be even better as it will assist in filing various records separately, for various members of the family, within the same folder.

The cover of the folder should be printed with the name of the PHC / CHC or any other health care providing unit who is responsible for health care of that family, and the address

and telephone number of the health care unit. In addition, the following details should be printed on the cover :

- The “Family Registration Number”. This is a unique number which is allocated to a particular family and acts as a unique identifier for the family, especially when computer based records have been made. The number is unique in that no two families should have the same number. The number may be allocated based on some registration given by the local self governmental body as panchayat, or may be developed by the health care providing unit. What is more important is that whatever system has been developed should be enforced, ultimately taking care that every family under health care has a registration number which is unique for that family. Secondly, every family head should be communicated about the number (preferably, given a laminated card having the number printed on it) and they should be advised to bring the laminated card whenever they come to the health centre.
- The name, father's / husband's name and date of birth of the head of the family.
- The detailed address of the household, including the post office and police station.
- Telephone number or any other contact number.
- The permanent address in case the family is of a “migratory” nature or is not a permanent native of that place.
- The date on which the folder was opened.
- The date on which the folder was last updated as a part of the regular survey for updating the family folders.
- The date on which the folder was updated, since some individual member of the family came in contact with the health care system (e.g., one of the ladies may be seen in an ante-natal clinic).

The inside surfaces of the folder may be provided with pockets made of thick plastic or strong cloth, for keeping important slips.

Confidentiality of Information : It should be ensured by the health care providers that all information recorded in the folder should be kept strictly confidential, and used for sole purpose of health / medical care, as per the laid down / acceptable codes of medical ethics.

Summary-Sheet : The inside of the front cover should have a printed table, in which the information should be filled up in pencil (to enable making changes); alternatively, the first sheet in the folder should have the information as given in Table-1.

In column (7) of Table - 1, a person who comes to stay temporarily

(as one of the sons who may be working in a town and coming to stay only during festivals) should be indicated accordingly. In column (8), if the person is known to be having any disease, the details should be entered; this should also include entries regarding current pregnancy. The remarks column should include any relevant which is considered to be important for the health care provider to know, at the first glance.

Sheet for Socio-Demographic Details

The next sheet in the family health folder should be for the socio-demographic details of the family, recording the following details :

- Total number of members in the family
- Distribution according to age and sex

Age groups	Males	Females	Total
Upto 1 year			
1 to 5 years			
6 to 14 years			
15 - 45 years			
45 - 64 years			
> = 65 yars			

- Total family income per month (all sources included) Rs.
- Per capita per month family income & Social Class
- Distribution according to Educational level

Educational level	Males	Females	Total
Graduate & above			
Matriculate but not graduate			
Educated more than 5th standard but not literate			
Educated upto 5th standard			
Illiterate			

Vital Statistics Record Sheet : Information regarding births, deaths, marriages, divorces, in-migration and emigration should be recorded in this sheet, starting from the day the family folder is commissioned for the particular family, recording the date and details of each such event.

Table - 1

Sl. No.	Name	Date Of Birth	Age	Sex	Relation With Head	Permanent Or Temporary Resident	Current Health Status	Immunisation status	Occupation	Contraceptive use	Remarks
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)	(12)

Sheet for Record of Housing and Environmental Sanitation:

This sheet should record the following information

- General description of the area, approach, access roads
- Evidence of water logging and potential mosquito / housefly breeding points
- Type of house, condition of roof, floor and walls
- Total floor area
- Total living rooms
- Total floor area per person and total space (in cubic feet) per person
- Any evidence of overcrowding
- Area of Doors and Windows
- Ventilation
- Availability of electricity
- Details of water supply (source, safety and potability, quantity, storage)
- Condition of kitchen, eating place and food sanitation practices
- Details of disposal of night soil
- Details of disposal of solid wastes
- Details of disposal of waste water and storm water

Individual Health Record Sheets : One health record sheet should be prepared for each individual. It should contain the details of the general health check up as well as the records of results of investigations and hospitalization, if any. The same sheet should continue to have entries of treatment given, as and when the individual reports sick to the health care facility. The special health cards (as ante-natal card, under-fives health card and child health record card) as applicable should also be filed alongwith the general health record card for that individual.

Special Health Record Sheets : These would include the ante-natal and post-natal health care card, the under-fives health card and the school-age child health record card. These should be prepared for each individual member of the family, as applicable, as per details given in the relevant chapters in the section on maternal and child health care. These special health record cards should be filed, in the family folder, alongwith the general health record sheet for that individual.

Sheets for Record of Special Studies / Surveys : There should be a separate sheet for recording the findings of special studies in respect of the family. For example, if a nutritional survey or a geriatric age group survey and so on have been conducted in that area, the findings of these studies / surveys in respect of the concerned family should be recorded on this sheet.

Medico-Social History Taking & Family Case Studies

As said earlier, every medical, nursing and paramedical person should view a given disease in totality, in context of the various socio-cultural, psycho-emotive and economic factors which initiate and perpetuate the disease process, and not simply confine themselves to only the medical aspects of the disease. It is for this reason that undergraduate medical and nursing students as well as post-graduate students in the specialty of Preventive & Social Medicine (Community Medicine; Public health) are required to be trained and examined in the various aspects of medico-social case taking and family case studies,

as a part of the University curriculum. Similarly, considering the over-riding importance of the role of family in health and disease, a family is allotted as a project and often during the examination, to be studied and presented as a “unit”, rather than presenting an individual case with a disease.

The details of family-case taking have been already dealt with in detail, earlier in this chapter, while discussing the family health folders. The details of medico-social case work up are being discussed herewith in the succeeding paragraphs.

Approach to the patient : Introduce yourself with a friendly greeting, giving your name and status. Explain the purpose of your visit, ask for and remember the patient’s name and request permission to interview and examine the patient. Some patients rapidly tire of being questioned or examined, and others may be depressed because they are ill or apprehensive. If there are difficulties in establishing a rapport, try to determine the reason; if in doubt, consult the medico-social worker or nursing staff. Show tolerance, particularly with the elderly and the challenged. Seek first to understand and not judge the patient so that you don’t react to patients with criticism, anger or dismissal. Some additional tips for effective medico-social case taking are :

- Maintain good eye contact.
- Listen attentively.
- Facilitate verbally and non-verbally.
- Touch patients appropriately.
- Discuss patients’ personal concerns.
- Give the patient your undivided attention
- Keep your notes-taking to a minimum when the patient is talking
- Use language which the patient can understand
- Let patients tell their own story in their own way
- Use open questions initially and specific (closed) questions later
- Clarify the meaning of any lay terms which patients use
- Remember that the history includes events up to the day of interview
- Summarize (reflect back) the story for the patient to check
- Utilize all available sources of information

The fundamental principles underlying medico-social case

work-up : The basic principle which must be kept in mind while undertaking a medico-social work-up is that while the patient is the core issue, his disease is actually a result of complex psycho social interactions between the patient, his / her family members, the environment at the workplace (including school), the immediate community members comprising of friends and close associates, the community at large within which the patient lives, and the larger society which consists of the governmental and non-governmental systems. A systematic assessment of all these factors is therefore necessary to be able to reach the root of the problem and to effectively plan a holistic therapy, taking care of not only the biological cause of the disease but also the wider social reasons that lead to the causation and perpetuation of the disease. The factors to be considered at various levels are :

1. Factors Within the Individual : The following variables should be recorded in detail :

- Age

- Education
- Occupation
- Level of protection against common infectious diseases, by way of immunization or previous infection
- Lifestyle : details of habitual physical exercise, diet, tobacco, alcohol and substance abuse, sexual promiscuity
- Knowledge, Attitudes & Practices (KAP) as regards common diseases and their prevention
- Psycho-Emotive state : whether cheerful and optimistic or anxious / depressed or concerned.
- Separation from family members / near & dear ones.
- Attitudes towards
 - Personal protection, as use of helmets, use of mosquito-nets, etc.
 - Personal hygiene, as regular bathing, hand washing, oral care, etc.
 - Health Care System, whether positive and trusts the health care system or unhappy / skeptical.
 - Attitudes as regards the disease from which the patient is suffering, and his / her concerns as regards it's perceived future course / management / rehabilitation

2. **Factors in the family** : These will include three broad categories of factors, viz., Social Factors, Physical Factors And Psycho-Emotive Factors.

(a) Social Factors in the Family

- Type : Whether joint, three generation or nuclear
- Organisation & Composition : Total number of members, head of the family, description of family members by name, age, sex, and position relative to the head.
- Religion and caste
- Education : general level of education; attitudes towards formal education; proportion of members who are professionally qualified / having degree / educated / illiterate
- Occupational patterns in the family
- Income : Total family income; income of the index case; Per capita per month income
- Socio Economic Status according to acceptable scales as Kuppuswamy or Prasad scale.
- Knowledge, Attitudes & Practices in the family, in general towards healthy lifestyle, personal protection and prevention of common diseases.
- Health Care services for the family. These should be assessed in terms of :
 - Availability
 - Accessibility
 - Affordability
 - Quality
 - Utilisation
- Social Aberrations if any in the family, as promiscuity, alcoholism, delinquency

(b) Physical Factors in the Family : These will include -

- Housing : General description, type of construction, area & space, ventilation, overcrowding, lighting, other comforts.
- Water Supply : Source, hygienicity, adequacy, storage
- Disposal of night soil, solid wastes, animal wastes, waste

water.

- Food hygiene : Methods of cooking, storage of raw and cooked food, food hygienic practices.
- Nutrition : Assessment of intake of overall calories and major macro / micronutrients; deficiency diseases; relative distribution of food among various members; percentage of monthly income spent on food.
- Exposure to and protection from insect vectors of diseases.

(c) Psycho-Emotive Factors in the Family : These include

- Level of Interactions / Bondages
 - Between family members
 - Of family members with the Index Case
- Family Support System : In terms of financial support, physical support (as readiness to physically assist the patient in activities of daily living) and emotional support; and, readiness of family members to provide "support".
- Understanding, by the family members, of the disease and it's determinant psycho-social problems that the patient is facing

3. **Factors in the Workplace** : (Note that for children, school is to be considered as workplace)

- General description of the workplace or school
- Attitude & Support (Emotional, Physical, Financial) on part of
 - Employers / Superiors / Teachers
 - Colleagues / Classmates
 - Subordinates / ancillary staff in school
- Availability of facilities, in school / workplace, to cater to special needs of the patient

4. **Factors in the Immediate Community** : (Immediate community consists of the Village / Mohalla in which the patient is living).

- General description (income levels and standards of living in general, major occupations, general types of housing, educational levels, social aberrations as alcoholism, delinquency, etc.)
- Community Organisation, strength of "we" feeling, cohesiveness between the families in the community.
- Interactions, of various community members, with the Index Case and his / her family members
- General attitude of community towards disease prevention & health care
- Availability of Physical, Financial & Emotional Support Systems within the community.
- Health care facilities available
- Availability of School / Special School catering to the special needs of the index case.
- Availability of NGOs / Voluntary Bodies and description of their capabilities.
- Availability of organised public health & social services as central water supply and it's purification, disposal of wastes, transportation and communications.
- Political will of the community as strength of its representation in elected bodies
- Identification of peers & influential leaders and their capabilities.

5. Factors in the Community at Large : This includes the larger social environment as the District / State where the patient is living.

- General Attitude
 - Towards Health maintenance, Disease Prevention & Rehabilitation
 - Towards the disease in question
- Availability of treatment facilities
- Availability of Rehabilitation facilities
- Statutory and Administrative provisions to protect / facilitate the index case.
- Availability of VHAs / NGOs

6. Summarize The Medico-Social Findings

- What are the “*Key Psycho-Social Issues*” in the index case, his / her family, workplace, immediate community and the community at large.
- What is the “*Social Pathology*”, i.e. the major “weaknesses”; for example, in a medico-social case of an adolescent polio affected girl child, the major weaknesses and hence the social pathology operative in that case could be summed up as “Alcoholism in the family” with “Poor purchasing power” with “ Adverse attitudes towards the girl child”
- What is the “*Social Diagnosis*” i.e., those adverse psychosocial effects that the social pathology (major weaknesses) would lead to; for example, in the hypothetical example of the case of polio affected girl child, “ Gross Physical handicap with Poor Rehabilitation facilities with Broken family and adversely predisposed community” may be identified as the social diagnosis, which will result from the identified social pathology, and will therefore need to be “treated”, the way we treat a disease diagnosed by us.
- What are the “*Major Strengths*” in our case. This will be worked out by analyzing the support systems - Physical, Social, Vocational, Emotional and Financial, which are available within the family, workplace, and community systems, as also the strengths within the index case (as determination, residual abilities, etc.).

7. Write down the Plan of Management & Social therapy

- Write down in a line each, the following, for the case being worked up :
 - The social pathology
 - The social diagnosis
- Write down your summarized analysis of the Strengths, Weaknesses, Opportunities and Threats (SWOT) in this case.
- Write down what all
 - Should be done, ideally, in this case
 - Can be done in this case (“Do-Ability” analysis), after considering the SWOT.
- Write down the overall aim and key objectives for the medical management part as well as the psycho-social management for the case.
- Now, write down a detailed plan for each of the following aspects, indicating “who will do what, how, and in what time-frame”
 - Medical management

- Prevention of Other Diseases and for leading a healthy life
- Disability Limitation
- Physical rehabilitation, eg, physical help for activities of living, for going till the health care centre, etc.
- Vocational rehabilitation - training, education, earning a livelihood, reservation in job and education, etc.
- Emotional Rehabilitation
- Social Security

Summary

It is abundantly clear by now that every disease has a tremendous social component. Thus, for having a totalistic or holistic overview of our patient and to really treat the disease effectively, “from the root causes”, we must take a proper medico-social history, work out the various sociological parameters and treat, not only the clinical disease, but also the social causes. Medico-social history taking is an essential requirement at both under and postgraduate level but other than focusing on the individual patient, it is also very important for the public health manager to consider the “family” as a unit of action for her various health care activities.

It is highly desirable that Medical Officers in-charge of a Primary Health Centre (PHC) / Community Health Centre (CHC) should develop “Family Health Folders” for each and every family in their area of health care and these should be regularly updated. Family folder should be generally 12 inches X 10 inches, with hard cover and having “multiple leaflets” so as to record separately, for various members of the family, within the same folder. The cover of the folder should be printed with the name, health care providing unit along with the address and telephone number. In addition on the cover it should have “Family Registration Number” (unique number for each family), name and date of birth of the head of the family, detailed address of the household, telephone number, date on which folder was opened and date on which folder was last updated. On the inside of the front cover or the first sheet in the folder should have a printed Summary-Sheet which would have details of all the members of the family. Other details of the family would be recorded on Sheet for Socio-Demographic Details, Vital Statistics Record Sheet, Sheet for record of Housing and environmental sanitation, Individual Health Record Sheets, Special Health Record Sheets, Sheets for Record of Special Studies / Surveys. Finally it should be ensured by the health care providers that all information recorded in the folder should be kept strictly confidential.

All medical professionals should not simply confine themselves to only the medical aspects of the disease but view a given disease in totality. This can be achieved by training in the various aspects of medico-social case taking and family case studies. The various essential aspect of medico-social case work up are, to start with, initial approach to the patient whereby you should introduce yourself with a friendly greeting, try and remember the patient’s name and request permission to interview and examine the patient. Show tolerance, particularly with the elderly and the challenged. Seek first to understand

and not judge the patient so that you don't react to patients with criticism, anger or dismissal.

The basic principle which must be kept in mind while undertaking a medico-social work-up is that while the patient is the core issue, his disease is actually a result of complex psycho social interactions and a systematic assessment of all these factors is therefore necessary to be able to reach the root of the problem and to effectively plan a holistic therapy. For this factors need to be considered at various levels, these are Factors within the Individual which would include age, education, occupation, lifestyle including consumption of tobacco, alcohol etc, Knowledge, Attitudes & Practices (KAP) as regards common diseases, Psycho-Emotive state and attitudes towards personal protection, personal hygiene etc. Factors in the family which would involve taking detail history under following headings Social Factors in the Family, Physical Factors in the Family, Psycho-Emotive Factors in the Family. After family one would like to find out factors in the Workplace, Immediate Community and Community at Large influencing the individual and the disease. Now summarize the Medico-Social findings under the following heads Key Psycho-Social Issues, Social Pathology, Social Diagnosis, Major Strengths. Finally write down the plan of management & social therapy keeping in mind SWOT analysis (Strengths, Weaknesses, Opportunities and Threats) for this case and details indicating "who will do what, how, and in what time-frame".

Study Exercises

Short Notes : (1) Enumerate broad headings under which one would do medico social case work up (2) SWOT analysis.

MCQs & Exercises

- 1) All are true about "Family Registration Number" except : (a) This is a unique number (b) no two families would have the same number (c) may be given by the central government (d) may be developed by the health care providing unit
- 2) Following dates should be written on the cover except : (a) The date on which one of the family members were vaccinated (b) The date on which the folder was updated, since some individual member of the family came in contact with the health care system (c) The date on which the folder was last updated as a part of the regular survey (d) The date on which the folder was opened
- 3) Immunization status is recorded in : (a) Vital Statistics Record Sheet (b) Sheet for Socio-Demographic Details (c) Summary-Sheet (d) Sheet for record of Housing and environmental sanitation
- 4) Special Health Record Sheets include all except (a) Under-fives health card (b) School-age child health record card (c) Post-natal health care card (d) Ration Card
- 5) For effective medico-social case taking one should : (a) Not Maintain good eye contact (b) Touch patients appropriately

- (c) Not discuss patients' personal concerns (d) Not give patient undivided attention.
- 6) In KAP "P" stands for : (a) Prevention (b) Practice (c) Psycho-emotive state (d) Physical factor
- 7) "SWOT" analysis stand for all except : (a) Strength (b) Weakness (c) Opportunities (d) Treatment.
- 8) Health Care services for the family should be assessed in terms of all except : (a) Availability (b) Accessibility (c) Affordability (d) Accountability
- 9) Socio Economic Status according to Kuppuswamy or Prasad scale is calculated under which broad heading: (a) Social Factors in the Family (b) Physical Factors in the Family (c) Psycho-Emotive Factors in the Family (d) Factors in the workplace
- 10) Physical Factors in the Family include all except : (a) Total no. of family members (b) Housing (c) Water Supply (d) Nutrition
- 11) Family Support System includes : (a) Financial support (b) Physical support (c) Emotional support (d) All of the above
- 12) Immediate community consists of : (a) Village (b) District (c) State (d) Country
- 13) Factors in the Immediate Community include all except : (a) Community Organisation (b) Strength of "we" feeling (c) Interaction between family members (d) Cohesiveness between the families in the community
- 14) "Major strengths" of a case can be worked out by analyzing : (a) Social Diagnosis (b) Social Pathology (c) Psycho-emotive state (d) support systems
- 15) Plan of Management & Social therapy includes all except: (a) Medical management (b) Giving money (c) Disability limitation (d) Emotional support.

Fill in the Blanks

1. Public Health manager should consider _____ as a unit.
2. Family health folder should be updated regularly by visits to household by the paramedics preferably once in _____ and definitely once in _____.
3. Family health folder should of size _____ by _____ inches.
4. Factors in the family include three broad categories of factors which are _____, _____ and _____.
5. KAP stands for _____, _____ and _____.

Answers : MCQs : (1) c; (2) a; (3) c; (4) d; (5) b; (6) b; (7) d; (8) d; (9) a; (10) a; (11) d; (12) a; (13) c; (14) d; (15) b.

Fill in the Blanks : (1) Family (2) 6months; one year (3)12; 10 (4) Social factors, Physical factors and Psycho-Emotive factors (5) Knowledge, attitudes and practices.

SSL Parashar

Health education is the application of scientific health knowledge or translation of what is known about health into desirable individual and community health behaviour and actions. It removes ignorance and promotes intelligent understanding of individual and community health needs. It helps people to achieve health by their own actions and efforts.

In earlier times, public health dealt with the sanitation of the environment and the control of communicable diseases enforced by law, if found necessary. However stimulating and helping people to assume responsibility for themselves needs understanding people's behaviours and the factors influencing it. Health education attempts to influence the health related knowledge, attitudes and behaviours of individuals and communities. In fact, in contemporary public health practice, providing health education, with a view to achieve positive health related attitudes and behaviour form community members is the most important requirement, be it prevention and control of HIV / AIDS or lifestyle (non-communicable) diseases or prevention of infectious diseases and so on.

Definition : Health education is a process that informs , motivates and enables people to adopt and maintain healthy practices and lifestyles. It also advocates environmental changes as needed to facilitate this goal and conduct professional training and research to the same end. In other words, Health education may be defined as a process of bringing about change in the individual's knowledge, attitude and behaviour so as to enable him to achieve health.

Principles of Health Education :

1. *Community involvement* in planning health education is essential. Without community involvement the chances of any programme succeeding are slim.
2. The promotion of *self esteem* should be an integral component of all health education programmes.
3. *Voluntarism* is ethical principle on which all health education programme should be built without it health education programmes become propaganda. Health education should not seek to coerce but should rather aim to facilitate informed choice.
4. Health education should respect *cultural norms* and take account of the economic and environmental constraints face by people. It should seek positively to enhance respect for all.
5. Good *human relations* are of utmost importance in learning.
6. *Evaluation* needs to be an integral part of health education.
7. There should be a responsibility for the *accuracy* of information and the *appropriateness* of methods used.
8. Every health campaign needs *reinforcement*. Repetition of messages at intervals is useful.

Information Education Communication (IEC)

IEC is a broad term comprising a range of approaches and activities. Visible component of IEC is frequently the material produced and used. Effective IEC makes use of a full range of approaches and activities. IEC activities are grounded in the concepts of primary health care, concerned with individual behaviour change and changes in social or community norms. IEC can be defined as an approach which attempts to change or reinforce a set of behaviour in a target audience regarding a specific problem in a predefined period of time. It is multidisciplinary and client centered in its approach drawing from the field of diffusion theory, social marketing, behaviour analysis and anthropology. Embodied in IEC is the process of learning that empowers people to make decisions, modify behaviours and change social conditions. Activities are developed based upon needs assessments, sound educational principles, and periodic evaluation using a clear set of goals and objectives.

Communication

A good working definition for effective communication is to share meaning and understanding between the person sending the message and the person receiving the message. The key element is "understanding."

Verbal & Non-verbal Communications : In verbal communication, the tone of voice can communicate feelings and emotions that are as significant as the words being spoken. Accordingly, it is important to choose words that do not offend in any way and that are easily understood. One should avoid using trigger words, jargon, medical or other sophisticated terms. The use of particular languages may be important in reaching all sections of a community. In non-verbal communication, body position, gesture and facial expression, often referred to as body language, can communicate as much as words. It is often through such body language that we express our attitude towards an issue, a person or a person's behaviour. Service provider must become skilled in interpreting the body language of users as this may assist them understanding users' needs and concerns more fully. Service providers must also be aware of their body language and signals they may be unknowingly sending to users (e.g. movements or expressions that indicate fatigue, boredom, fear, frustration, indecision) (women may speak fewer languages than men, for example).

Communication Process

In health communication we communicate for a special purpose to promote improvements in health behaviour through the modification of the human, social and environmental factors that influence behaviours. It is necessary to understand how communication works. The various components involved in the process of communication are depicted in Fig. - 1.

Components of the Communication process : It is apparent that several elements are involved in the process of communication. It will also be appreciated that communication is two way process. This implies that just as the sender (source) is communicating with the receiver; so is also the receiver communicating with the sender. The components are :

The Sender : Sender is the source of Communication. Sending the message to the receiver will depend on his personality, mannerism, conviction conduct etc. The following aspects need to be particularly considered with regards to the sender :

- His own competence and expertise in the subject.
- His own convictions about what he speaks.
- His own mannerism, which include non-verbal communication skills.

The Receiver : Also called the audiences who are receiving the message sent by sender.

The Message : This refers to the information which desires to communicate and must possess the following attributes :

- Message should be precise and to the point
- The ambiguity in the message may create more harms than good.
- The information should vary from person to person or from group to group depending upon their background.
- The message must necessarily contain clear concrete suggestions for action in day to day life of the receiver.

The Medium (Channel) : The communication channel through which the message moves from the sender to receiver is the medium. These include the various methods (as lecture or exhibition) and the “aids” (as slides, slide projector) which are utilized to communicate the message.

Encoding : This process includes the language expression, gestures and actions utilized for the purpose of making the information intelligible to the receiver. Obviously the receiver must be familiar with the code.

Decoding : The process by which the receiver assigns meaning to the symbols transmitted by the sender. In other words, the process by which the receiver understands or interprets the message is called decoding.

Feed back : Feedback is the mirror of communication. Feedback is the receiver sending back the message to the sender, the message as perceived. Without feedback communication is one-way. The part of the receiver’s response that the receiver communicates back to the sender.

Propaganda and Advocacy : Propaganda is merely a publicity campaign aimed presenting a particular thing or concept in a favourable light in such a way that public may accept it without thinking. It is a deliberate attempt planned with a view to altering and controlling ideas and values along predetermines lines. The widely employed techniques are an appeal to emotions, feelings and sentiments. It prevents or discourages thinking by readymade slogans. The knowledge is

spoon-fed and passively acquired. As a mass-communication activity propaganda tends to have short-run situationally-defined aims with an appeal to diverse population on the basis of immediate interest, fears or desires. The objective is to not so much influence the individual deeply as to win his support for some immediate issue.

The aim of ADVOCACY is to place health problems issues on the political agenda and effectively reach the influential group of policy makers, elected representative, professionals and other interest group to formulate and implement policies to create pressure groups and supportive systems in order to respond appropriately to the health problems. It helps in identifying potential allies and building alliances and relevant policy and decision making channels. The information concerning position on the issue is collected and provided. A common understanding among stakeholders concerning issue is created through advocacy and negotiating action on the basis of common understanding is taken. Through advocacy reasoning, influencing, lobbying, pushing and persuading decision makers and other stake holders. The directions of advocacy are; (a) Advocacy for policy design (b) Advocacy for decision making at various levels (c) Advocacy for implementation .There are two types of advocacy : Proactive and Reactive advocacy. Proactive advocacy is bringing a particular issue in to public focus and providing a definite shape for the audience that is sought to be influenced and reactive advocacy entails addressing particular situation or problem once it has already surfaced in the open. It involves addressing attitudes and opinions after they have been formed in the recent past.

Barriers in Communication

Unplanned distortion during the communication resulting in the receiver obtaining a different message than that sent by the sender is referred to as barriers in communication (also called as “Noise” or “distortions” in communication). These can be :

Physiological : Difficulties in hearing, expression.

Psychological : Emotional disturbances.

Environmental : Noise, invisibility, congestion in the classroom, etc.

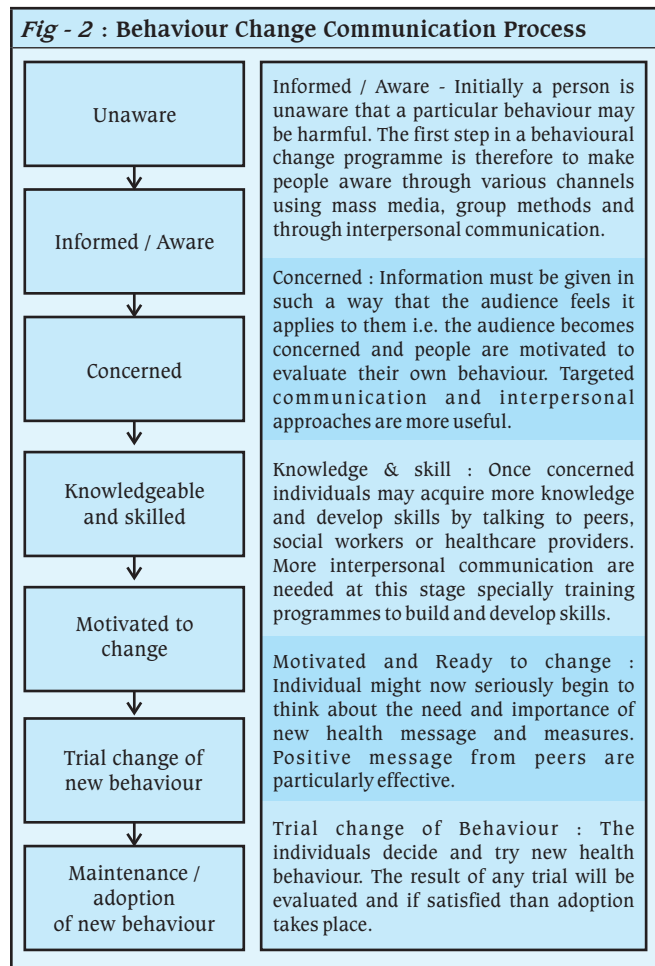

Cultural : Level of knowledge, understanding and receiver’s beliefs, etc.

All barriers should be identified and removed for achieving effective communication. One of the main challenges in the design of effective health communication programs is to identify the optimal contexts, channels, content, and reasons that will motivate people to pay attention to health information.

Communication skills are required to make communication effective, the following are the skills required at source level. These include greeting skills, speaking skills, listening skills, questioning skills, and summarizing skills. In short communication process would be effective if the communicator has skills in introduction, skills in presenting and skills in conclusion. The non-verbal skills play an important role. It affects the communication process. Body language is an important constituent of non-verbal communication and consists of gesture, postures facial expressions, eye contact, manipulating the eyebrows etc.

Behaviour Change Communication Process (BCC)

This is depicted in Fig. - 2.

Components of Health Education Process

Health Education has three broad components :

- Levels of Health Education
- Methods of Health Education
- Activities undertaken in individual methods

Levels of Health education : Health education is carried out at three main levels, viz. individual and family, group level and general public (mass) level.

Individual and Family Health Education : There are plenty of opportunities for individual health education. It may be administered during personal interviews in the consultation room of the doctor or in the health centre or in the homes of the people. The individual comes to the doctor or health centre because of illness. The opportunities are utilized in educating him on matters of interest - diet, causation and nature of illness and its prevention, personal hygiene, environmental hygiene etc. Topics for health counseling may be selected according to the relevance of the situation. By such individual health teaching, we will be equipping the individual and family to deal more effectively with health problems. The patient will listen more readily to the physician. A hint from the doctor may have

a more lasting effect than volumes of printed word. The nursing staff has also ample opportunities for undertaking health education. Public health supervisors are visiting hundreds of homes; they have plenty of opportunities for individual teaching in working with individual. The health educator must create an atmosphere of friendship and allow the individual to talk as much as possible. It is useful to remember, "An effective communicator is not the one who talks too much but one who listens too much." An effective method of individual education is, Counseling, which is defined as a confidential dialogue between a client and a health care provider aimed at enabling the client to cope with stress and take personal decisions related to disease. The counseling process includes an evaluation of personal risk of disease transmission and facilitation of preventive behaviour. The aim of counseling must always be based on the needs of the client. The purpose of counseling is three fold : to help clients manage their problems more effectively, to develop unused opportunities to cope more fully, and to help and empower clients to become more effective self helpers in the future. Helping is about constructive change and making a substantive difference to the life of the client. However, ultimately, it is only the client who can make the difference. The counselor is merely an instrument to facilitate that process of change. In the short-term, counsellors use basic skills to help clients make personal decisions about their behaviours. The counsellor's role is to provide accurate and complete information to help the user make her / his own decision about which, if any, part of the service(s) she / he will use. The role of the counsellor is not to offer advice or decide on the service to be used. For example, the counsellor will explain the available family planning methods, their side effects and for whom they are considered most suitable. The user then makes a decision, based on the information given, about which method she / he wishes to use.

Group Health Education : Our society contains groups of many kinds - schools children, mothers, industrial workers, patients etc. Group teaching is an effective way of educating the community. The choice of subject in group health teaching is very important it must relate direct to the interest of the group health. The methods in group health education are focus group discussions, health talks, demonstration, panel discussions, workshops etc. The group health education methods are effective in promoting behavioural change, influences opinion, develop critical thinking and increase motivation. Use of "aids" to education greatly facilitates group education. Examples of commonly used "aids" are given in Box - 1.

Box - 1 : "Aids" in Health Education

Auditory : Radio, Telephone, Audio cassettes, Tape records

Visual : Text Books, Posters, Charts, diagrams, film strips, comic strips, pamphlets, internet

Audio-Visual : Movies, lectures combined with slide presentations, Television.

Focus Group Discussions (FGD) : A Focus group discussion is a group discussion of 6-20 persons guided by a facilitator during which group members talk freely and spontaneously about a certain topic or health problem. The purpose of a focus

group discussion is to obtain in-depth information on concept, perceptions and ideas of group on a particular topic.

Education of the General Public (Mass education) : For education of the general public we employ “Mass Media” of communication. Mass media are generally less effective in changing human behaviour than individual or group methods because communication is one way. Nevertheless they do have quite an important value in reaching large numbers of people with whom there is no contact in a short period of time. The continuous dissemination of information and views about health through all the mass media contribute in creating awareness and raising of the level of knowledge in the community. Examples of Mass-Media are given in Box - 2.

Box - 2 : Examples of “Mass Media”

Television; Radio; News Paper; Films; Health Magazines; Posters ; Health Exhibitions; Health Museums; Printed Materials

For effective health education mass media should be used in combination with other methods. Television, News Paper, and Radio are the most basic channel of health information communication. In addition, the internet is one of the new channels of health information communication that is becoming more popular. The internet and other advance communication technologies such as mobile telephone message and satellite television are important channel for health information communication. They have had more influence in the younger generation and in urban community. These communication channels are emerging and being adapted rapidly in the movement toward modernization.

The communication of health information is important for changing knowledge, attitudes and behaviour. Suitable communication methods are adopted by health care providers. Thus the integration of communication methods has much potential and more effective strategies.

Methods of Health Education : Methods are generic descriptions of how change is to be brought about within the target group; for example, mass media and community development are two terms being used to describe a host of health education activities. While planning health education programs, it is not that any method can be used (as delivering lectures to all concerned) but rather the most appropriate method most suited for the topic and the target audience should be selected. The available methods are listed in Box - 3 (2).

Activities in Health Education : The various methods of health education, as enumerated above, are utilized through different activities, depending on the objectives and the type of target audience. For example, a small group / focus group discussion can be undertaken using a LCD projected slide show, or through a flip chart, or may be simply an open multi-way discussion without using any teaching aid. Similarly, mass education process may be through the activities of traveling through the streets with a loud speaker or by inserting TV footages or through a documentary cinema. The appropriate of the method and how this method is going to be processed (i.e., the activities) should be decided by the health education planner.

Box - 3 : Commonly Used Health Education Methods
Individual Instruction (as counseling, patient instruction)
Lecture - Discussion
Educational Television / Computer (Use of television, computer and internet for viewing of prepared programs)
Audio-Visual Methods (See Box - 1)
Mass Media Methods (See Box - 2)
Peer Group Discussion / Focus Group Discussions
Programmed learning (use of teaching machines or programmed texts)
Simulation & games (games, dramatizations, role playing)
Inquiry Learning (an approach in which students formulate and test their own hypothesis)
Behavioral change methods (including behavior modification and skill development methods)

Central Health Education Bureau (CHEB)

Central Health Education Bureau (CHEB) is an apex institution created in 1956 at Delhi under the Director General of Health Services (DGHS) Min. of Health and Family Welfare, Govt. of India for health education and health promotion in the country on the recommendation of the Bhore committee and the Planning commission. It plans and formulates programmes for the promotion of health education in the country through organizing training programmes to prepare health education professionals conduct behavioural research, studies in the field of health education and promotion provides training in social research methods to the health professionals, providing training to the teachers, Para medical professionals for promoting health education activities. Production of various printed and electronic mass media material and educational aids is another important activity of the Central Health Education Bureau (CHEB). The objectives of CHEB are as to :

1. Interpret the plans, programmes and achievements of the Ministry of Health and Family Welfare.
2. Design, guide and conduct research in health behaviour, health education processes and aids.
3. Produce and distribute ‘proto-type’ health promotion and education material in relation to various health problems and programmes in country.
4. Train key health and community welfare functionaries in health education and research methods. Evolve effective methodology and tools of training.
5. Help schools and teacher training institutes for health education and health promotion of the school population.
6. Provide guidelines for the organizational set-up, functioning of health education units at the state, district and other levels.
7. Render technical help to official and non-official agencies engaged in health education and health promotion and coordinate their programme.
8. Collaborating with international agencies in promoting health education activities.

Divisions of the Bureau : In order to achieve its objectives,

CHEB has four technical and one administrative Division, each headed by a senior officer. These Divisions are :

- Media and Editorial Division
- Health Promotion and Education Division
- School and Adolescent Health Education Division
- Training , Research and Evaluation Division
- Administrative Division

The CHEB provides Pre-service training, in-service training and orientation training (refresher course) to the health personnel.

Since health education of the various social groups of population can be taken by state Govts, a scheme was formulated in 1958 for the establishment of State health education bureau with central assistance. Now the State health education bureau are called Information Education Communication Bureau (IEC).

Summary

Health education is a process that informs, motivates and enables people to adopt and maintain healthy practices and lifestyles. It is a process of bringing about change in the individual's knowledge, attitude and behaviour so as to enable him to achieve health. It helps people to achieve health by their own actions and efforts. The principles of health education are Community involvement; promotion of self esteem; Voluntarism; respecting cultural norms and taking into account of the economic and environmental constraints; developing good human relations; Evaluation of needs; responsibility for the accuracy of information and the appropriateness of methods and lastly reinforcement.

IEC is a broad term comprising a range of approaches and activities. It can be defined as an approach which attempts to change or reinforce a set of behaviour in a target audience regarding a specific problem in a predefined period of time. It is multidisciplinary and client centered in its approach drawing from the field of diffusion theory, social marketing, behaviour analysis and anthropology. A good working definition for effective communication is to share meaning and understanding between the person sending the message and the person receiving it. It is either Verbal (the tone of voice) or Non-verbal (body language). The various components involved in the process of communication are Sender (source of Communication); the message, encoding and decoding it; the communication channel (as lecture or exhibition) and the "aids" (as slides, slide projector); the Receiver (audience); and the feedback.

Propaganda is merely a publicity campaign aimed presenting a particular thing or concept in a favourable light in such a way that public may accept it without thinking. The aim of Advocacy is to place health problems issues on the political agenda and effectively reach the influential groups. Barriers in Communication can be Physiological (Difficulties in hearing, expression); Psychological (Emotional disturbances); Environmental (Noise, invisibility, congestion in the classroom, etc); Cultural (Level of knowledge, receiver's beliefs). All barriers should be identified and removed for achieving effective communication. In Behaviour Change Communication Process (BCC), Information is given to the unaware people so that they become concerned, acquire more knowledge and develop skills and motivated to change their behavior & adopted a new one.

The three broad components of Health Education are Levels of Health Education, Methods of Health Education and Activities undertaken in individual methods. The three main levels are individual and family, group level and general public (mass) level. The various methods of health education, as enumerated above, are utilized through different activities, depending on the objectives and the type of target audience. An effective method of individual education is counseling and the methods in group health education are focus group discussions, health talks, demonstration, panel discussions, workshops etc. Television, News Paper, and Radio are the most basic channels of health information for general public. For effective health education mass media should be used in combination with other methods. Central Health Education Bureau (CHEB) is an apex institution created in 1956 at Delhi under the Director General of Health Services (DGHS) Min. of Health and Family Welfare, Govt. of India for health education and health promotion in the country on the recommendation of the Bhore committee and the Planning commission. It plans and formulates programmes for the promotion of health education.

Study Exercises

Long Question : Discuss the Principles of Health Education with examples.

Short Notes : (1) Principles of Health Education (2) Components of Health Education (3) Components of the Communication process (4) Barriers in Communication (5) Counseling (6) Focus group discussions (7) Mass Media.

MCQs :

1. Which of the following is not a one way communication (a) Symposium (b) Lecture (c) Group Discussion (d) Stage show
2. The best method of health instruction is (a) Providing reading assignments (b) Organizing film show (c) Setting an example (d) Giving lectures
3. The best way of teaching an urban women about ORS is (a) Lecture (b) Flash cards (c) Role play (d) Demonstration
4. Receiver's false beliefs are a _____ type of barrier in communication. (a) Physiological (b) Environmental (c) Cultural (d) Psychological
5. The method which is generally more effective among the following in changing human behaviour is (a) Counseling (b) Focus group discussion (c) Mass media (d) A series of lectures

Answers : (1) c; (2) c; (3) d; (4) c; (5) a.

In contemporary public health practice, health education of the community (whether small groups or large masses) or of individuals (patients or healthy individuals) is one of the most important health care activity. Medical officers and specialists in Community Medicine (Public health and Preventive Medicine) should therefore be well versed in the various steps to be undertaken while planning, organizing, implementing and evaluating health education programmes. This involves a series of scientific and sequential steps, which are being explained in this chapter.

Step 1 - Situational Analysis : The first, and one of the most crucial steps in health education programme planning is “Situational Analysis”, also known as “Community Analysis” or “Needs Assessment”. This is the essential step for gaining insight into the health problems, so that programmes can be developed and directed towards conditions which are significant issues for the community members. This step of community analysis consists of following five sequential steps, viz. analyzing the community backdrop, analysis of the health status of the community, analysis of the health care system of the community, analysis of social systems of the community, and SWOT analysis. These sequential steps are vital for making the community diagnosis. We discuss each of these steps, as follows.

Step 1 (a) - Analysing the Community Backdrop : The first thing is to get to know the area and the community in your health care jurisdiction (or the community for which you are planning the health education program) very well. Drive (preferably walk) around the entire area. Find out where are the work places, location of various governmental and non-governmental offices, location of various, markets, eating joints, recreation facilities, industrial areas, schools, hospitals, other health care facilities (as PHCs / subcentres), residential areas, slums, etc. See for yourself the minute details, as what are the roads and other communication systems, the pattern of residential accommodation, water supply system, night-soil disposal system, solid-waste disposal system, and environmental conditions. Don't forget to find out about sensitive issues like defined red-light areas, clandestine sexual avenues, tobacco kiosks, alcohol shops and so on. Listen to the local radio and see the local television programmes, which would further assist you in getting an insight into the community backdrop.

After the initial inspection, define some tentative boundaries that can demarcate the larger area into smaller, more homogenous aggregates. The most obvious choices are the major physical boundaries as major roads, rivers or government boundaries as those delimiting the village or Taluka or district. Another workable method may be to divide the area into five or six “sectors” for purpose of various preventive health care

activities. Having done this detailed exercise, make a detailed “spot map” showing all these various aspects as described above. For a public health manager, developing and regularly updating such spot maps should be considered an indispensable duty. Whenever you take over as the District health Officer / Public Health officer or a health programme manager, the first thing you should do is to undertake a detailed, on-ground assessment of your area under health cover and update the spot maps. Similarly MOs in-charge of PHCs / CHCs should assess the details and update the spot maps for their respective areas.

Find out the details of the socio-demographic characteristics of the community under your health care. Find out the total population, distribution according to social status, according to age groups, according to women and children, and further according to the different geographical sectors that you have made to demarcate the community. See the main occupations, industry and business patterns. Now write down the details in a textual form, complemented by the spot maps, tables of various demographic characteristics and other graphics. It is important to develop a written document at this stage since it will come very handy later on while implementing the health education programme. It is very desirable that all Public Health programme managers should always keep such a written document, duly updated, since it will be an essential and basic document for planning all health care activities including health education; the document can also be placed before the Governmental Administrators, as and when they visit them.

Step 1 (b) - Analysis of Community Health Status : In this step, the data related to important epidemiological parameters is collected from various sources as hospital records, official reports, and, if required, by a quick sample survey (Details of important epidemiological parameters and sources of epidemiological information have already been covered in the section on “Epidemiology”). The main parameters, depending upon requirements include Birth rate, death rate, IMR, MMR and Neonatal MR according to major socio-economic categories (as age groups, sex and social class). Thereafter, mortality and hospitalization rates per 1000 (or per lac) population are worked out, for the past 3 years, for the leading 10 or 15 causes, separately for males, females and children (preferably for different age groups). These rates give us a clear idea of the leading causes of death and disease for various age and sex groups. These rates are then compared with the rates for various leading causes of death and hospitalization that have occurred, overall, in the state or in the country, to see if there is any particular difference in the leading causes of ill health between the area where we are planning our health education activities and the overall state or country. The data should be arrayed in simple tables, showing the names of leading diseases in the first column, the rates per 1000 (or per lac) in the second column and the overall rates in the state / country in the third column.

Sources which need to be explored to obtain this information include Census office, Registrar of vital events, Civil hospital/ PHC / CHC and Private hospital records and interviews with medical practitioners / government Doctors.

An additional and extremely important part of this step is to also obtain data on health-behaviour related aspects of the clientele. This is best done by undertaking a cross-sectional and quick survey from a representative sample, obtaining data on leading lifestyle factors (diet, exercise, tobacco and alcohol use, obesity and sexual practices), personal hygiene and use of personal-protective measures (use of road safety and occupational safety devices, protection against insect vectors of diseases, bathing, hand washing and oral hygiene) and on water and food hygiene practices. This quick survey may bring forth some very important issues (which may not be evident by simple comparison of routine mortality / morbidity data) and which need to be tackled by health education programmes.

Step 1 (c) - Analysis of Community Health Care System : The third step of situational analysis (community analysis) is to collect and analyse data describing the resources for providing health care (both curative as well as preventive) as are available to the community. This is undertaken by describing, firstly, the formally recognized health institutions, as government and private hospitals, dispensaries, health centres, sub-district hospitals, preventive health care programmes and institutions executing them. Secondly, informally recognised practitioners as those of traditional systems are described. The medical and paramedical manpower is thereafter described, as number of physicians, surgeons, according to sub-specialties, nursing personnel, health / sanitary workers, laboratory trained personnel and so on. The organization of service delivery, referral systems and local health departments are studied. Finally the “grey areas” in health care, including communities/ locations which are underserved or disadvantaged are identified. The last step is important since community groups who are actually in maximum need of health education are usually also the ones who are underserved / disadvantaged or living in inaccessible areas.

Step 1 (d) - Analysis of Community’s Social Organization and Support Systems : In this step, the social structure and the social support systems are studied and analysed. The overall organisation of the community, the major community groups, the interaction between various community groups, the peers / leaders, the opinion formers and the political climate is studied. In addition, the various “Support Systems” available in the community (Voluntary organizations, NGOs, agencies which can organise financial assistance, charitable organizations, and so on) are studied, with a particular reference to how these can be gainfully utilized in relation to the proposed health education programmes.

Step 1 (e) - Analysis of Strengths, Weaknesses, Opportunities and Threats (SWOT) : Strengths are advantages that are of a permanent nature and exist in the community ethos or in the general environment, and they must be gainfully utilized by the health provider; e.g. conservative attitude of a community is a strength for anti-alcohol educational programme. Weaknesses are disadvantages of permanent nature in the community ethos or environment which will need to be neutralized or bypassed for success of the programme; e.g. conservative attitude in the community may be a disadvantage while launching a sex education programme for school children. Opportunities are temporary, often flitting occurrences which the health provider

should always be on the look-out for and utilize them to her benefit; e.g. if an outstanding sports person becomes the mayor of the city, it is an opportunity to contemplate launching a community educational program for healthy lifestyle and physical fitness. Threats are temporary phenomena which may be inimical to the programmes; recent occurrence of vaccine related adverse effects among children may be a threat to educational program for promoting vaccination coverage and this would need to be either circumvented or else tackled energetically.

Step 2 - Making the “Community Diagnosis” : This is a vital step, wherein we identify the “target populations” and their health problems. The first step in making the community diagnosis is to summarize the findings of the earlier step of “situational analysis” (community analysis), through sub-steps 1 (a) to 1 (e). This summary will give us an idea of the “needs” of the community. The needs so identified are of 2 categories; firstly the “professionally assessed needs” also called as the “normative” needs, i.e. those needs which are worked out by the health care provider, based on community analysis data. This would include the leading causes of morbidity and mortality (as chicken pox, hepatitis, injuries, etc.) and leading determinants of diseases (as smoking, inadequate levels of physical exercise, dietary patterns, sexual promiscuity, etc.). Secondly, equally important are the “felt needs” of the target population, i.e. those areas of concern which are articulated most commonly by the target population. These felt needs are the most pressing problems experienced by groups and individuals in the target population and usually reflect the problems currently in focus (1 - 4).

In short, in the step of community diagnosis, we clearly define the following aspects. A consolidated statement clarifying these undermentioned issues would serve as the basic guideline for further planning of our health education programme :

- *What are the “target communities” which are to be addressed by our proposed health education, or by other health care programmes or by a combination of health education and health care programmes? Delimiting the target audience(s) will define premises of our proposed programme and help us focus our entire energies on to these defined groups, with a view to get the maximum results. Target communities are those groups or subgroups which have the maximum ill-health (mortality, morbidity or unhealthy lifestyle) and are likely to give significant results, if concerted health education programmes are focused on them.*
- *What are the major health problems as assessed by us which need to be addressed by health education programmes or health care programmes?*
- *Besides our assessed needs, what are the other “felt needs” of the target audiences, which should also be addressed either by health education or other health care programmes.*

Step 3 - Defining the “Premises” and “Goal” of the Proposed Programme : Premises are the outer boundaries within which our proposed programme will function; we will not be going out of these limits in so far as the particular programme is concerned. Thus, this helps us focus our attention our

programme and our goal and not mix up our actions with other issues. Premises are generally defined in terms of the population characteristics, place, time and the broad issues which will be the concern of the programme. While defining the premises and the goal, one should be clear that while a number of issues may be identified as major “needs”, it is not necessary (and also not usually feasible) to address all these identified needs through health education programmes. Some of the needs would be better resolved using public health or other medical care approaches. For example if we have two major issues as HIV - AIDS and problem of open defaecation, we may, depending on the situation, decide to focus on HIV - AIDS through educational efforts and tackle the problem of open defaecation by sanitary measures. It is therefore important to clearly delineate at this stage, which of the needs will be addressed by health education programme and which would be addressed by other public health / medical care steps.

Once we have defined the premises and sorted out the “needs” according to which all will be addressed by our proposed health education programme, we enunciate the overall “goal” of the programme. Goals are broad statements which reflect the end result that we desire to achieve, i.e. they are the intended consequences of the program (5). Program goals should not be confused with “educational goals”, which will be discussed later under step - 6.

Step 4 - Consolidating Data on Knowledge, Attitudes and Behaviours : It is apparent that the ultimate goal of any health education program is to increase the knowledge and obtain a favourable change in attitudes and behaviour by the target population. Hence, we will need data as regards the current state in respect of the knowledge, attitudes and behavior, for the goals that have been identified. Behaviour should be assessed in terms of “events” and “outcomes”. An event is the actual behaviour (e.g. smoking, sexual promiscuity); an outcome is the result of that event (e.g. IHD, AIDS). A sample survey of the target population, if the same has not been done in step 1 (b), should be now undertaken and data on current levels should be recorded (6 - 9).

Step 5 - Assemble the Planning Group / Coordination Council: Community health education cannot be accomplished by a single health educator. All representatives from the community, especially those who can facilitate the program should be approached to consent for being a part of the planning group (also sometimes called as coordination council or governing board). From this step onwards, all plans are discussed and finalized, progress monitored and difficulties sorted out by personal involvement of members of this group. This group should include the public health manager / health education specialist, who should be the secretary of this group. The chairperson is usually an eminent / influential political or administrative person. The members include technical specialists, administrators and above all, representatives of each of the target populations identified earlier.

Once a planning group has been constituted, all members should be given an initial briefing to orient all members as regards the various aspects of the program. This activity is very relevant since many of the members may not be very aware about the technical intricacies of health education and medical care, as

also about the details and sequence of planning process.

Step 6 - Reconfirming the program goals, enunciating the educational goals and the objectives : Once a planning group has been formed, one of the first activities to be undertaken by this group is to firstly, reconfirm that the original program goal (vide step - 3) is finally acceptable or else it needs to be changed. Secondly, the group should enunciate broad statements, for different identified “needs” and different target groups, as to what the educational process aims at finally achieving. The overall program goal should be kept in mind when formulating the educational goals. The educational goals should be stated in precise language so that all members of the planning group thoroughly understand the exact intention of the statements (5, 10).

Having specified the educational goals, the educational objectives are enunciated. As compared to goals, which are generalized & broad statements, objectives are precise statements which indicate as to how the goal will be realized. For one goal, there could be a number of objectives. Objectives should be specific, measurable and quantifiable in terms of magnitude of change and time-line. Within each objective, the parameter which will measure change is called the “indicator” and the magnitude of change proposed to be achieved is called the “target”. For example, in an objective “Proportion of persons who are smokers should reduce from current 45% to 25% in next 2 years”, the statement “Proportion of persons who are smokers” is an indicator while the part “reduce from current 45% to 25% in next 2 years” is a target.

Step 7 - Resource Analysis : The important issue at this stage is how we can convert the desired objectives into an effective “action plan” so that the objectives can be achieved. For this purpose, we have to now analyse our resources, i.e. what all do we have to take action. In general, resources are analysed in terms of 3 broad headings, viz. men, money and material. Resource analysis for manpower would include the medical and paramedical personnel, and other key personnel as epidemiologists, trained health educators, data operators and statisticians, along with their locations, who would be available for the health education program, either full-time or part-time. This aspect of manpower also includes the ‘supportive manpower’ as political leaders, administrative authorities and peers who would support the program. Money refers to assessment of funds / finances which will be required for development of health education material, training material, communications and transport, purchase of health educational and medical equipment if required, payment of salaries, etc. The source of finances could be government (public funds) or funds generated by voluntary / non-governmental organizations. Finally, material refers to technical equipment, expendables and logistics. This would need assessment of various aspects like availability of class-rooms, lecture halls, buildings, electricity, announcement systems, projection systems as slide / overhead projectors, computers, LCD projectors, posters and charts for exhibitions and mobile panels for posters; models, and so on. In addition, equipment pertaining to “logistics” as vehicles for transportation of target population, petrol, tentages, generators, etc., would also need to be assessed, as required. It is only after making a detailed assessment of resources (already available

and expected over reasonable period of time), that the program planner would be able to decide as to how best can an action plan be drawn to meet the objectives; at this stage, it may also be a consideration to drop one or two objectives if adequate resources are not available.

Step 8 - Identify Methods and Activities for Health Education : In the earlier chapter, we have deliberated on the various types of methods (as lectures, focus group discussions, exhibitions, mass media communication methods etc.) and the activities that are conducted within each of these methods. Detailed decisions should now be taken to see which particular method(s) will be most appropriate to address the objectives for different target groups, and within each method, what all educational activities will be undertaken. The details of the decided methods and activities for each target group should be written down.

Step 9 - Writing and disseminating the Action Plan (Implementation Plan) : Having clearly enunciated the methods and activities, a detailed action plan should be written down. This is a detailed document which clearly specifies as to *who will do what, to whom all, where, in what manner and how frequently*. The document should specify all details of

- Dates / days of the week or month and timings, on which the educational sessions will be held for the entire duration of the educational program.
- The locations at which the sessions will be held.
- Who all will attend the sessions at the particular locations, dates and time.
- Who will be administratively responsible for ensuring that the target audience reaches the particular location of educational session, well in time.
- Who will be responsible for providing the administrative support.
- Who will conduct the session.
- Who will be responsible for technical aspects of the session.
- Who will be the overall coordinator for the educational activities.

The details should be discussed by the Program Planning Committee (PPC) and then issued by a senior administrative officer to all concerned.

Step 10 - Implementation and Evaluation : Once the instructions for implementation have been issued, the health educator's responsibilities further increase since he is now not only responsible for providing health education to the various target populations but also often responsible for coordination of the various administrative aspects, and to ensure that all aspects of the program progress as scheduled in the action plan. In real life scenarios, everyday there will be problems, which would need to be actioned and rectified. Sometimes the vehicle may not turn up to ferry the health educator's team and equipment, sometimes the officer responsible for administrative coordination for one of the target populations may simply forget that there was a session planned for that day, sometimes a holiday may be announced suddenly on the day of planned session. All these issues need to be visualized and addressed. In health education programmes & for that matter in any public health program, perseverance and determination always pays.

Alongwith implementation of action plan, evaluative process also needs to be planned and conducted. As explained in detail in the section on epidemiology (planning & evaluation of programs), evaluation is undertaken for six different aspects, viz. relevance, adequacy, process, and outcome (including efficacy, effectiveness and efficiency). In the usual settings of health education programs, evaluation is undertaken for "process" (i.e. whether the activities are being undertaken as planned) and for outcome (i.e. to what extent the objectives have been met). Evaluation for process is to be undertaken concurrently, say once in 3 months for a program planned for 1 to 2 years. Outcome evaluation is undertaken both, concurrently (e.g. what percentage of target population have shown improvement in knowledge and behaviour) and terminal evaluation at the end of the program (whether targets as envisaged at the planning stage have been achieved). It should be remembered that evaluation should always be an ongoing process, with the drawbacks/deficiencies noticed further analysed and change in program actions undertaken to rectify defects that have been identified.

Step 11 - Writing the Final Report : Once the program has been completed or terminated for whatsoever reasons, the program planner must write down a detailed report of the program, including the background, the target audience, the educational and program objectives, the action plan, details of process, final results, and recommendations for future programs. Such report is invaluable in assessing the current program and also serves as a basic reference document for any subsequent health education programs.

Summary

To make an effective IEC campaign the public health functionaries must be aware of various steps to be undertaken in planning, organizing, implementing and evaluating health education programmes so as to make it successful. The first step in this regards is situational analysis which aims at gaining insight in the health problems of the community to enable us to make a community diagnosis. It involves analyzing the community backdrop in the defined area, by taking the information about socio-demographic characteristics and other issues of relevance. Thereafter, analysis of community health status is done by collecting data about important epidemiological parameters about health problems of the communities from various readily available sources or by a quick sample survey. Thereafter, the community health care system is analysed so as to find what all are present and what all are lacking. Based on the collected information, a SWOT analysis is done to identify the Strengths, Weaknesses, Opportunities and Threats in the community.

The next step involves making a community diagnosis based on the situational analysis. The aspects which are clearly defined in community diagnosis are target communities, professionally assessed needs and felt needs of the communities. The third step includes defining the premises and goals of the programme. Premises are the outer boundaries within which our proposed programme will function and goals are broad statements which reflect the end result that we desire to achieve. In the fourth step, data as regards the current state of knowledge, attitudes and behaviours is assessed by a sample survey of target population.

In the next step, the planning group / coordination council is assembled. This includes the public health manager / health education specialist as the secretary, an eminent / influential political or administrative person as chairperson, while the other members include technical specialists, administrators, and above all, representatives of each of the target populations identified earlier.

In the sixth step, the planning group reconfirms the original program goal. Having specified the educational goals, the educational objectives are enunciated, and within each objective indicators and targets are defined. In the next step, resources are analysed in terms of men, money and material. Men include primary manpower as health care workers and supportive manpower. Money refers to assessment of funds/ finances which will be required, while material refers to technical equipment, expendables and logistics. It is only after making a detailed assessment of resources that the program planner would be able to decide as to how best an action plan can be drawn to meet the objectives. In the eighth step, detailed decisions are taken to see which particular method(s) of health education will be most appropriate to address the objectives for different target groups, and within each method, what all educational activities will be undertaken. In the next step, after having clearly enunciated the methods and activities, a detailed action plan should be written down. This is a detailed document which clearly specifies as to who will do what, to whom all, where, in what manner and how frequently.

Finally the programme is implemented and measures are taken to ensure that all aspects of the program progress as scheduled in the action plan. Along with implementation of action plan, evaluative process also needs to be planned and conducted. Evaluation is undertaken for six different aspects, viz., relevance, adequacy, process, and outcome (which includes efficacy, effectiveness and efficiency). Evaluation should always be an ongoing process, with the drawbacks / deficiencies noticed further analysed and change in program actions undertaken to rectify defects that have been identified.

Once the program has been completed or terminated for whatsoever reasons, the program planner must write down a detailed report of the program. Such report is invaluable in assessing the current program and also serves as a basic reference document for any subsequent health education programs.

Study Exercises

Long Question : Describe your plan of planning, conduct and evaluation of a health education programme for HIV - AIDS prevention at the level of a district.

Short Notes : (1) Peer Groups (2) Community Diagnosis (3) Assessment of health educational needs

MCQs & Exercises

Match the following

1. Objectives	a. Precise statements which indicate as to how the goal will be realized
2. Goals	b. Parameter which will measure change
3. Indicator	c. Magnitude of change proposed to be achieved
4. Target	d. Generalized & broad statements

MCQs

- Which of the following is not part of situational analysis: (a) Analysing the Community Backdrop (b) Analysis of Community Health Status (c) Analysis of Community Health Care System (d) Defining target communities
- Which of the following is not a part of community diagnosis : (a) Defining target communities (b) Defining major health problems (c) Defining felt needs (d) Defining the premises
- The aspects considered for outcome evaluation does not include : (a) Relevance (b) Adequacy (c) Process (d) Resources
- The correct order of following steps is : 1. Assemble the Planning Group / Coordination Council; 2.Consolidating Data on Knowledge, Attitudes and Behaviours; 3. Resource Analysis; 4. Reconfirming the program goals, enunciating the educational goals and the objectives (Pick up your choice from one of a, b, c, or d as follows : (a) 1,2,4,3 (b) 2,1,4,3 (c) 2,1,3,4 (d) 1,2,3,4
- The best method for health education on treatment of diarrhea/ ORS use for urban slum population is : (a) Lecture (b) Demonstration (c) Focussed group discussion (d) Symposium
- Resources include all of the below except : (a) Money (b) Material (c) Manpower (d) Methodology
- Which type of study is most convenient to undertake to obtain data on health-behaviour related aspects of the target population : (a) Cross-sectional study (b) Case-control study (c) Cohort study (d) Ecological study
- Source for assessing health status of the community include all except : (a) Census office (b) Registrar of vital events (c) Civil hospital (d) Labor office
- Normative needs is : (a) Needs felt by community (b) Health needs of community assessed by health workers (c) Normal day to day needs of community (d) Needs other than health
- Chairperson of health education programme should be (a) Public health specialist (b) Influential politician (c) Superspecialist doctor of concerned topic (d) Senior teacher

- 11) Target communities are the groups of people who : (a) Have the maximum ill-health (b) Have maximum representation (c) Are the most influential section of society (d) Are poor
- 12) Which of the following is an individual health education method : (a) Lecture (b) Focused group discussion (c) Counseling (d) News paper
- 13) Following is/are the type/s of outcome evaluation : (a) Concurrent (b) Terminal (c) Both (d) None of the above

Fill In the Blanks

- 1) "Situational Analysis" is also known as _____ or _____
- 2) _____ are advantages that are of a permanent nature & exist in the community ethos or in the general environment.
- 3) The first step in making the community diagnosis is _____
- 4) _____ are those areas of concern which are articulated most commonly by the target population.
- 5) _____ are the outer boundaries within which the proposed programme will function.
- 6) _____ is a detailed document which clearly specifies as to who will do what, to whom all, where, in what manner and how frequently.

Answers

Match the following : 1-a; 2-d; 3-b; 4-c.

MCQs : (1) d; (2) d; (3) d; (4) b; (5) b; (6) d; (7) a; (8) d; (9) b; (10) b; (11) a; (12) c; (13) c.

Fill in the Blanks : (1) Community Analysis, Needs Assessment (2) Strengths (3) To summarize the findings of situational analysis (4) Felt needs (5) Premises (6) Action Plan

Sandip Mukherji & Kunal Chatterjee

Meteorology is the science concerned with the phenomena occurring in the atmosphere. The elements, which comprise the meteorological environment, are atmospheric pressure, air temperature, humidity, rainfall, direction and speed of wind and movement of clouds and weather. In all meteorological observations, the results obtained by different observers at different stations are recorded by instruments, which are similar in form and exposed in the same manner.

Early information about the weather conditions is essential to take preventive measures against its adverse effects. This method is termed as weather forecasting and it also helps in planning for the prevention and control of diseases, predict the level of human efficiency and forecast the dangers of climatic extremes and vagaries on human life. Forecasting the weather and climate is carried out by correlating the present and previous meteorological observations with the norms observed over considerably long retrospective periods. The different elements of weather and the instruments to measure them are discussed in the subsequent paragraphs.

Measurement of Atmospheric Temperature

Atmospheric temperature measurement is an important data for weather forecasting. This is recorded by a thermometer, which is exposed in open sheds to allow free circulation of air and protected from direct rays of the sun by a thick roof. Both mercury and alcohol thermometers are used for this measurement. Mercury boils at a higher temperature, has an even expansion and is easily visible against the glass background while alcohol has the advantage of not solidifying even at very low temperatures.

Dry and Wet bulb thermometer : These are ordinary mercury thermometers, which measure the air temperature. The wet bulb is the same as dry bulb thermometer except that its bulb is kept wet by a muslin cloth fed by water from a bottle through a wick. The evaporation of water from the muslin cloth lowers temperature of the mercury. The wet bulb thermometer therefore shows a lower temperature than the dry bulb thermometer. In case both the thermometers record similar readings, then it is presumed that the air is completely saturated with moisture as happens during rains.

Maximum thermometer : This is a mercury thermometer with a very fine constriction near the neck of the bulb. It is hung up almost horizontally with the bulb end slightly lower than the other end. The capillary stem of the thermometer has a small metal indicator, which is pushed along by the mercury and fits tightly enough to remain behind when the mercury recedes. With the rise in temperature, the mercury expands and rushes across the constriction pushing the indicator. Once the temperature falls and the mercury recedes, the indicator, which fits tightly in the capillary, is measured at its lower end to give the maximum temperature reached. The thermometer is reset each time by pulling down the indicator with a magnet until it comes in contact with the mercury.

Minimum thermometer: Minimum thermometer has alcohol inside, in which a dumb-bell shaped index is immersed. When the temperature falls the spirit drags the index down towards the bulb end, but when the temperature rises the spirit expands and runs past the index. At the end of any period of observation, the position at the end of the index farthest from the bulb is considered as the minimum temperature recorded. The maximum and minimum thermometer are installed on a wooden base which is placed inside a box such as the Stevenson's screen described below, for accurate recording of temperature.

Maximum and minimum thermometer : Here the two thermometers are conjoined and made as a glass tube with three limbs, which combines the principles of maximum and minimum thermometers. The commonest such instrument is the Six's thermometer, which is not considered accurate for meteorological measurements and is not used by Indian Meteorological department.

Stevenson's screen : To ensure an accuracy of measurement of air temperature, the thermometers are mounted in a box of approved pattern called as the 'Stevenson's screen'. It is a double louvered box whose internal dimensions are 76 cms length, 45 cms width and 48 cms height. It has a double roof, the upper one projecting 5 cms beyond the sides of the box and sloping from front to back, and has an open base. At the front is a hinged door opening downwards. The box is mounted on four posts with its door opening to the North or South depending on whether it is placed in a region in the Northern or Southern hemisphere respectively. The bulbs of thermometers are placed at a height of 120 to 180 cms from the ground, and at least 6 m away from the nearby buildings or large structures to provide unobstructed flow of air around the equipment. The thermometers are hung inside the box such that no bulb comes within 8 cms of roof or sides of the box. They can be easily read in this position without being disturbed or touched (Fig. - 1).

Temperature recordings : The mean daily temperature is obtained by adding twenty-four hourly observations and dividing this by twenty-four. The temperature of a month is

the mean of those thirty days, and the temperature of a year is the mean of those of twelve months. The temperature of the air varies at different parts of the day. It is increased by the absorption of solar radiation during the day. The variation of temperature with a maximum and a minimum, dividing the day into periods of eight and sixteen hours, is the diurnal variation with the difference called as the diurnal range.

Some simple precautions are also necessary in taking the readings in these instruments. Sufficient time should be allowed for the mercury to come to thermal equilibrium with the surrounding air. Nearness of the instruments to surfaces much hotter or cooler than the air will also give a false reading.

Measurement of Solar Radiation

The Sun's rays warm up the atmosphere, which is measured by the instruments described above. Another factor, which contributes to rise in environmental temperature is the heat given out by hot objects on the earth's surface, after they have absorbed heat. This heat given out is known as radiant heat and is in the infrared range of spectrum. These objects record higher temperatures than that of the surrounding atmosphere. To measure the warmth of an atmospheric condition, it is thus essential to measure the radiant heat also.

Campbell - Stokes Sunshine Recorder : The number of hours of sunshine are recorded by the Campbell-Stokes Sunshine Recorder. This comprises of a charted paper placed on a concave surface of the recorder. A solid glass globe brings to focus the sun's rays on to this paper, which chars the paper at the point of focus. With the movement of sun throughout the day, a charred line is created on the paper, which when measured gives the number of hours of sunshine in the day (Fig. - 2).

Fig. - 2 : Campbell-Stokes sunshine recorder

Solar radiation thermometer : This instrument measures the intensity of solar radiation on a given day. It comprises of a black bulb thermometer enclosed inside a glass shield. The glass shield is devoid of air to avoid any aberrance in measurements. Black colour being absorbent of heat, the thermometer records a higher temperature than ambient air temperature, when it is exposed to sun rays. The difference in the maximum thermometer reading taken inside the Stevenson screen and the Solar radiation thermometer denotes the intensity of solar radiation.

Black Globe thermometer : The Black Globe thermometer measures the radiant heat directly. It comprises of a hollow copper globe of about 15 cms diameter, with an opening at a

side. Through this opening is inserted a calibrated mercury thermometer such that its bulb is placed in the centre of the globe. The globe is painted with matt-black paint and the equipment is suspended outside on a stand. The matt-black paint absorbs radiant heat from the surrounding objects. If the surrounding environment is windy, a black globe with 20 cms should be used. The instrument should be placed in the environment for about 20 minutes by which time it reaches equilibrium. The temperature is recorded thereafter. The globe thermometer records a higher temperature than the ordinary air temperature thermometer, since it is affected both by the air temperature and the radiant heat.

Various modifications have been made in the standard black globe thermometer such as the wet globe thermometer, which has a wet black cloth covering the sphere or the modified globe developed by Hellon & Crockford, which reaches equilibrium in 8 to 10 minutes and is made of a lighter gauge material and has an internal air stirring mechanism (Fig. - 3).

Fig. - 3 : Black Globe thermometer

Measurement of Atmospheric Pressure

The atmospheric pressure close to sea level on the earth's surface is measured as 760 mm of mercury (Hg) and is called as 1 atmosphere of pressure. This pressure falls as the altitude increases and rises as the altitude decreases at the rate of 1 atmosphere for each 33 feet depth below sea level.

Atmospheric pressure is measured with the help of an instrument called as a barometer. These could be the aneroid or mercury barometer, of which the latter are more accurate. Some of the well-known barometers are Fortin's barometer, Kew Pattern station barometer, commonly used by the Indian Meteorological Department. The barograph is a continuous measurement of the atmospheric pressure over a 24 hour period. The instrument is a circular box, the walls of which collapse or distend when the atmospheric pressure rises or falls and are supplied with the recording device and spare charts. More sensitive barographs recording very minimal fluctuations of pressure are called as 'Microbarographs'. The fluctuations

seen in a barometer are considered to be of importance in determining the pattern of weather conditions. Ordinarily the barometric readings during field studies are recorded on the aneroid barometer, which needs regular calibration with the mercury barometer.

Measurement of Atmospheric Humidity

Atmospheric humidity or the moisture content of air is generated from large watery surfaces, which are exposed to atmosphere. Moisture is also added to air by living animals and plants due to their constant discharge of water vapour from the lungs or leaves. The moisture content of air can be expressed in two different manners as Absolute humidity and Relative Humidity (RH). Absolute humidity is the amount of water vapour per unit weight or volume of air expressed as grams per litre or grams per cubic metre of air and is measured by absorption hygrometers. Relative humidity describes the moisture content of air at any given temperature as a percentage of the maximum possible moisture content i.e. the ratio of amount of water vapour actually present in the air to the amount that would be present where the air saturated with moisture expressed as a percentage out of 100.

The amount of water vapour necessary to cause saturation of air varies directly with the temperature, the higher the temperature of air, more the water vapour it can hold before saturation point is reached. When the air becomes completely saturated, evaporation from any surface in that area ceases altogether. If the air is cooled, the excessive moisture precipitates for the particular temperature. This is called 'Dew Point'. Humidity has an effect on the comfort levels, though not directly on the physical health of a person. At relative humidity levels above 65 percent the air inside a room feels sticky, while air at RH below 30 percent is unpleasant.

Mason's Hygrometer : This is the most widely used instrument for measuring humidity at the permanent meteorological stations. It consists of two similar thermometers mounted side by side on a Stevenson screen. One of them is a dry bulb thermometer, which measures the ambient air temperature. The other thermometer is the wet bulb thermometer, which is similar to the dry bulb thermometer but has its bulb covered with a muslin cloth kept moist by a cotton wick, which dips in a reservoir of distilled water. This thermometer records air temperature as influenced by the rate of evaporation from the muslin cloth. The drier the air the greater the rate of evaporation and lower would be the readings on the wet bulb. In a saturated atmosphere, the readings of dry and wet bulb coincide. The difference in the reading is called as 'Depressions of the wet bulb' and is inversely proportional to the atmospheric moisture. The readings recorded on the hygrometer could be used to determine the relative humidity, the vapour and the dew point with the help of hygrometric tables.

A stationary wet bulb creates a zone of higher humidity immediately surrounding it when the air movement is sluggish due to continuous evaporation of water. This may give rise to falsely higher readings on the instrument and is obviated by providing an air velocity artificially by mechanically moving the two thermometers, as is carried out in the Sling Psychrometer described below.

Whirling or Sling Psychrometer : This instrument has a dry and a wet bulb thermometer mounted side by side on a metal strip, which is fixed on a wooden frame. The frame has a handle on a side, which acts as a pivot on which the wooden frame can be rotated. The wet bulb thermometer is kept wet by a piece of wick which soaks water from a small cylindrical water container. The instrument, once ready, is whirled standing with the back to the sun at the rate of 4 rotations per second. The readings on the thermometer show a dip due to evaporation of water brought about by the air movement created due to the rotation. Successive readings are noted on the wet bulb thermometer till they do not show any further change i.e. two successive readings on the wet bulb thermometer are the same and this reading is recorded. The reading on the dry bulb thermometer is also recorded at this point of time. The two thermometer readings are used to determine the relative humidity of the air using suitable tables and charts. The rotation could also be carried out using a motorised device or a modification carried out on the psychrometer called as the 'Assmann Psychrometer' which draws air at the rate of 5 metres per second onto the thermometers using clockwork fan. These devices give more accurate measurements (Fig. - 4).

Measurement of Air Movement

Air movement determines the cooling power of air and it influences the comfort levels in an environment. The equipment used to measure air movement are Kata thermometer and anemometers. The latter could be of propeller type, thermoanemometers or the hot wire anemometers.

Kata Thermometer : The Kata thermometer is useful in measuring air velocities as low as 10 feet per minute. 'Kata' is a Greek word meaning 'down' and the Kata thermometer is an alcohol thermometer with a glass bulb 4 cm long and 1.8 cm in diameter. The bulbs are silvered to reduce the errors due to radiation. These thermometers are available to cover the following cooling ranges :

- Standard Kata (Red coloured alcohol) with a cooling range between 100°F to 95°F.
- High temperature Kata (Dark Blue coloured alcohol) with a cooling range between 130°F to 125°F.
- Extra High temperature Kata (Magenta coloured alcohol) with a cooling range between 150°F to 145°F.

Each Kata thermometer has a given kata factor determined by the manufacturers and is provided with standard charts with

instructions for use. Two thermometers are used to record air movement, the bulb of one is covered with a wet muslin cloth, called as the wet kata and the other is the dry kata. The two thermometers are set prior to taking readings by immersing them in hot water to warm them slightly above 130°F, when the alcohol rises to a small reservoir at the top of the instruments. The bulb of dry kata is wiped dry. Then both the instruments are suspended in air at the point of observation about 60 cms away from the observer. The time in seconds is recorded using a stop watch for the alcohol to drop across the cooling range for example, from 100°F to 95°F for the standard kata. The observations are repeated four times and after discarding the first, an average of the other three are taken and an average length of time is arrived at. The kata factor for the instrument divided by the average length of time gives the wind velocity in millicalories per square centimetre per second. Kata charts can also be used for this purpose. A dry kata reading of 6 and above and a wet kata reading of 20 and above were regarded as indices of thermal comfort (Fig. - 5).

Fig. - 5 : Kata thermometer

Anemometer : These are used to measure the unidirectional wind velocity and are of the rotating vane or the propeller type. The propeller comprises of two short metallic arms joined rigidly in the middle at right angles to each other. At each of the four free ends of these two arms is attached a half-hemispherical hollow cup with its rim in a vertical plane and the hollows of all the four looking in the same direction. This is mounted on a vertical spindle such that the arms can move free in a horizontal plane. When this is mounted on the top of tower unobstructed by trees and buildings and the wind blows from a direction, it catches one or more of these cups and sends them whirling at a speed equal or proportional to the wind velocity. The spindle is further attached to the anemometer box and there is a counter inside the box called 'cyclometer' to measure the wind speeds.

Thermo-anemometer and Hot Wire anemometer : A thermo-anemometer is a mercury anemometer with an electrically heated metallic coil around its bulb. A rheostat regulated the

voltage in this coil. The velocity of air can be measured upto 5000 cms per seconds or more using suitable voltage in the coil and the calibration charts.

A hot wire anemometer is made up of three pieces of electrically heated fine platinum wires. The change in resistance produced by the cooling effect of air current is measured by a potentiometer or a galvanometer. This instrument can measure very low air speeds below 100 centimetres per seconds.

Measurement of Precipitation

Precipitation is a collective term used for all forms of water precipitated from the atmosphere such as rain, snow, hail, dew and frost. Rainfall is measured by rain-gauges in inches or millimetres per time unit (day or month). The Indian Meteorological Department uses the Symon's rain-gauge at its rainfall measuring stations. The rain-gauge consists of a funnel for collecting rainfall, a receiving vessel and a measuring glass (Fig. - 6).

Fig. - 6 : Rain gauge

The funnel is made of copper and is cylindrical in its upper part with a diameter of 20.3 cm. The receiving vessel is a small copper can, which fits inside an outer casing. The measuring glass is calibrated and specific to a particular rain-gauge. The outer casing of the instrument along with the receiving vessel and collecting funnel is sunk in an open level ground in a masonry or concrete foundation. The top of the receiving funnel should be placed exactly horizontal one foot above the ground level. It should be ensured that there are no obstructions such as trees or buildings nearby. After the desired time has elapsed, the collecting funnel is removed, the receiving vessel lifted out and the contained water poured carefully into the measuring glass and read off. Similar instrument could also be used to measure snowfall.

Summary

Meteorology is the science concerned with the phenomena occurring in the atmosphere. The elements, which comprise the meteorological environment, are atmospheric pressure, air temperature, humidity, rainfall, direction and speed of wind and movement of clouds and weather. Climate and weather

have marked effects on health and diseases. Early information about the weather conditions is essential to take preventive measures against its adverse effects. This method is termed as Weather forecasting and it also helps in planning for the prevention and control of diseases, predicts the level of human efficiency and forecast the dangers of climatic extremes and vagaries on human life.

Atmospheric temperature is recorded by a thermometer, which is exposed in open sheds to allow free circulation of air and protected from direct rays of the sun by a thick roof. Both mercury and alcohol thermometers are used for this measurement. The various instruments available for its measurement are Dry and Wet bulb thermometer, Maximum thermometer, Minimum thermometer, Maximum and minimum thermometer and Stevenson's screen. A rise in environmental temperature is due to radiant heat and sun's rays hence to measure the warmth of an atmospheric condition, it is essential to measure the radiant heat also. It is measured by Campbell - Stokes Sunshine Recorder, Solar radiation thermometer and Black Globe thermometer. The difference in the maximum thermometer reading taken inside the Stevenson screen and the Solar radiation thermometer denotes the intensity of solar radiation.

Atmospheric pressure is measured with the help of an instrument called as a barometer. These could be the aneroid or mercury barometer of which the latter are more accurate. Some of the well-known barometers are Fortin's barometer, Kew Pattern station barometer commonly used by the Indian Meteorological Department and the Barograph. The barograph is a continuous measurement of the atmospheric pressure over a 24 hour period. The fluctuations seen in a barometer are considered to be of importance in determining the pattern of weather conditions.

Atmospheric humidity or the moisture content of air can be expressed in two different manners as Absolute humidity and Relative Humidity (RH). At relative humidity levels above 65 percent, the air inside a room feels sticky, while air at RH below

30 percent is unpleasant. Mason's Hygrometer is the most widely used instrument for measuring humidity at the permanent meteorological stations. Whirling or Sling Psychrometer and Assmann Psychrometer give more accurate measurements.

Air movement determines the cooling power of air and it influences the comfort levels in an environment. The equipment used to measure air movement are Kata thermometer and anemometers. The latter could be of propeller type, thermoanemometers or the hot wire anemometers.

Precipitation is a collective term used for all forms of water precipitated from the atmosphere such as rain, snow, hail, dew and frost. Rainfall is measured by rain-gauges in inches or millimetres per time unit (day or month). The Indian Meteorological Department uses the Symon's rain-gauge at its rainfall measuring stations.

Study Exercises

Short Notes : (1) Kata thermometer (2) Psychrometer.

MCQs

1. Stevenson screen is used for measuring (a) Air Temp (b) Cooling power of Air (c) Humidity (d) Air movement.
2. Globe thermometer is used to measure (a) Air Temp (b) Cooling power of Air (c) Humidity (d) Mean Radiant Temp.
3. The measuring liquid of kata thermometer is (a) Alcohol (b) Mercury (c) Water (d) None.
4. Kata thermometer was devised to measure (a) Air Temp (b) Cooling power of Air (c) Humidity (d) Air movement.
5. The speed with which the air should pass over the bulb in a wet bulb thermometer is (in m/Sec) (a)5 (b)10 (c)50 (d)100.
6. Air velocity is measured by (a) Anemometer (b) Psychrometer (c) Globe thermometer (d) Stevenson screen.
7. Kata thermometer can record air velocities as low as (in ft/min) (a)10 (b)2 (c)20 (d)1.

Answers : (1) a; (2) d; (3) a; (4) d; (5) a; (6) a; (7) a.

Public Health Aspects of Adverse Effects of Extreme Hot Environment

RajVir Bhalwar

The term "heat stress" is applied to any degree of environmental heat that causes physiological thermoregulatory mechanisms to get activated. Human beings are homoeothermic creatures whose physiology attempts to maintain a constant core body

temperature of 37°C (range 36 to 38°C). Obviously, this requires balancing of the body heat production with heat loss which is achieved by a combination of physiological mechanisms (as peripheral vasodilatation or vasoconstriction, changes in heart rate, sweating or shivering) and behavioral mechanisms (increase or decrease in voluntary physical activity, seeking appropriate shelter etc). In addition, environmental conditions viz., temperature, humidity and speed of air also greatly determine whether a person will be subjected to thermal stress. Prevention and management of thermal stress disorders therefore requires an understanding of these physiological, behavioral and environmental mechanisms and manipulating

them appropriately. For the purpose of thermoregulation, the human body can be conceived of having two “layers” - an outer periphery or “shell” consisting of skin, subcutaneous tissue and muscles, and an inner “core” consisting of brain, heart and viscera.

Epidemiology

Adverse effects of heat stress are an important cause of morbidity and mortality not only in developing countries, but in the developed countries as well. In India, 3,194 deaths due to heat-stroke have been recorded over the 5-year period - 1999 to 2003; the actual magnitude may be much more. The central and northern plains, western deserts and tropical forest areas of North - East have environmental conditions causing heat stress during the months of April to September. In India, more than 1600 heat related deaths were reported during the year 2003 (1).

Human (Host) Factors

A wide array of host factors have been implicated in increasing the risk of heat illnesses, as shown in Box - 1.

Box - 1 : Persons at high risk of heat stress
Extremes of age (<5 years or >65 years)
Pregnancy
Occupation : military, agricultural, construction & industrial settings, labourers, sports-persons and miners
Low level of physical fitness
Lack of acclimatization to environmental heat
Obesity
High ambient temperature, high atmospheric humidity, low air velocity
Alcohol use - acute and chronic
Skin diseases : Extensive prickly heat, psoriasis, pyoderma
Sleep deprivation
Co-existing febrile illness, renal, thyroid, cardio-vascular and metabolic diseases
Previous history of heat-illness
Use of drugs or habit forming substances : Phenothiazines, anti-cholinergics, ACE-inhibitors, MAO-inhibitors, cocaine, amphetamines
Residence on floors higher than ground floor, especially top floors, and urban areas
High population density as occurs during social and religious conglomerations
(Sources : References 2 - 13)

Physical activity and adverse effects of hot environment:

Physical activity in a hot/humid environment is a major determinant of heat illness. With the broad group of physical activity, certain variables determine the occurrence and severity as follows :

(i) *Nature of physical activity* : The nature of physical activity and its strenuousness, at a given time is one of the

most important determinants, since it directly determines the metabolic heat being produced by the body which, in turn, reflects the intrinsic heat load of the body. It also needs to be noted that running or jogging at fast pace leads to very high metabolic heat production and may be particularly hazardous during hot weather.

(ii) *The amount of load being carried* : This could be either external load (as baggage) or as a part of body weight itself (e.g. an obese persons). For every additional kilogram of such “load”, an additional 2 kcal/hour of additional heat will be produced, when walking at ordinary pace. This would further increase as the pace increases.

(iii) *The type of terrain* : As compared to walking on an ordinary black topped road, the metabolic heat production will progressively increase when walking (at the same speed), on a cross country track, on recently ploughed fields, on snow or on over heavy sand, in which case the heat production may be almost two times when compared to walking on road. (The hot environmental conditions associated with sandy terrain are, in any case, additional).

(iv) *The Inclination (Gradient)* : Heat production increases, at a given pace, as the gradient increases. Even a 10% increase in the gradient may substantially increase metabolic heat production.

(v) *The duration of physical activity* : In harsh, hot & humid environment even well trained persons may suffer from adverse effect of hard physical activity if continued for more than half an hour unless adequate rest pauses are interspersed.

The type of clothing and adverse effects : There are three aspects, in relation to clothing, which determine the dissipation of metabolic heat, being produced in the body.

- The *insulation*, measured in Clo units (8). The insulation should be, ideally, as low as possible in a hot environment.
- The *permeability to moisture* which should be as high as possible.
- Absorption of “*radiant energy*” which is quite high for dark clothing.

Synthetic material has poor permeability and should be avoided. Similarly multilayered clothing, which ‘trap’ layers of still air between them tend to increase the insulation even if they have good permeability. Thus the correct approach would be to use light coloured loose fitting clothing, in one or two layers, and made of ‘breathable’ material as cotton.

Environmental Factors

While various attributes of the human host, as described earlier, play an important role in determining who will and will not ultimately get affected by heat illness, a major role in these health issues is played by the physical environment - the air temperature, humidity, air movement, and radiant heat from sun or other hot objects.

From the physical environment point of view, the major factor which emerge as determinants of heat illness are, the temperature of ambient air (usually determined by Dry Bulb Thermometer (DBT), the relative humidity (usually determined by using psychrometric charts, using the reading of both the

DBT and the Wet Bulb Thermometer (WBT), the Mean Radiant Temperature (MRT) whose main source is either solar radiation or radiations from hot objects as furnaces, and which is usually determined by the Globe Thermometer (GT), and the speed of the air (usually determined by anemometers or specialized thermometer). Based on the permutation and combination of these parameters, certain indices of environmental heat illness have been developed. A brief description of these “*thermal stress indices*” is as follows :

(a) Effective Temperature : ET is defined as the subjective feeling of warmth (or cold) at a given temperature of air (DBT), when RH is 100%, the air is almost still (minimal air movement) and the subjects are ordinarily clothed. In general, when a person is at rest with a body metabolic heat production of 100 kcal/ hour, in an environment of 100% RH and minimal air movements, an air temperature (DBT) of 36°C is the ET and marks the upper limit of 4 hourly tolerance. If heat production increases, by strenuous activity to about 425 kcal/hour, under the same environmental conditions, a DBT of 31°C is the upper limit of ET for 4 hourly tolerance (14). For the outdoor setting, the preferred index is ‘Corrected Effective Temperature (CET)’, where Globe thermometer temperature (GT) is used in place of DBT.

(b) Oxford (syn - Wet-Dry - WD) Index : The Oxford Index is a simple and quite effective Index, based on DBT and WBT : $WD\ Index = 0.85\ WBT + 0.15\ DBT$.

(c) Wet Bulb Globe Temperature (WBGT) : WBGT index is the most commonly used index of thermal stress. It takes into account the effect of MRT (as measured through Globe Thermometer (GT) in addition to WBT and DBT as follows :

Outdoor WBGT = 0.7 WBT + 0.2 GT + 0.1 DBT

Indoor WBGT = 0.7 WBT + 0.3 GT

WBGT levels of 30°C and above indicate definite thermal stress and care needs to be exercised (15). From May to August, most of the Indian subcontinent (except the northern hilly areas) tends to have WBGT values of more than 30°C.

Prevention of Heat Related Illness

Governmental as well as the public health functionaries cannot afford to ignore the potential dangers of sustained heat wave and should develop a contingency plan. Although heat stroke is amenable to medical treatment, control can best be achieved by applying the principles of public health surveillance, public education, outreach to vulnerable persons, availability of life saving first aid and enlistment of the help of the entire community can save lives (16). A structured approach towards prevention and control of Heat illnesses in communities consist of :

- Public Health measures directed towards communities and large population groups
- Specific preventive measures directed towards individuals/ small groups identified to be at high risk of heat illnesses due to certain occupational characteristics
- Early detection and first aid.

Public Health Measures Directed Towards Communities and Large Population Groups : In tropical countries like India, millions of people among the general population are at

risk during the hot/humid months, especially when spells of heat wave strike. In such settings, heat related casualties may occur in large numbers in short duration, creating almost a disaster like situation and hence the need for public education, provision of preventive amenities at vantage points, and quick first aid. From the public health angle, the following aspects need to be addressed :

(i) Public education regarding preventive measures : Creating public awareness should be high on the list for the public health administrators. Full use of audio-visual and print mass media must be made during the onset of hot weather and also well before the expected heat wave. The *messages* should include the following aspects :

- Do not venture out in the sun, especially between 10 am to 4 pm unless the same is necessary.
- Avoid strenuous physical exertion between 10 am to 4 pm during the hot weather unless the same is necessary for reasons of occupation.
- Drink at least 4 to 5 litres of cool water in a day even if not feeling thirsty. If undertaking strenuous physical activities, drink a quarter to half litre of water after every half an hour, as long as strenuous activity continues.
- Do not wait for ‘thirst’ to develop. Keep drinking water regularly even if not thirsty.
- If exposure to sun is necessary, place a wet hand towel around your neck.
- Put on a wide - brimmed hat of light colour when going out. Simple caps as golf cap may not give enough protection.
- Put on sunglasses when going out in the sun.
- Apply a sun screen ointment with a Sun-Protection-Factor (SPF) of at least 15, which should be able to protect against both UVA and UVB rays, when going out in the sun.
- Avoid alcohol consumption during hot humid months. If consumption becomes necessary, keep the same within limits of less than 2 small drinks of hard liquor or one bottle of light beer per day.
- Keep children less than 5 years and elderly (aged 65 years and above) away from sun as far as possible.
- Never leave children (or pets) in a closed, parked car. Try and park your car in cool, shaded place.
- Use a car-sun visor to minimize the effect of direct radiant heat produced by the sun, to enter inside the parked car.
- Dress for hot, humid weather should be ‘breathable’ i.e. Loose fitting, light weight, light colored, preferably of cotton material and in one or two layers only.
- Carry a water bottle with cool drinking water whenever you go out in summer months.
- If you feel exhausted, confused or running out of memory/ consciousness, move to a shaded place, sit/lie down, drink cool water and seek help.

(ii) Provisions of basic preventive amenities at vantage points on a large scale basis, during high risk periods : There are four basic amenities which all public health managers must strive to provide to the general public during the hot weather or else, if some high risk activity as sports events or religious/ social gatherings are likely. They are :

- Cool drinking water at vantage points.
- Covered/shaded areas for taking rest pauses.

- Facilities for first aid in a way that they are early accessible to all, particularly the high risk groups.
- Public information system to make all aware about the facilities and the telephone numbers/addresses of key persons and first-aid facilities, who may be contacted during need.

(iii) Identification of high risk groups and enlistment of community support : Studies have revealed, there are certain high risk groups like agricultural workers, manual labourers, young children, old people those who are unable to care for themselves and those who form part of large social or religious gatherings/ festivals, are more vulnerable to the effects of heat. And enlistment of community support as part of voluntary services with outreach efforts towards these high groups can be of much utility in minimizing the public health impact of heat.

Public Health Surveillance, Early Warning Systems and Disaster Plan : The need to have a good epidemiological surveillance system for heat illnesses as well as various environment conditions that determine those illnesses need not be over emphasized. This should be established not only for specialized groups like Armed forces or industries but also for the general community as well. It is only through ongoing collection of data and monitoring of trends of occurrence of illness and environmental factors, that proper policy decisions on public health aspects of heat illnesses can be taken (3, 17, 18). An effective heat illness surveillance system must include reporting of all heat illness cases according to diagnostic categories, both for indoor and outdoor cases separately. It should have at the minimum, data related to time and place of exposure, as well as basic clinical data, besides including the antecedent/precipitating factors and personal risk factors. It should also have the essential meteorological data (WBT, DBT, GT) for various locations. The data should be analyzed in an ongoing manner and a 'Heat and Health Early Warning System' should be developed to issue early warnings and use of public health/preventive measures to the physician as well as to the general community. Simple warning criteria based on WBGT for outdoor exercises as running and cycling, for general public can be that, at the place where and time when an outdoor exercise or sports event is being planned, if WBGT index is more than 28°C, or else the WBT recording is more than 26.5°C, the event should not be held (17). If both, the Dry Bulb (DBT) readings and Relative Humidity (RH) levels are known, a rough guidance for outdoor physical exercise can be as shown in Table - 1. Note that these meteorological parameters should be recorded as near the place of outdoor exercise as possible.

Specific Preventive Measures Directed Towards Individuals and Small Groups : Specific preventive measures directed towards individuals or specific high risk groups as industrial workers, military personnel, sports persons etc., are undertaken to achieve the following objectives :

- Proper protective measures in the industries as isolation of furnaces, and spray of cold aerosols.
- Seeking shade and wind to the extent possible.
- Frequent rest pauses interspersed between phases of physical activity.

<i>Table - 1</i>		
Dry Bulbs Temp. (DBT)°C	Relative Humidity (RH) levels (%)	
	Moderate risk	High risk
29.5°C	100%	-
32.2°C	70-99%	-
35.0°C	50-70%	>80%
37.8°C	40-50%	60-80%
40.6°C	20-40%	50-60%
43.3°C	10-30%	40-50%
46.1°C	10-20%	30-40%
48.9°C	1-10%	20-30%

(The interpretation of Table - 1 is as follows : for example if the outdoor DBT is 37°C and the RH is 48%, there is moderate risk of developing heat illness; if the RH at the same temperature is 65%, there is high risk.)

- Putting on proper clothing of low insulation, low energy absorption and high permeability.
- Reducing the amount of exercise in terms of duration or intensity or both.
- Avoiding carrying of load or reducing the load.
- Acclimatization to heat and proper hydration.
- Avoidance of obesity, alcohol and other habit forming agents as cocaine, cannabis and caffeine.
- Avoidance of self medication.
- Avoiding physical activity and exposure to hot environment during febrile illness, until fully recovered.
- Ensuring proper sleep of 7 to 8 hours in the night and cooler parts of early morning. An afternoon rest in a shaded place may be of further protective value.
- Maintenance of general hygiene and sanitation, regular bath and care of skin, proper immunization and hygiene of food & water, to avoid GIT infections.
- Nutritious and palatable meals with plenty of drinking water.
- Treatment of skin conditions as prickly heat, psoriasis, sun burns etc.

Acclimatization to heat : Acclimatization to heat is a process of undertaking gradually increasing physical exercises in gradually increasing hot environment with a view to develop physiological changes, so that the individual, so acclimatized, is able to perform physical activities in the hot environment for which he/she has been acclimatized, with much less risk of suffering adverse effects of heat. The individuals to be acclimatized are subjected to physical exercise in a hot environment in which they are ultimately required to work. The schedule should be in a graded manner, starting with lower intensity of physical exercise for lesser duration (about an hour) in less hot environment. This is gradually increased, both in intensity and duration (about 90 -120 minutes) and to the required hot environment, by the 6th or 7th day and continuing thereafter for another 7 days. It takes about 10 to 14 days for status of acclimatization to be achieved. During the

process of acclimatization, individuals should be encouraged to drink plenty of water/oral fluids and additional salt may be given with meals (not as salt tablets).

Maintenance of Hydration : During the process of acclimatization and also after acclimatization, it is imperative that adequate hydration be maintained, other wise the entire process of acclimatization will be negated. It needs to be noted, and explained that there is no substitute to adequate hydration even after full acclimatization since acclimatization itself works on the principle of increasing the sweating. One can acclimatize to physical work in heat but there is nothing like acclimatization to dehydration.

Persons should be encouraged (even, at times, forced or ordered) to keep drinking water regularly while working in hot environment, even when not thirsty. It must be explained clearly that thirst is quite a poor index of dehydration and should not be relied upon. Drinking only when thirsty will result in inadequate replacement of water losses and result in dehydration of more than 2% of body weight, which may be dangerous. The best fluid for drinking is cool, hygienic water. It would be worthwhile to drink half a litre of water, about an hour before starting physical activities in hot weather, as a 'prehydration' method and to negate any pre-existing water deficit. Thereafter every person should drink 300 to 350 ml water (equal to the usual steel tumbler) every half hourly, during the exercise, without waiting for thirst. In-fact, more frequent intakes of smaller amounts (250 ml i.e. one ordinary size glass tumbler every 20 minutes) may be even better. At the same time, care should be taken not to drink so much that it leads to abdominal distension.

Adverse Effects of Environmental Heat & their Emergency Management

Heat Stroke (HS) : The classical clinical description of HS is the triad of hyperpyrexia (rectal temperature >40°C), CNS dysfunction and anhidrosis. Anhidrosis, however, is not a diagnostic requirement, since it may appear later when volume depletion is severe. Moreover, in cases which initially start as HE or cases of HS which occur among young people who have been exerting physically, the skin may be moist. Brain dysfunction is usually severe (coma, stupor or delirium), but may sometimes be subtle, manifesting as inappropriate behaviour or impaired judgment. In fact, any person who develops irrational or confused behavior following exposure to heat stress either with or without a history of physical exertion, should be treated as a potential HS patient. Other clinical features include evidence of dehydration, shock, convulsions and, sometimes, mild icterus. Two forms of HS are recognized, viz. the classical (CHS) and the exertional (EHS) form. It is important to recognize the clinical differences between the two forms (Box - 2).

Heat stroke should be considered as a possibility in any patient who presents with elevated body temperature and altered mental functions. Important and common diseases which need to be excluded are tropical infectious diseases like cerebral malaria, encephalitis and meningitis. The diagnosis of HS is usually one of exclusion and the typical history of exposure to hot environment during the immediate past is an indication towards heat stress hyperthermia. HS must be treated as a serious medical emergency. Delay in institution

Box - 2		
	CHS	EHS
Age group	Elderly	15 to 45 years
Previous health status	Usually compromised	Healthy
Concurrent activity	Sedentary	Strenuous activity
H/o drug use	Often present	Usually present
Sweating	Often absent	Often present
Skin	Dry	Moist
Rhabdomyolysis	Unusual	May be severe

of appropriate therapy by even few minutes may make all the difference between life and death. The treatment objectives are, firstly, rapid cooling to bring down the core temperature to below 39°C, reducing it by approximately 0.2°C per minute; secondly, rehydration and care of comatose patient; and, thirdly to support the organ system function. Cooling measures should be stopped once core temp falls below 39°C. The steps in management at first aid level, and at primary care/solo physician level are shown in Box - 3 and 4 respectively.

Heat Exhaustion (HE) : The features which differentiate HE from HS are that core temp is less than 40°C and there is no evidence of CNS dysfunction, though some patients may be anxious or irritable. The main features are feeling of exhaustion, nausea, headache or light headedness, features of dehydration, hypovolaemia (tachycardia, loss of skin turgor, dry mucous membranes and thirst) and syncope. Sweating is usually profuse and skin is moist. Rectal temperature is usually between 39°C to 40°C, though some patients may have a normal temperature. Urinary output is reduced and urine may be light to dark yellow in colour. Depending on how energetically the patient has been replacing either water or salt, two subtypes, viz. Water Depletion HE and Salt Depletion HE may occur. In water Depletion HE, as compared to Salt Depletion HE, vomiting and muscle cramps are not a prominent feature, while thirst is prominent, and serum Na⁺ is normal or raised. However, mostly a mixed picture, as described earlier is seen.

Treatment consists of shifting the patient to a cool, shaded and ventilated place. The clothing should be loosened, patient placed in recumbent position and feet should be elevated. If patient can drink, give one litre of water (or, preferably, "Oral Rehydration Solution" 1 packet dissolved in one litre water or else a solution of 2.5g common salt and 2.5g baking soda in 1 litre water) orally in about 30 min. Give a total of 2 litres in about one to one-and-a-half hours. Simultaneously, measures for cooling, as described under heat stroke, should be initiated. Keep monitoring rectal temp; if rectal temp goes beyond 39° C, the patient may be passing on to heat stroke and should be shifted to a medical facility for appropriate management.

Other Adverse Effects of Hot Environment

Heat Cramps : These manifest as spasms of muscles, especially lower extremity and shoulder, following heavy muscular exertion in hot environment, with associated intake of hypotonic oral fluids. Treatment consists of oral administration of 0.1% to 0.2% salt solution.

Box - 3 : Heat Stroke : First Aid
Record rectal temperature. If it is not possible to record rectal temp, record oral temp and add 0.5°C.
Try and move patient to a cooler, shaded place.
Remove the clothes.
Spray skin with water at 25 to 30°C or wrap the patient with a sheet soaked in water at 25-30°C.
Continue fanning manually or with an electrical fan.
Keep vigorously massaging the skin to prevent cutaneous vasoconstriction during cooling.
If available, place ice packs or towel soaked in cold water around the neck, axillae and groin.
Nurse in the comatose position; clear oral secretions.
Transport to the medical facility as an emergency.

Box - 4 : Heat Stroke Management at the Level of Solo-Physician or at Primary Health Care Level
Initiate measures outlined under first aid if not already initiated
Establish IV-line; take blood sample for investigations.
Start normal saline (or Ringer lactate) drip at 20-25°C. Give a challenge of 1 litre fluid in 15 to 30 minutes. Add other electrolytes such as K ⁺ , as guided by subsequent investigations.
If any evidence of seizures, give IV Diazepam 5-10mg over 10mts
If facilities are available, intubate the patient and initiate ventilatory support.
If rectal temp is not coming down or there is evidence of cerebral, hepatic or renal complications consider transferring the patient to a hospital with adequate facilities.

Heat Tetany : Symptoms include carpopedal spasms and paraesthesiae following short exposures to excessively hot environment, leading to hyperventilation and respiratory alkalosis. Treatment consists of removing the patient to a cool environment and asking him to slow down the respiration.

Heat Syncope : This manifests as syncope following exposure to heat stress as a result of peripheral vasodilatation. One should exclude other serious causes of syncope. Treatment consists of removal of patient to cool environment and oral rehydration.

Heat Oedema : This presents with pitting oedema of hands and feet, usually in the elderly, following exposure to heat stress. Other causes of oedema should be excluded. Treatment consists of reassurance, elevation of affected limbs and, if required, compression bandage.

Prickly Heat (Lichen Tropicus, Miliaria Rubra) : It manifests as erythematous, pruritic, maculopapular rash. If the condition is allowed to progress, extensive prickly heat that can progress to chronic dermatitis and superinfection can occur. Prevention consists of regular baths with cool water after gently scrubbing the skin and wearing loose, light weight clothing. Local application of calamine lotion or chlorhexidine lotion alongwith oral antihistamines is helpful.

Summary

The term “heat stress” is applied to any degree of environmental heat that causes physiological thermoregulatory mechanisms to get activated. Humans are homoeothermic creatures whose physiology attempts to maintain a constant core body temperature of 37°C (range 36 to 38°C). For the purpose of thermoregulation, the human body can be conceived of having two “layers” - an outer periphery or “shell” consisting of skin, subcutaneous tissue and muscles, and an inner “core” consisting of brain, heart and viscera.

Adverse effects of heat stress are an important cause of morbidity and mortality. In India, the central and northern plains, western deserts and tropical forest of North - East have environmental conditions causing heat stress during April to September. The high risk conditions include extremes of

age (<5 years or >65 years), pregnancy, workers in military, agricultural, construction & industrial settings, labourers, sports-persons and miners, those having poor physical fitness, lack of heat acclimatization, obesity, alcohol use, skin diseases, sleep deprivation, co-existing febrile illness, renal, thyroid, cardio-vascular and metabolic diseases, previous history of heat-illness & use of drugs or habit forming substances e.g. Phenothiazines, anti-cholinergics. Besides the factors mentioned, certain other Human (Host) Factors are implicated in causation of heat stress as gender, racial and genetic factors, physical activity, type of clothing, lack of concurrent hydration, floor of the residential building, urban rural differences & social and religious conglomeration. Environmental factors involved are temperature of ambient air, relative humidity, Mean Radiant Temperature (MRT) & air speed. Certain indices of environmental heat illness based on the permutation and combination of these parameters are Effective Temperature, Oxford (syn : Wet-Dry : WD) Index & Wet Bulb Globe Temperature (WBGT) index.

A structured approach towards prevention and control of heat illnesses in the community consist of Public Health measures directed towards communities and large populations groups, specific preventive measures directed towards high risk individuals/small groups & early detection and first aid.

In Public health measures directed towards communities and large population groups, the aspects that need to be addressed are public education on various preventive measures such as not venturing out in the sun, especially between 10 am to 4 pm during the hot weather, drinking at least 4 to 5 liters of cool water in a day even if not feeling thirsty; provisions of basic preventive amenities at vantage points on a large scale basis, during high risk periods; identification of high risk groups and enlistment of community support; and development of Public Health Surveillance, early warning systems and disaster plan.

Specific preventive measures directed towards individuals and small groups should be directed to high risk groups as industrial workers, military personnel, sports persons etc., to achieve the objectives of proper protective measures in the industries,

seeking shade and wind to the extent possible, frequent rest pauses, proper clothing of low insulation, low energy absorption and high permeability, reduced physical exercise, avoiding carrying/reducing the load, heat acclimatization and proper hydration, avoidance of obesity, alcohol, habit forming agents, self medication, physical activity and exposure to hot environment during febrile illness; ensuring proper sleep of 7 to 8 hours in the night and cooler parts of early morning with an afternoon rest in a shaded place; maintenance of general hygiene and sanitation, regular bath and care of skin, proper immunization and hygiene of food & water, nutritious and palatable meals with plenty of drinking water, treatment of skin conditions.

Acclimatization to heat is the process of undertaking gradually increasing physical exercises in gradually increasing hot environment with a view to develop physiological changes, so that the individual is able to perform physical activities in the hot environment for which he/she has been acclimatized, with much less risk of suffering adverse effects of heat. It is in a graded manner, starting with lower intensity of physical exercise for lesser duration in less hot environment which is gradually increased, both in intensity and duration. The physiological changes consequent to acclimatization are increased sweating in response to exercise, lowered threshold for exercise induced sweating, lesser rise in heart rate and lesser rise of skin and rectal temperature in response to exercise, decreased amount of salt excretion in sweat, increased ability to sustain sweat production during prolonged exercise and redistribution of sweating from truncal region to the extremities.

Maintenance of hydration by drinking water regularly while working in hot environment, even when not thirsty is extremely important. Advise should be to drink 300 to 350 ml water (equal to the usual steel tumbler) every half hourly, during the exercise, without waiting for thirst.

Adverse effects of hot environment include Heat Stroke (HS) which is a triad of hyperpyrexia (rectal temperature $>40^{\circ}\text{C}$), CNS dysfunction (usually severe) and anhidrosis. Other features include evidence of dehydration, shock, convulsions and mild icterus. Two forms of HS are recognized, viz. the Classical (CHS) and the Exertional (EHS) form. The treatment objectives are, firstly, rapid cooling to bring down the core temperature to below 39°C , reducing it by approx $0.2^{\circ}\text{C}/\text{min}$; secondly, rehydration and care of comatose; and, thirdly to support the organ system function. Heat Exhaustion (HE occurs when the core temp is less than 40°C with no evidence of CNS dysfunction. The main features are feeling of exhaustion, nausea, headache or light headedness, dehydration, hypovolaemia, syncope, profuse sweating and moist skin. Treatment consists of shifting the patient to a cool, shaded and ventilated place, loosening the clothing, recumbent position and feet elevation. If patient can drink, give one litre of water (or, preferably ORS) orally in about 30 min. Give a total of 2 litres in 1-1½ hours. Simultaneously, measures for cooling as under heat stroke, initiated. Other adverse effects of hot environment include heat cramps, heat tetany, heat syncope, heat oedema & prickly Heat.

Study Exercises

Long Question : Discuss the public health and community based preventive actions that you will adopt, as the District

health officer, for dealing with an expected heat wave that is likely to last for about 3 to 4 weeks, in the state of Punjab.

Short Notes : (1) Heat stroke versus heat exhaustion (2) Risk factors for adverse effects of hot environment (3) Thermal stress indices (4) Acclimatization to heat.

MCQs & Exercises

- For every additional kilogram of load being carried, how much of additional heat will be produced, when walking at ordinary pace : (a) 1 kcal/hour (b) 2 kcal/hour (c) 3 kcal/hour (d) 4 kcal/hour.
- All the following are important aspects which determine the dissipation of metabolic heat, in terms of the clothing being worn except : (a) Insulation (b) Radiance (c) Permeability (d) Absorption.
- The commonest skin disease which interferes with sweat function thereby reducing heat tolerance is _____.
- Febrile illness, as a consequence of infection or following immunization, increases the _____ of the body, as well as the heart rate.
- During heat-wave conditions, the morbidity and mortality in urban areas tends to be higher as compared to rural areas due to _____ effect.
- Globe Thermometer is used to measure : (a) Relative humidity (b) Ambient temp (c) Radiant heat (d) Air velocity.
- Oxford Index is dependent on (a) DBT (b) WBT (c) DBT & WBT (d) None of the above.
- Which is the most commonly used index of thermal stress (a) DBT (b) WBGT (c) WBT (d) Oxford.
- A good sun screen ointment should have a Sun-Protection-Factor (SPF) of at least, to be able protect against both UVA and UVB rays, when going out in the sun : (a) 10 (b) 15 (c) 20 (d) 25.
- Acclimatization to heat takes how many days? : (a) 2 - 6 days (b) 6 - 10 days (c) 10 - 14 days (d) 14 - 18 days.
- Unit of measurement of insulation of clothing is _____.
- Anemometers are used to measure : (a) Relative humidity (b) Ambient temp (c) Radiant heat (d) Air velocity.
- Which WBGT levels indicate definite thermal stress and that care needs to be exercised : (a) 10°C - 20°C (b) 20°C - 30°C (c) 30°C & above (d) All are correct.
- Drinking only when thirsty will result in inadequate replacement of water losses and dehydration due to loss of how much water as percentage of body weight : (a) $<1\%$ (b) 1% (c) 2% (d) $>2\%$.
- Heat stroke is a triad of hyperpyrexia (rectal temperature $>40^{\circ}\text{C}$), CNS dysfunction and _____.

Answers : (1) b; (2) b; (3) Prickly heat (Malaria Rubra); (4) Heat load; (5) Heat Island; (6) c; (7) c; (8) b; (9) b; (10) c; (11) Clo units; (12) d ; (13) c; (14) d; (15) Anhidrosis.

Public Health Aspects of Extreme Cold Environment

RajVir Bhalwar

Adverse effects of extremes of cold environment have been an important public health issue in the history of mankind (1, 2). Deleterious effects of extreme cold are inherent in the atmospheric environment at high altitude, but they also occur at low altitudes as in the Polar Regions. Even sub tropical areas like the plains of Northern India experience severe winters, where such illnesses do occur. Extreme cold conditions occur in India in the Himalayan, Sub - Himalayan and the northern Indian plains with cold waves and deaths being recorded every year. Over the 5-year period - 1999 to 2003, a total of 3,524 deaths due to cold exposure have been reported; the actual magnitude may be higher.

Human exposure to extreme cold produces significant physiologic and psychological challenges. Cold is considered as an important environmental stressor, in view of its serious consequences (3). The human body becomes even more susceptible to the adverse effects of cold when chronic exertional fatigue, sleep loss, and inadequate nutrition are also co-existent (4). Groups at particularly high risk include military personnel, agriculturists, mountaineers and persons engaging in adventure or winter sports. From socio - economic aspect, persons with low income, poor housing and inadequate clothing are at particularly high risk especially during the cold wave conditions. Extremes of age (<5yrs or >65yrs), physical exhaustion, pre - existent malnutrition or starvation, use of alcohol and underlying diseases (hypothyroidism, hypoadrenalism, diabetes and CV Disease) increase the risk.

Adverse Health Effects of Cold

Adverse effects of cold environment can manifest as either

generalized effects (hypothermia) or local "tissue-freezing" effects as frost bite, or Non-Freezing Cold Injuries (NFCI) as trench foot and chilblains.

Generalised Hypothermia : The normal core (rectal) temperature of normal healthy human beings is 37 to 37.5°C. Early symptoms of generalised adverse effects of cold become apparent as the "core" (rectal) temp. drops below 36°C and are clearly evident once it is below 35°C. Depending on the core temp, hypothermia may be classified as borderline (36 to 35°C), mild (35 to 32°C), moderate (32 to 28°C) and severe (<28°C). One of the earliest symptoms of hypothermia is change in behaviour but, unfortunately, the victim is the last person to notice such changes himself. There are mild mood changes, lack of affect, apathy, uncoordinated movements, ataxia, confusion and decreased ability to sense cold.

Initially, there is tachycardia, tachypnoea & shivering which can be voluntarily controlled. However, as hypothermia becomes more severe, (32 to 35°C) there is bradycardia and decrease in respiratory rate. Higher reasoning becomes impaired; shivering becomes violent and cannot be stopped voluntarily. As the core temp falls below 32°C, shivering stops. Skin becomes blue and puffy. Patient becomes semiconscious and muscles start becoming rigid. Trismus is often present. There is marked bradycardia and lowering of respiratory rate. Cardiac dysrhythmias are very common, especially atrial/ventricular fibrillation.

Once the core temp drops to 28°C or less, the patient is completely unconscious with severe bradycardia. Radial pulse may not be palpable and carotid pulse may reveal as low as 2 to 3 beats per mt. Respiratory rate is also reduced to 1 to 2 per min. Muscles become rigid and pupils dilated. *At this stage the patient may appear dead but may not be so. Carotid pulse must be carefully palpated in all such cases.*

Hypothermia should be treated as a medical emergency. Early recognition and institution of therapy may make all the difference between life and death. The basic principle of

management is quick warming of the “core” without causing simultaneous vasodilation of the periphery, from the level of first aid till the most elaborately equipped critical care facility. The steps in management at the first aid level and at the primary care/ solo physician level are shown in Box - 1 & 2, respectively.

Localized Effects of Cold

Frost Nip and Frostbite : Frost nip involves freezing of top layers of skin tissue. It is generally reversible and manifests as numbness and white, waxy or rubbery feeling of the affected skin but the deeper tissue is still soft. Frostbite is the more severe form and affects all layers of the skin and often the deeper tissue also. Frostbite is of four degrees, depending on the depth of the tissue involved. As an urgent first aid measure, remove any constrictive clothing or bands. Start local warming by placing the affected part in a warm water bath at 40-42°C. If nothing is available, place the affected part in the axillae or on the stomach of another healthy person. Analgesics and sedatives should be given for relief of pain. Initiate immunisation with tetanus toxoid and evacuate to a surgical facility at the earliest opportunity. If generalised hypothermia and local frost bite both are present, first treat the patient for generalized hypothermia. Local rewarming for frostbite should be undertaken only after core temp has returned to normal.

Non - Freezing Cold Injuries : These include chilblains and trench (immersion) foot, occurring due to prolonged exposure to cold environment with wet conditions. Chilblains manifest with initial pallor of affected area (usually fingers, toes, cheeks or earlobes) followed by erythema, pruritus and intense pain. Prevention by way of avoidance of exposure to cold and wet conditions among susceptible persons is the most important.

Otherwise, there is no specific treatment, though symptoms may be ameliorated by oral Nifedipine in some cases.

Trench foot is caused by prolonged exposure of feet to cold and wet conditions. The skin is reddened with tingling pain and itching. Gradually the skin becomes pale, mottled and finally dark purple, gray or blue. If the circulation remains impaired for more than a few hours, permanent damage to the affected part can occur. Treatment consists of gentle drying, elevation of the affected limb and keeping it at an environmental temperature of 18 to 22°C while keeping rest of the body warm. NSAIDS may be given for relief of pain. The patient should not walk on the affected limb till fully cured. Prevention is, once again, very important and consists of keeping the feet clean and dry, dabbing the feet with aluminium hydroxide powder thrice daily, and changing into dry socks and shoes at the earliest .

Epidemiology

Environmental Factors : The following are the major environmental factors which determine the severity of cold induced diseases :

Severity of Cold : Severity of atmospheric cold and its abrupt occurrence increases the liability of incidence of cold injuries among non-acclimatised, non-resident individuals.

Duration of Exposure : It is an important factor determining the final injury. About 10 hours of exposure to minus 10°C is needed to cause the cold injury, but may occur in shorter period of time, in intense cold.

Wind Movements : These hasten tissue cooling. The combination of ambient low temperature and wind movement is termed as the ‘Wind-chill factor’. The probability of cold climate to cause cold injuries is directly proportionate to the

Box - 1: Management At First Aid Level

Remove wet clothing only when patient has reached a warm, dry and sheltered environment and not in the open.

Immediately wrap the patient all around, including head, with warm clothes, blankets, quilts, sleeping bags - whatever insulatory material is available, even news papers or rags. Make an “insulatory wrap” of about 4 inches thickness all around the patient. Provide a wind and water proof outer most layer, as polythene sheets.

Make hot packs with warm water bottles covered with a cloth, or warm pads, at 42°C to 45°C, and apply them to axillae, groin and neck.

Do not warm the extremities at this juncture. Place arms and hands on the sides and not on the abdomen or in axillae.

Do not let patient do any physical activity. Treat as a “stretcher case”.

If patient can take orally give warm, sweetened tea or milk to provide “fuel”.

Do not massage the limbs.

Do not give alcohol or tobacco

Evacuate to a sheltered place preferably to a medical facility at the earliest.

Box - 2 : Management at Solo Physician/Primary Care Level

Check rectal temp and other vital parameters.

Quickly open up the insulatory layer, remove wet clothing (if not already removed at first aid level). Change patient to dry clothing.

Apply warm packs at axillae, groin and neck. Reapply the “insulatory layer” around the patient, as described under first aid.

Establish IV line and start 5% dextrose (or any other crystalloid) preferably warmed to 37 to 41°C. Initial fluid challenge should be 500 ml to 1 litre in half to 1 hour.

Start oxygen inhalations with face mask, 4 litres/min, preferably warm and humidified oxygen, if equipment is available.

If facility exists, pass an indwelling bladder catheter. Start monitoring urinary output.

Keep monitoring core temperature. The rectal thermometer should be inserted to at least 15 cm into rectum. If there is no increase in core temp despite rewarming efforts in more than an hour or else if patient is not shivering and unresponsive, consider evacuation to a well-equipped hospital. Evacuate as a stretcher case.

Institute CPR if carotid pulsations are absent.

'wind-chill' factor rather than its temperature alone. Increased wind velocity, by increasing the 'wind-chill' factor, increases chances of generalised and localized injuries due to cold. For example, at 0°C ambient temperature, the conditions become equal to minus 18°C, if the wind is blowing at a speed of 40 km per hour.

Moisture : Moisture is a good thermal conductor and its presence in contact with the skin interferes with the natural insulating action of the sebaceous material on the skin. Wet clothing, either due to external wetting or internal wetting due to sweat, is therefore dangerous.

Hypoxia : High altitude hypoxia deprives the cardiac muscle of oxygen and thereby decreases the cardiac output, lowering the peripheral blood and oxygen tension and reducing the tissue oxygen saturation. Hypoxia also devitalises the capillary endothelium and increases exudation into tissues. All these increase the proneness of the extremities to get cold injuries; skin, being the least vital organ, suffers the most.

Clothing and shelter : An extremely important determinant of cold illnesses and their prevention is the adequacy of clothing and shelter in such weather. Clothing insulates the body from its surroundings. It can also cause radiant heat gain (mainly from solar radiations) as well as retard conductive and convective heat loss in cold climate. The index of thermal resistance of clothing is measured in 'Clo' units. To maintain a person in comfort, clothing with higher clo units will be required if metabolic heat production decreases, or ambient temperature decreases, or RH decreases, or air movement increases. At 0°C, persons undertaking light work or else complete rest, will need clothing 2.6 and 5.4 clo units respectively; at - 20°C these requirements will be 4 and 8.3 clo respectively. As a rough guideline, without wind penetration or air movement around the clothing, the Clo values for a given weight of clothes equals 35% of the clothing's weight in Kg; e.g. wearing of total of 10 Kg clothing will produce Clo value of 3.5 Clo units, and will be reasonably good enough for a person doing very light work (1.5 MET) at an ambient air temperature of 0 degrees C, in a still air environment.

Human (Host) Factors in cold illnesses

Age and Sex : People at extremes of age (less than 5 years or more than 65 years) are known to be more susceptible. Women seem to be protected possibly due to the increased subcutaneous fat. There is preliminary evidence from laboratory studies that dark skinned people may be more susceptible to adverse effects of cold as compared to whites.

Circulatory Stagnation : Local circulatory stagnation allows local temperature to be lowered, increases liability of exudation through the already damaged vascular endothelium and also deprives the tissues of nutrition and oxygen, thereby increasing devitalisation. This may be caused by forced immobility due to being pinned down in shelters or vehicles, or during conditions of prolonged bad weather. Tight fitting clothes, boots or socks may also cause constriction.

Physical Inactivity : It increases risk of cold injuries. Activity increases the metabolic heat production and is an important prophylaxis against cold injuries.

Nutrition : Adequate, or even increased, calorie intake is necessary to sustain the increased heat production and the increased work required to function in a cold environment (5). Vitamin A deficiency increases liability to infections especially of mucous membranes. Vitamin C deficiency increases capillary permeability and decreases healing power of tissues. The presence of adequate subcutaneous fat definitely increases the insulation and hence protects against cold (6, 7).

Poor Physical Health : Intercurrent /chronic diseases, convalescence and physical exhaustion decrease the general tissue vitality, physical activity and also power of acclimatisation, and hence increase the liability to cold injuries.

Poor Mental Health : Mental apathy, fatigue, fear and anxiety which are common in a cold climate, especially under hypoxic conditions at high altitude, cause neglect of precautions and increase in physical inertia, thereby increasing liability to cold injuries.

Local diseases : Local injury or skin infection predisposes the particular part to cold injuries.

Tobacco : Use of tobacco increases the risk of frost bite due to severe vasospasm induced by it and definitely aggravates the injury itself when once established.

Alcohol : Alcohol has been universally regarded as a very important and avoidable risk factor in cold illnesses. Its consumption, especially if followed by exposure to cold, or excessive physical activity or lethargy after alcohol consumption, increases risk of general hypothermia and also local cold injuries.

Cold Adaptation : Adaptation to cold, although not as good as acclimatisation to heat or high altitude, is nevertheless an important factor determining individual vulnerability to cold injuries.

Prevention of Cold Illnesses

Clothing : Special attention should be given to clothing in cold weather, in a scientific manner. In providing insulation from the cold, the mesh of the cloth fibres traps air that then becomes warm. Several layers of light clothing or garments lined with wool, fur, feathers or synthetic fabrics provide better insulation than a single, bulky layer. The clothing layer in contact with the skin should effectively "wick" moisture away from the body's surface to the next insulating clothing layer for subsequent evaporation. Wool or synthetic (e.g. polypropylene) that insulate well, as well as dry quickly, serve this purpose. A woollen cap very effectively contributes to heat conservation since nearly a third (33%) of all body heat loss is from the head region alone. If clothing becomes wet either due to external moisture (snow or rains) or due to condensation from sweating, it loses as much as 90% of its insulating properties; this may actually start facilitating heat loss from the body rather than conserving heat. Hence, wet clothing should be changed at the earliest opportunity in cold environment.

Secondly, it must be ensured that while the clothing should provide adequate insulation (by way of adequate material and layers, as described above), it should, at the same time, allow for water vapour to escape through the clothing, if sweating occurs. If this does not happen and sweat accumulates near the

skin layer, its condensation may become another hazardous situation, which was faced by the expeditions to Polar Regions. Hence, scope must be left to allow some layers to be removed if required, without exposing the body to cold. The basic rules for dressing in a cold climate are :

- Keep the clothing clean otherwise the wicking / moisture repelling action will be compromised.
- Do not sweat unnecessarily; undertake activities in a way that sweating is kept to the minimum.
- Keep the clothing dry; wet clothing will grossly reduce the insulatory power.
- Dress in layers (as explained above).

It must be noted that clothing must be worn in sequence, with undergarments and thermal inners being the innermost layer, followed by shirt, trouser, sweaters, and finally the jackets/thermal or feather coveralls. The fit of each item is very important; each item should be tried in its correct sequence. If clothing is too tight, it will restrict the blood flow and increase the predisposition to cold injury.

Boots : In cold weather when two pairs of socks are worn, boots become tight and this may compel the individual to discard them. Therefore, boots should be a loose fit, kept soft and water proof and every person should have an extra dry pair of socks and boots to change into, if feet get wet. One must remember never to sleep with boots on; before going to sleep, boots should be removed and dried.

Socks : A pair of thin nylon / polypropylene socks should form the inner layer, being worn next to the skin and the next layer should be the heavy woollen socks to absorb moisture. These should not be tight. Every person exposed to intense cold should wear extra pairs of woollen socks. Damp socks should be changed immediately.

Shelters : Shelter used in cold environment should be designed on the same basic principles of layering as for cold weather clothing. The tents should have a strong, tightly woven outer shell, which should be impervious to rain and snow. The inside liner is a lighter weight fabric and is hung to provide an air space along the outer shell. Ideally the tent should have a floor made of impervious material. If ever a stove is burnt inside the tent for heating purposes, the potential dangers of Carbon Monoxide (CO) poisoning and fire hazards is to be kept in mind. Arrangements for ventilation must be ensured in such circumstances.

Nutrition : Energy requirement in the cold environment is more due to higher metabolism. In general, for civilian population, who are also likely to be indulging in some sort of winter or mountain sports activities, the energy requirement may be 3000 to 3500 Kcal for women and 3500 to 4000 Kcal for men. Provision of adequate hot and appetising meals should be ensured. Vitamin C is also necessary for the cellular reformation, vascular endothelial integrity and as a steroid sparer. It may be given in the form of multivitamin tablets.

Exercise : Regular moderate exercise to keep up the circulation without causing any exhaustion or excessive sweating should be undertaken frequently. When climatic conditions do not permit movement in the open, static physical activity by frequent vigorous movements of limbs, movements of neck

and back, wriggling of toes and moving of fingers should be continuously practised. Face muscles should be wrinkled to keep up the circulation.

Venous Congestion : People should not sit for long periods cramped up in enclosed places or upon the railing with feet hanging down and especially over the edge of seats as this leads to venous congestion. Too tight clothing also causes venous stagnation.

Alcohol : Alcohol is best avoided when confronted with harsh, cold environment. In any case, it should never be consumed in excess over a short duration and none at all when one is likely to go out into cold environment.

Smoking : It is advisable not to smoke at all. Those who cannot avoid smoking should do so only in moderation. It should be definitely prohibited once the cold injury occurs.

Buddy System : For small parties on adventures / expeditions, it is always a good practice to have a “buddy system”, i.e. to pair up people and make them responsible to look after each other, by watching each other's face and feet for observing any early tissue damage. Buddies also watch out for each other's personal hygiene, nutrition, and behaviour so that any aberration is identified at the earliest and first aid is given.

General Personal hygiene : It should be maintained at the highest level. Besides ensuring local cleanliness and preventing infections, it will enhance the general feeling of well being, so essential in tough, cold environment. Proper bathing is preferred; however, even a basin of water for a sponge bath will help. When no water is available, simply rubbing the body, preferably with a wool rag, is worth the effort. It is recommended that such a procedure be followed weekly. Changing to clean or even airing of soiled socks and underwear periodically will help to maintain body cleanliness. At least two or three hot baths in a week in snowbound and cold environs are necessary. Bathing places should be sheltered from wind and snowfall. However, too frequent use of too much soap is not good as it removes the greasy sebaceous material and decreases insulation.

Foot Hygiene : The feet should be inspected before going to bed every night, for any swelling, ulcer or numbness. Wriggling the feet and toes before going to sleep and even within the boots, while walking, should be an inculcated habit. It is much better to make two partners responsible for inspecting each other's feet. Feet must be washed with warm water, thoroughly dried and smeared with a little Vaseline, before sleeping. This helps prevent frost bite. An individual with ulcers and abrasions on the foot should not move around until they are healed. Talcum powder should be used before wearing socks in the morning to decrease dampness during exertion and reduce friction with socks.

Oral Hygiene : By daily cleaning the teeth with a piece of gauze or other cloth wrapped around a finger is an effective practice in the absence of toothbrush.

“Feel Good” : Keeping well is especially important when one is stranded. While physical fitness of the body decides survival, yet a positive mental attitude is just as important. Personal cleanliness, dry clothing, ventilated shelter without drought, a warm bed, and adequate recreational activities are helpful.

Re-exposure : Persons who have once suffered from cold injury should be very careful when getting exposed to cold environment again.

Adaptation to Cold : Systematic acclimatisation to cold can be carried out by exposing newly inducted people to the atmospheric temperature of 0°C to 5°C for three or four hours a day for three consecutive weeks. During the first week people should be dressed in vest cotton, full sleeves flannel shirt, pullover, woollen trousers, woollen cap, gloves and boots with only one pair of woollen socks. Outside the exposure hours, people can put on the additional clothing as jackets, coveralls, etc. During the next two weeks, pullover is also removed, so that people stay in flannel shirt and trousers for 3 to 4 hours. The site selected for exposure should be sheltered from wind. If there is any wind or breeze, people should wear a thin nylon wind-cheater. Since physical exercise warms the body and hence impedes the acclimatisation process, during the hours of exposure, therefore, physical exercise should not be allowed; however, normal sedentary recreational work as reading, knitting, playing cards etc., which do not involve much physical activity, may be carried out. People should be assured that exposure to cold for cold acclimatisation will cause no harm. If any complaints like rhinitis, pharyngitis, fever, excessive shivering or cramps are noticed; the exposure should be discontinued for the day or until cured. It can be restarted and gradually increased day by day when the individual has recovered.

High Altitude Acclimatization : Often, cold environment co-exists with high altitude environment. Adverse effects of high altitude will worsen the physical and psychological adversities due to cold and vice-versa. Proper acclimatization to high altitude should be therefore undertaken, as described in the chapter on high altitude.

Early diagnosis, first aid and prompt treatment : These are aimed at prevention and arrest of tissue damage. Early detection and first aid would go a long way in prevention of further damage, in both generalised as well as local cold injury. The details have already been discussed earlier in this chapter.

Protection against Snow Blindness : Humans can make no natural adjustments to the reflection of bright sun from snow, ice, and water, even with an overcast sky. Dark glasses are, therefore, a must. One must not wait until eyes start hurting. If the glasses are lost, improvised eye protection, by either wearing a muffler or stockings over one eye through which one can barely see. Treat snow blindness by getting the victim to a dark place. Apply eye shades to both eyes. Cool compresses may help to relieve the pain. Time is the only cure for temporary snow blindness.

Protection against Sunburns : Sunburn can occur even at temperatures below freezing point especially at higher elevations. Sunlight reflected upwards from bright surfaces may rapidly burn the most tender spots, viz., lips, nostrils, upper portion of ears and eyelids. Sunburn also may occur on cloudy days. A strong wind makes the burn even more severe. Sunburn cream should be applied frequently to all exposed skin surfaces.

Summary

Extreme cold conditions occur in India in the Himalayan, Sub-Himalayan and the northern Indian plains with cold waves and deaths being recorded every year. Human exposure to extreme cold produces significant physiologic and psychological challenges. Groups at particularly high risk include military personnel, agriculturists, mountaineers and persons engaging in adventure or winter sports, low income groups with poor housing and inadequate clothing, extremes of age (<5yrs or >65yrs), physical exhaustion, pre-existent malnutrition or starvation, sleep loss, use of alcohol and underlying diseases. Environmental Factors as Severity of cold, duration of exposure, wind movements, moisture, hypoxia, clothing and shelter also play a significant role.

Adverse effects of cold environment manifests as either generalized effects (hypothermia) or local "tissue-freezing" effects as frost bite, or Non-Freezing Cold Injuries (NFCI) as trench foot and chilblains. Generalised Hypothermia, depending on the core temp, may be classified as borderline (36 to 35°C), mild (35 to 32°C), moderate (32 to 28°C) and severe (<28°C). Earliest symptoms are change in behaviour, mood, and lack of affect, apathy, uncoordinated movements, ataxia, confusion and decreased ability to sense cold. Tachycardia, tachypnoea & shivering occur initially followed by bradycardia, decreased respiratory rate, impaired reasoning & violent shivering, paradoxical undressing with stuporous gait as hypothermia becomes more severe (32 to 35°C). Below 32°C, shivering stops with blue, puffy skin, semiconsciousness, muscle rigidity, trismus, marked bradycardia, lowered respiratory rate & cardiac dysrhythmias, especially atrial/ventricular fibrillation occurs. At 28°C or less, complete unconsciousness with severe bradycardia, reduced respiratory rate, muscle rigidity with dilated pupils is seen. Hypothermia should be treated as a medical emergency. Basic principle of management is quick warming of the "core" without causing simultaneous vasodilation of the periphery.

Frost nip involves freezing of top layers of skin tissue, is reversible and manifests as numbness and white, waxy or rubbery feeling of the affected skin. Frostbite is the more severe form affecting all layers of the skin involving the deeper tissue. It is of four degrees, depending on the depth of the tissue involved. As an urgent first aid measure, remove any constrictive clothing or bands, local warming by placing the affected part in a warm water bath at 40-42°C, analgesics, sedatives & Tetanus toxoid are to be administered. Evacuate to a surgical facility at the earliest. Non-Freezing Cold Injuries in the form of chilblains manifest with initial pallor of affected area followed by erythema, pruritus and intense pain. Prevention comprises of avoidance of exposure to cold and wet conditions. Trench foot is caused by prolonged exposure of feet to cold and wet conditions manifesting as reddened skin, tingling pain and itching. Gentle drying, elevation of the affected limb and keeping it at an environmental temperature of 18 to 22°C while keeping rest of the body warm along with NSAIDs is the treatment. Prevention consists of keeping the feet clean and dry, dabbing the feet with aluminium hydroxide powder thrice daily, and changing into dry socks and shoes at the earliest.

Prevention of Cold Illnesses involves clean, dry & layered clothing; loose fit, soft & water proof boots, an extra dry pair of socks, inner thin nylon / polypropylene socks and outer heavy woollen socks with at least four pairs of woollen socks; strong, tightly woven impervious tents; provision of adequate hot and appetising meals ; regular moderate exercise, static physical activity by frequent vigorous movements of limbs, movements of neck and back, wriggling of toes and moving of fingers; not sitting for long periods cramped up in enclosed places or upon the railing with feet hanging down; avoiding smoking & alcohol; practice “buddy system”; personal hygiene including oral & foot hygiene; precautions on re-exposure; cold adaptation; high altitude acclimatization; early diagnosis, first aid and prompt treatment. In harsh, extreme cold climate, in the face of an emergency, survival techniques in the form of skills pertaining to shelter construction, first aid, map and chart orientation and sanitation should be a major element of preparation. Protection against Snow Blindness involves use of dark glasses. Treatment is by getting the victim to a dark place; apply eye shades to both eyes & cool compresses to relieve pain. Protection against sunburns should be practised by applying sunburn cream frequently to all exposed skin surfaces.

Study Exercises

Long Question : Forward a detailed plan of advise on preventive aspects as well as emergency first aid which you will give to a group of approximately 40 mountaineers who will be taking part in a national expedition to climb a mountain peak located at height of 25,000 feet.

Short Notes : (1) Acclimatization to cold (2) Principles of dressing for prevention of cold (3) First aid in hypothermia (4) First aid in frost bite.

MCQs & Exercises

- Age group which is most vulnerable to effects of cold is (a) <5 yrs (b) 5-65 yrs (c) >65 yrs (d) a & b (e) a & c.
- Which of the following is a Non-Freezing Cold Injury (NFCI) (a) Frost bite (b) Trench Foot (c) Hypothermia (d) Frost nip.
- What is the Core body temp in Severe Hypothermia (a) <28°C (b) <29°C (c) <30°C (d) <31°C.
- The normal core (rectal) temperature of normal healthy humans is : (a) 36 to 36.5°C (b) 36.5 to 37°C (c) 37 to 37.5°C (d) 37.5 to 38°C.
- In _____ , a person with hypothermia starts removing the clothes rather than putting on more clothes.
- ECG shows _____ wave at the junction of QRS complex in Hypothermia.
- The basic principle of management in Hypothermia is : (a) Quick warming of the “core” without causing simultaneous vasodilation of the periphery (b) Quick warming of the “periphery” (c) Quick warming of the “core” with simultaneous vasodilation of the periphery (d) None of the above.
- In Frost bite, local warming is done by placing the affected part in a warm water bath at (a) 36 to 38°C (b) 38 to 40°C (c) 40 to 42°C (d) 42 to 44°C.

- Treatment in Trench foot consists of keeping the affected part at what environmental temperature, while keeping rest of the body warm : (a) 14 to 18°C (b) 18 to 22°C (c) 22 to 26°C (d) 26 to 30°C.
- About _____ hours of exposure to _____ °C is needed to cause cold injury. (a) 5 hours, minus 10°C (b) 10 hours, minus 10°C (c) 10 hours, to minus 5°C (d) 5 hours, minus 5°C.
- The probability of cold climate to cause cold injuries is directly proportionate to the _____ rather than its temperature alone.
- The index of thermal resistance of clothing is measured in _____ .
- A woollen cap very effectively contributes to heat conservation since nearly _____ % of all body heat loss is from the head region alone : (a) 13% (b) 23% (c) 33% (d) 43%.
- If clothing becomes wet either due to external moisture (snow or rains) or due to condensation from sweating, it loses what % of its insulating properties : (a) 60% (b) 70% (c) 80% (d) 90%.
- Energy requirement in the cold environment is _____ Kcal for women and _____ Kcal for men : (a) 2000 to 2500 , 2500 to 3000 (b) 2500 to 3000 , 3000 to 3500 (c) 3000 to 3500 , 3500 to 4000 (d) 3500 to 4000 , 4000 to 4500.

Answers : (1) e; (2) b; (3) a; (4) c; (5) Paradoxical undressing; (6) ‘J’ (Osborn); (7) a; (8) c; (9) b; (10) b; (11) ‘wind-chill’ factor; (12) ‘Clo’units; (13) c; (14) d; (15) c.

RajVir Bhalwar

High Altitude illness is a collective term for the syndromes that can affect unacclimatised travellers, shortly after ascent to high altitude (1). The term “unacclimatised travellers” also includes the native highlanders who are re-inducted into high altitude after a sojourn to lower altitude or if they move to a still higher altitude from the normal place of stay in high altitude. The term “high altitude illness” encompasses the syndromes of Acute Mountain Sickness (AMS), High Altitude Cerebral Oedema (HACO) and High Altitude Pulmonary Oedema (HAPO) (1).

With the present body of knowledge, there does not seem to be any clear cut demarcation as to the height above sea level that constitutes “High Altitude (HA)”. The general opinion varies and is dependant on the altitude at which definite manifestation of high altitude illness are likely to occur in a noteworthy proportion of the subjects. Generally, an altitude of 2700 m (9000 feet) and above defines high altitude, with increasing grades of high altitude as 2700 to 3600 m, 3601 to 4500m and 4501 to 5400m. Altitudes above 5400 m in are often referred to as “extreme high altitude” wherein permanent successful acclimatization becomes very difficult. However, the above levels cannot be sacrosanct boundaries; in fact high altitude illness is being increasingly recognised at “moderate” altitudes of 2200 to 2500m (2)

Around 140 million people over the globe live permanently at altitudes of over 2500 m (3) and approximately another 40 million enter high altitude area every year for reasons of occupation, sporting or recreation. Miners in South America go for work to altitudes as high as 6000 m, while Indian soldiers are deployed at even higher altitudes. Persons who are at a definitely increased risk of being affected by high altitude illness include Native highlanders who re-enter high altitude after stay at lower altitudes; Mountaineers; Soldiers; Trekkers; Adventurers; Miners at high altitude; and, Pilgrims and porters (4, 5).

The High Altitude Environment

Effects of high altitude are encountered among visitors to high altitude terrestrial environments and in high altitude aviation. The environmental conditions at high altitudes which influence physiological processes are : the lowered atmospheric pressure and partial pressure of oxygen, lowered temperature and humidity, increased intensity of sunshine and cosmic electrical conditions and the isolation under monotonous mountain conditions. The chief hazards on health, however arise from the low atmospheric pressure, coupled with low partial pressure of O₂ in the alveolar air leading to low oxygen tension in the blood and low ambient temperature, all of which worsen as the altitude increases. The main problem with high altitude terrestrial environment is, in fact, the declining atmospheric pressure. For instance, the atmospheric pressure which is 760

mm Hg at sea level drops down to only approx. 500 mm Hg at around 11000 feet above Mean Sea Level (MSL). Now, as we know from a very basic law of physics (Boyle's Law) that the partial pressure of a mixture of gasses is equal to the sum of the partial pressure (pp) of these gasses; and the partial pressure of these individual gasses is proportional to their concentration in the gaseous mixture. For all practical purposes, air is mainly a mixture of Nitrogen (N) and Oxygen (O) in the proportion of 80% and 20% respectively. Thus the pp of N will be four fifth and that of O will be one-fifth that of the atmospheric pressure at a given location. Hence, at sea level, where the atmospheric pressure is 760 mm Hg, the partial pressure of 'N' is 4/5 of 760 i.e. approx 608 and that of 'O' is approx. 152 mmHg.

Now as the atmospheric pressure drops with ascent from sea level (by very roughly, 25 mm Hg for every 1,000 feet ascent), hence at 11,000 feet it would be approx. 500 mm Hg; and, by Boyle's law, at this height, the partial pressure of Nitrogen would be (4/5 of 500) i.e. 400 mm and that of Oxygen will be 100 mm Hg. It is this progressive decline in partial pressure of oxygen in ambient air (commonly referred to as “thinning or air” or, “rarefied air”) that results in reduction of alveolar oxygen pressure, with all the resultant pathological issues of high altitude. Thus, though the concentration of oxygen in atmospheric air at high altitude is still one-fifth, the net result because of such reduction of partial pressure of oxygen is as if there was a lack of Oxygen in the air. Thus, at around 11,000 feet, the effect is as if oxygen in the air were 13.8% instead of 21% normally seen at sea level. The details are depicted in the Table - 1. This is the basic environmental issue that triggers a massive cascade of physiological responses, intended to be protective, once a human being is inducted into high altitude.

Table - 1 : Altitude, pressure, temperature, oxygen partial pressure and percentage

Altitude		Pressure (mm Hg)	Oxygen Partial pressure (mm Hg)	Equivalent Oxygen percentage
Feet	Meters (mm Hg)			
0	0	760.0	159.2	20.96
9,000	2,743	543.2	113.8	14.96
12,000	3,658	483.2	101.2	13.31
15,000	4,572	428.8	90.5	11.81
18,000	5,486	379.4	79.5	10.45
20,000	6,096	349.2	73.1	9.61

Physiological Adaptation : The lowered atmospheric oxygen partial pressure at high altitude causes alveolar and arterial hypoxia leading to tissue hypoxia. As described earlier, the oxygen partial pressure in alveoli is decreased at high altitude and hence, to compensate for this, circulatory and haemopoietic adjustments are made by the body physiology. There is increased frequency of respiratory and cardiac rhythm. Finally the increased amplitude of respiratory and cardiac movements gradually occurs. Interstitial fluid is diverted to the vascular compartment which alters the haemodynamics and cause hypervolaemia, thereby overloading the pulmonary circulatory system and cardiac function. These mechanisms are usually

uneventful and insensible up to about 2500 to 3000 m; however, above that height when pronounced physiological mechanisms are called to action, the symptoms of 'early mountain sickness' which in reality are the symptoms of 'rapid acclimatization', become manifest. If acclimatization is inadequate, or if it breaks down, or if the ascent to higher altitude is too rapid, the essentially beneficial adaptive responses become aberrant and the disease processes occur.

The common acute high altitude syndromes are Acute Mountain Sickness (AMS) and High Altitude Pulmonary Oedema (HAPO). Less commonly, High Altitude Cerebral Oedema (HACO), a cerebral syndrome may occur at sudden induction into very high altitudes of 4500 mtrs and above. Chronic Pulmonary Hypertension is a rare syndrome occurring after prolonged residence at high altitude areas.

Acute Mountain Sickness (AMS) : The latent period of AMS (time elapsing from entry into high altitude to onset of first symptom) is usually 6 to 12 hours. Sojourns to high altitude which last for less than 6 hours are not likely to be associated with AMS. AMS is quite uncommon below the altitudes of 2000 m. The incidence of AMS has been quite variable in different studies and primarily depends on the altitude reached, the rate (speed) of ascent to high altitude and physical exertion after entry into high altitude, besides other variables. Various workers have observed incidence of as low as 6% to as high as more than 60% (6 - 11).

High Altitude Pulmonary Oedema (HAPO) : The incidence of HAPO has been found to be quite variable, between 0.5% to 5%, as reported by various workers. Any person irrespective of age, gender or race, who enters into a high altitude terrestrial environment, is at risk of HAPO, including native highlanders who enter into high altitude after a stay at lowlands. However, certain groups seem to be at a higher risk due to Socio-behavioral or occupational reasons. These include soldiers, mountaineers trekkers, adventurers, mountain-sports persons, miners working at high altitude, porters, and land pilgrims to high altitude shrines. Most of the epidemiological studies indicate that the 'latent period' or 'induction time" (period elapsing from entry into high altitude to the onset of first manifestation of HAPO) is usually between 6 to 96 hours, though rare cases can occur as late as ten days also. Onset beyond this range is quite uncommon (12 - 16). Therefore, it is logical to conclude that the period of first 72 hours following induction into high altitude seems to be important, with the initial 48 hours being most crucial for enforcing preventive measures regarding acclimatization, especially avoidance of any physical activity (except for self-care activities of a routine nature).

Risk Factors for AMS and HAPO : The major risk factors for both, AMS and HAPO are :

Physical exercise soon after induction into high altitude: Physical exercise even of moderate intensity, undertaken within 72 hours of arrival into high altitude is an important determinant and is almost universally upheld by all experts. The risk has been observed in nearly all the studies, at various places in the world, and the estimates show a strong and significant association. Thus, the association fulfils the required epidemiological parameters of strength of association,

temporality, consistency, dose response and plausibility. However, it is noteworthy that physical exercise is not an 'essential' determinant, since the condition can occur even among persons who have not exerted/are asleep/are at rest, especially if ascent to high altitude has been rapid, as by air.

Lack of Acclimatization : AMS and HAPO commonly affect subjects who have not properly acclimatized themselves to high altitude environment soon after arrival. Acclimatization is a gradual process by which the body physiology gets adjusted to high altitude environment.

Altitude of ascent : The "critical altitude" at which the risk of developing AMS or HAPO is very high has been reported as 3000 m in the Himalayas, 3600 m in the Andes and somewhat lower (2600m) in the Rocky mountains. This is not to be confused with the definition of "high altitude" which is generally taken as > 2500 mtrs. AMS can however, occur even at lower altitudes of 2500 mtrs.

Rate of ascent : Epidemiological studies have clearly shown that the speed with which an individual reaches high altitude, especially into a crucial altitude of 3000m and above, seem to be an important determinant in causing high altitude illness. Observations have shown that both among soldiers as well as tourists who move to high altitude areas by air, ascending almost 3000m (or even more) within less than an hour, the incidence rates are much higher when compared to the same location being reached by road transport over 3 to 4 days. The slow ascent by road over a few days may allow some acclimatization.

Prevention of Adverse Effects of High Altitude

Individual tolerance to hypoxia varies and has no correlation with physical fitness in its ordinary sense. Complacency or bravado which in itself is one of the symptoms of hypoxia, encourages excessive physical activities without proper and adequate acclimatization. Rapid ascent without acclimatization followed by physical activity increases the risk of effects of hypoxia.

Acclimatization : In general, acclimatization should be undertaken whenever a person reaches an altitude of 2500 metres or above, though a night spent at moderate altitude of 1500 to 2500 m before ascent to high altitude, is likely to further aid in acclimatization process.

Acclimatization is undertaken by 1 to 2 days of complete rest (allowing for only daily activities of living), followed by gradually increasing physical effort for next 2 to 4 days at a particular level of high altitude. This process should be repeated for every 1000 mtrs gain in altitude, i.e. after the person reaches another stage of stay in high altitude which is 1000 metres higher than the previous level at which he / she had acclimatized, another similar round of acclimatization (of 2 days of complete rest followed by 3 to 4 days of gradually increasing physical activity) should be undertaken for each such 1000 metres gain in altitude.

While negotiating high altitude areas, *gradual ascent*, thereby giving time for acclimatization to develop, is the key strategy in prevention. In general, at altitude greater than 3000 m, each

night should be spent at an altitude of not more than 300 m above the previous night, with a rest day after every 2 to 3 days (i.e. after every 1000 m of ascent). In certain situations, as tourists coming for mountaineering, this rate of ascent may be considered to be slow and unrealistic and may be modified so that the altitude difference between two consecutive “sleeping sites” should not be more than 600 m per day.

All recommendations emphasise “*sleeping altitude*” which means that it is permissible to ascend more than the recommended daily rate as long as descent is made for sleeping, i.e. the time tested maxim of “climb/work high but sleep low”.

Visitors to high altitude areas also need to be educated that the actual pathophysiological changes at high altitude take 6 to 24 hours to gradually develop and hence they may not get any symptom during initial 6 to 8 hours or even during first day; however, they should not take this as an immunity from adverse effects of high altitude. Many serious cases have occurred because tourists started exerting on the first or second day because they did not have any symptoms.

Chemoprophylaxis : Acetazolamide orally, for three days before induction into high altitude areas has been recommended by some authorities as it may help in reducing the occurrence or severity of AMS / HAPO, but evidence from RCTs is still not available.

Other Measures : Environmental cold is generally present at high altitude areas and care should be taken to adopt preventive measures, as explained in the previous chapter. Ensuring adequate intake of fluids by mouth and avoidance of tobacco and alcohol is also desirable.

Physical performance at High altitude : It needs to be noted that even after complete and successful acclimatization, the capability to perform any given exercise or physical task will be reduced at high altitude in comparison to lower altitudes. This was clearly evident during Mexico Olympics of 1968, held at an altitude of 2300m wherein most of the world class athletes experienced as much as 13% reduction in their performance. Leaving aside the world class sports persons, evidence suggests that for normal, healthy and properly acclimatized subjects, the physical capability will be just about 70 to 75% at an altitude of 3100 m (Compared to capability at sea level altitude) and would be about 50 to 60 % at 4000 m. Care should be taken, therefore, by all persons moving to high altitude, to make realistic readjustment in their expectations regarding task performance.

Summary

High Altitude illness is a collective term for the syndromes that can affect unacclimatised travellers, shortly after ascent & encompasses the syndromes of Acute Mountain Sickness (AMS), High Altitude Cerebral Oedema (HACO) and High Altitude Pulmonary Oedema (HAPO). High altitude (HA) is defined as an altitude of 2700 m (9000 feet) and above, with increasing grades. Altitudes above 5400 m are referred to as “extreme high altitude”. High risk groups are the native highlanders who re-enter HA after stay at lower altitudes, mountaineers, soldiers, trekkers, adventurers, miners, pilgrims and porters.

Health hazards in HA arise from the low atmospheric pressure,

with low partial pressure of O₂ in the alveolar air leading to low oxygen tension in the blood and low ambient temperature. Progressive decline in partial pressure of oxygen results in reduction of alveolar oxygen pressure. Physiological Adaptation at HA involves lowered atmospheric oxygen partial pressure causing alveolar and arterial hypoxia leading to tissue hypoxia which is uneventful and insensible up to 2500 to 3000 m & above that height, symptoms of ‘early mountain sickness’ which are the symptoms of ‘rapid acclimatization’ appear. The common acute high altitude syndromes are AMS with a latent period of 6 -12 hours & uncommon at <2000 m, incidence varies between 6% - 60% & depends on the altitude reached, rate of ascent and physical exertion after entry into HA; HAPO with an incidence between 0.5% - 5% with certain groups at a higher risk due to socio-behavioural or occupational reasons, latent period being 6 - 96 hours, with the initial 48 hrs being most crucial for enforcing preventive measures regarding acclimatization.

Risk Factors for AMS & HAPO include physical exercise soon after induction, lack of acclimatization, altitude (higher the altitude more the risk) & fast speed of ascent. Prevention of adverse effects requires avoidance of complacency or bravado, acclimatization as per the recommendations with gradual ascent being the key strategy in prevention, not having an altitude difference of more than 600 m / day between two consecutive “sleeping sites”, chemoprophylaxis with Acetazolamide orally X 3 days before induction & other measures such as ensuring adequate intake of oral fluids, avoidance of tobacco & alcohol and precautions against environmental cold. Physical performance at HA is reduced. Care should be taken to make realistic readjustment in the expectations regarding task performance.

Study Exercises

Short Notes : (1) Acclimatization to high altitude (2) Acute mountain sickness (3) High altitude pulmonary oedema (4) Lake Louise criteria

MCQs & Exercises

1. The term “unacclimatised travellers” also includes the native highlanders who are re-inducted into high altitude after a sojourn to lower altitude (True/false)
2. “High altitude illness” encompasses the syndromes of all except : (a) Acute Mountain Sickness (AMS) (b) High Altitude Cerebral Oedema (HACO) (c) High Altitude Pulmonary Oedema (HAPO) (d) Cold stroke.
3. Altitude of _____ defines high altitude & Altitudes of _____ are often referred to as “extreme high altitude.
4. Globally, how many people live permanently at altitudes of over 2500 m : (a) 10 million (b) 40 million (c) 100 million (d) 140 million.
5. The environmental conditions at high altitudes which influence physiological processes are all except : (a) Lowered atmospheric pressure (b) High partial pressure of oxygen (c) lowered temperature and humidity (d) increased intensity of sunshine.
6. The adverse effects of environmental cold occurring at high altitude, as compared to when they occur at plains are not aggravated due to atmospheric and tissue hypoxia (True/false)

7. Progressive decline in partial pressure of oxygen in ambient air is commonly referred to as _____ .
8. What is the partial pressure of oxygen (in mm Hg) at an alt of 3600m, where atmospheric pressure is about 485 mm Hg & equivalent O₂% being 13.5% ? (a) 91.2 (b) 101.2 (c) 201.2 (d) 301.2 .
9. What is the latent period of AMS (time elapsing from entry into high altitude to onset of first symptom) : (a) 3 to 6 hours (b) 6 to 12 hours (c) 12 to 18 hours (d) 18 to 24 hours.
10. What is the usual incidence of HAPO ? : (a) 0.5% to 1% (b) 0.5% to 3% (c) 0.5% to 4% (d) 0.5% to 5%.
11. Which period is most crucial for enforcing preventive measures regarding acclimatization? (a) Initial 4 hours (b) Initial 14 hours (c) Initial 24hours (d) Initial 48 hours.
12. The "critical altitude" above which the risk of developing AMS or HAPO is very high in the Himalayas is (a)1000 m (b) 2000 m (c) 3000 m (d) 4000 m.
13. The process of Acclimatization should be repeated for every _____ mtrs gain in altitude : (a) 100 (b) 500 (c) 1000 (d) 1500.
14. Altitude difference between two consecutive "sleeping sites" should not be more than : (a) 200 m per day (b) 400 m per day (c) 600 m per day (d) 800 m per day.
15. Which drug is recommended for Chemoprophylaxis three days before induction into high altitude areas (a) Acetazolamide (b) Furosamde (c) Doxycycline (d) Paracetamol.

Answers : (1) True; (2) d; (3) 2700 m (9000 feet), above 5400 m; (4) d; (5) b; (6) False; (7) Thinning of air" or "rarefied air"; (8) b; (9) b; (10) d; (11) d; (12) c; (13) c; (14) c; (15) a.

Water constitutes one of the important physical environments of man and has a direct bearing on his health. Water is a prime natural resource, a basic human need and a precious national asset. Water is important to man and therefore, WHO refers to "control of water supplies to ensure that they are pure and wholesome as one of the primary objectives of environmental sanitation". Water is essential for drinking, cooking, bathing and washing, laundering, ablution, domestic sanitation, domestic animals and industries.

Safe and Wholesome water : Drinking water should be safe as well as wholesome. Water is termed safe when it does not harm

the consumer even when ingested over prolonged periods. Safe and wholesome water thus, must be

- (a) Free of pathogenic organisms
- (b) Free from harmful chemical substances
- (c) Acceptable to taste and appearance
- (d) Usable for domestic purposes

Water Requirements : The supply of water must be satisfactory in quality and adequate in quantity, readily available to the user, relatively cheap, and easily disposed after it has served its purposes. The Environmental Hygiene Committee in the code of basic requirements of water supply, drainage and sanitation along with National Building Code recommends minimum of 135 lit per capita per day (lpcd) for residences with full flush system for excreta disposal. The recommended values for domestic and non domestic purpose are given in Table-1.

Table - 1 : Recommended Per Capita Water Supply Levels For Designing Schemes (1)

S No	Classification of towns/cities	Recommended maximum water supply levels (lpcd)
1	Communities where water is provided through public stand posts	40
2	Towns provided with piped water supply but without sewerage system	70
3	Cities provided with piped water supply where sewerage system is existing	135
4	Metropolitan and mega cities provided with piped water supply where sewerage system is existing	150

Sources of Water

Rain Water : Rainwater is used as a direct source on islands, such as Bermuda, where the rain is collected and led into cisterns to serve as the only available water supply. Catchment areas for direct capture of rainwater are also useful for individual households as in South West USA or small communities as in Gibraltar where paved catchments are used. Rain water is usually soft, plumbosolvent and mildly acidic due to its reaction with carbon dioxide in the atmosphere to form carbonic acid. Physically it is clear, bright and sparkling. Bacteriologically, rain water from clean surroundings is free from pathogenic agents.

Surface water : It usually originates from rain water. It includes rivers, streams, upland reservoirs and lakes. Surface water is moderately soft and prone to contamination from human and animal sources. The extent of contamination at a particular time and place will depend upon the proportion of pollution to the amount of water available, from the feeding streams, upstreams or springs, the extent of stagnation or outflow over a given time and the extent of natural self purification. Surface water sources include Lakes and ponds; Impounding reservoirs; Rivers; irrigation canals; Sea water; and, Waste water reclamation.

a) Lakes and ponds : The water is more uniform in quality than water from flowing streams. Lakes are increasingly becoming vulnerable to pollution as they are quite accessible for human activities. Long storage permits self purification, sedimentation, oxidation of organic matter, and a tremendous drop in bacterial count. If there is proper cleanliness and sanitation in catchment area, then the stored water may not require any treatment other than disinfection. The concentration of pollution increases as water evaporates. The degree of self purification is negligible and the amount of pollution added to it each day is unpredictable. Therefore, water from fresh water lakes, which are properly protected, fenced and patrolled is generally pure and can be made potable whereas that from a pond is never recommended for human consumption. Unfortunately, it constitutes one of the main sources of water supply in the rural areas of this country. The improvement can be achieved

by applying the basic techniques of modifying a part of the pond into a filter bed. The filtered water is then drawn into gravity fed well and finally chlorinated before supply.

b) Impounding Reservoirs : These are the collections of water harnessed in the impounding reservoirs by constructing earth, concrete or masonry dams across at convenient places in the valleys in the mountainous regions. These collections are relatively pure in general but may get polluted due to grazing of animals and human activity. Impounding reservoirs are subject to same conditions as natural lakes and ponds. While top layers of water are prone to develop algae, the bottom layers of water may be high in turbidity, carbon dioxide, iron, manganese and, on occasions, hydrogen sulphide.

c) Rivers and Streams : These are natural drainage channels of the land. The quality of river water depends upon the geological strata through which it has travelled, the seasons of the year, and the amount of pollution that has occurred during its course. Generally, it is moderately hard but some river waters are brackish and may get contaminated while traversing long distances from sewage and other waste discharge from habitations located along their course. Other sources of pollution are the industrial effluents, carcasses and human dead bodies. The inadequacy of traditional methods of water treatment to tackle gross river water pollution may be indicated by the outbreaks of viral hepatitis in New Delhi in 1955-56, when there were 30,000 cases. In wet periods, the water in rivers and streams may be low in dissolved solids content but often of a high turbidity. In dry periods, river flows are low and the load of dissolved solids is less diluted.

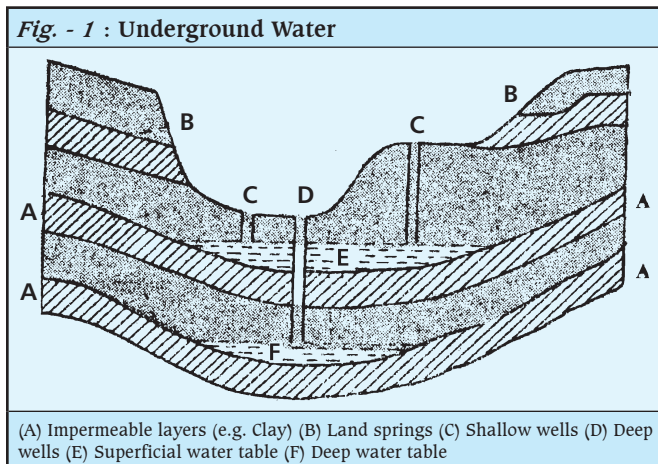

d) Sea Water : Sea water is huge and plentiful source of water but it is difficult to economically extract water of potable quality because it contains 3.5% of salts in solution. Offshore waters of the oceans and seas have a very high salt concentration and hence are unfit for consumption. Desalting or demineralising process involves separation of salt and water from saline waters. The most appropriate method for desalination of sea water is thermal distillation as done in Middle East and the West Indies. Several different processes, including electro dialysis, reverse osmosis, and direct-freeze evaporation, have been developed for this purpose.

Underground water : Rain water percolating in the ground and reaching permeable layers in the zone of saturation constitutes ground water source. Underground Water (Fig. - 1) is of major importance to civilization, because it is the largest reserve of drinkable water in regions where humans can live. Underground reservoirs have the following major advantages:

- (a) Bacterially, groundwater is much better than surface waters
- (b) They do not lose water through evaporation
- (c) Their quality is not so likely to be affected by natural, urban or industrial pollution as surface water.
- (d) They do not require expropriation of large areas of land.
- (e) They may be located nearer to the points of use than are surface impoundments.

Generally, ground waters are clear and colourless but are harder than the surface waters of the region in which they occur. Although groundwater is a renewable resource, reserves are replenished relatively slowly. Because groundwater is recharged

and flows so slowly, once polluted it will remain contaminated for extended periods. Contamination arises from leaking underground storage tanks, poorly designed industrial waste ponds, and seepage from the deep-well injection of hazardous wastes into underground geologic formations. Almost all highly industrialized areas in our country have contaminated their groundwater due to industrial wastes and agricultural run-offs (CPCB, 1994). Even all the villages too, do not have access to safe water. A "problem village" is defined as one where no source of safe water is available within a distance of 1.6 km or where water is available at a depth of more than 15 meters or where water source has excess salinity, iron, fluorides and other toxic elements or where water is exposed to the risk of cholera and guinea worm.

Springs : Springs are due to the emergence of groundwater to the surface. Springs can be 'shallow springs' and 'deep springs' depending upon whether the water comes from the superficial or the deep water tables. Deep springs can be turned into well like reservoirs by building parapets around them.

Wells : The subsurface sources include springs, wells and galleries. Wells can be classified according to construction process as Dug wells, Bored wells, and step wells. Alternatively, they can be classified depending on the depth and the layer of water table as shallow wells, deep wells and artesian wells.

Shallow Wells : These tap the 'superficial water table' i. e. the water table above the first impervious layer of the earth. They are of utility in abstracting limited quantity of water which usually goes dry in summers. The quality of water depends upon the geological formation and the degree of pollution by seepage from the adjacent area, which is unpredictable. Shallow wells are, therefore, inferior to deep wells as sources of water for human consumption as they are prone for contamination. The Cholera outbreaks in Delhi in 1988 were due to contamination of shallow wells.

Shallow well can be made sanitary by deepening the bottom, installing a handpump with screen and then filling the well with coarse sand upto water level; clay is then put over sand till it reaches a little above the surface level and then left for consolidation. When the material used for filling is consolidated a platform and drainage may be constructed.

Deep Wells : These tap the deep water table lying between the two impermeable strata and their yield is constant. Because of longer travel of groundwater to reach previous layers below the top impermeable layers, deep wells yield a safer supply than shallow wells. An ideal deep well is the one which is sunk to a sufficient depth below the first impermeable geological stratum, well stained with stones or bricks set in cement concrete provided with a covered parapet with a coping or sloped platform around and fitted with a pump. The depth of water should be sufficient to ensure an adequate quantity and sedimentation. The differences between shallow and deep wells is given in Table - 2.

S No		Shallow well	Deep well
1	Definition	Water from above first impermeable strata	Water from above second impermeable strata or impervious layer
2	Chemical quality	Moderately hard	Much hard
3	Bacteriological quality	Fair but prone for contamination	Good
4	Yield	1 gpm	100 gpm

Artesian wells : Artesian groundwater is groundwater, that is, by an overlying impervious layer, prevented from rising to its free water table level, and therefore is under pressure. The name is derived from French Artesian of Artois, a province where such wells were first drilled in modern times. Artesian wells are not common in India.

Sanitary Well : A properly located, well constructed and protected against contamination, yielding safe water supply is known as Sanitary Well. Sanitary well can be constructed as :

a) Location : located at least 50 ft away from likely source of contamination on the higher ground but not more than 100 mt from consumers.

b) Lining : lining of the well is built by bricks or stones in cement upto a depth of about 20 ft. This lining is carried 2-3 ft above the ground level inside the parapet.

c) Parapet : Wall around well upto a height of 60-90 cm above the ground with lining inside.

d) Platform : There should be 2-3 ft wide cemented platform around parapet with sloping outwards.

e) Drain : A cemented drain is made around platform to drain storm water and spilled water to the main drain or soakage pit which should be constructed away from cone of filtration of well.

f) Covering : The top of the well should be covered with some gap for aeration and ventilation. The gaps should be such that impurities cannot go inside.

g) Handpump : A manual or electric pump should be connected to draw water hygienically.

h) Consumer Responsibility : Strict cleanliness should be enforced in the near vicinity of the well, personal ablutions, animal droppings, washing of clothes and animals, bathing etc should be prohibited.

i) Water stagnation : Water should not be allowed to stagnate near well to prevent breeding of mosquitoes.

j) Quality : The physical, chemical and bacteriological quality of water should conform to the acceptable standards of quality of safe and wholesome water in rural settings.

Water Sources - Selection and Protection : In order to expect a safe and wholesome water for human consumption, the proper source and site should be selected keeping in view the liability and degree of pollution and its dilution, power of self purification, daily yield, duration for which available, wholesomeness of water, and the approach to the area. The area all around the source and delivery point should then be protected against pollution by fencing and prohibiting entry of animals and unauthorized persons. The activities like defecation, bathing and washing should not be allowed even in near vicinity of the area (catchment area). Water from streams and lakes should be drawn from the upstream side of the township and as far from the banks as possible and pumped into the treatment tanks. Personnel attending to the water treatment/distribution should be protected against typhoid and other infectious diseases and medically inspected.

Health Hazards Due to Impure Water

Health may be affected either directly by consuming contaminated water or indirectly through food chain and also by use of water for recreational, agricultural, trade and other purposes. The health hazards of water pollution may be classified as Biological, Chemical and Radiological. The diseases related to water supply and caused by biological agents of disease are summarised in Table - 3.

Water Purification

Comprehensive details of water treatment processes in settings of small scale communities, as well as large scale community supplies are laid down in standard publications (1, 4-6). Reference No. 1 is generally accepted as a standard reference by various Public / civil engineering agencies in our country.

Medical Officers dealing with water supply systems are advised to refer to these manuals.

Purification of Water on a Large Scale

The aim of water purification is to produce and maintain water that is hygienically safe, aesthetically attractive and palatable, in an economical manner. The testing of water quality should not be restricted to treatment facilities but to be extended to the point of consumer use.

Conventional treatment of water includes prechlorination, aeration, flocculation (rapid and slow mixing) and sedimentation, rapid gravity filtration and post chlorination to render water safe for consumption. First few steps of water treatment are also called as Clarification which removes suspended matter and later disinfection kills pathogenic organisms. Disinfection without clarification may be practiced if water is beyond any doubt free of pollution and is visibly clear, or under extreme urgency. For example, ground water may need no treatment, other than disinfection. Surface water which tends to be turbid and polluted requires extensive treatment. The components of a typical water purification system comprise one or all of the following measures, viz., (a) Pretreatment, (b) Filtration and (c) Disinfection

Pretreatment : The sub-steps included in pre-treatment are Storage, Coagulation, Rapid Mixing, Flocculation, and Sedimentation. The details are described as follows.

(a) Storage : Even when water appears very clear, clarification should be insisted upon particularly for surface water. Minute particles of suspended organic matter which usually give lodgment to microbes particularly the viruses are not usually destroyed by the usual dosage of chlorine. Efficient clarification, therefore, eliminates besides the suspended matter, harmful organisms, cysts, ova, mollusc and Cyclops, and thus reduces the chlorine demand of water. The two methods available for clarification are sedimentation and filtration. Filtration is superior to sedimentation provided that the suspended matter is not too dense. Sedimentation requires more time (several hours) than filtration and the amount of water that can be dealt with is limited by the size of tanks available. Sedimentation less efficiently eliminates ova and cysts than filtration. However, efficient sedimentation prior to filtration definitely results in

Table - 3 : Classification of Water related diseases (3)	
Category	Diseases
<i>Water borne diseases</i> : Caused by the ingestion of water contaminated by human or animal faeces or urine containing pathogenic bacteria or viruses.	Cholera, typhoid, amoebic and bacillary dysentery, viral hepatitis, leptospirosis, giardiasis.
<i>Water washed diseases</i> : Diseases due to lack of water. Poor personal hygiene favours spread.	Scabies, skin sepsis & ulcers, yaws, trachoma, conjunctivitis, flea-, lice-, and tick- borne diseases, in addition to the majority of water borne diseases which are also water washed
<i>Water based diseases</i> : Caused by parasites found in intermediate organisms living in water. Infecting agents spread by contact or ingestion of water. An essential part of life cycle of agent takes place in aquatic animal eg snails, Cyclops etc	Schistosomiasis, dracunculiasis and some other helminths
<i>Water related diseases</i> : Transmitted by insect vectors which breed in water	Yellow fever, dengue, encephalitides, filariasis, malaria, onchocerciasis, trypanosomiasis, sleeping sickness

a better final clarity of water, and relieves the filters of the clogging debris.

Sedimentation is carried out by allowing water to stand in concrete, masonry or canvas tanks over a variable period from 2 to 6 hours for settling the coarse suspended matter. This process can be hastened and improved in quality by coagulation and flocculation, which precipitates particulate and colloidal matter. The coagulation and flocculation are greatly influenced by physical and chemical forces such as electrical charges on particles, exchange capacity, particle size and concentration, pH and water temperature, electrolyte concentration and mixing.

(b) Coagulation : Coagulation describes the effect produced by the addition of a chemical to a colloidal dispersion, resulting in particle destabilisation. Operationally, this is achieved by the addition of alum and its rapid mixing for obtaining uniform dispersion of the chemical. The chemical coagulants employed are pure aluminium sulphate $Al_2(SO_4)_3$ (alum) or more commonly aluminoferric, which is an impure form of alum containing about 1 percent of ferric sulphate. Both salts are readily soluble in water and forms aluminium hydroxide which engulfs and precipitates with it the minute particles of suspended matter. The optimum reaction for rapid and efficient sedimentation is at pH 7, at which the addition of 35 g of alum or aluminoferric per 1000 l will rapidly clarify any turbid water. If water is exceptionally turbid, as much as 70 g per 1000 l may have to be used. Finely divided clay, fuller's earth, bentonites and activated carbon are commonly used materials used as Coagulant aids which improves or accelerates the quick forming, dense and rapid settling flocs.

(c) Rapid Mixing : Rapid mixing is an operation by which the coagulant is rapidly and uniformly dispersed throughout the volume of water, to create a more or less homogenous system. Water is agitated violently and the chemical is injected in the most turbulent zone. Generally large sludge volumes are produced with alum which requires frequent desludging operations at the treatment plants causing increased wastage of water. There is also the possibility of aluminium carry over in water treated with alum. High levels of aluminium in potable water are reported to cause Alzheimer's disease, a form of senility. However at present there is no clear evidence to suggest a link between aluminium and Alzheimer's disease (Cole, 1990). Poly aluminium chloride (PAC) has been developed as an alternative coagulant for alum by an Indian manufacturer. PAC hydrolyzes with great ease as compared to alum, emitting polyhydroxides with long molecular chains and greater electrical charge in the solution, thus contributing to maximize the physical action of the flocculation. Better coagulation is obtained with PAC as compared to alum at medium and high turbidity waters. Floc formation with PAC is quite rapid. The sludge produced by PAC is more compact than that produced by alum.

(d) Flocculation : Flocculation is the process of gentle and prolonged stirring of coagulated water in the flocculation chamber for the purpose of forming settle able particles (flocs) from destabilised colloidal sized particles through the aggregation of the minute particles. After coagulation, the individual floc particles are easily observed by the naked eye, being of the order of 1-2 mm in diameter. In practice, the velocities in flocculation tanks vary from 1 m/s at the entrance,

decreasing to about 0.2 m/s near the outlet, with a retention time of 30 minutes. Slow mixing is the hydrodynamic process which brings the particles to collide and then agglomerate resulting in the formation of large and readily settle able flocs of aluminium hydroxide. These can be subsequently removed in settling tanks and filters. The mechanical type of flocculator is widely used in which paddles rotate at 2 to 4 rpm. In actual practice this quantity of alum or aluminoferric brings the natural alkalinity of the vast majority of waters down to a pH of 7 and no other treatment is required.

(e) Sedimentation : Sedimentation is the separation of suspended particles from water by gravitational settling down. The coagulated water is now led into sedimentation tanks where it is detained for periods ranging from 2-6 hrs, where the flocculant precipitate settles down in the tank together with impurities and bacteria. The precipitate or sludge which settles at the bottom is removed from time to time without disturbing the operation of the tank. For very turbid water sedimentation may be better carried out in two stages; initial settling of the bulk of the coarse debris followed by chemical flocculation. Leading the flow of water through long tortuous broad channels at slow velocity and storage in large reservoirs before its entry into the sedimentation tanks helps to achieve better sedimentation. This also exposes water to the natural purifying effects of the sun's rays and fresh air, and the biological effect of minute aquatic fauna and flora. These processes render the water highly suitable for filtration and bring down the bacterial content of water considerably.

Filtration

Filtration is a process for separating suspended and colloidal impurities from water by passage through a porous media. Filtration, with or without pre-treatment, has been employed for treatment of water to effectively remove turbidity. It is almost universally adopted in a large scale purifying process of water in municipal, cantonment, garrison or base areas where permanent water works exist. Storage and sedimentation, with or without flocculation depending upon the quality of water, almost always precede the process of filtration. Filters are slow and rapid sand filters and mechanical filters. Mechanical filters are used in small, more sophisticated water plants and also in the water tank trucks and trailers. Sand, coal, crushed coconut shell, diatomaceous earth and powdered or granular activated carbon have been used as filter media but sand filters have been most widely used as sand is widely available, cheap and effective in removing impurities. The driving force to overcome the fractional resistance encountered by the flowing water can be either the force of gravity or applied pressure force. The filters are accordingly referred to as gravity filters (Paterson's filter) and pressure filters (Candys filter). Depending on flow rates the filters are classified as : (i) Biological or slow sand filters, and (ii) Mechanical or rapid sand filters

Slow Sand or Biological Filters

Slow sand filters were first used for treatment of water in 1804 in Scotland and subsequently in London. Then their use spread out throughout the world. These are large masonry tanks 2.5 m - 4 m deep rectangular or circular, containing sand supported on gravel and the water is passed through them slowly from above downwards. As the filter plants need extensive tracts

of land these are usually situated on the outskirts of town located on the bank of a river. To avoid choking of the media preliminary sedimentation and clarification is necessary.

Filter Bed : The filter beds are usually rectangular in shape, arranged side by side in rows and may be either open on top or covered. Each bed usually covers an area from one tenth of an acre to one acre land. The filter bed consists of

- (a) Supernatant water layer - 1-1.5 mt
- (b) A bed of filter medium - sand bed 1-1.2 mt.; graded gravel 0.3-0.5 mt.
- (c) An underdrainage system - 0.16 mt
- (d) Set of control valves and appurtenances

The supernatant provides the driving force or constant head for the water to overcome the resistance of filter bed and provides waiting period of some hours for the raw water to undergo sedimentation, oxidation and particle agglomeration. A layer of graded gravel of about 30 - 50 cm thickness is placed over the perforated pipes. Above the gravel is the sand bed having a thickness of about 1-1.2 m. The sand grains have an effective diameter between 0.2-0.3 mm. The underdrainage system which is about 16 cm in depth, consists of porous or perforated pipes which serves the dual purpose of providing an outlet for filtered water as well as supporting the filter media above. A system of control valves facilitates the regulation of filter rate and adjustment of water level in the filter. An important component of the regulation system is the "V-notch" or "venturimeter" which measures the flow of water or bed resistance or loss of head.

In a slow sand filter, water is subject to various purifying influences as it percolates through the sand bed. Impurities are removed by combination of straining, sedimentation, bio-chemical and biological processes. Shortly after the start of filtration, slow sand filter acts primarily biologically by forming a slimy 'zoogeal' layer also known as 'Vital Layer' or '*Schmutzdecke*' on the sand bed. This layer is slimy and gelatinous and consist of thread like algae and biological organisms like plankton, diatoms and other minute plants and protozoa. They feed on the organic matter and convert it into simple harmless substances. The vital layer which is also the heart of the filter removes organic matter, holds back bacteria & oxidises ammonical nitrogen into nitrates & helps in yielding, bacteria free water. Till the vital layer of the filter bed is fully formed (called ripening of bed), the filtrate is run to waste.

Filter cleaning : After several months of running of the filter, the bed resistance increases necessitating cleaning. When the filter has attained the maximum permissible head-loss, it is taken out for service for cleaning. The inlet is closed and the supernatant is drained out, then water level is lowered 10-15 cm below the top of sand bed by opening the valves. Without allowing the bed to dry up, the filter is cleaned manually by removing the top layer of 2-3 cm of sand along with the filter skin. This is done manually by scraping the vital layer. After several years of operation when the thickness of the sand bed reduces to about 0.4 to 0.8 m, it is necessary to make up the sand depth to the original level. The plant is to be closed down and a new bed is to be constructed.

Mechanism of Action of Slow Sand Filters : In a slow sand

filter, due to the fine grain size, the pores of the filter-bed are small. The filter is capable of reducing the *Esch. Coli* content and the total bacteria count. It will remove protozoa such as *E. histolytica* and helminths such as *S. haematobium* and *A. lumbricoides*. Trouble free operation is only possible when the average turbidity of the raw water is less than 5 nephelometric turbidity units (NTU) with occasional peak values below 20 NTU permissible. Removal of impurities is brought about by different processes such as :

- (a) Straining
- (b) Sedimentation
- (c) Adsorption
- (d) Biochemical and microbial actions

In straining, suspended particles that are too large to pass through the pores are retained at the surface or top layer of the filter. In the upper part of the filter-bed, sedimentation of fine suspended solids also takes place. Settling efficiency is very high due to the large surface area (10,000 to 20,000 sq. m per cu. m of the filter sand) and slow rate of filtration. The rate of filtration of water lies between 0.1 to 0.4 m³/hour/sq mt of sand bed surface.

Advantages of slow sand filter	
1.	Simple to construct and operate.
2.	The cost of construction is cheap.
3.	The quality of filtered water is very high.
4.	Preferred for rural or small community water supplies.

Performance standards for slow sand filter	
1.	The filtrate should be clear with a turbidity of 1 NTU or less.
2.	The filtrate should be free from colour.
3.	When raw water turbidity is around 30 NTU, the filter runs should normally be not less then 6 to 8 weeks, with the filter head not exceeding 0.6 mt.
4.	The initial loss of head should not exceed 5 cm.

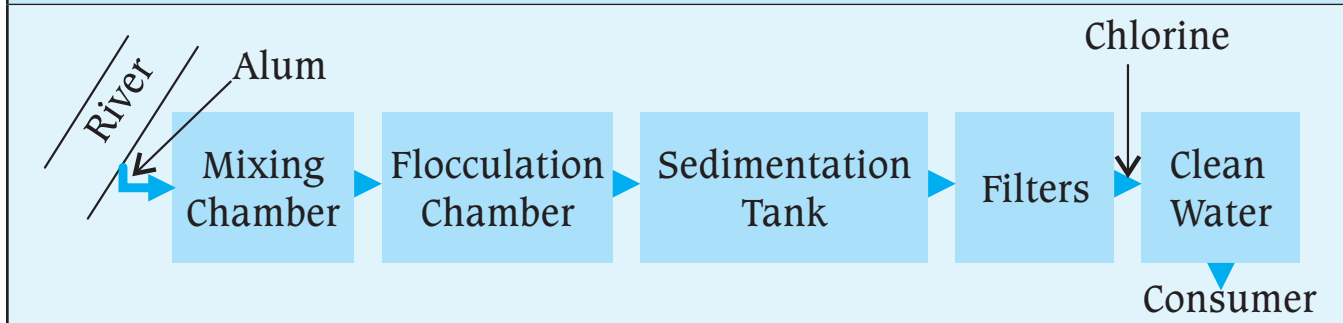

Rapid Sand Filters

In 1885, the first rapid sand filter was installed in USA, and since then they are popular worldwide. These are of two types 'gravity type' (Paterson's filter) and the 'pressure type' (Candy's filter). While the former is usually used in large installations, the latter is used in smaller installations such as swimming pools. The various steps in the working of a gravity type rapid sand filter are shown in Fig. - 1.

Filter Bed : The filter bed is a watertight rectangular chamber with a surface area of about 90 m². The depth of the sand bed is usually one meter having sand particles whose sizes are bigger than the ones used in slow sand filters. The filter bed consists of :

- (a) Supernatant water layer - 1-1.5 mt
- (b) A bed of filter medium - sand bed 1-1.2 mt.; graded gravel 0.3-0.5 mt.
- (c) An underdrainage system - 0.16 mt
- (d) Set of control valves and appurtenances

Fig. - 1 : Rapid sand Filtration Plant

Below the sand bed is a layer of graded gravel of about 40 cm thickness. The 'effective size' of the sand particles is between 0.4-0.7 mm. The under drainage is below the graded gravel layer which collects the filtered water.

Filtration : The alum floc makes a tough slimy layer (chemical) over the sand bed, which acts mechanically. Oxidation of ammonia also takes place during the passage of water through the filters. In this system there is no time wasted for ripening of the bed. The rate of filtration in a rapid sand filter is about 100 times faster than of slow sand filter. The rate of filtration is 5-15 m³/m²/hour. When the bed gets clogged after use for a day or so, it is cleaned by back washing by reversing the flow of filtered water.

Filter Cleaning : Rapid sand filters need frequent washing daily or weekly, depending upon the loss of head. The process of cleaning the filter bed is called Backwashing, in which water or compressed air is passed in the reverse direction or below upwards to dislodge the impurities and loosen the sand bed. The backwash rates of 42-54 m³/m²/hour is used to clean filters. The washing is stopped when clear sand is visible or wash water is clear. After backwashing, the filter bed is put to use immediately and not after 24 hours or so as is required for the formation of biological film in a slow sand filter.

Advantages of rapid sand Filter	
1.	Rapid sand filter can deal with raw water directly.
2.	The filter beds occupy less space.
3.	Filtration is rapid, 40-50 times that of slow sand filter.
4.	The washing of filter bed is easy.

Performance standards for rapid sand filters	
1.	The filtrate should be clear with a turbidity of 1NTU or less.
2.	The filtrate should be free from colour.
3.	The filter runs should normally be not less than 24 hours, with the loss of filter head not exceeding 2 mt.
4.	The wash water consumption should not exceed 2% of the quantity filtered in between washing.

Disinfection

For purification of water after pre-treatment and filtration, the disinfection of water is carried out. The need for disinfection

to prevent water borne diseases and its inclusion as one of the water treatment processes is considered necessary. Disinfection of water means making it fit for drinking by destroying all pathogenic organisms that may be present in it. Broadly, modern disinfection processes include :

1. *Physical methods* such as thermal treatment and ultrasonic waves.
2. *Chemicals* including oxidising chemicals such as chlorine and its compounds, bromine, iodine, ozone, metals like silver etc
3. *Radiation.*

Chlorination : In water treatment or purification practise, the term disinfection is synonymous with chlorination. Disinfection of water is therefore, usually carried out by the use of chlorine who fulfils all the criteria's of good disinfectant. Gaseous chlorine is greenish yellow in colour and is 2.5 times heavier than air. Under pressure, it is a liquid with an amber colour, oily nature and approximately 15 times as heavy as water. Chlorine gas is powerful irritant to lungs and eyes with odour threshold of 3.5 ppm by volume. The safety limit for a working environment is 1 ppm of chlorine in air by volume for an exposure period of 8 hours. When chlorine is added to water it forms hydrochloric acid and hypochlorous acid. Hypochlorous acid further dissociates into hydrogen ions (H⁺) and hypochlorite ions (OCl⁻).

The reaction is reversible. The disinfection action of chlorine is mainly by hypochlorous acid and partly by hypochlorite ion. Chlorine acts best when pH of water is around 7 because of predominance of hypochlorous acid. Fortunately most waters in India have a pH between 6 to 7.5. However sporing organisms, protozoal cysts, helminth ova, molluscs, cyclops and cercariae are not affected by the usual dosage. Organic matter or reducing salts deviate chlorine which results in uncertainty of its action.

Chlorine Demand : Chlorine and chlorine compounds by virtue of their oxidising power can be consumed by a variety of inorganic and organic materials present in water before any disinfection is achieved. It is therefore, essential to provide sufficient time and dose of chlorine to satisfy the various chemical reactions and leave some amount of unreacted chlorine as residual either in the form of free or combined chlorine adequate for killing the pathogenic organisms. The recommended concentration of free

chlorine is 0.5 mg/L for one hour. The difference between the amount of chlorine added to water and the amount of residual chlorine after a specified contact period (usually 60 minutes), at a given temperature and pH of water is defined as 'chlorine demand'.

Breakpoint chlorination : The point at which the free residual chlorine appears after the entire combined chlorine residual has been completely destroyed is referred to as breakpoint and the corresponding dosage is the breakpoint dosage. The point at which chlorine demand of water is met is called 'breakpoint chlorination'. If chlorine is added further, it only increases free chlorine. Breakpoint chlorination achieves the same results as superchlorination in a rational manner and can therefore be construed as controlled superchlorination.

A high chlorine dose creates unpleasant chlorinous taste in water. Initial high dose of chlorine application or the uncertain chlorine content of the unstable bleaching powder used may result in excessive chlorine application. Free chlorine in the strength of 0.5 ppm in water is imperceptible; but over 0.5 ppm the chlorine taste becomes faintly noticeable; whilst above 1 ppm a definite chlorine odour and taste are apparent.

Dosage of Chlorine : Under conditions assuring efficient clarity of water, 30 min of contact with the 'disinfecting dose', freedom from chlorinous taste and presence of 0.2 to 0.5 ppm of free chlorine is considered adequate to achieve health safety.

Superchlorination : Under worse conditions or in the presence of actual or potential danger of outbreak of intestinal infections or when water is heavily polluted or fluctuate rapidly in quality, large doses of chlorine is added to the water called 'Superchlorination'. The dose of chlorine may be as high as 10-15 mg/L with contact periods of 10-30 minutes. Decolourisation should be carried out before consumption of water. The sporing organisms like the welchii group, the protozoal cysts like those of *E. histolytica*, helminth ova, molluscs, cercariae and viruses of infectious hepatitis and poliomyelitis in water require a higher concentration of chlorine maintained over a long time for disinfection.

Methods of Chlorine Application : Chlorine can be applied to water by three methods :

- 1) By the addition of a weak solution prepared from bleaching powder, HTH etc. for disinfecting small to medium quantities of water. It is simple, does not require electricity and relatively safe but instability of bleaching powder, its hygroscopic nature and low percentage of available chlorine makes it difficult to reach desired levels of free chlorine.
- 2) By the addition of weak solution of chlorine prepared by electrolysis of a solution of brine which requires deployment of electrochlorinators which is still an emerging technology.
- 3) By the addition of chlorine, either in gaseous form or in form of solution made by dissolving gaseous chlorine in small auxiliary flow of water, the chlorine gas being obtained from pressurised chlorine containers.

Chlorine Gas : In the modern water works application of gaseous or liquid chlorine with the help of mechanical injector called 'Chloronomes' is the method of choice. Since chlorine

gas is an irritant to the eyes and poisonous, it should be applied only through chlorinating equipment called Patersons Chloronome. In this process the charging of the water supply with chlorine, ascertaining persistence of free chlorine content are all carried out automatically. By ensuring 0.5 ppm of free chlorine at the treatment plant and if the delivery of water is not delayed for more than 6 hours, generally results in 0.2 ppm of free chlorine at consumers end. If quantity of water to be treated is more than 500,000 litres per day, chlorine gas has been found to be the most economical.

Chloramination : Chloramines are loose compounds of chlorine with ammonia. They impart less chlorinous taste in water and give a more persistent type of residual chlorine. This prolonged residuum confers the power of long resistance to contamination during the flow of water through the pipe system and hence may be advantageously used in large urban water plants where the pipeline runs for several million meters. Their drawback is that they have slower and inferior action than chlorine.

Bleaching Powder : Bleaching powder is used for disinfection of water in small water supplies having capacity upto 0.5 mld and rural areas. Bleaching powder is a variable mixture of calcium hydroxide, calcium chloride and calcium hypochlorite also known as chlorinated lime (CaOCl). It was first introduced for sterilization of water by Horrocks in 1914. When it is mixed with water, the calcium hypochlorite decomposes into calcium chloride and chlorine. It is a white amorphous powder with pungent smell of chlorine. When freshly made it contains about 33 percent of available chlorine. It is, however, very unstable and its chlorine is readily set free by the action of moisture, CO₂, heat, light, and possibly even by continued vibration sustained during long journeys. Bleaching powder is also difficult to introduce in accurate doses into large quantities of water, leading to further error in the dosage and finally to taste trouble. Bleaching powder is stored in corrosion free air tight containers made of wood, ceramic or plastics and kept away from sunlight. Bleaching powder is generally made into a thin slurry with the water and the supernatant is applied to water.

Water Sterilising Powder (WSP) : Bleaching powder is considerably improved in its keeping quality by the addition to quicklime in the proportion of 80 : 20 when it is known as water sterilising powder. Its available chlorine should not be less than 25 percent. WSP is usually used for disinfection of water under field service conditions. It is supplied in packs of 50 g, 100g, ¼ kg, ½ kg, 1 kg and 25 kg. WSP is soluble in about twenty times its weight of water, yielding an insoluble precipitate consisting mostly of Calcium Hydroxide Ca (OH), silica etc. This settles quickly, if too thick a paste is not made; otherwise a gelatinizing action takes place and great difficulty in settling is encountered. It is not necessary or desirable to grind or break up the lumps thoroughly and too much agitation is detrimental to prompt settling. 500 g of WSP mixed with 5 : 1 water contains approximately 2.5 percent available chlorine if the powder is of 25 percent strength. Chlorine solution can maintain its strength for weeks if properly corked in brown bottles.

Hypochlorites : The chemicals used are Sodium Hypochlorite and Calcium Hypochlorite which can have 60-70% available chlorine. Calcium hypochlorite can be fed either in the dry or

solution form, while sodium hypochlorite is fed as solution. Corrosion resistant materials such as ceramics, glass, plastic or special rubber should be used while handling hypochlorite solutions.

Agents Other than Chlorine : Broadly there are three main types of disinfectants other than chlorine :

1. Physical agents including heat
2. Chemical agents such as ozone, halogens
3. Radiations of various types such as Ultraviolet rays, Gamma rays and X-rays.

Heat : Boiling of water can disinfect it but it cannot be used to disinfect large scale supplies. It can be used in emergency for individual or household drinking water.

Ozone : It is a powerful oxidizing agent. It removes undesirable odour, taste, colour and organic matter. It even inactivates viruses in a few seconds and hence can be used most advantageously for destruction of enteropathogenic viruses. Since ozone decomposes and disappears within short time there is no residual germicidal effect. Hence, a minimal dose of chlorine may be added to the ozonised water before distribution. In this combined treatment, the two methods complement each other. The ozone dosage required for potable water treatment varies from 0.2 to 1.5 mg per litre. Ozonisation of water is presently practiced in the advanced countries. The combination of ozone for pretreatment while providing some disinfection, to be followed by chlorination, has become a popular sequence in Europe and is beginning to be used in USA to reduce the level of trihalomethanes in finished water. Some disadvantages of ozone treatment are :

1. Its high cost of production.
2. Inability to provide residual protection against recontamination.
3. Its onsite generation due to instability.

Ultraviolet Irradiation : UV radiation may kill a cell, retard its growth, change its heredity by gene mutation. Wavelength region from 2500-2650 Angstrom units is recommended for maximum destruction of cells.

A mercury vapour arc lamp emitting invisible light of 2537 Angstrom units applied to water by a low pressure mercury lamp constructed of quartz or special glass which is transparent and produces a narrow band of radiation energy, is a useful method of disinfection used in the Soviet Union. The advantages of UV radiation are that exposure is for short periods, no foreign matter is actually introduced and no taste and odour produced. Overexposure does not result in harmful effects.

Other Halogens : Halogens are oxidising agents and agents like fluorine, iodine, bromine can also be used for disinfection. In view of the formation of organochlorine compounds by chlorine which are either known or suspected carcinogens, many chlorine alternatives such as bromine and iodine substances are receiving renewed interest. These substances for the present, however, do not seem to be a viable alternative to chlorine.

Tests for Chlorination : Before disinfecting any source of water the chlorine demand of the water source should be calculated, this will give adequate disinfection and a desired level of free chlorine. The test used for calculation of chlorine

demand of water is called Horrock's Test. The object of this test is to determine the quantity of the particular sample of WSP required to sterilize any particular sample of water. The test is carried out by means of the 'case water testing sterilization' (Horrock's Box). The Horrock's box contains :

- six white cups of 200 ml capacity each
- one black cup of 240 ml capacity;
- two metal scoops, each of which holds 2 g of WSP when filled level with the brim;
- a bottle of stock cadmium iodide-starch solution;
- a bottle containing 85 ml of 50 percent glacial acetic acid;
- 25 sodium thiosulphate tablets 100 mg each;
- seven glass stirring rods.
- one pipette
- two droppers

The test should be carried out while the water receptacle is being filled with clarified water (7).

Procedure : A standard solution of the particular sample of WSP is prepared in the black cup. First a thin paste with one level scoopful of the WSP and a little clarified water is made and then gradually more water is added up to the mark on the inside of the cup and the mixture is stirred with a clean glass rod. The lime in suspension gradually settles down. This is known as stock solution or mother solution. The six white cups are then filled with clarified water to within half a centimetre from its top. Drops of the standard WSP stock solution from the black cup are added to each of the white cups by the pipette, so that the first cup receives one drop; the second cup receives two drops and so on serially increasing until finally the sixth cup receives six drops. One drop represents one part of chlorine in a million parts of water when added to the white cupful of water. The pipette must be held vertical when delivering the drops. The contents of each cup are stirred with a clean stirring separate rod, starting at the first cup, and allowed to stand for half an hour, shading them from sunlight. After that time three drops of the starch-cadmium iodide indicator solution are added to each cup from the drop bottle/dropper and stirred with a clean stirring separate rod. Some of the cups will show a blue colour. This indicates the presence of free residual chlorine.

The serial number of the cup showing definite blue colour indicates the number of scoopfuls of the particular sample of water sterilizing powder required to sterilize 455 L of water and to leave 1 ppm of free chlorine after chlorine demand of that sample of water is satisfied during half an hour contact with chlorine.

For example, if cups 3, 4, 5 and 6 show a definite blue colour, then three scoopfuls of WSP are required to sterilize 455-500 L of the particular water sample and leave 1 ppm residual free chlorine after half an hour contact. If superchlorination is indicated one more scoopful of WSP per 500 L of water is required to be added. This will give 2 ppm of free chlorine in water after 15 min contact. In the example given above a total of 4 scoopfuls of WSP per 500L will be needed for superchlorination. The WSP used for chlorination or superchlorination should be from the same tin from which the WSP for Horrock's test was used.

An indicator solution can be made by preparing a uniform paste of 1.5 g of starch in 25 ml of distilled water and then adding

it slowly to 75 ml of boiling distilled water while continually stirring it, and boiling for subsequent 15 min. After cooling, 7.5 g of cadmium iodide is added to the mixture and dissolved by shaking. In an emergency potassium iodide may be used if cadmium iodide is not available. The solution should be stored in a well-corked dark brown bottle in a dark and cool place. The keeping quality of the solution is enhanced by the addition of 1ml formalin to this solution.

Tests for Adequacy of Chlorination : Adequate control must be kept on chlorination by a regular examination of the treated water to make sure that the requisite amount of free chlorine has persisted in the water for the requisite time. This can be done by means of starch-iodide, thiosulphate with starch-iodide, orthotoluidine, orthotoluidine arsenite or neutral red.

Orthotoluidine (OT) Test : This is the most commonly used test in public health practice. It is carried out with the 'Comparator type of apparatus' (Lovibond Comparator) indicates chlorine below 1 ppm. The test was developed in 1918 and it uses analytical grade O-tolidine, dissolved in 10% solution of hydrochloric acid. 0.1 ml of orthotoluidine solution is added to 1 ml of water in a standard glass cell or tube. The yellow colour, which develops, is matched against tinted glass discs. The immediate (flash) reading within 10 seconds shows the free chlorine and that taken after 5 min (delayed) gives the combined content of chloramines and free chlorine. OT reacts with free chlorine instantaneously but reacts more slowly with combined chlorine. In the absence of the Comparator, the appearance of intensity of yellow colour can give rough estimate of amount of free chlorine present.

Orthotoluidine Arsenite Test (OTA) : It is a modification of OT test. Certain interfering substances such as nitrates, iron, manganese etc which when present in water also gives yellow colour with orthotoluidine. The OTA reagent overcomes this drawback and hence gives better determination of free and combined chlorine separately.

Colour Test : Fill a white cup with chlorinated water to be tested and stir into it 10 drops of fresh cadmium-iodide-starch indicator solution. If there is one or more parts of free chlorine in million parts of water a blue colour will appear. In this test the residual chlorine replaces iodine and combines with cadmium radical; iodine so released combines with starch and turns it blue.

Determination of Chlorine Content in WSP : A rough and ready field test can be carried out by the use of the Horrock's Box. A WSP solution is made by mixing one level scoopful of the WSP powder to be tested in the black cupful of clarified water. One scoopful of this solution is mixed with a scoopful of cadmium-iodide indicator solution in a white cup and a tablet of acid sodium bisulphate is added to it. The 0.05 percent neutralising reagent is prepared by dissolving a 100 mg tablet of sodium thiosulphate in a white cupful of water. Scoopfuls of this solution are added to the blue mixture of indicator-WSP solution and stirred. The number of scoopful of the thiosulphate solution added until the blue colour first disappears indicates the percentage of chlorine in the WSP under test.

Purification of Water on a Small Scale (Households and small groups of people)

Boiling : It is very effective and kills all bacteria, viruses, spores, cysts and ova when the water is boiled for 5 to 10 min called "rolling boil". It also removes temporary hardness by driving off CO₂ and precipitating the calcium carbonate. The taste of water is, however, altered. Boiled water has also no residual protection against subsequent contamination and hence care to be taken to avoid contamination during storage.

Chemical Disinfection : It may be carried out with either chlorine solution, bleaching powder, WSP, perchloron, chlorine tablets, high test hypochlorite or iodine solution. The chlorine tablets manufactured by the National Environmental Engineering and Research Institute, Nagpur (NEERI) are about 15 times more potent than ordinary halogen tablets and are available in the market. A single tablet of 0.5 g is sufficient to disinfect 20 l of water. The tablets are mostly used while travelling or by soldiers during march or field areas. Potassium permanganate is no longer recommended, as it is not a satisfactory water disinfecting agent although it is a powerful oxidizing agent. It has other drawbacks such as alteration of colour, smell and taste of water.

Filtration : It is done through ceramic filters such as Pasteur Chamberland, Berkefeld and Katadyn filters. The essential part of a filter is the candle, which is made of unglazed porcelain in Pasteur Chamberland type, and of Kieselgurh in Berkefeld type. The surface of the candle in Katadyn filter is coated with a silver catalyst. The bacteria coming in contact with filter candle get killed by the oligodynamic action of silver ions. Filter candles are liable to be clogged. These are to be cleaned by scrubbing with a hard brush under running water. The candles should be boiled at least once a week. Relatively clean water should be used with ceramic filters. Filter candles, however, removes bacteria but do not remove filter-passing viruses. Most of the household filters available in market work on electricity on principles of disinfection by UV radiation.

Disinfection of Wells : It is sometimes necessary on a large scale during epidemics of cholera and other gastro-intestinal infections. Chlorination with bleaching powder is the most effective and cheapest method for this purpose. The quantum of water in the well is first worked out and the amount of WSP required is then estimated by Horrock's test. The required quantity of WSP is then made into a thin paste with little water in a bucket. The bucket is filled three-fourth with water stirring all the time. About 5 to 10 min time is allowed for the chalk to settle down. The supernatant clear solution is then transferred to another bucket and the chalk is discarded. The bucket containing the clear chlorine solution is lowered into the well and the well water agitated by lowering and drawing the bucket several times. After half an hour's contact, orthotoluidine test is carried out. If fresh residual chlorine is less than 0.5 mg/l, additional quantities of WSP will have to be added. During epidemics, wells should be disinfected every day. Steps in well disinfection are :

a) Find the volume of water in a well by formula

$$(3.14 \times d^2 \times h \times 1000) \div 4$$

(Where d = diameter of well, h = depth of water column)

Or, find out by following formula (measurements of depth and diameter are in metres)

Circular well : Depth of water x square of diameter x 785 = liters of water in the well.

Rectangular : Depth of water x length x breadth x 1000 = liters of water in the well.

- b) Find the amount of bleaching powder required for disinfection by Horrock's test.
- c) Dissolve bleaching powder in water
- d) Delivery of chlorine solution into the well.
- e) Contact period
- f) OTA test

Water Quality Standards and Criteria

The WHO has published in 1993 vol 1 and in 1996 vol 2 of second edition of Guidelines for Drinking water quality on various parameters for drinking water quality to be used by different countries in making their own standards. They are laid down in standard references (8, 9, 10, 11) and should be referred to as and when required. The methods of examination of water are also given in details in the publications of ICMR (12). In brief the standards are as follows

1. Acceptability Aspects.
2. Microbiological Aspects
3. Chemical Aspects.
4. Radiological Aspects.

Acceptability Aspects

The drinking water should not only be safe but also pleasing in appearance, taste and colour. Wholesomeness and acceptability of drinking water is determined by the following factors :

Turbidity : Turbidity should be less than 5 NTU and before chlorination should be < 1 NTU. Turbidity above 5 NTU, becomes unacceptable to the consumer. Turbidity indicates incomplete treatment of water and also interferes with disinfection of the water.

Colour : The acceptable limit for colour in drinking water is 15 true colour units (TCU). Colouration of water may be due to presence of organic matter such as peat, metals like iron and manganese or due to industrial wastes.

Taste and Odour : Even though no guideline limit values have been laid down, any water with significant degree of taste and odour is unacceptable to the user. Taste and odour may be due to mineral matter, presence of organic matter and occasionally due to excessive residual chlorine in treated waters.

Total Dissolved Solids (TDS) : The amount of TDS in water has an important effect on its taste. Water with very low concentrations of TDS, such as the rain water is not relished by the consumer because of the flat, insipid taste. The palatability of waters with TDS levels below 600 mg/litre is considered to be good and those above 1200 mg/litre become unpalatable and objectionable due to scale formation in pipes, heaters and household appliances. The guideline value for TDS is to be below 1000 mg/litre.

pH : The guideline value for pH of water is 6.5 to 8.5. Water with pH levels below this range may corrode pipelines, resulting in increased levels of certain chemical substances, such as lead, in water. At pH levels above this range, the efficiency of the disinfectant action of chlorine is reduced.

Hardness : Depending on the interaction of other factors, such as pH, water with hardness above 200 mg/litre may cause scale deposition in the distribution system and may result in excessive soap consumption. On the other hand, water with a hardness of less than 100 mg/litre has a low buffer capacity and is corrosive for water pipes. For domestic use the amount of hardness of water should not be more than 300 ppm. For laundries and boilers the softer the water the better it is.

Dissolved Oxygen : Even though no health based guideline value has been laid down, depletion of dissolved oxygen content in water encourages microbial reduction of nitrates and sulphates to nitrites and sulphides respectively, with consequent odour problems.

Ammonia : Ammonia in water is an indicator of possible bacterial, sewage and animal waste pollution. It may be present in a non-ionised or ionised form. The guideline value is 1.5 mg/litre. Ammonia may be free (F), saline(S), or Albuminoid (Alb). If both types of ammonia are low i.e. F and S are 0.05 ppm or less and Alb. 0.1 ppm or less, the water is probably good. If both types of ammonia are higher than the above figures then the water is bad.

Chlorides : The guideline value for chloride is 250 mg/litre even though the maximum permissible level is kept at 600 mg/litre. Other indications of pollution will also help in arriving at conclusions.

Iron : A trace of iron is almost always present in water. Iron upto 0.3 mg/L is acceptable. Above that it causes constipation, colic and results in the colouration of vegetables while cooking and staining of linen.

Microbiological Aspects

a. Standards of Bacterial Quality : The primary bacterial indicator recommended are coliform group of organisms, whereas supplementary indicator organisms are faecal streptococci, sulphite reducing clostridia etc.

Coliform Organisms : It includes all aerobic and facultative anaerobic, gram negative, non sporing, motile and non motile rods capable of fermenting lactose at 35-37 deg. C in less than 48 hrs. The coliform group includes both faecal and non faecal organisms. e.g. Faecal group is *E Coli* and non faecal group is *Klebsiella aerogenes*. The coliform organisms are chosen as indicators of faecal pollution in water because :

- a. Coliform organisms are present constantly in the human intestines but they are foreign to potable waters and hence their presence in water indicates faecal contamination.
- b. They are easily detected by culture methods.
- c. They survive longer than other pathogens.
- d. The coliform organisms have greater resistance to the forces of natural purification.

Faecal Streptococci : In doubtful cases, the finding of faecal streptococci is regarded as important confirmatory evidence of recent faecal pollution of water. Streptococci are highly resistant to drying and may be valuable for routine control testing after laying new mains or repairs in distribution systems or for detecting pollution by surface run off to ground or surface waters.

Cl perfringes : The spores of *Cl perfringes* survive longer time and resist chlorination at the doses normally used for disinfection. Their presence in water, in absence of other organisms indicates the faecal contamination occurred at some remote time.

Bacteriological Standards - Treated Water : Ideally, all samples taken from the distribution system should be free from coliform organisms. In practice this standard is not always attainable and the following standard for water collected in the distribution system is therefore recommended throughout any year : *95 percent of samples should not contain E Coli coliform organisms in 100 ml water sample taken during that 12 month period; no consecutive samples should contain coliform organisms in 100 ml of water samples.*

Bacteriological Standards - Individual or Small Community Supplies : The standards outlined above may not be attainable in the case of waters from wells and springs. In these waters, the coliform count should be less than 10 per 100 ml. Persistent failure to achieve this particularly if *E Coli* is repeatedly found calls for rejection of water supply.

b. Standards of Viral Quality : As stated earlier, water free of faecal coliform need not necessarily be free of viruses. Enteroviruses, reoviruses and adeno-virus have all been detected in water. As per WHO standards not more than one plaque forming unit (PFU) per liter of water is considered potable. There should also be complete absence of enteropathogenic viruses and faecal bacteriophages. Ozone has been shown to be most effective viral disinfectant.

Table - 4 : Inorganic chemicals of health significance in drinking water

Constituents	Recommended maximum limit of concentration (mg/lit)
Antimony	0.005
Arsenic	0.01
Barium	0.7
Boron	0.3
Cadmium	0.003
Chromium	0.05
Copper	2
Cyanide	0.07
Fluoride	1.5
Lead	0.01
Manganese	0.5
Mercury	0.001
Molybdenum	0.07
Nickel	0.02
Nitrate	50
Nitrite	3
Selenium	0.01

Chemical Aspects

These indicators are of two types, viz., inorganic constituents and organic constituents.

a. Inorganic Constituents : The details are shown in Table-4.

b. Organic Constituents

Polynuclear Aromatic Hydrocarbons (PAHs) : Most of the PAHs identified in the environment are from combustion and pyrolysis processes. The main source of human exposure to poly aromatic hydrocarbons is via food with drinking water contributing only minor amounts. Some of these are known to be carcinogenic. Their concentration, in general should not exceed 0.2 g / L.

Pesticides : Chlorinated hydrocarbons and their derivatives, herbicides, soil insecticides and pesticides that leach out from the soil are of importance in connection with water quality. The recommended guideline value for human beings are given in Table - 5.

Table - 5 : Guidelines for Chlorinated Hydrocarbons for Humans	
Pesticides	Upper limit of concentration (microgram/lit)
Aldrin/dieldrin	0.03
Chlordane	0.2
DDT	2
Hexachlorobenzene	1
Lindane	2
Methoxychlor	20
Pentachlorophenol	9

Radioactive Substances

The effects of radiation exposure are called 'Somatic' if they manifest in exposed individual, and called 'Hereditary' if they affect the descendants. There is an increasing hazard of pollution of water supplies by radioactive substances. Malignant diseases are the most important delayed somatic effect. The radioactivity of water is measured in picocuries per liter (pCi/l). The WHO has proposed the following limits of radioactivity as acceptable :

- Gross alpha activity 3 pCi/l.
- Gross beta activity 30 pCi/l.

Surveillance of Drinking Water Quality

Drinking-water supply surveillance is "the continuous and vigilant public health assessment and review of the safety and acceptability of drinking-water supplies" (WHO, 1976). This surveillance contributes to the protection of public health by promoting improvement of the quality, quantity, accessibility, coverage, affordability and continuity of water supplies (known as service indicators) and is complementary to the quality control function of the drinking-water supplier. The following are the component steps for establishing a water quality surveillance system :

a. Sanitary Survey

A sanitary survey is an on-site inspection and evaluation by a qualified person of all the conditions, devices, and practices in the water supply system which pose a danger to the health and well being of the water consumer. The hygiene inspection of the source, surroundings and site of water supply is carried out by making a plan and following it systematically. The site for obtaining water for human consumption from the selected source should also be properly examined before final selection. No bacteriological or chemical examination can take the place of a sanitary survey as the pollution is often intermittent and may escape the laboratory testing.

Sanitary Surveys should be undertaken when :

- A new source is contemplated
- Laboratory analysis indicates hazard to health
- An outbreak of waterborne disease occurs in the area
- To interpret bacteriological, chemical and physical analyses of samples
- When any change takes place that can affect the water system, e.g. industries coming up in watershed and
- Also on a regular basis depending on size and available staff and resources and population / area under coverage. Majority of samples should be from problem areas, i.e. those with poor results in the past, low pressure zones, areas with high leakage, densely populated areas with inadequate sewerage, dead ends on pipelines, areas far away from waterworks etc.

b. Sampling

Sampling of water should be done with strict aseptic precautions. It should be carried out by competent and trained personnel in accordance with the methods and frequency of sampling prescribed in the WHO guidelines for drinking water quality.

c. Bacteriological Surveillance

The World Health Organization (WHO) recommends the measurement of *E Coli* in drinking water samples as the best indicator of water quality. The WHO guideline for potable water is less than one *E Coli* per 100 ml of drinking water (World Health Organization 1998). The following tests are conducted for bacteriological surveillance of drinking water :

Presumptive Coliform Test : The available methods are

Multiple Tube Method : This test is based on estimating the Most Probable Number (MPN) of coliform organisms in 100 ml of water. The test is carried out by inoculating measured quantities of the sample water (0.1, 1.0, 10, 50 ml) into tubes of McConkey's Lactose Bile salt Broth with bromocresol purple as an indicator. If the samples can't be inoculated on the spot then, they should be packed in ice and sent expeditiously to the laboratory. Bottles containing McConkey's broth, the sample of water and a small inverted tube are incubated for 24 to 48 h at 37°C. The multiplication of the faecal organisms present in water under test produces acid and gas. From the number of tubes showing acid (as shown by the pink colour of the mixture) and gas, as seen in the inverted tubes, an estimate of the MPN of coliform group of organisms per 100 ml water

is ascertained from the standard tables. The estimates are therefore 'presumptive' and not actually existing. Details of the procedure are given by Cheesbrough (13).

Membrane Filtration Technique : In some countries membrane filter technique is used as a standard procedure to test for the presence of coliform organisms. A measured value of the water sample is filtered through a membrane made of cellulose ester. Bacteria present in water are retained on the surface of the membrane. The membrane is then directly inoculated face upwards on suitable media at appropriate temperature. Within 20 h the colonies grow and can be counted (13).

Faecal Streptococci and *Cl. perfringens* Detection : The significance of these two tests have been discussed earlier. Their presence provides useful confirmatory evidence of the faecal pollution of water.

Colony Count : The colony count on nutrient agar at 37°C and 22°C provide an estimate of the general bacterial content of water. A single count is of little value, but counts from the same source at frequent intervals are of considerable value. A sudden increase in the count serves as the earliest indicator of contamination and hence this test is gainfully used in the public water works. The recommended plate counts are given in Table - 6.

Water at consumer end	Plate count after 2 days at 37°C	Plate count after 3 days at 22°C
Disinfected	0	20
Not disinfected	10	100

Plate count on yeast extract agar at 22°C for 7 days is even a better indicator due to the absence of chlorine residue when there is uninhibited bacterial growth.

Colilert Method : Colilert is a recently available method to determine the MPN of coliforms. Colilert uses defined substrate technology to detect and quantify total coliforms and *E Coli* from water samples. Colilert is simpler to use, allows greater output and requires less time to standardize than standard methods. Colilert is an acceptable method to measure the presence and quantity of coliforms in water samples in a developing country setting (14).

Organic matter

Data on the level of organic matter in treated water provide an indication of the potential for the regrowth of heterotrophic bacteria (including pseudomonads and aeromonads) in reservoirs and distribution systems. Organic matter can be measured as Total Organic Carbon (TOC), Biochemical Oxygen Demand (BOD) or Chemical Oxygen Demand (COD). BOD is primarily used with wastewaters and polluted surface waters, and TOC is the only parameter applicable to drinking water. Measurement of these three parameters requires basic laboratory facilities and adequately trained personnel.

Hardness of Water

Hardness of water may be defined as its soap destroying power. Hardness is undesirable because it wastes soap, retards washing, causes encrustation of the water carrying system and

heating utensils resulting in wastage of fuel and even explosion of boilers (1, 4 - 7). Vegetables cooked in very hard water may be less digestible. It reduces the life of fabrics also. Hardness is of two types :

- *Temporary or carbonate Hardness* : It is due to Calcium bicarbonate or Magnesium bicarbonate
- *Permanent or non carbonate Hardness* : It is due to Calcium sulphate, Magnesium sulphate, Chlorides and nitrates of calcium and magnesium or else Iron, manganese and aluminium compounds

Hardness is expressed in terms of milli-equivalents per litre (mEq/L). One mEq/L of hardness producing ion is equal to 50 mg (CaCO_3) (50 ppm) in one litre of water. The four grades of describing hardness are : Soft water : <1 mEq / L (<50 mg/L); Moderately Hard : 1-3 (50 - 150 mg/L); Hard Water : 3-6 (150-300 mg/L); Very Hard Water : >6 (>300 mg/L). Softening of water is recommended when hardness exceeds 3 m Eq/L.

Drinking water should be moderately hard. It has been observed that in some localities supplied with soft drinking water showed a significantly higher prevalence of either arteriosclerotic heart disease, degenerative heart disease, hypertension, sudden death of cardiovascular origin, or a combination of these. However, it is based on purely circumstantial evidence and further studies are in progress to establish the association.

The methods of removal of hardness are briefly stated as below:

Temporary Hardness : This can be removed by boiling, addition of lime, addition of sodium carbonate or by permutit process.

Permanent Hardness : This can be removed by addition of sodium carbonate or by base exchange process.

Fluoridation of Water

Fluorine is naturally present in water supplies. Its removal is necessary when the concentration in drinking water is more than 1.5 ppm. The optimum concentration in countries like India where people consume a lot of water should be between 0.5 to 0.8 ppm. Fluoride concentration over 1.5 ppm causes dental fluorosis. A still higher concentration causes skeletal fluorosis. People in the States of Rajasthan and Punjab are presently facing this problem of water supply. The excess quantity of fluoride in water may be removed by 'Nalgonda technique'. On the other hand if fluoride content of water is less than 0.5 ppm then it is associated with dental caries. The term 'Flouridation' has been given to the process of supplementing the natural fluoride content of potable waters to the point of optimum concentration.

Detection of Poisons in Water

Water is the most vital source of all kinds of life on this planet. There is every possibility of sabotage of the drinking water source by the enemy/militants. It must be ensured that water is free from poisons before it is declared potable. Testing of poison in drinking water requires elaborate laboratory facilities, which are not possible in remote areas. A set of Kit has been developed by DRDE Gwalior and marketed by Hindustan Metal Industries, Nai Sarak, Gwalior-1(MP) keeping in view the above requirement and facilitated testing of most commonly present poisons, sulphur mustard, nerve agent and microbial

contaminations. The kit is housed in aluminium container having shoulder strap to carry for field use. The kit is provided with the reagents/material, sufficient for testing poisons 50 times.

Sanitation of Swimming Pool

A swimming pool is an artificial structure where water volume per swimmer is relatively small. The recommended area is 2.2 sq m (24 sq ft) per swimmer. The water is thus exposed to contamination by ammoniacal and other organic substances as well as organisms from skin, nasopharynx and other orifices of the swimmer. The health hazards associated with swimming in these pools are usually fungal, viral and bacterial infections of the skin, eye, ear, nose, throat and upper respiratory tract, intestinal tract and so on. Proper maintenance of pools is, therefore, of vital importance. General guidelines on sanitation of swimming pool are being given in subsequent paragraphs. Further details are available in standard texts (15).

A continuous inflow or a daily change of water, though ideal, is usually not feasible. The modern pools are equipped with continuous filtration and chlorination system. The "fill and empty" system is also encountered. Considerable attention is thus necessary to ensure that water is maintained continuously in a pure state in such pools. If the water is turbid provision for sedimentation in a separate settling tank may become inescapable. The water must be renewed at least once a week and 10-15 percent of the water should be replaced by a fresh daily inflow. When the pool is emptied, the floor and the sides should be thoroughly scrubbed and lime washed. Addition of copper sulphate 2g per 1000 l once a week will prevent algal growth and accumulation of slime.

Chlorination is carried out by injecting gaseous chlorine by the use of chloronome. Continuous maintenance of 1 ppm of free residual chlorine provides adequate protection against bacterial and viral agents. When chloronomes are not installed or not functioning, the required amount of WSP as calculated by Horrock's test is first made into a thin mixture and distributed evenly over the surface of water. The water is then stirred with paddles. Subsequently, each day until the next filling, half that amount of WSP should be added half an hour before the swimming time. Tests for free residual chlorine is to be carried out daily half an hour after adding WSP. It will be ideal to keep the pH of water between 7.4 to 7.8 as irritation of eyes due to chloramine formation will be minimum. In a swimming pool the process of chlorination preferred is 'breakpoint' chlorination. When chlorine is added to water it immediately forms chloramines with ammonia, which is always present. The process continues till all the ammonia present is used up and the concentration of chloramines reaches its peak. Chloramines are, however unstable and react with excess free chlorine present in water and get oxidized completely to nitrogen and thus water contains no longer any free chlorine. Break point is said to have been reached when water no longer gives 'flash' reaction of free chlorine. Any further addition of chlorine hereafter causes a proportionate rise in the residual free chlorine, which acts as efficient germicidal agent. The bacteriological quality of swimming pool water should reach as nearly as possible the standard of drinking water. The test should be carried out weekly.

Water Supply in Emergencies and Disasters

The following is a list of hygiene practices that protect health in disasters and emergencies.

People's ability to achieve these protective actions depends on the availability of material resources, such as adequate clean water, soap, toilets, etc. and personal resources, such as time and energy. The details are shown in Table - 7.

The International Drinking Water Supply and Sanitation Decade 1981-1990 (16, 17)

The 'Decade' was launched at a special meeting of the United Nations General Assembly on 10 November 1980 following the recommendation of the UN Water Conference at Mardel Plata in 1977. The priority given by the above conference to the provision of safe water supply and sanitation was influenced by the joint report of WHO and World Bank which showed that in 1975 some 1230 million people were still without safe water supplies and 1350 million people had lack of adequate sanitation facilities. Among the rural populations of developing countries, only 22 percent had access to reasonable safe water and only 15 per cent had facilities for excreta disposal. The Mardel Plata action plan also urged the individual countries to establish goals for 1990, which match the global target of the Decade. In India, under the International Drinking Water Supply and Sanitation Program the laid down target was 100 percent safe water supply, in both urban and rural areas. As per available reports, till 1994-95, 85 percent of the target has been achieved.

Targets of the Decade (1991-2000) : The targets were fixed by the Indian Government for the decade as

- 100% urban and rural supply
- 50% urban sanitation
- 25% rural sanitation

The Guinea worm eradication programme was linked with this decade. In 1986 the National drinking water Mission (NDWM) popularly unknown as Technical Mission was launched in order to provide scientific and cost effective content to the centrally sponsored Accelerate Rural water supply programme. In 1987 the National Water Policy was announced that has given high priority to drinking water.

Eleventh Five Year Plan (2005-2012) in Relation to Safe Water Supply

Past Programmes and Outlays : Government of India's major intervention in water sector started in 1972-73 through *Accelerated Rural Water Supply Programme* (ARWSP) for assisting States/UTs to accelerate the coverage of drinking water supply. In 1986, the entire programme was given a mission approach with the launch of the Technology Mission on Drinking Water and Related Water Management. This Technology Mission was later renamed as *Rajiv Gandhi National Drinking Water Mission* (RGNDWM) in 1991-92. In 1999, Department of Drinking Water Supply (DDWS) was formed under the Ministry of Rural Development (MoRD) to give emphasis on rural water supply as well as on sanitation. In the same year, new initiatives in water sector had been initiated through Sector Reform Project, later scaled up as *Swajaldhara* in 2002.

An investment of about Rs.72,600 crores has been made (under both State and Central Plans) from the beginning of the planned era of development in rural water supply sector. This investment has helped to create assets of hand pumps, public stand posts, mini-piped water supply schemes and multi village schemes in the country under the Rural Water Supply Programme.

The *Swajaldhara* programme was launched in 2002-03. The programme involves a community contribution of 10% of the

Table - 7 : Water Safety

At the source	Water for drinking is collected from the cleanest possible source. If necessary, a distinction is made between water for drinking and water for other uses, such as bathing, laundry, watering animals.
	Water sources are protected from faecal contamination by fencing (to keep animals away), and by siting latrines or defecation fields at least 10 - 30 metres away, depending on ground conditions.
Collection, storage and use of water at household level	Water is collected and stored in clean, covered containers. Water is taken from the storage container with a clean, long-handled dipper or through a tap placed slightly above the bottom container.
	Efforts are made not to waste water.
Use of water	If there is a risk that water is not safe, it is filtered and/or chlorinated or boiled.
	Water for making food or drinks for young children is boiled.
Personal Hygiene	
Water for washing	If possible, plenty of water is used for washing. Clothing is laundered regularly.
	The most readily-available water is used for personal and domestic hygiene.
Hand-washing	All family members wash their hands regularly : after defecating; after cleaning a child who has defecated and disposing of the stool; before preparing food; before eating; before feeding a child.
	Adults or older children wash the hands of young children.
Note : To make water safe for drinking, it should be brought to a vigorous rolling boil. If boiling or chlorination are not possible at household level, then low-turbidity water may be disinfected by exposing it to bright sunlight for at least one day (Reed 1997).	

project cost to instill a sense of ownership among the people and also to take over the O&M of the schemes constructed under the programme. The Centre provides 90% of the project cost as grant. The proportion of population covered till now is shown in Table - 8.

Year	Urban Population (million)	Percentage of Population Covered with Water Supply
1981	152	78
1991	217	84
2001	285	89
2004	308 (Projected)	91

Eleventh Five Year Plan Targets for Rural Water Supply : To “Provide clean drinking water for all by 2009 and ensure that there are no slip-backs by the end of the Eleventh Plan” is one of the monitorable targets of Eleventh Five Year Plan. Under *Bharat Nirman Programme* it is proposed to provide safe drinking water to all habitations. The Government is also committed to provide 100% coverage of water supply to rural schools. The ARWSP includes school water supply also. Accelerated Rural Water Supply Programme has provision of water supply to existing schools; the new schools are covered under other programmes like Sarva Shiksha Abhiyan of Ministry of Human Resources Development.

Strategies during the Eleventh Five Year Plan : In order to achieve 100 per cent coverage of clean water and sanitation in rural areas, rural sanitation programme will be linked with the National Rural Health Mission. Efforts will be made to launch a Sarva Swasthya Abhiyan in the county that will cover the primary health care, safe drinking water and sanitation in urban areas. The strategies include :

- Convergence of health care, hygiene, sanitation and drinking water at the village level
- Participation of stake holders at all levels, from planning, design and location to implementation and management of the projects
- Institution water quality monitoring and surveillance systems by involving PRIs, community, NGOs and other civil society organizations
- Increased attention to IEC campaign

Local Participation

Involvement of the community in the monitoring of the water supply works is recommended. Department of Drinking Water Supply has initiated monitoring of the water quality under the National Rural Drinking Water Quality Monitoring and Surveillance Programme under which the Gram Panchayat/Village Water and Sanitation Committee provided with user friendly field test kits for testing both bacteriological and chemical contaminants followed by testing of the samples at district and state level laboratories. Such initiatives need to be extended to the other regular programmes under the Accelerated Rural Water Supply Programme also.

Recommended Outlays for Eleventh Five Year Plan : The full coverage of rural drinking water supply is to be achieved by March 2009 and 100 % sanitation coverage by the end of Eleventh Plan (2012) with mass awareness and Nirmal Gram Puraskar. The Eleventh Plan Central sector GBS is Rs.41,826 crore (at 2006-07 prices) and Rs.47,306 crore (at current prices) and this provision will draw matching provision in the State Plan to the tune of Rs. 49,000 crore. Thus the total outlays in the Eleventh Five Year Plan for Rural Water Supply & Sanitation sector would be close to Rs. 1,00,000 crore. The total outlay for Urban Water Supply and Sanitation sector would be Rs. 75,000 crore.

Summary

For drinking water to be wholesome it should not present a risk of infection, or contain unacceptable concentrations of chemicals hazardous to health and should be aesthetically acceptable to the consumer. The infectious risks associated with drinking water are primarily those posed by faecal pollution, and their control depends on being able to assess the risks from any water source and to apply suitable treatment to eliminate the identified risks. Rather than trying to detect the presence of pathogens, at which time the consumer is being exposed to possible infection, it is practice to look for organisms, while not pathogens themselves, that show the presence of faecal pollution and therefore the potential for the presence of pathogens.

It is also important to be able to check on the effectiveness of treatment processes at eliminating any pathogens that might have been present in the untreated source, and ‘indicator’ organisms fulfil that role. Treatment should be able to eliminate all non-spore forming bacteria and enteric viruses and the less restricted the parameter chosen the more suitable it should be. Water quality can deteriorate in distribution due to ingress or regrowth and measures of regrowth potential are described.

Study Exercises

MCQs

1. Which of the following is considered an adequate water supply/head/day in urban areas (a) 50-100 L (b) 100-150 L (c) 150-200 L (d) 200-250 L
2. Purest water in nature is from (a) Lakes (b) Springs (c) Rains (d) Ponds.
3. Salt concentration in sea water is (a) 1.5% (b) 2% (c) 3.5% (d) 5%.
4. Ground water has the following advantages : (a) Likely to be free from pathogenic organisms (b) Usually requires no treatment (c) Supply is likely to be certain even during dry season (d) Likely to be hard.
5. Guinea worm disease was a health problem where there were : (a) Dug wells (b) Artesian wells (c) Tube wells (d) Step wells.
6. Which one of the following is not a waterborne disease : (a) Kala azar (b) Poliomyelitis (c) Giardiasis (d) Roundworm
7. The vital layer of the slow sand filter is also known as : (a) Superficial layer (b) Sand bed layer (c) Schmutzdecke (d) Chemical layer.

8. The disinfecting action of chlorine is mainly due to (a) Chloride atom (b) Hypochlorous acid (c) Chloride ion (d) Hypochlorite ion.
9. Action of chlorine is maximum when water pH is around (a) 3 (b) 5 (c) 7 (d) 9.
10. Chlorination does not affect in normal doses (a) Salmonella (b) Polio (c) Shigella (d) HIV.

Answers : (1) b; (2) c; (3) c; (4) d; (5) d; (6) a; (7) c; (8) b; (9) c; (10) b.

Disposal of human excreta assumes greater importance than any other waste. The methods of disposal can be classified as follows :

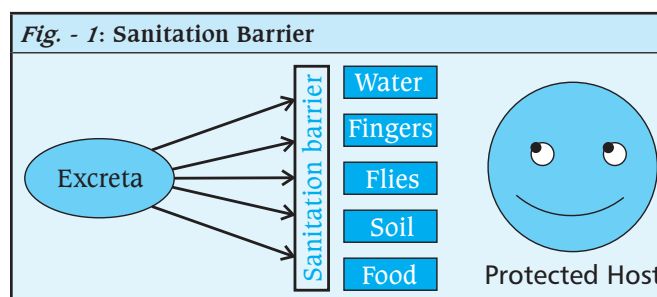

(a) **Insanitary Methods** : These include open defecation and conservancy system.

(b) **Sanitary Methods** : These are further subdivided into two methods, depending whether sewerage (water carriage system) is available or not, as follows :

- Unsewered Areas : The methods include trench latrine, dug well or bore hole latrine, water seal latrines, septic tanks, aqua privies and chemical closets.
- Sewered areas : The system in these areas includes the standard sewerage system.

Sanitation Barrier : The sanitation control which aims at interruption of transmission of the disease agent from the reservoir to the new host can be achieved at several levels such as segregation of excreta and wastes, protection of water supply, protection of food and drinks, control of flies and the

practice of personal hygiene. The most effective measure out of all these would be segregation of excreta and arrangement for its proper disposal so that the disease agents do not get a chance to reach the new host. The sanitation barrier (Fig. 1) in the simplest way can be provided by a sanitary latrine and a disposal pit.

Excreta Disposal in Non-Sewered Areas

Open defecation fields

In some cultures, defecating in the open is preferred to using a latrine. Open defecation can never be accepted as a satisfactory system of excreta disposal but it might be inevitable in certain circumstances. In these situations, open defecation areas

should be clearly demarcated rather than littering the entire area. The principles of hygiene must be kept in mind (as discussed below) and the method must be followed for as short a period as possible. Open defecation may be the only option (for a displaced population in disaster) in the initial phase and might work well for 24 to 48 hrs, provided appropriate facilities of open defecation areas are set up and the following aspects are carefully considered. The community must be encouraged to use better alternatives as soon as the latrines are ready for use.

Location

- It should be located as centrally as possible to the people who are going to use it (within 50-100 m or 1 minute walking distance, of shelters if possible) but away from public buildings or roads.
- It has to be located at least 30m, preferably 50m from water sources or food storage/preparation areas. The fields where crops are grown should not be used for this purpose.
- It is preferable to have adequate space and vegetation to allow people to find an appropriate defecation space so that there is enough privacy.
- The field should be surrounded by a drain so that surface water cannot enter it and to prevent any runoff from the field contaminating other areas.
- The field should be on land sloping away from the camp and surface water sources and downhill of settlements. Consideration should be given to the direction of prevailing winds, to reduce the nuisance caused by odour. Areas subject to flooding or containing running water should be avoided. The soil should be easy to dig so that faeces can be buried.

Setting up : As a first measure, it may be necessary to make temporary open defecation fields by just marking off areas with tape. Defecation areas or fields may be surrounded by screening/ plastic /canvas sheeting. Segregated sites for each sex are desirable.

Usage

- Attendants will need to be recruited and provided with training to encourage correct use and hand-washing.
- Users need to be encouraged to use one strip of land at a time and the strip furthest away from the entrance. Used areas must be clearly marked.
- Users should cover the faeces with soil.
- Provide anal-cleansing materials (water in small pots / mugs) and methods for their safe disposal.
- People must wash their hands afterwards. A 200 lit plastic barrel or a large bucket fitted with tap can be situated at the entrance of the area for hand-washing. Soap or ash should also be provided for effective hand washing. If soap or ash is not available, a barrel can be filled with 0.05% chlorine solution. This can be made by adding half a tablespoon (7.5g) of High Test Hypochlorite HTH (70% active chlorine) granules, or 15g of bleaching powder (approx 35% active chlorine), to 10lit of water.

Service Type Latrines (Conservancy System)

In the conservancy system, night soil is removed by a human agency using a bucket. Night soil is transported in buckets

on the head or in night soil carts manually to a disposal site. Disposal may be done through dumping, composting or burial by shallow trenching. This is totally unacceptable not only considering human dignity but is not acceptable through hygiene point of view either. It is filthy and insanitary. Night soil lying at home awaiting disposal stinks and attracts flies. The collection, transport and disposal of night soil, all perpetuate the infection cycle. Absence of manpower for this job puts the system to a halt.

It was recommended by the Environmental Hygiene Committee, in 1949, that service areas must be replaced by sanitary latrines. The founder of Sulabh International, Dr B Dubey, also took up the issue in a big way. He showed the way forward by almost revolutionizing the sewage disposal to eliminate human carriage of night soil and installing low cost sanitary latrines instead.

Shallow Trench Latrines

Shallow trench latrines are trenches 20-30cm (about a foot) wide and 15-30cm (about ½ -1 foot) deep. The dimensions can however vary. The trench field can be divided into strips 1.5m wide with access paths. Trenches are dug in parallel with an interval of at least 60 cm in between two trenches. The earth removed should be neatly piled at its head end which could be used to cover the excreta by each user, and subsequently to fill the trench. The issue of privacy is also important. Plastic sheeting, bamboo-mat etc. can be used to make 'walls' (Fig.-2). The trench is used by squatting astride it, with a foot on either side and not both feet on the same side. After defecation the excreta must be covered by earth with a scoop.

Advantages : It is rapid to implement. Faeces can be covered easily with soil.

Constraints : Limited privacy, short life and requirement of considerable space are some of the constraints. Fly breeding occurs if excreta is not covered with earth.

Deep Trench Latrines

Deep trench latrines could be an appropriate short term solution to the immediate requirements of a displaced community or for camps of a longer duration(1, 2). While they are much more hygienic than the Shallow Trenches and can be used for a relatively prolonged period but at the same time more manpower, tools and materials are required to set them up. The recommended maximum length of trench is 6m, providing six cubicles. Trenches should be 0.8m -1m wide and 2m - 2.75m deep. (Fig. - 3). A deep trench latrine of the above dimensions (80 cm to 100 cm wide by 2 m to 2.75 m deep) which is 3.75 m long can be used by 100 people for few months. One must work on a minimum standard of at least one 'toilet seat' for every 20 persons (1,3).

Advantages : It is cheap and quick to construct; no water is needed for operation. It is easily understood by the community.

Constraints : Unsuitable where water-table is high, soil is too unstable to dig or ground is very rocky; often odour problems; cleaning and maintenance of communal trench latrines are often poorly done by users.

Improved Deep Trench Latrine

An improvisation of Deep Trench Latrine may be carried out by placing the seats fitted with modified water closets, 1.5m in front of the long edge of the trench. As many as 3 to 5 Indian type water closet seats of plastic / fiber glass / chinaware are fitted to enable maximum number of people use it simultaneously. The seats are fitted with a water seal (bend pipe) which is connected to a pipe leading into the trench. Small quantity of water (2.5 to 3 liters) is sufficient to flush the seats after each use. The excreta is flushed through sewage pipes into the trench. This type of latrine, therefore, is more hygienic and acceptable. It is similar in principle to the hand flushed water seal latrine. The water seal prevents access to flies by sealing off the night soil and escape of foul gases (4). A storm water drain dug all around prevents rainwater from entering the trenches.

Simple Pit Latrines (Dug Well Latrine)

Simple pit latrines are simple and quick to construct and generally inexpensive. The pit should be as deep as possible (at least 2m in depth) and covered by a latrine slab. If the soil is loose, at least the top 1m of the pit should be lined to prevent collapse. This should be firmly supported on all sides and raised above the surrounding ground level to prevent surface water entering the pit. A squat or drop-hole is provided in the slab which allows excreta to fall directly into the pit-this can be covered with a removable lid to minimize flies and odour. The

superstructure can be made from materials available locally.

The advantages are that it is cheap; quick to construct; no water needed for operation. However, the constraints are that it is unsuitable where water-table is high, soil is too unstable to dig or ground is very rocky; often odour problems (Fig. - 4).

Improved Pit Latrine (The Ventilated Improved Pit Latrine)

This latrine is an improved pit latrine designed to minimize odour and flies. A vent pipe covered with a gauze mesh or fly-proof netting extending at least 0.5m above the superstructure roof is incorporated into the design to remove odorous gases and prevent flies entering and trap any flies trying to leave. Air should be able to flow freely through the squat hole and vent pipe; therefore no drop-hole cover is required. The superstructure interior is kept reasonably dark to deter flies, but there should be a gap, usually above the door, to allow air to enter (Fig. - 5).

Advantages : Reduced odour & flies and good results.

Constraints : Difficult and expensive and time consuming to construct properly; dark interior may deter young children from use; does not deter mosquitoes.

Borehole Latrines

Emergency demands quick work. A borehole latrine fulfills this requirement. It can be constructed very rapidly if an auger or

a drilling rig is available. Borehole latrines are most appropriate in situations where a large number of latrines must be constructed rapidly, and where pits are difficult to excavate, either because of ground conditions or the lack of a labour force.

Dimensions : The borehole has a typical diameter of 400mm and a depth of 5-10m. At least the top 0.5m should be lined (Fig. - 6).

Advantages : The borehole can be excavated quickly; suitable in hard ground conditions and appropriate where only a small workforce is available.

Constraints : Drilling equipment is required; there is a greater risk of groundwater pollution due to greater depth than pit latrines; lifespan is short; sides are liable to be fouled, causing odour and attracting flies; and there is a high likelihood of blockages. This option should only be considered in extreme

Fig. - 4 : Simple pit latrine (1)

Fig. - 5 : Ventilated Improved Pit (VIP) Latrine (1)

conditions when pit excavation is not possible. A hole 300mm (1 foot) in diameter and 5 metres deep should last for (a family of) five people for two years.

Pour-Flush Latrines (Water Seal Latrines)

Pour-flush (hand flush or water seal) latrine is a very hygienic mode of excreta disposal. It functions on the principle of a 'water seal'. Water acts as a hygienic seal and helps remove excreta to a wet or dry disposal system. The simplest pour-flush latrines use a latrine pan incorporating a shallow U-bend which retains the water (water seal). After defecation, a few litres of water must be thrown into the bowl in order to flush the excreta into the pit or sewerage system below. Pour-flush latrines may be constructed directly above a pit or may be offset whereby the waste travels through a discharge pipe to a pit or septic-tank (Fig. - 7).

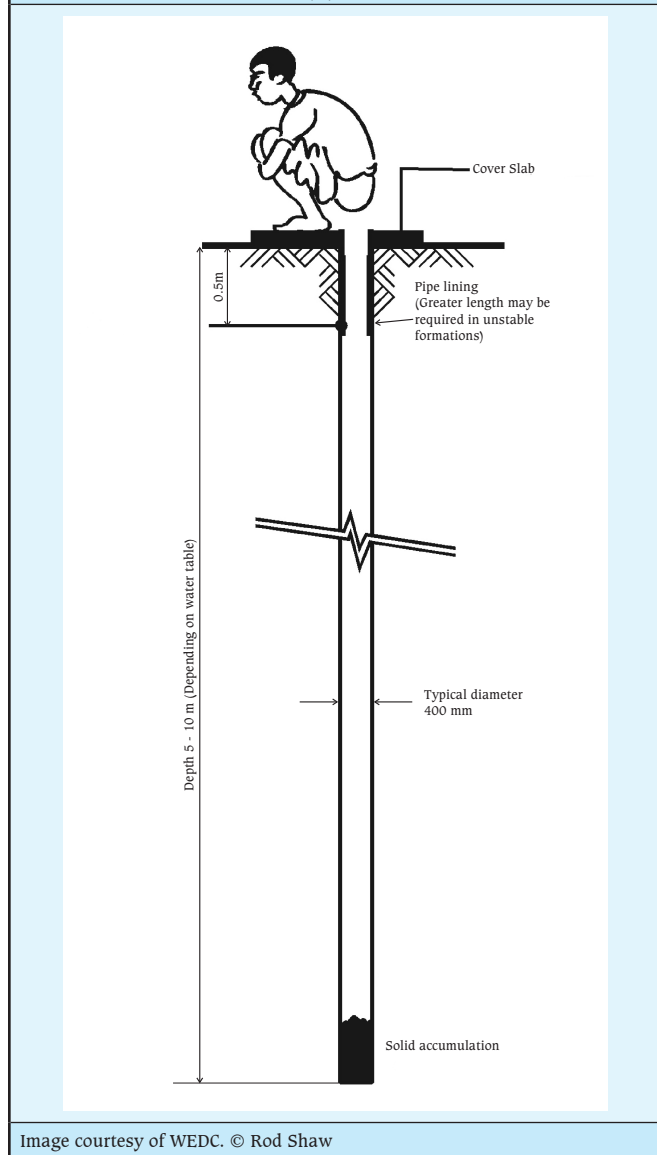

Dimensions : The amount of water required to flush the system will depend on the type and size of the water-seal construction. A 90mm (3") U-bend normally requires 2-3 litres to flush effectively, while a 120mm (4") U-bend generally requires 4-5 litres to flush. These quantities are significantly less than the amount required to flush most western water-closet toilets which may use as much as 15 litres per flush.

Advantages : Lack of odour; relatively less water is used up. It is ideal where water is used for anal-cleansing; easy to clean; off-set design does not require a self-supporting latrine slab.

Constraints : Solid anal-cleansing materials may cause blockages; more expensive than simple pit latrines.

Variants : Several designs have been tried and are in use. Noteworthy of these are those made by Planning Research and Action Institute (PRAI), Lucknow and by Research cum Action Project (RCA), Ministry of Health. The RCA latrine is widely in

Fig. - 6 : Borehole latrine (1)

use.

Design of a RCA Latrine : The RCA latrine comprises of a squatting plate, made of an impervious material like cement-concrete. This is easy to clean and maintain. Raised footsteps are included in the squatting plate. There is a pan directly underneath the squatting plate. The pan receives the night soil. Pan is connected to the trap, which is a bent pipe. The trap holds water and serves as a water seal. The depth of the water seal is 2 cm (Fig. - 7C). It prevents access to flies and avoids release of odour. The trap is connected to the pit (which could be a dug well), through a connecting pipe. When the pit fills up another one can be dug up and pipe may be accordingly shifted. The pit can also be made directly underneath the pan; in that case there is no requirement of the connecting pipe. An appropriate superstructure can be made.

It is easy to maintain the latrine. Latrine is hand flushed by

Fig. - 7 : Pour-flush latrines (1)

Dimensions of sealed pan

Image courtesy of WEDC. © Rod Shaw

pouring 1 to 2 lit of water every time the latrine is used. The squatting plate should also be washed clean every day.

Certain modifications can be undertaken for more efficient functioning. A pre-fabricated Indian type of commercially available squatting plate made of china clay can be used instead of a concrete one. This would be most hygienic. Secondly, rather than using a 'dug-pit' for disposal of night soil, a septic tank can be built. One will have to incur extra cost on these modifications but these would make the latrine close to an ideal system.

Septic Tank

Septic tank is an ideal system for hygienic final disposal of excreta in the absence of a central sewerage system. Excreta from many pour-flush latrines can be discharged into a septic-tank. A septic-tank is designed to collect and treat excreta and toilet wastewater. Its use is likely to be appropriate where the volume of wastewater produced is too large for disposal in pit latrines, and water-borne sewerage is uneconomic or unaffordable. Septic-tanks are, therefore, particularly suited to systems involving high water use, especially where water is used for flushing and anal-cleansing. However, they are difficult to manage for very large populations and are best suited to single households or a group of households or institutions such as hospitals or schools. The efficiency of a septic tank system is inferior to the sewage works but is much cheaper, quicker and easier to provide and maintain than sewage works.

Design and Construction : Septic tank consists of an underground concrete tank usually double chambered. A tank with more than two chambers is expensive and has no additional advantage. Even a single chambered tank has been found satisfactory for a small installation. The latrines should preferably be grouped together with one or more tanks placed close to a group. The sewers leading from the latrines to the tanks should have manholes at every 100m and at every change of direction. Two or more medium sized tanks arranged in parallel instead of one large tank are preferable as these facilitate removal of sludge without disturbing the functioning of the system.

The capacity of the tank should be at the scale of 20-30 gallons per user with a minimum size of 3mx3m (500 gallons). It may be 1.5 to 2m deep. The entire length of the tank should provide a minimum air space of 30 cm above the liquid level. The septic tank is covered by a concrete slab with a manhole in it. The aeration chamber should be ventilated by one or more shafts, the opening of which should be screened with wire-gauze. The inlet and exit pipes to the tank should be trapped. The effluent may be disposed into a soak-well (Fig. - 8).

Functioning : The septic tank functions by the biological process of anaerobic and aerobic digestion. The crude sewage on entry to the anaerobic chamber is allowed to stand for 2 to 3 days and is acted upon by the anaerobic microorganisms. A colloidal solution is formed which is only partially digested and hence has an offensive smell. The complete oxidation and mineralization of the colloidal matter is carried out by the aerobic micro-organisms in the aerobic chamber. Though most of the pathogens, after having undergone aerobic treatment, die but the cysts and ova of the intestinal parasites survive.

The effluent loses most of its offensive smell. The minerals are absorbed from the soil by the plants. The use of ordinary household soap in normal amounts is unlikely to affect the digestion process of a septic tank.

Maintenance : The operation and maintenance of a septic tank is simple. To commission a septic tank it has to be first filled with water and then seeded with a bucketful of sludge from another tank. Not less than 25 lit of water per day per user must enter the tank. Use of soap water and chemicals should be avoided. Sludge from the tank is to be bailed out once in a year or two. The tank cover or roof, which usually consists of one or more concrete slabs, must be strong enough to withstand any load that will be imposed. Removable cover slabs should be provided over the inlet and outlet. Circular covers, rather than rectangular ones, have the advantage that they cannot fall into the tank when removed.

Routine inspection is necessary to check whether desludging is needed, and to ensure that there are no blockages at the inlet or outlet. A simple rule is to desludge when solids occupy between one-half and two-thirds of the total depth between the water level and bottom of the water tank. The most satisfactory method of sludge removal is by vacuum cleaner.

Communal Aqua-Privies

An aqua-privy is a latrine constructed directly above a septic-tank. Aqua-privies are appropriate where pit latrines are unacceptable. The amount of water required for flushing is much smaller than for a septic-tank due to the location of the tank. It helps to exclude odours from the superstructure.

Advantages : Reduced odour; ideal where water is used for anal-cleansing; easy to clean.

Constraints : Increased quantity of water required; solid anal-cleansing materials may cause blockages; more expensive and difficult to construct than simple pit latrines.

Minimum standards : Not more than four families per latrine.

Sulabh Shauchalaya

The concept of Sulabh Shauchalaya was introduced by Dr B Dubey. He modified the standard hand flush latrine to suit rural Indian community. It consists of a specially designed pan and a water seal trap. It is connected to a pit 3x3x3 feet. Minimal water is needed in the process. The excreta gets decomposed to manure in the pit. Sulabh International also maintains a chain of Sulabh Shauchalayas, community latrine, across the country. This provides clean and sanitary toilets to the users at a minimal cost. These are also maintained by the Sulabh International society.

Chemical Toilets

Chemical toilets are sanitation units that consist of a squatting pan placed above a water-tight excreta-holding tank, which usually contains a chemical solution (formaldehyde, etc) to aid digestion and reduce odour. This is contained in a single prefabricated plastic unit with a lockable door. These can be adopted as temporary solutions where pit latrines or septic-tanks are unsuitable or unacceptable, as in aircrafts or trains. The initial charge of chemical is adequate for 40 to 160 uses.

Fig. - 8 : Septic tank (1)

Image courtesy of WEDC. © Ken Chatterton

Uses : These are used in aircrafts and as a short term measure in disasters, etc.

Advantages : Portable; hygienic; minimized odour; can be mobilized rapidly.

Constraints : High cost; unsustainable for long periods; regular servicing and emptying required.

Water carriage system

The water carriage system is useful for large residential and commercial. The human excreta and waste water are carried away by a network of underground pipes called sewers to the ultimate disposal site. Obviously this is the method of choice for urban areas having piped water supply (5). In India the water carriage system was used for the first time in Calcutta in 1867. But even today, unfortunately not more than 20 percent of the urban areas in India can boast of this method of sewage disposal. In large cities this is the ideal system of sewage disposal.

Laying down such a system is infrastructure and capital intensive. It amounts to digging up lanes and by-lanes. Skilled manpower is a must to establish the system. Piped water supply is mandatory to run the system. On - going maintenance has to be done to keep the pipes going. Importance of sewerage system was realized during floods at Mumbai in the year 2005 when heavy rains lashed Mumbai. The water carriage system being inadequate, ill maintained and choked, couldn't cope up with the excessive rain water and caused flash floods. This had drastically disrupted life in the commercial capital of India leading to heavy economic losses and outbreak of Leptospirosis.

Classification

There could be two types of sewerage systems, the combined and the separate systems. The combined system carries both sewage and storm water in the same sewerage line. In the separate system, however, the surface water is not admitted into the sewers. The latter is the system of choice.

Components

The water carriage system consists of household sanitary fittings, house sewers, street sewers and sewer appurtenances.

(a) Household Sanitary Fittings : These include water closets, urinals, washbasins, bathtubs along with their plumbing systems.

(b) Soil Pipes : These are pipelines, which carry excreta from the water closets to the house drain. They are fitted with outlet ventilators for the escape of foul gases and hence are placed outside along rear walls of the houses and are carried above the roof tops.

(c) House Drains : It is an underground iron or stoneware pipe usually of 10 cm diameter and is laid in the courtyard 15 cm below the ground level on a bed of cement concrete mix with sufficient gradient towards the public sewer. It carries away the discharges from the household sanitary fittings to the street sewers.

(d) Public Sewer : It is a network of underground pipelines varying in diameter from 22 cm to 3 m for carriage of sewage from domestic, industrial and commercial areas to the place

of final disposal. While laying the pipelines sufficient gradient is to be ensured for self-cleansing velocity of sewage. This velocity varies from 60 cm to 90 cm per second.

(e) Sewer Appurtenances : These are manholes and traps installed in the sewerage system :

(i) Manholes : Manholes are the openings built in sewers for the purposes of repairs and cleaning. They are placed wherever there is change in the direction of sewers, at the junction of two or more sewers and at a distance of 100 meters in the long, straight run of the sewers. Workers entering manholes are at a risk of gas poisoning and asphyxiation; so due precautions must be taken while entering them.

(ii) Traps : Traps are devices designed to prevent entry of foul gases inside the house and to remove sand, grit, grease etc. from sewage. Traps are placed at three points (1) under the water closet, (2) at the junction of the house drain and the street sewer and (3) where the surface water enters the sewers. There are several designs of traps. The simplest one is a bent pipe containing water as a seal (Fig. - 7C). The water seal in a trap is the distance between the highest level of water in the trap and the lowest point of the trap's concave upper surface.

Composition of Sewage

Sewage contains 99.9 percent water and 0.1 percent solids, which are partly organic and partly inorganic. Sewage teems with living organisms, some of which may be pathogenic. The strength of the sewage may be expressed in terms of biochemical oxygen demand, chemical oxygen demand and suspended solids.

Biochemical Oxygen Demand (BOD)

It is defined as the amount of oxygen absorbed by a sample of sewage during a specified period, generally 5 days at a specified temperature, usually 20°C for aerobic digestion. This is the most important test carried out on sewage. Sewage with a BOD value of 300 mg/l (300 ppm) or above is termed as strong while that of 100 mg/l (100 ppm) or below is termed weak.

Chemical Oxygen Demand (COD)

Chemical oxygen demand is the amount of oxygen required to oxidize the organic matter by use of dichromate in an acid solution and to convert it to carbon dioxide and water. The value of COD is always higher than the BOD because many organic substances can be oxidized chemically but not biologically. Commonly, BOD is used to test the strength of untreated and treated municipal and biodegradable industrial waste waters. COD is used to test the strength of wastewater that is either non biodegradable or contains compounds that inhibit activities of microorganisms.

Suspended solids

If the suspended solids are 100 mg/l or more, it is termed strong.

Sewage Purification

The aim of sewage treatment is to convert an offensive and potentially dangerous mixture into an inoffensive effluent and sludge which can be disposed off safely and without causing nuisance into river, sea or on land. The conversion of complex organic matter in the sewage to simpler substances takes

place by two processes, viz aerobic and anaerobic. The aerobic method requires a continuous supply of free dissolved oxygen for the aerobic microorganisms to break the organic matter into simpler substances such as carbon dioxide, ammonia, water, nitrite, nitrate, sulphate etc. The anaerobic process is more effective where the sewage is highly concentrated and contains plenty of solids. Hence, this method is usually gainfully utilized for digestion of sludge in sewage works. The end products of anaerobic decomposition are methane, ammonia, carbon dioxide, hydrogen etc.

Sewage Treatment Plant : The sewage treatment undergoes through many stages. These can be conveniently divided into Primary, secondary and tertiary treatment stages.

- Primary treatment : The first stage is the physical treatment to remove solids (from the liquid). This physical treatment is often referred to as primary treatment.
- Secondary treatment : The primary treatment is followed by biological treatment brought about by aerobic and anaerobic bacteria.
- Tertiary treatment : Treatment rendered in addition to the conventional secondary treatment for improving further the quality of effluent is termed 'tertiary treatment' or advanced waste treatment process. The sludge is also given treatment for stabilization and dewatering. Chemical treatment by the addition of coagulants may be used to assist sedimentation and sludge treatment. Flow diagram of a modern sewage treatment plant is shown in (Fig. - 9).

Primary Treatment

(a) Screening : It is the first step in the sewage treatment for removing the larger solids. The raw sewage is passed through bar-screens with openings of 8 to 10 cm between the bars placed across the inflow channels. The screenings can be manually raked from the screens and buried.

(b) Grit Removal : Combined sewerage systems carry grit from roads or other debris from general sullage and fine granular

inorganic material. This material which otherwise causes heavy wear in pumps and tends to settle out and cause difficulty in later treatment processes must be removed in grit chambers and channels. The sewage is allowed to flow in a channel at a controlled velocity of about 30 cm/s, which is slow enough for the heavy non-organic solids to settle down but fast enough to carry the lighter organic solids forward. The grit is removed periodically, washed free of organic matter and dumped on waste land for reclamation or to fill excavations and quarries without causing nuisance.

(c) Primary Sedimentation : It is the third step to remove as much of the organic solids as possible from the liquid sewage. The same principles as those for the treatment of water are employed. Sedimentation tanks may be rectangular with a horizontal flow, hopper-shaped with vertical flow, or circular with radial centrifugal flow. Slow moving paddles to encourage flocculation of solids and increased settling velocities may be incorporated. The sewage is retained in sedimentation tanks for 4 to 12 hours. The process removes 50-60 percent of the suspended solids and about 40 percent of the BOD of the sewage. The settled sludge is removed by mechanical scrapers to hoppers from which it is drawn off either continuously or at frequent intervals to prevent it from becoming septic. The sewage is then treated biologically.

Secondary Treatment

The secondary or biological treatment of sewage essentially involves the oxidation of suspended and dissolved organic matter by aerobic bacteria. Carbonaceous matter is converted to carbon dioxide and water, and nitrogenous material to ammonia, nitrites, and nitrates. Fungi, algae, ciliate protozoa, insects and worms supplement the bacterial digestion. The main processes employed for biological treatment are as under:

(a) Percolating or Trickling Filters : The effluent from the primary sedimentation tanks is brought into the percolating filter through a central pipe. The effluent is sprinkled uniformly

Fig. 9 : Flow Diagram of Modern Sewage Treatment Plant.

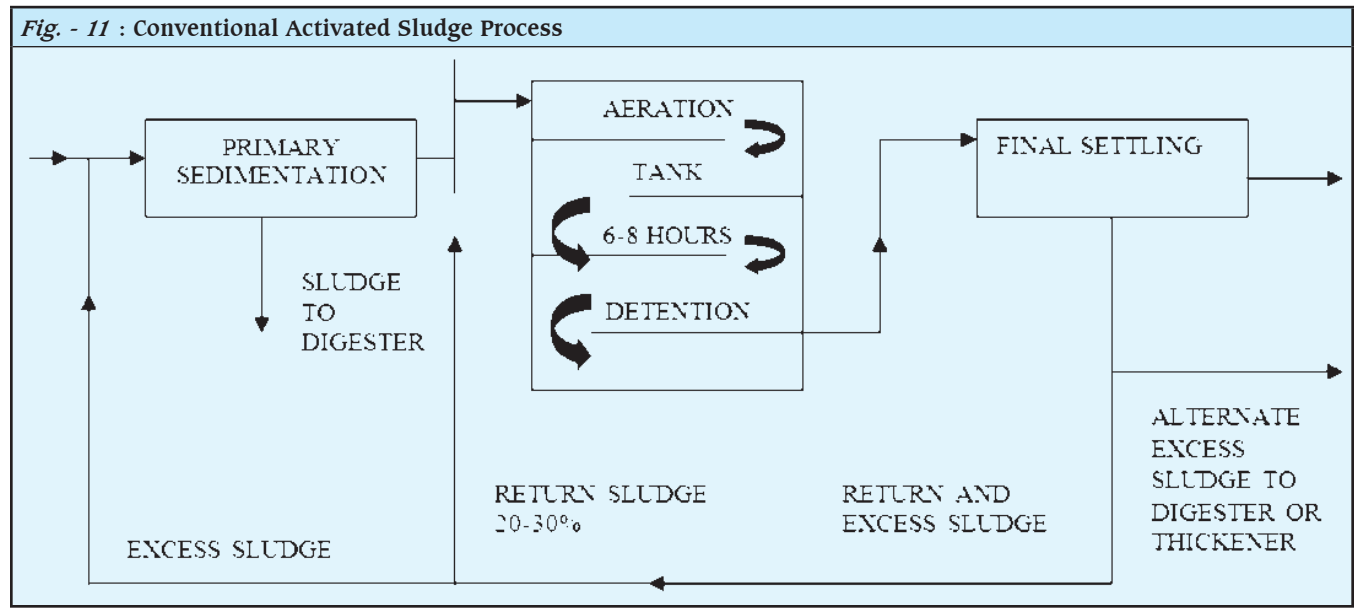

on the surface of the bed by a revolving device. This device is nothing but an assembly of pipes with rows of multiple holes in them (spraying nozzles). The rotating pipes sprinkle a thin layer of effluent on the surface of the filter. This effluent then trickles down the filter. The percolating filter consists of beds 1.5 to 2 m in depth, made of stone, cinders, slag, brick pieces or other impervious material generally from 3 to 8 cm in size. The beds are usually circular. A slimy 'zoogical' film of aerobic bacteria and other organisms develops on the surface of the stones. In trickling downward through the bed, the sewage donates its organic content to the vital zoogical film for its nutrition and in return receives soluble organic salts produced by oxidation. Access of air through the filter is essential for the zoogical fauna to oxidize the organic matter. A competent percolating filter plant reduces the BOD of the raw sewage by 85 to 95 percent. Percolation is followed by final settling into secondary sedimentation or humus tanks to remove the particles of the zoogical matter and innocuous debris (Fig. - 10).

b) Activated Sludge Process : Activated sludge process is an alternative to the percolating or trickling filter method described above.

Principle : The principle is to add sufficient quantity of sludge obtained from the final settlement tank (called 'activated sludge' or return sludge) to sewage that is to be treated (the effluent from the primary sedimentation tank). Activated sludge contains active aerobic bacteria vital for decomposition of sewage. This mixture (called the 'mixed liquor') is mechanically aerated in an aeration tank to facilitate bacterial decomposition. In the presence of ample oxygen the aerobic bacteria utilize the raw sewage and convert it into stabilized, odourless compounds.

Process : The process requires air supply and thorough mixing which brings about an intimate contact of the organic solids with oxygen and aerobic bacteria. First the effluent from the primary sedimentation tank is mixed for an hour or two with the activated sludge returned from the final sedimentation tank to form the 'mixed liquor'. Now the oxygenation of this mixed liquor is carried out for 4 to 6 hours by one or more of these methods :

- (i) Diffused Air System : Compressed air is blown through porous plates, domes or pipes fixed at the bottom of aeration channels (Fig. - 11).
- (ii) Simplex Surface Aeration : Motor driven propellers are used

to mix and break up the sewage into fine spray, bring it in contact with air and induce circulation in hopper bottomed chambers.

The plant : The plant consists of a long channel or a series of chambers through which the sewage passes while aeration process proceeds. The aeration is followed by settling in tanks. The sludge is removed and the clear purified final effluent flows out for safe discharge. Most of this activated sludge is returned to be mixed with the sewage from the primary settling tanks as described above. Thus there is a continuous circulation of activated sludge within the system.

The activated sludge method is a more efficient than trickling filter method. Activated sludge plant occupies one tenth of the space occupied by a trickling filter and is also faster. This however is costlier to install and run. It is best suited for large towns.

Following secondary treatment, there are two types of substances that are left, viz., the semisolid sludge and the watery effluent. These two products are dealt in the following ways :

Sludge Treatment

The sludge from primary or final sedimentation tanks contains 90 to 95 percent water. This high water content needs to be reduced for converting the sludge to a solid condition in which it may be used or disposed off harmlessly. Anaerobic digestion is the most preferred sludge treatment method. The sludge is pumped daily into enclosed digestion tanks. With anaerobic fermentation a gas comprising of about 70 percent methane and 30 percent carbon dioxide is produced. This sludge gas is a valuable fuel. It can be used to generate the entire power needed for running the activated sludge plant. Power is used for pumping, air compression, electricity generation, and heating on the plant. The surplus gas may be compressed and used as vehicle fuel or cooking.

For most effective digestion and gas production, the digesters are heated to about 32°C. Digestion converts much of the organic solids to gas and soluble matter, and so reduces the quantity of solids to be handled eventually. Digested sludge is a black liquid with a tarry odour and is more amenable to subsequent dewatering than undigested sludge. Apart from digestion, the main object of sludge treatment is to de-water it so that it can be handled as relatively compact, moist solid rather than as a much greater volume of liquid with a low solid content. The following processes are used for dewatering the sludge and may be applied to either raw or digested sludge.

a) Air drying : Liquid sludge, after digestion, is placed on sand beds for air drying. Percolation into the sand and evaporation are the chief processes involved in the dewatering process. Air drying requires dry, relatively warm weather for greatest efficiency, and some plants have a green-house like structure to shelter the sand beds. The semisolid sludge, which is left, is lifted manually or mechanically. Dried sludge in most cases is used as a soil conditioner; sometimes it is used as a fertilizer.

b) Lagooning : Sludge is stored in open basin, a few meters deep to allow settlement of solids. Clarified liquid may be drawn off, and the solids are eventually dug out.

Sewage sludge contains useful nitrogen and phosphorus, and although rather deficient in potassium, it forms a moderately good fertilizer. Undigested primary sludge and undigested activated sludge are easier to apply to land, and their humus content improves the soil. In suitable circumstances sewage sludge may be composted with municipal refuse. Where sludge cannot be used either as a fertilizer or for composting, or, in a few cases, for recovery of by-products, it is usually tipped for land reclamation, dumped at sea, or incinerated.

Disposal of Effluent

The effluent after treatment is usually discharged on land or into water bodies.

a) Disposal on Land : If suitable land is available the effluent can be used gainfully for irrigation purposes. Over the past few decades, there has been a considerable revival of interest in the use of wastewater for crop irrigation in arid and semiarid regions owing to the scarcity of alternative water supply and the need to increase food production. Reuse of treated effluent for the irrigation of crops and urban 'green spaces' (such as parks and golf courses) has expanded significantly in many countries.

Risks in sewage farming : Enteric viruses appear to be particularly persistent in sewage, under natural conditions. Sewage farming or spread of treated effluent on farms is still used in many countries, particularly those having low rainfall and high temperatures. Enteric viruses have been found in raw sewage in concentrations of 1-10 per ml in various countries. Thus the risk of transmission of infections through sewage farming remains alive. The risk increases if the sewage had not been treated adequately, prior to its discharge for sewage farming.

(b) Disposal by Dilution : Discharging the effluent into bodies of water such as rivers, streams, lakes and sea for the purpose of dilution and oxidation of the impurities by the dissolved oxygen in water is termed as "disposal by dilution". The BOD content of the effluent and diluting capacity of the bodies of water are the important considerations before discharging effluent into the water body. Since river water is used for drinking, effluent must be adequately treated before discharging. Lately industrial waste and chemicals are being dumped into the sewage, which poses a threat to people's health, when the effluent is eventually discharged into rivers. The aquatic flora and fauna is also adversely affected.

Oxidation pond

Oxidation pond is also known as the "Redox Pond, Sewage Lagoon and Waste Stabilization Pond". It is probably the cheapest method of satisfactory sewage disposal. It is an open shallow pool up to 5 feet deep with an inlet and outlet. The presence of algae, bacteria decomposing organic matter and sunlight are mandatory for the functioning of oxidation pond. Bacteria oxidize sewage to carbon dioxide, ammonia and water. The algae, with the help of sunlight utilize carbon dioxide, water and other organic substances for its growth. Algae releases oxygen during photosynthesis, which is used by bacteria. So the pond works as an aerobic system during the sunlight hours, and anaerobically during the dark (night) hours, especially in the lower layers (Fig. - 12). The effluent can be used for farming

or can be discharged into rivers after suitable treatment. If the pond runs well, it is an accepted method for sewage disposal in small communities.

Oxidation Ditch/Aerated Lagoon (6)

This process used in oxidation ditch or aerated lagoon utilizes mechanical rotors for extended aeration and thus minimizes the requirement of land area. The land requirement in this method is barely one tenth of oxidation pond. During primary sedimentation itself, a reduction of 30-40% in the number of coliforms is obtained (as against 90% and 95% in other biological treatment processes). On stabilization with a 30-day retention, coliforms reduce to 99 - 99.9%. Most other vegetative bacterial pathogens also appear to be removed in the same proportion as coliforms. Certain helminthic eggs may be effectively removed by primary sedimentation and even more effectively by stabilization pond treatment of 5-7 days duration; viruses are less effectively removed. Coagulation and filtration remove 98 to 99.9% of viruses.

Ponds have the advantage of providing a fairly high degree of treatment at relatively low cost, with minimal requirement of equipment or skilled operators.

Biolatrine (Biogas plant)

The biolatriner is an example of 'appropriate technology'. It not only takes care of the sewage in an efficient manner, the gas obtained as a by-product is utilized for cooking. Moreover the digested substrate may be utilized as fertilizer (18 - 20). It functions on the principle of anaerobic degradation of excreta. The main focus is however mostly on sanitary aspects, i.e. clean toilets with low maintenance demand, rather than high gas productivity.

Design : Biolatrines are designed as integrated fixed-dome biogas plants, where up to 6 latrines can be installed around a dome. The main advantage of biolatrines is that they are generally run without water (except for the start-up phase) thus substantially reducing water demand and related costs. The urine will provide sufficient liquid for the substrate to be able to flow. The toilet chamber is connected to a vent pipe corresponding to those of the VIP latrine. The soil conditions is a consideration and should allow effluent and slurry

absorption.

Usage : A biolatriner may only be an appropriate if at least 25 people are connected to its use. The excreta of 25 people will produce an average of about 1 m³ of biogas per day (40 l per person a day), representing the approximate cooking energy demand of one household. For institutions with 500 or more people, the produced biogas may supply sufficient energy for a canteen. Application may occur for institutions like schools, prisons, religious centres, or for public facilities like markets. In Ralegaon Siddhi (Dist. Ahmednagar), Maharashtra community latrines have been connected to biogas plants. Biogas produced is being distributed to houses for cooking purposes.

Disposal of Animal Excreta

Animal excreta is also required to be disposed off in a sanitary manner. It might not directly cause disease but it carries enormous potential for fly breeding. It can be managed by disposing it in biogas plants, sanitary land fill or composting (disposal along with biodegradable solid waste).

a) Disposal in Biogas Plant (Gobar Gas Plant) : In view of the increasing energy crisis, this method is gaining rapid popularity, particularly in countries having large cattle population. In this method the dung gets anaerobically converted into good quality manure under hygienic conditions and there is also generous liberation of biogas energy.

The digester is partly an underground masonry tank with an incomplete partition in the middle. It has an inlet and an outlet pipe. Dung mixed with water in equal proportion is put inside through the inlet. In the plant, excreta is often mixed with straw or other vegetable waste, and equal quantity of water is added to make slurry which is fed to the inlet side of the chamber. Effluent slurry is removed after retention time of 30-50 days. Biogas production is greater at higher temperatures. This gas can be used as fuel in the kitchen, for running engines, lighting and other purposes. A biogas plant is inexpensive, simple in construction, easy to handle and can be made locally from indigenous materials.

(b) Composting : It is often carried out in conjunction with solid waste and night soil. Chapter on solid waste disposal can be referred to for details.

Summary

Effective and hygienic disposal of excreta is called for not only as a social need but as a health need as well. Many diseases like cholera, typhoid, dysentery, diarrhoea, hookworm, roundworms, poliomyelitis, hepatitis etc can be transmitted through fingers, flies, food, fomites and water contaminated by excreta.

There are various methods of sewage disposal. While open defecation might still be a preferred method in many rural areas, it remains the most unsatisfactory one. It can only be resorted to in the eventuality of a disaster when the population is displaced and has to be accommodated in a relief camp for a short duration. The conservancy system (carrying excreta manually to the disposal site), is also a detesting method and is fortunately waning. In the areas where there is no sewage system, simple pit latrines (dug well latrine), bore hole can be used. But the pour flush latrine is the ideal one as it contains

an eater seal. PRI and RCA types are its modifications that are in use.

Septic tank is a suitable method of final disposal of night soil. Trench latrines (deep and shallow) can be used for camps for short durations. Chemical closets are also used for short duration use.

Water carriage system is the ideal system of sewage disposal and is used in large cities. Networks of pipes from households connect to a labyrinth of underground sewage pipes to the final disposal site, i.e. the sewage treatment plant. Biological and mechanical processes break down the sewage into innocuous products that can be discharged safely into land or water bodies.

Other methods of sewage disposal are the oxidation pond and oxidation ditch. Biogas plant is also one method. Animal excreta can be disposed off through a *Gobar* gas plant or composting.

Study Exercises

Long Questions : (1) Enumerate the diseases that can be caused by poor disposal of sewage. Describe one method for the disposal of sewage in a village at a family level (2) What do you mean by secondary treatment of sewage ? Describe the activated sludge process in detail.

Short Notes : (a) Oxidation pond (b) Sanitation barrier (c) Water seal (d) Trickling filter (e) *Gobar* gas

MCQs

- The depth of the water seal is : (a) 2 cm (b) 2" inches (c) 20 inches (d) 20 cm
- Septic tank uses (a) Aerobic digestion (b) Anaerobic digestion (c) Both (d) None
- Which is not a method of secondary treatment of sewage (a) Trickling filter method (b) Activated sludge method (c) Screening (d) Sludge treatment

- In immediate aftermath of disaster, displaced population can use this method (a) Open defecation (b) Water carriage system (c) Biogas method (d) Communal aqua privy.
- Oxidation pond works on : (a) Aerobic principle during night and anaerobic during day (b) Aerobic principle during day and anaerobic during night (c) Aerobic in both day and night (d) Anaerobic in both day and night

Match the following

Population group with most suitable method of sewage disposal	Population group Most suitable method of sewage disposal
6. Joint family in a village	(a) Trench latrine
7. Large city	(b) Septic tank
8. Group of 20 households	(c) Water carriage system
9. Temporary camp	(d) Pour flush latrine
10. Family in a town	(e) Biogas plant

Answers : (1) a; (2) c; (3) c; (4) a; (5) b; (6) e; (7) c ; (8) b; (9) a; (10) d.

Kunal Chatterjee

Solid wastes include rubbish or materials that are not economically useful, present in solid, liquid or gaseous form, which originate from a wide range of human operations, such as industry, commerce, transport, agriculture, medicine and domestic activities. It contains food waste, demolition products, dead animals, manure and other discarded material but should not contain nightsoil.

Waste produced by human activities is increasing in most parts of the World. The output depends on the degree of urbanisation, dietary habits, lifestyles and living standards. In most of the countries the per capita daily solid waste produced is between 0.25 to 2.5 Kg. Majority of this waste is diverted towards recycling in developing countries, while in the developed countries sophisticated methods are used to dispose the ever increasing waste generated (Solid wastes disposal in all the countries is done through landfill). With the rise in urbanisation, land areas available for filling are getting lesser and lesser. The alternate methods of disposal such as burning or incineration are neither cost effective nor environment friendly. Toxic products from wastes disposed in

landfill sites increasingly leach into groundwater or cause the generation of explosive methane gas. These waste materials are also attractive to cockroaches, flies and rodents and hence need early and effective disposal.

Environmental impact of solid waste disposal : Solid wastes, if allowed to accumulate and not disposed off properly have a tendency to cause the following impacts :

- Contamination of ground water by leachate generated by waste dump
- Surface water contamination by run-off from the dump
- Waste decomposes and favours fly breeding, attracts rodents and pests
- It is aesthetically unpleasant and generates foul odour
- Generation of inflammable gas such methane and green house gases inside the waste dump
- Bird menace on the dump, which affect the flight of aircraft
- Transmission of disease through pests, stray animals and cattle

Classification of Solid wastes : A thorough knowledge of quantity, composition and type of waste is essential to plan effective disposal. Solid wastes could be of different types such as :

(a) **Refuse** could be generated from street sweepings, markets, stable litter comprising of animal droppings and left-over feeds, industrial refuse ranging from inert to toxic and explosive compounds and commercial refuse from retail stores, hotels, warehouses and offices.

(b) **Rubbish** a general term applied to solid wastes originating in houses, commercial establishments and institutions, excluding garbage and ash. It includes paper, clothing, bits of wood, metal, glass, dust and dirt.

(c) **Ash** is the residue from burning of wood, coal, charcoal, coke and other combustible materials used for cooking and heating purposes in domestic, commercial and industrial establishments. Ashes consist of a fine powdery residue, cinders often mixed with small pieces of metal and glass.

(d) **Garbage** is a term used to describe animal and vegetable wastes resulting from the handling, storage, sale, preparation, cooking and serving of food. It contains organic matter, which decomposes to emit foul odour and hence requires urgent disposal.

Plastics and their role in waste disposal: Plastics are organic polymeric materials that can be transformed into desired shapes by different industrial processes. These may contain natural elements such as natural rubber, cellulose or synthetic elements such as polythene or nylon. Plastics have excellent thermal and electrical insulation properties and good resistance to acids, alkalis and solvents. Plastics are widely used in commercial and industrial sectors such as packaging industry, building, motor manufacturing and consumer goods industry. However these plastics are not easily destroyed during waste management processes and are poorly biodegradable. Moreover the chlorinated plastics emit toxic gases when thermally treated. Plastics are known to clog or choke water lines, sewers or storm water drainage systems. They are easily blown by wind and litter the areas near waste dumps thereby

being aesthetically unappealing

Solid Waste Management

The activities associated with the management of solid wastes in a community from the point of generation to its disposal revolves around the following functional elements (a) waste generation (b) waste handling (c) sorting, storage and processing at source (d) collection (e) sorting, processing and transformation and (f) disposal (Fig. - 1). These elements are relevant to all manner of solid waste disposal be it from urban localities, slums, rural areas or after any calamitous event in an area. In the latter event the urgency to dispose off the waste material is extreme. The waste material in a post disaster situation depends on the type of disaster, which has occurred. It could range from household goods to building material and in extreme situations include human and/or animal bodies.

Solid Waste Disposal in an Urban Area

Urban areas include cities and towns and have a higher density of population by virtue of which the quantity of solid wastes generated is very high. Besides this there are people from different professions, socio-economic status, ethnic and cultural backgrounds living in varied accommodations in these areas. They thus produce equally diverse kinds of waste material from their domestic, commercial and industrial professions/establishments. Composition of solid wastes changes from place to place even in the same country due to this heterogeneity.

Major constituent of waste is putrescible organic matter with the balance of the content comprising of metal, glass, ceramics, plastics, textiles, dirt and wood in proportions depending on the local factors. Studies have shown that while the quantity of paper waste increases with the rise in income of the countries, the density, moisture content and proportion of food waste is

more in the waste generated in low income countries.

Studies conducted by National Environmental Engineering Research Institute, Nagpur have shown that in India out of the wastes generated, the biodegradable fraction is very high due to the habit of using plenty of fresh vegetables in food preparation. It demands frequent removal of waste from the collection points. The proportion of ash and fine earth content in the waste are also high due to the inclusion of the street sweepings, drain silt and construction and demolition debris in it. The most ideal arrangement for collection of solid waste in an urban area would be door-to-door collection of waste material by a team of waste handlers. However this is not practicable in all places in the cities especially in the urban slums.

Waste Management Plan

(a) Sorting : This indicates 'separation and storage of individual constituents of the waste materials'. Sorting helps in removing the material, which needs to be recycled and ensures that the hazardous wastes are handled separately. It assists in minimising the waste and ensures reduction in landfill space for final disposal. Sorting could be carried out at household level, at the municipal bin, central sorting facility, waste processing site or the landfill site. At the household level sorting is carried out by the inmates. Traditionally, items such as newspapers, used bottles, jars, old clothes, strong plastic bags are not mixed with everyday household wastes. These are reused or sold at a later date to informal recycling trade middlemen or the '*kabariwallah*'. Garden wastes from houses gets mixed with the municipal waste, there being no separate mechanism for its disposal. At the next stage of sorting at the municipal bin the ragpickers take over and collect waste material of use to them such as plastics mostly water bottles, paper, rags, metal cans and rubber items to resell or recycle them. This business continues at the landfill site where the pickings include small metal pieces, plastic bags or any item considered to be of economic value. Thus at the primary level an intensive sorting is carried out. The recovered material thereafter reaches the next level of sorting where the informal recycling trade middlemen sort out all metals, plastics and all types of paper. The salvaged items out of the waste is purchased by the wholesale dealer, who does more sorting, since he is the final link in the chain before the recycling factory. The balance of waste material is disposed off in the landfill. After sorting the waste is divided into the following streams :

- Dry recyclables
- Construction and demolition waste
- Biodegradable waste
- Bulky waste
- Hazardous waste
- Mixed wastes

Sorting could be carried out manually or by semi-mechanised or fully mechanised systems. The manual system employs handpicking of waste for reuse, which is followed in most cities in developing countries, by the ragpickers and the informal recycling trade middlemen, while in the semi-mechanised system the waste material is placed on a conveyor belt and then hand-picked off the belt, for reuse. The mechanised system involves size reduction of waste through shredders and crushers followed by screening, density and magnetic

separation of waste followed by its compaction by balers and crushers.

(b) Storage : This is the first essential step in management of solid wastes. Every household, shop, industry, commercial centre or establishment generates waste that it needs to be stored safely prior to giving it for collection. Presently such establishments and institutions do not maintain receptacles of adequate size for storage of waste as a result of which the solid waste lies overflowing the bins or littering the streets causing public nuisance. In some instances the waste generated is simply thrown out to the streets for the municipal sweeper to sweep it up. Wastes of the recyclable variety are mixed with organic waste and not sorted out or at worst the wastes may be thrown into the municipal sewers or drains, which end up blocking them and obstructing the flow of water in them.

It is therefore essential at first to educate the people to store waste at source, dispose waste as per directions of the local bodies and effectively participate in the activities of local authorities to keep the cities clean. The type and size of waste bins need to be described to households, shops, offices, institutions, hotels, vegetable & fish/meat markets, street vendors, marriage halls, construction sites and health care establishments. It needs to be emphasised that the recyclable wastes should be kept separate from the organic matter capable of decomposition. The food/ biodegradable waste should be stored in a non-corrosive container with lid. Building associations, communities and commercial complexes must keep central waste storage bins of adequate capacity to ensure that they hold the wastes generated till the time they are cleared by the waste lorries. Construction and demolition wastes should not be dumped on the streets, public spaces, footpaths and pavements.

(c) Collection of waste : The next essential step in waste management is primary collection of waste matter. This ensures that the waste from the source is collected regularly such that it is not disposed in the streets, drains or water bodies.

Doorstep collection of waste from households, shops and establishments is insignificant in the urban areas and wherever it is introduced through private sweepers or departmentally, the system does not synchronise further with the facility of waste storage depots and transportation of waste. This results in its indiscriminate disposal in public places.

Waste collection measures : A daily waste collection service should be provided to all sources of generation for collection of putrescible organic waste from the doorstep because of the hot climatic conditions of the country. Recyclable material can be collected at longer intervals as this waste does not normally decay and need not be collected daily. Domestic hazardous waste is produced occasionally hence needs to be collected less frequently and could be disposed off by the community in central bins kept for the purpose.

Collections could be made from doorstep or at the community level by hand carts/ tricycles or motorised vehicles. The hand carts or tricycles should have detachable containers of 30 to 40 litres capacity, made of sturdy material, with a handle at the top and a rim at the bottom for easy handling. Similarly the community bin carrier or the bin lorry should have the capacity to carry 40 containers from a central point in the communities

or slums to the place of final disposal.

Waste storage depots (secondary) : Wastes collected from the source could be temporarily stored at depots till the time they are taken to the final disposal site. At present most municipal areas have cement-concrete-cylindrical bins, masonry bins, metal rings or open sites for storage of wastes. Improper storage at the bins or littering of waste gives an unsightly appearance and also attracts rodents, pests and animals that further spread the litter or could carry diseases from the decomposing matter.

Temporary waste storage depots, which synchronize with primary collection and transportation system, are required to be located at suitable sites in a municipal area. Large metal containers, which are covered, could be placed at specific points. These places should have concrete or asphalt flooring. The waste material could thereafter be transported at regular intervals by Lorries having mechanised equipment to lift and load the bins to take them to the final disposal sites.

(d) Disposal of solid waste : Solid waste disposal in developing countries is mostly carried out by filling up land sites. In India this nature of disposal accounts for most of the municipal refuse. This is followed by incineration and to a very minimal extent by composting. The choice of disposal method depends on the economic considerations, availability of land, local labour and circumstances. Some of the technologies in use in these countries include sanitary landfill, incineration, composting, biogas plant, Effective Microorganisms technology and salvaging.

Dumping : The refuse collected from the cities and municipal areas are dumped in the low-lying areas or open tracts of lands, usually by the roadside. This process, though not a correct method of disposal of solid waste, is nevertheless practised in many cities in the country and in certain locations in a particular municipal area limit. The city of Kolkata in India practises the method of dumping of municipal solid wastes after its sorting. Some of the reclaimed lands, where refuse is dumped, are also given thereafter for cultivation.

This method has the disadvantage of lying in the open ground thereby being dispersed by the wind to nearby places, attracting rodents, insects and birds causing a risk of transmission of diseases and encouraging breeding of flies. Besides this the

open waste dump lying on the roadside emits foul odours and is an aesthetic nuisance. The urban areas thereafter resort to burn these wastes to reduce their bulk, thereby causing air pollution. The malodourous fumes and the toxic gases, which are emitted due to burning of wastes such as plastics and other materials, are spread in the direction of wind movement. Besides, these dumps are accessible to animals and scavengers or ragpickers since these areas are usually not made secure from ingress of these elements. The drainage from these dumps contributes to the pollution of surface and ground and the soil around.

Dumping of waste disposal should be outrightly discouraged as an unsanitary practice. Only dumping of demolition materials could be permitted in low lying areas outside the cities or municipalities (Fig. - 2).

Landfill : Landfill (Controlled tipping) is a method of selecting depressed areas or creating artificial trenches where waste matter is thrown and compacted with a layer of earth on top of it. This method is suitable if adequate land is available, within the economic range of the waste source. The modern day landfill is utilised for disposal of wastes two to three times a week and differs from dumping in that if properly carried out it reduces the nuisance of foul odour, menace of flies, rodents and animals. It also prevents any dispersal of the waste matter and is protected from scavengers. Soil, water and air pollution is avoided and the reclaimed land could be utilised for growth of vegetation or parks after a period of time (Fig. - 3).

Site selection : The site selection for a landfill is carried out away from habitation. A hollow low lying area is usually selected such as an abandoned quarry, depression in land or swampy area, which is not a source of rain water harvesting or natural aquifer for a municipal area. If such land area is not available, as an alternative to this, trenches are dug in an open and flat area with the help of dozers. Some of the points which should be remembered while selecting a site for landfill are :

- Waste site should not be subject to flooding easily
- Deep sands with shallow water tables should be avoided, to prevent seepage of toxic wastes into the drinking water
- Fractured limestone soils, humid areas or wetlands with easy percolation should be avoided.
- Soil with pH 6.5 or above should be chosen such that the

Fig. - 2 : Dumping

Fig. - 3 : Landfill

metals such as cadmium, mercury, lead, chromium and copper are less soluble in the subsoil water and reduce the chance of pollution.

Sites

(a) Trenches - where long trenches of 2 to 3 m depth and 4 to 12 m width are dug and the refuse is compacted and covered with excavated earth. It is estimated that an acre of flat land area would be required for ten thousand population.

(b) Ramps or slopes - where moderately sloping lands are selected and soil is excavated for compacting purposes. The waste dump should be prevented from damage by rain water and thus upland drainage should be diverted.

(c) Unused areas - such as disused quarries, pits and land depressions wherein the solid waste is packed and consolidated in uniform layers using mechanised equipment.

Process of disposal : The refuse or solid waste is collected and deposited in these sites using bulldozers or crawler type tractor. In trenches the filling takes place from the farthest end. Each layer is upto 2 to 2.5 m deep. At the end of the day or as per the desired frequency the top of the refuse is layered with earth of at least 30 cms thick using mechanised equipment and evenly levelled. The mass is covered with clinkers and fast growing shrubs. Over a period of time due to physical, chemical and biological processes in the buried waste matter, heat is generated and anaerobic decomposition of the organic matter takes place, which also destroys pathogens. Thereafter the process cools down and the waste is converted into an innocuous mass by the end of six months of burial. The land could thereafter be used as a green belt or parks could be developed on it.

Notable features: The trenches could also be lined and the filled could be contoured to minimise pollution of soil nearby. Methane gas is generated during the decomposition of solid waste, which is explosive in nature. This land should therefore not be used for construction purposes. Vents could be created in the topsoil cover to release this gas. Dumping of bulky goods such as household equipment should be avoided. These goods could be recycled or incinerated. The method has a drawback that it requires soil cover, which has to be made available at all landfill sites.

Composting : It is a method where in the combined disposal of solid waste is carried out alongwith stable litter, night soil and sludge. Compost is humus like material, which is generated due to the breakdown of organic matter under bacterial action, and is rich manure. Thus the final product of degradation in composting has a recyclable component and the compost could be sold at a price to agriculturists. Composting uses aerobic method of digestion (Fig. - 4).

Pre-treatment : The refuse or solid waste is pre-sorted to remove materials that could be recycled or have salvage value or those ones, which cannot be composted. It is thereafter ground to reduce the waste particle size and this improves the efficiency of decomposition process.

Methods

(a) **Bangalore method :** It was evolved under the auspices of Indian Council of Agricultural Research at the Indian Institute of Science, Bangalore. It is also known as the hot fermentation

process due to the generation of heat in the process to decompose the waste.

In this method long trenches are dug each with a depth of 1 m and width of 1.5-2.5 m. Greater depths is not recommended since they delay the process of decomposition and therefore decrease its effectiveness. The refuse is then placed in the trench at the bottom making a layer of about 15 cms thick. Over this a layer of nightsoil is put to a depth of 5 cms. In this manner alternate layers of solid waste and nightsoil are layered one above the other till the heap rises 30 cms above the ground level. The top layer is recommended to be of refuse of about 25 cms thickness. Thereafter the heap is covered with excavated earth firm enough to not allow a person's legs to sink in the heap while walking.

Fig. - 4 : Composting

Process : The fermentation process begins in a week's time with generation of considerable amount of heat, which stays for 2 to 3 weeks. The organic mass is decomposed and pathogenic microorganisms are destroyed in the process, which is completed in 4 to 6 months. Gases such as ammonia, methane, carbon dioxide and nitrogen produced in the process are released into the atmosphere. The resultant manure is well-decomposed, odourless, innocuous material of high manurial value. The soluble material produced may leach into the underlying or surrounding soil or ground water.

(b) **Mechanical composting :** It is a process in which the compost is manufactured in a short period of time with use of waste materials and night soil. A sorting is done in the initial stages and items such as rags, bone and metal pieces and glass, which are likely to interfere with grinding operation, are removed. The waste matter is then pulverised by mechanised equipment and thereafter mixed with night soil or sludge in a rotating machine. This mixture is then incubated under controlled conditions of pH, temperature and aeration. The compost is ready in 4 to 6 weeks time as humus like material with a total nitrogen, phosphorus and potassium content of 1 to 3 percent. The product thereafter is cured, blended with additives, bagged and marketed.

(c) **Vermicomposting :** It is a method of disposal of kitchen and

plate wastes, which serves the dual purpose of disposing off the garbage as well as proving eco-friendly. Here a suitable area is chosen which is bound by a 2 to 3 feet high brick wall and few hundred earthworms are introduced in it. The waste is dumped in this area and water is sprinkled daily on this dump. The waste matter is broken down by the worms and compost, which could be used as bio-fertiliser, is produced in 2 to 3 months.

The process does not generate any explosive gases or leachate and can be used in agriculture and organic farming. It enriches the soil due to the deep burrowing worms and bacteria in the organic matter. The process could generate green areas and is used in small scale disposal of waste matter.

Notable features : The process of vermicomposting has the advantage of dual disposal of nightsoil and solid waste in a manner that the end product could be reused as organically rich manure. However the process needs training of manpower who are required to handle the mixing and incubation of night soil with refuse and may generate hesitation on their part to be involved in the process.

Effective Microorganisms (EM) Technology : This is a modern eco-friendly technology consisting of use of friendly microorganisms such as phototropic bacteria, lactic acid bacteria, Actinomyces and yeasts. These microorganisms are added to kitchen wastes in specially designed drums. The wastes are converted into compost, which can thereafter be utilised as manure. The EM solutions available commercially are classified into EM 1 and EM 2 categories depending on their shelf life, which varies from 30 days in the latter to 6 months in the former. EM technology also has the advantage of keeping the drains clean by decomposing the sewage and suppressing its bacterial content.

Incineration : This is a process of disposal of solid waste material by thermal technology and has gained popularity in several developed countries. The incinerators use heat recovery process and also have air pollution controls. Incineration is also chosen in those places where suitable land mass is not available. Many industrialised countries are practising this method under strictly controlled environment, with appropriate training to the waste handlers. Waste generated in hospital premises is disposed off in this manner in most countries.

Incineration of waste material is not a useful method for India because of the fair proportion of ash, which is contained in it. The ash contained in the refuse makes its combustion difficult. Hence pre-treatment of the waste material is required, which is expensive and requires heavy infrastructural outlay. Besides this incineration involves wastage of precious bio-fuels and deprives the communities of much needed manure.

Solid Waste Disposal in an Urban Slum

Urban slums comprise a congregation of temporary or semi-permanent structures, which are constructed by the new settlers in an urban area, due to lack of proper housing facilities and in most instances by illegal occupation of land. These settlements usually house people from low socio-economic strata, who are poorly educated and as a consequence show a lack of awareness regarding the hygiene and sanitation issues especially related to solid waste management.

The houses in slums are constructed in rows with a narrow path in between them. The storm drainage system is usually rudimentary and temporarily constructed. The slum dwellers use common toilets and bathing facilities, where the waste water or night soil is connected to the sewers or in certain instances to the larger storm water drains. Disposal of solid wastes in the slums has the following peculiarities :

- Quantity of waste generated is lesser as compared to other areas in the urban locality.
- Solid wastes mostly comprise of used bottles, tins, plastics and ashes, since most of the salvageable items are recycled.
- Animal manure and feeds are a significant part of solid wastes from slums since small farm animals co-habit with humans.
- Vegetable peels and kitchen wastes are discarded in large quantities while the food product packages are not usually a part of the waste matter.
- Slums localities in the various cities also have small-scale or cottage industries, which generate waste materials. Sometimes these industries give rise to hazardous or toxic chemicals such as from the dyeing and tanning industries. Some industries are also engaged in recycling of goods salvaged from the refuse bins. Hence the wastes from these places need to be disposed off properly.
- There is no existing system of door-to-door collection of waste items. The people in the slum community deposit their garbage in the public bins located centrally.
- The roads/paths in the slums are narrow, hence the refuse lorries are unable to negotiate the paths and therefore the waste bins are placed at fewer points.
- The wastes from these bins require more frequent emptying to prevent waste matter to spill over in the ground below and create nuisance.
- Adequate sorting of the wastes take place in the bins located in the slum localities, hence the remaining waste meant for final disposal is non-recyclable matter.

Waste Disposal

Waste disposal in slums is carried out in the same manner as the solid waste, which is disposed from the rest of the municipal locality. The waste bins are placed at the pre-determined points and the community is made aware of the place. The wastes are collected at these sites from the households and these are thereafter taken to the disposal area. Sorting of the wastes is carried out by the rag-pickers at the municipal bins and the recyclable material salvaged by them is sold to informal middlemen. The second stage of sorting by the rag-pickers is carried out at the municipal waste disposal area. The remaining wastes comprise of non-recyclable material, which is easily decomposed by the processes such as sanitary landfill, composting or incineration or any modern day technology discussed in the previous paragraphs.

Solid Waste Disposal in Rural Areas

Rural areas comprise of villages and some temporary nomadic settlements or camps. In the last census conducted in 2001 the rural population in India comprised more than 70% of the total population of the country. The rural economy is primarily

agrarian with the population engaged in cultivating crops or vegetables for selling in the market and for consumption, depending on the nature of farming practised in the area or economic need. Some rural areas also practise poultry farming, fish farming or apiculture. The farm work is steadily becoming mechanised in most parts of the country with machines sowing and harvesting crops throughout the year. As a result of this large amounts of unused parts of the crops or vegetables are generated as wastes, which require regular disposal. Some of the rural areas also have small-scale industries, which produce solid wastes or liquid chemical wastes. These also require disposal in an appropriate manner.

The community residing in the villages comprise of a large population who belong to the lower socio-economic strata. The levels of literacy are lower compared to cities and the health status indicators of morbidity, mortality and natality compare unfavourably with the urban areas. The density of population is lesser in villages, while more number of families live jointly, with all of its members contributing to the family occupation.

Waste generated in the rural areas is lesser in quantity compared to urban wastes. It consists primarily of organic matter from the households or the rural industry such as vegetable peels, crop wastes, manure, fodder, animal feeds, ash and lesser quantities of tins, bottles or paper unless there is a particular industry located in the rural area. Majority of the recyclable wastes are salvaged before disposal to be used in households.

Current disposal methods : In the rural areas at present there is no system of organised collection and disposal of refuse, which is temporarily deposited in a pit or a bin to be disposed later by burning or dumping outside the village or is thrown around indiscriminately. The waste ends up polluting the nearby soil, water and air and at times hazardous wastes from small industries could be harmful to the human life. The local self-governing bodies or the Panchayati Raj Institutions are responsible for maintenance of hygiene and sanitation in the rural areas and they influence the methods of waste disposal.

Methods of disposal

(a) Manure pits : This method of waste disposal could be practised by the individual households in the rural areas. Pits could be dug near the house and the wastes such as kitchen wastes, cattle dung, fodder or animal feeds, leaves could be thrown into them. The wastes should be covered by earth at the end of each day and reused the next day. Two such pits could be dug simultaneously of 1 to 1.5 m and used one at a time. When one pit is filled up it is covered with a top layer of soil and compacted. In 5 to 6 months time, the wastes are decomposed and converted into manure, which could be returned to the fields.

(b) Burial : Burial method of disposal is suitable for disposal of refuse of the village or small settlements. This could be undertaken in an area if sufficient land is available. The method is similar to sanitary landfill and the involves digging a trench 2 m deep and 1.5 m wide in which the refuse from the village or camp is deposited and at the end of the day the refuse is covered with 20 to 30 cms of earth. The disposal continues in this manner till the time the level in the trench is 40 cms from ground level, when the trench is filled and compacted and

a new trench is dug out. The waste matter is decomposed in 4 to 6 months time when it can be taken out and used as manure in the fields. A trench of this size and 1 m long would suffice for 200 persons for a week. The length of the trench could be varied depending on the requirements of the rural area. The method of burial needs to be practised in the correct manner to avoid any rodent or pest nuisance.

(c) Biogas plant : The animal excreta generated in the rural areas are fairly large in quantity and could be utilised to generate bio-fuels and thus be recycled (Fig. - 5). In the rural areas this excreta is mixed with straw to make dung cakes which are used as fuel for cooking purposes.

Animal excreta also carry an enormous potential of fly breeding and thus its sanitary disposal is required. This could be achieved by disposing them in bio-gas plants or through landfills or by composting. Details of biogas plant have already been discussed in the chapter on excreta disposal.

Solid Waste Disposal in Post Disaster Situations

Disasters produce solid wastes in large amounts. Natural or man-made disasters produce debris comprising of soil, building material and green waste such as trees and shrubs. The type and quantity of the waste depends upon the type and magnitude of the disaster. Most of the times the destruction created in the wake of the disasters are of such magnitude that it overwhelms the capacity of the affected community to dispose off the debris.

Solid Wastes during Disasters

These wastes are mostly in the form of debris, which stands for 'the remains of anything that is broken down or destroyed'. Hurricanes leave behind debris made of construction materials, damaged buildings, sediments, green waste and personal property. Earthquakes generate sediment from landslides besides building materials and personal property; the waste material due to fires and explosions may increase the ash and toxic waste contents in the debris. Floods notoriously produce

mud, sediment and sandbags beside the rubble of dismantled houses. The household goods damaged due to inundations are disposed off by the communities. Fire debris also includes charred remains of vehicles, wood, ash and metal objects. In addition to all this, there could be bio-hazardous and radiation wastes due to manmade disasters, which need specialised disposal techniques. Disasters also tend to take a heavy toll of human and animal lives and thus disposal of dead bodies or animal carcasses has to be carried out on priority after identification of the bodies. Post disaster wastes also include the wastes from relief material, which arrives in bulk at the disaster affected sites and have a potential to cause aesthetic nuisance.

Managing Disaster Debris or Solid Wastes

The management of solid wastes after disaster situations must be based on the existing regulations in a community and it must be consulted on all occasions. The cycle of waste management comprising of collection, storage, staging, recycling, disposal, hazardous waste identification and handling, administration and dissemination of information to the public needs to be adhered to ensure efficient disposal of waste matter.

Planning for disposal : Post disaster situations require additional quantity of specialised equipment and supplies such as saws, portable generators, vehicle repair equipment and water storage arrangements. It is important to pre-select temporary debris storage and processing sites at a convenient place to allow the collection crews to reduce travel time when transferring debris to processing or disposal facilities. These sites should be accessible to heavy equipment with low impact on the environment and adjacent housing areas.

Waste management : After the disposal of the dead bodies and the carcasses in a hygienic manner, the task that needs to be carried out next on priority is to dispose off organic matter first. This comprises food wastes, animal feeds, plants and trees, soil, decomposable household goods, waste from the relief materials and manure. The existing methods of sanitary landfill, composting or incineration could be used for this purpose. Equipment are needed to quickly prepare the area for disposal of refuse. Incinerators, which are not damaged, could serve as the best method of early disposal of solid waste in a post-disaster situation.

Large bulk of disaster generated waste matter comprises of building rubble and damaged infrastructure. This could first be removed to a temporary storage site and thereafter be disposed off by landfill, filling up land depressions or for road construction or levelling, after suitable grinding and breaking down to pieces of desirable size. Care should be taken to ensure that no hazardous waste matter is included in this waste bulk. Broken trees, poles, metal roofs, sandbags, cables, packing material from relief goods, which are salvaged, could thereafter be disposed off by selling or reusing them to construct the infrastructure in the affected area.

The local authorities should establish communication strategies to coordinate with the affected communities in implementing disaster plans. Staffing patterns should be improved and they should be trained to handle increased number of telephone calls and requests concerning waste removal. Additional staff would

be required to train and monitor debris collection contractors, enforce disposal restrictions and help solve implementation problems.

Legal Framework : The following acts and rules govern the disposal of solid wastes in India, published by the Ministry of Environment and Forests, which is the nodal Central Govt ministry responsible for the proper disposal of solid wastes :

- (a) Environment (Protection) Act 1986
- (b) Bio-Medical Waste (Management and Handling) Rules 1998
- (c) Municipal Wastes (Management & Handling) Rules 1999

Summary

Solid wastes include rubbish or materials that are not economically useful, present in solid, liquid or gaseous form, which originate from a wide range of human operations, such as industry, commerce, transport, agriculture, medicine and domestic activities. It contains food waste, demolition products, dead animals, manure and other discarded material but should not contain nightsoil. The output depends on the degree of urbanisation, dietary habits, lifestyles and living standards. In most of the countries the per capita daily solid waste produced is between 0.25 to 2.5 kg.

Solid wastes, if allowed to accumulate and not disposed off properly have a tendency to contaminate drinking water sources, favour fly breeding, attract rodents and pests, generate foul odour and inflammable gases and transmit various diseases. Solid wastes could be of different types such as Refuse generated from street sweepings and markets, Rubbish originating in households excluding garbage and ash, Ash which is residue from burning of wood or coal and Garbage including animal and vegetable wastes

The management of solid wastes in a community include (a) waste generation (b) waste handling (c) sorting, storage and processing at source (d) collection (e) sorting, processing and transformation and (f) disposal.

Urban areas produce diverse kinds of waste material from their domestic, commercial and industrial professions/ establishments. Sorting could be carried out at household level, at the community refuse collection site or the landfill site. It segregates the different types of wastes. Collection of wastes could be made by waste handlers at household level, shops and small establishments, while at the community level it could be carried out by hand carts/ tricycles or motorised vehicles equipped with detachable containers of 30 to 40 litres capacity. Wastes collected from the source could be temporarily stored in cement-concrete-cylindrical bins or masonry bins till the time they are taken for final disposal. The waste material could thereafter be transported at regular intervals by Lorries having mechanised equipment to lift and load the bins to take them to the final disposal sites. Final disposal of solid waste is carried out by sanitary landfill, incineration, composting, biogas plant or Effective Microorganisms technology.

Waste disposal in urban slums, is carried out in the same manner as the rest of the municipal locality though the type and quantity of waste generated is slightly different. Waste generated in the rural areas is lesser in quantity and

consists primarily of organic matter from the households or rural industry. The local self-governing bodies or Panchayati Raj Institutions are responsible for maintenance of hygiene and sanitation in the rural areas. The main methods of waste disposal here are manure pits, burial, biogas plants and other technologies such as composting and incineration. Solid wastes during disasters are mostly produced in the form of debris, dead bodies or animal carcasses and wastes from relief material. The management of solid wastes after disaster situations must be based on the existing requirements of the affected community. Additional quantity of specialised equipment and supplies such as saws, portable generators, vehicle repair equipment and water storage arrangements are required in these situations.

Community participation is the key to ensure success in the implementation of solid waste disposal. To ensure that community participation is optimum, strong and sustained Information, Education and Communication programme needs to be adopted. The acts and rules governing the disposal of solid wastes in India, published by the Ministry of Environment and Forests are Environment (Protection) Act 1986, Bio-Medical Waste (Management and Handling) Rules 1998 and Municipal Wastes (Management & Handling) Rules 1999.

Study Exercises :

Long Questions : Enumerate the health hazards due to improper Solid waste disposal and describe the methods for solid waste disposal in an Urban area.

Short notes : (1) Solid waste disposal in an Urban Slum (2) Solid waste disposal in a rural area (3) Sanitary landfill (4) Incineration (5) Composting

MCQs :

1. Waste paper is an example of (a) Refuse (b) Rubbish (c) Garbage (d) none
2. A method of selecting depressed areas or creating artificial trenches where waste matter is thrown and compacted with a layer of earth on top of it is (a) Manure pit (b) Controlled tipping (c) Burial (d) Dumping
3. Bangalore method of Composting is a type of (a) Aerobic (b) Anaerobic (c) both (d) none
4. Bangalore method of refuse disposal is not recommended for population above (a) 100,000 (b) 200,000 (c) 300,000 (d) 400,000
5. Dual disposal of nightsoil and solid waste is seen in (a) Manure pit (b) Controlled tipping (c) Composting (d) Sanitary landfill
6. The method of solid waste disposal which is not ideal/feasible for rural setup is (a) Manure pit (b) Biogas plant (c) Burial (d) Mechanical composting

Answers : (1) b; (2) b; (3) b; (4) a; (5) c; (6) d.

Kunal Chatterjee

Biomedical waste could be defined as “any solid, fluid or liquid waste, including its container and any intermediate product, which is generated during the diagnosis, treatment or immunisation of human beings or animals, in research pertaining thereto, or in the production or testing of biologicals and the animal waste from slaughter houses or any other like establishments”. As per the Biomedical waste (management and handling) rules 1998, under the Environment Protection Act of India, proper management of biomedical waste is a statutory requirement and these rules have been elaborated in the Gazette notification of the Ministry of Environment and Forests, Govt of India dated 20 Jul 1998.

Majority of the waste generated in a health care establishment is non-hazardous waste of general nature. It is comparable to domestic waste and is produced due to administrative and house-keeping functions of these establishments. Almost four-

fifths of hospital wastes comprise this category of general waste. The rest 20 percent of health-care waste is hazardous and could be infectious, toxic or radioactive and cause significant risk to the health of community members.

How do we Classify Biomedical Waste?

The Ministry of Environment and Forests of the Govt of India, in exercise of its powers conferred under the Environment Protection Act 1986, have categorised these biomedical wastes for the purpose of safe disposal, as given in the Table -1.

Quantity of Biomedical Waste Generated in Health Care Settings

The quantity of waste generated in a hospital would direct its waste management policy and is dependent upon the type of hospital and the health problems, hospital policies and practices followed and the nature of patient care provided in them. The reports available from developed countries indicate that this quantity is equal to 1 to 5 kg/bed/day with variations among countries, hospitals and specialities. In India, from the data available from regional or local studies, it is presumed that most hospitals generate roughly upto 1 to 2 kg/bed/day of biomedical waste. This quantity varies between Government

Table - 1 : Classification of Biomedical Wastes	
Waste category	Waste Class
Cat. No. 1	Human Anatomical Wastes
Cat. No. 2	Animal Wastes
Cat. No. 3	Microbiology and Biotechnology wastes
Cat. No. 4	Waste Sharps
Cat. No. 5	Discarded medicines and Cytotoxic drugs
Cat. No. 6	Soiled wastes include items contaminated with blood, body fluids such as cotton, dressings, linen, beddings etc.
Cat. No. 7	Solid wastes i.e. waste generated from disposable items other than sharps such as tubings, catheters, IV sets.
Cat. No. 8	Liquid wastes
Cat. No. 9	Incineration ash is generated of any biomedical waste.
Cat. No. 10	Chemical wastes

and private health care establishments. Most studies in India also inform that the waste generated contains less disposable material like rubber tubes, plastics etc. Most of the waste generated in a hospital (around 85%) is non-hazardous, while 10% are infective including sharps and pathological waste and the remaining 5% are non-infectious but hazardous such as chemical, pharmaceutical or radioactive wastes.

Principles of Control of Hazards of Biomedical Waste in Health Care Establishments

The biomedical wastes generated in a health care setting could be rendered safe by following certain principles of infection control as described :

- Each institution should develop its own *biowaste management policy* and ensure that the health care workers are adequately trained to handle biological waste.
- Measures such as *universal safety precautions, hand washing* and *proper segregation* of waste material should be encouraged.
- Rationale *patient management policy* should be followed and admissions restricted to those for whom it is felt absolutely necessary, to reduce incidence of hospital acquired infections.
- Proper *house-keeping* is essential and the hospital premises should be kept clean and well-ventilated.
- Use of *disinfectants* should be rationalised.

Steps in the Management of Biomedical Waste

The biomedical waste generated in a health care establishment is required to be disposed in an appropriate manner to prevent health hazard to the health care providers and the general community. As a pre-requisite to a good hospital waste management plan, it is essential to ensure the availability of safe and reliable supply of water, sanitation facilities, maintenance of cleanliness and demarcation of vital areas that need stricter sterility norms. After ensuring the availability of these basic facilities, the steps discussed below should be followed for management of biomedical waste :

(a) Survey of waste generated : A survey of waste generated in a health care establishment determines the quantity, type and source of waste generation inside the premises. It also

finds out the level of disinfection in a hospital and gives an insight to the disposal practices being followed by the hospital staff. In this manner proper attention could be given to dispose of all categories of waste safely with least harm to the environment and also provide specific training to providers to correct improper waste disposal practices.

(b) Segregation of hospital waste : Segregation could be defined as 'separation of different types of wastes by sorting'. It denotes the process where wastes of different types, hazardous nature and consistency are separated such that special attention could be given to their disposal. This ensures that the associated risks and the costs of handling the relatively smaller quantities of infectious and hazardous wastes are kept minimal. Accordingly, the non-hazardous waste, which is of general nature and disposed off with municipal garbage, could be dealt with less harm to health care providers and waste handlers. Therefore the best course of action is to segregate the wastes into various categories at the source/point of generation itself. This activity is best undertaken by the 'generator' of the biowaste that is the health care provider himself. The waste categories need to be segregated as per the categories described earlier. This categorisation should be displayed at such locations that most of the people i.e. patients, providers and attendants benefit from it. It would be of more benefit to prepare these instructions in the local languages.

(c) Collection & Categorisation of waste : This step in the waste management integrates into segregation of biomedical wastes. The wastes generated need to be collected in proper containers such as sputum mugs, urinals, plastic containers for sharps and so on. It is a good practice to colour code the containers holding different types of hospital waste (Table-2).

In such instances where the detailed colour coding system is not feasible on account of low level of training among the waste handlers it is preferred to use at least three colour codes for ease of understanding. These are -

- Green for general waste (non infectious)
- Red for infectious waste (microbiological, anatomical, pathological and soiled linen)
- Yellow for sharps, plastics and disposables

Table - 2 : Colour coding and type of containers for disposal of Biomedical waste

Waste category	Type of Containers	Colour code
Category 1	Plastic bags	Yellow
Category 2	Plastic bags	Yellow
Category 3	Plastic bags/ disinfected container	Yellow/Red
Category 4	Puncture proof plastic containers	Blue
Category 5	Plastic bags	Black
Category 6	Plastic bags/ disinfected containers	Yellow/Red
Category 7	Disinfected containers/ puncture proof containers	Red/Blue/White
Category 8	Not applicable	Not applicable
Category 9	Plastic bags	Black
Category 10	Plastic bags (for solids)	Black

Besides this colour coding, the categories of waste to be disposed should also be mentioned on the containers. If reusable bins/containers are used then they should be cleaned/disinfected properly before being used again. The containers should be of the correct size to hold the desired quantity of waste and devoid of sharp edges for ease of handling. The colour coded containers need to be located at the point of generation of wastes to ensure proper segregation at the source itself.

(d) Storage of waste : It means the 'holding of biomedical waste for such period of time, at the end of which waste is treated and disposed of.' The wastes, which are generated in a health care establishment, should ideally be disposed off immediately. However if there is a chance that the waste needs to be stored at some place as per hospital policy, then the place should be safe from tampering and access to rag-pickers. In most instances it is seen that the wastes are stored near the municipal dump pending final disposal and generally the hospitals shake their responsibility off it. This happens more often when the waste disposal is outsourced to a contractor and creates a potentially hazardous situation, due to unscrupulous elements picking up these wastes and recycling them. It is thus absolutely essential that no biomedical waste is stored at any place where it is generated, beyond a period of 48 hours. During the storage period the waste must not be allowed to decay or putrefy.

The storage containers should have the following characteristics -

- They should be made of sturdy, hard plastic or metal and should be leak proof and puncture proof.
- They should be of adequate size to avoid overflow with a secure lid and handle and should be colour coded.
- They should not be easily destroyable by rodents & should have smooth, rounded surfaces to hold plastic bags.
- Plastic bags should be large, sturdy and leak proof with no tears. They should line the complete storage bin from

inside and some portion should be outside.

- In case the wastes need to be incinerated along with plastic bag then the bags should be made of non-chlorinated plastics, to avoid environmental pollution.
- Bags should be colour coded, labelled and marked with a biohazard symbol (Fig. -1).
- The storage containers holding sharps, besides being leak proof, should also contain appropriate disinfectants such as sodium hypochlorite solution.

Fig. - 1 : Biohazard symbol

Storage area

- The storage area should be earmarked and protected from all sides. It should have a clear warning sign and accessible to only authorised persons.
- The facility should have adequate storage space for at least two days with a robust construction and proper drainage system.
- Radioactive wastes should be disposed off separately, in a demarcated area and labelled properly.
- The timings of waste collection should be fixed for specific areas and all the containers should be regularly cleaned and disinfected before reuse.

Biohazard symbol should be used as label on all containers and vehicles meant for storage and transportation of waste.

(e) Transportation of waste : Transportation is the vital link between the site of waste generation and the final disposal point. It involves movement of the waste generated from the source to interim storage site and its final disposal as per its category. While being transported, it should be secured from the public as well as waste handlers, who have inadequate knowledge of the waste and could be exposed to unnecessary risks. The vehicle used for transportation should be able to achieve the task with minimal effort, spillage or disturbance to the waste. Usually the health care establishments utilise push carts, waste trolleys and wheelbarrows to transport waste inside the hospital premises. Outside the hospital cycle rickshaw or waste van/lorry is used to transport the biomedical waste to its final site of disposal. It should be ensured that the transport used is of robust construction, has adequate space, is leak proof and covered. It should also not allow the mixing of hazardous and non-hazardous waste materials and the frequency and timings of transport should be informed to all sites of generation of waste in a health care establishment. The hospital authorities should keep proper documentation of the frequency of waste transportation.

(f) Technologies for waste treatment : Biomedical waste is treated before its final disposal to reduce its bulk and make it free from pathogenic organisms. Treatment changes the physical, chemical or biological characteristics or composition to render the waste non-hazardous to health and environment. The different types of waste treatment technologies are chemical

disinfection technology, thermal technology, mechanical technologies and irradiation technology. These are described as follows :

(i) Chemical disinfection Technology : It uses chemicals to destroy pathogenic organisms from any inanimate object. Generally the infectious wastes generated in a health care establishment are treated with this method. This method is used to treat the following wastes (Table - 3).

- Sharps contaminated with blood and body fluids
- Instruments, equipment that are used to cut, pierce or enter the natural orifices like needles, syringes and endoscopes
- Contaminated floors, surfaces, clothes, beds, beddings, enamel, crockery and bed pans
- Wet mopping of intensive care units, operation theatres, wards and patient waiting areas.

Table - 3 : Recommended concentration/dilution of Chemical disinfectants

Disinfectants	Contaminated condition	Grossly contaminated condition
Sodium hypochlorite 5% available chlorine as liquid bleach	20 ml/L	200 ml/L
Calcium hypochlorite 70% available chlorine	1.4 gm/L	7.0 gm/L
Sodium dichloro- isocyanurate powder	1.7 gm/L	8.5 gm/L
Chloramine 20% available chlorine	20 gm/L	20 gm/L
Tincture of Iodine/ Povidone Iodine	2.5%	2.5%
Ethyl alcohol	70%	70%
Isopropyl alcohol	70%	70%
Glutaraldehyde 2%	2.5%	2.5%
Formaldehyde 40%	5%	10%
Savlon	5%	10%
Dettol 4.8% v/v	4%	10%
Cresol	2.5%	5%

Notes : The choice of disinfectants would depend on factors such as effectiveness, availability and the cost considerations. A contact period of 30 minutes is required for effective disinfection by the disinfectants. Plastics, rubbers and metals could be treated by chemical disinfection, but not all instruments/ waste should be treated in this manner. Some of the waste materials require further disposal after chemical disinfection such as blood, secretions, excreta and body fluids, which have been spilled. It should also be ensured that the wastes, which are to be incinerated, are cleaned of chemical disinfectants, especially halogen compounds to avoid environmental pollution.

(ii) Thermal technology : It uses heat to decontaminate instruments and equipment and the temperatures in this process may rise to extremely high levels. Most of the microbes are destroyed at temperatures below 100°C. Thermal technologies could be broadly classified into two groups depending upon the range of temperatures used in the process. There are the low heat systems operating at temperatures below 150°C and high heat systems where temperatures could go upto 5000°C. The

former uses steam or hot water while the latter uses plasma torches or combustion pyrolysis to destroy the waste material. Thermal technologies include autoclave, hydroclave, microwave and incinerators.

Autoclave : This is a low heat process in steam at high temperatures is brought into contact with microorganisms for a specified period of time, to disinfect the waste matter completely. Autoclaves are used for sterilisation of reusable medical instruments, microbiology cultures and stock solutions (Fig. -2). The autoclaves used for biomedical waste management are of the following types :

- Gravity displacement type - where air is pushed out of the autoclave by steam under pressure. This system operates at temperatures of 121°C and has a cycle time of approximately 60 - 90 minutes. The material to be sterilised is packed inside and the steam needs to penetrate into the waste wads to ensure effective sterilisation. The system has its disadvantage that there may be pockets of air left within the waste layers, which may reduce the temperatures attained inside thus reducing efficiency of the system.
- Prevacuum type - here vacuum pumps are utilised to evacuate the air in the chamber of autoclave and steam under pressure is pushed in, which is able to penetrate the waste material more thoroughly. This technology thus reduces the cycle time to approximately 30 - 60 minutes and the temperatures attained are upto 132°C.

Fig. - 2 : Autoclave

Infectious wastes and bags are placed in the sealed chamber and exposed to the steam at required temperature and for a specified holding time. The wastes are reduced in volume minimally and the contaminating organisms are destroyed after the holding time period. The treatment process is monitored by placing spores of *Bacillus stearothermophilus* at the centre of waste load and checked.

Notes : The process has the advantage of having low operating costs, with minimal or non-toxic liquid or air emissions. However the waste volume is not completely reduced and certain categories of wastes such as cytotoxic or pathological wastes cannot be treated through this method. Moreover at times malodorous fumes are generated which need to be controlled. This method could be combined with shredding, grinding or compacting to reduce the volume of the waste material substantially.

Hydroclave : This is a steam sterilisation technology in which the steam is used as an indirect heating source thus allowing total dehydration of waste material.

Fig. - 3 : Hydroclave

The hydroclave (Fig. - 3) essentially comprises of a double-walled cylindrical container, which is horizontally mounted and has doors at the top and bottom for loading and unloading waste matter. In addition it has mixing arms inside the container that rotate to fragment the waste material. When steam is introduced into the outer jacket/wall it transmits heat rapidly into the wet waste inside the inner chamber. The waste matter is continuously subjected to tumbling motion by the motor mounted mixing arms whereby it produces its own steam and the pressure inside the chamber begins to rise. More steam is introduced from without to achieve the desired temperature and pressure. The holding time for waste is 15 minutes at 132°C or 30 minutes at 121°C. This continuous mixing ensures dehydration of the waste material and almost total dryness can be achieved inside the chamber. The organic components of the waste are hydrolysed and the waste matter is reduced by weight and volume. It has a mechanism of self-unloading after the treatment cycle, by opening the bottom door and reversing the rotation of the mixing arms. The mechanism has the advantage

of not requiring any pre-treatment of waste and complete dehydration of waste is achieved. The reduction in volume and weight makes it easy for final disposal of biomedical waste and the capital costs are low. However this mechanism also gives out malodorous fumes and certain pathological and cytotoxic wastes cannot be treated with this method.

Microwave : This low heat system uses microwaves to heat up the waste material from inside, unlike the external heat given in autoclave and hydroclave. Microwaves are electromagnetic waves that lie between the 300 to 300,000 mega hertz range in the electromagnetic radiation spectrum. They are able to penetrate materials and create vibrations in all the dipole molecules such as water in the waste materials. This vibration generates friction, which in turn produces heat to disinfect the waste material (Fig. - 4).

Fig. - 4 : Microwave

The waste matter is loaded manually on to a bucket hoist, which loads it into a sealed unit with a shredder, where the waste alongwith its bag is shredded and thereafter moistened with steam. This is then moved continuously by a screw auger, which is heated by series of microwave generators. The heat produced at 95 - 100°C for a holding period of 25 minutes kills all microorganisms without decomposing the material. Emissions are thus reduced and the air inside the microwave is passed through filter to eliminate potentially hazardous airborne pathogens. Wastes such as tubings, needles, syringes are rendered harmless and reduced in volume by 80%. These could then be used as landfill.

Notes : The process of microwave treatment renders waste matter acceptable for landfill. The water emissions are negligible; however air emissions are somewhat odorous. It requires a shredder for pre-treatment of waste and the microwaves are unable to penetrate large objects such as amputated limbs and specimens, which are part of anatomical wastes. The operational costs are high and skilled operators

are required.

Incinerator : Incineration is a high heat system process of burning combustible solids at a very high temperature in a furnace. It employs combustion of waste material in stages, followed by cleaning of the flue gas through a number of pollution control devices. The end product is devoid of infectious organisms and organic compounds of waste, which is aesthetically acceptable (Fig. - 5).

Fig. - 5 : Incinerator

Classification : Incinerators are classified into different types depending on the type of fuel consumed, stages of incineration process and mechanism of action. Based on the type of fuel consumed the division could be -

- Conventional incinerator using wood/charcoal
- Electrical incinerator
- Oil fired incinerator using some electricity and diesel oil

Currently the incinerators used are mostly of oil fired variety. This is almost maintenance free, quick to operate and almost smoke free. The incinerators could also be divided into stage I, II & III depending on the incineration process. Stage I involves thermally combusting the waste at temperatures above 800°C in a refractory lined heated chamber. This stage of combustion generates some volatile chemicals. The stage II incinerator is made of special refractory material and uses excess additional air to raise the temperature inside it to 1050 - 1100°C. This destroys the pathogenic organisms alongwith all chemicals/volatiles produced during stage I including harmful gaseous by products like dioxins and furans. Stage III incinerator uses venturi scrubbers, fabric filters, activated carbon and packed bed towers to eliminate polluting gases such as carbon monoxide, HCl, oxides of nitrogen and heavy metals such as mercury.

The hospital wastes that can be incinerated are :

- Surgical, autopsy and obstetrical wastes containing human or animal tissues.
- Dialysis, contaminated ward waste and isolation room waste.
- Blood and its products and microbiological wastes.

Notes : All materials of infectious nature are destroyed by incineration. The volume and mass of the waste material is reduced upto 80 - 95% thus ensuring safe final disposal. No pre-treatment such as shredding is required. However incineration process could give rise to air emissions of toxic materials such as particulate matter, acid gases, dioxins and furans. High operational costs and level of skill to operate the system is required. Certain radioactive wastes and aerosols containers cannot be incinerated.

(iii) **Mechanical Technology** : This technology is generally used to change the physical form and characteristic to enable ease of handling of the waste. This technology involves pulverising, compacting or shredding of waste matter to reduce its volume and weight. However this technology cannot be used of its own as final means of waste treatment, but has to be combined with other technologies especially thermal technology. Typically, these processes are carried out either before or after the waste has been decontaminated and are as under :

Compaction : Compacting is carried out by a hydraulic ram against a hard surface. Infectious content of waste is not reduced, while the possibility of formation of aerosols of infected matter and spillage of liquids does exist. Also, the process destroys the integrity of containers and requires skills to operate and maintain machines.

Grinding and shredding : Waste material is broken down into smaller particles under negative pressure to avoid any spillage outside the chamber. This method is used as a pre-treatment before technologies such as microwave and reduces the waste volume and renders it unrecognisable.

Pulverisation : This method consists of putting the waste in a hopper and mixed with large volume of water and bleach solution. The waste is torn to shreds and then fed to an ultra high speed hammer mill with large spin blades which pulverise the matter into small, safe particles. The solids and liquids are then separated and disposed off.

(iv) **Irradiation technology** : This involves exposing the waste matter to ultraviolet or ionising radiation in an enclosed chamber. Decontamination occurs when nucleic acids in the living cells are irradiated. The time of exposure, directness and level of relative humidity in the waste matter determines the efficiency of the procedure. The wastes are reduced by 20% in volume and the disinfected remains could thereafter be mechanically broken down and disposed off in landfill sites. The advantage with this technology is that energy input is minimal and it is used to treat items, which cannot be heated. The emissions are low however trained operators are required for this operation. The wastes need further treatment by another technology prior to disposal. Source of radiation also needs to be properly disposed off after its decay.

How to select a treatment technology : The health care establishments have to establish a fine balance between optimum use of consumable material/ disposables and selection of appropriate waste treatment technology. This selection would depend on the categories of waste generated, type of equipment/technologies available on-site and off-site and the appropriateness of the selected technology for a particular waste matter. Disinfection efficiency, automated system, reduction of waste volume/ weight and recovery of recyclable products should be primarily considered. The selected technologies should have minimal polluting effect, discharges and emissions should be low and operational and fuel costs must be low. Usually incineration and autoclaving are the most widely used technologies, the former for anatomical wastes and latter for other infectious wastes, which are not incinerable.

(g) Final disposal methods

General non hazardous wastes : These could be disposed off by landfilling at sites away from water sources and dwelling units and covered with suitable cover material. The site should be delimited with secure fences and sign postings. The sites could be trenches, sloping terrains or abandoned quarries. Mechanised equipment could be used for spreading the waste and trimming the top soil. Composting using night soil along with the biowaste could be used in trenches and vermiculture methods for garbage from kitchen and cafeteria could also be used. Large quantities of general wastes could be disposed using technologies, which convert the biodegradable wastes into fuel pellets, incinerable matter or biogas.

Liquid wastes : Liquid wastes from kitchens, cafeteria and laundry should be treated with a chemical disinfectant followed by neutralisation with reagent. The waste should thereafter be discharged into the sewerage system. In places with no sewerage system, the treated liquid wastes could be drained into soakage pits or waste stabilisation ponds.

Human anatomical wastes : These should be incinerated and thereafter the ash can be sent to landfill sites.

Sharps : These have the maximum chances of causing injuries due to mishandling and hence need precaution and care during disposal. They are stored in puncture proof containers in disinfectant solutions (e.g. plastic bread boxes), at the site of generation. Major portion of the sharps are needles, which can be cut by needle cutter and contained in 1% bleach solution or destroyed by needle destroyer. Some of the precautions in handling sharps are :

- The health workers employed in the hospital should be vaccinated against Hepatitis B
- Infectious waste handlers should wear heavy duty gloves while dealing with waste matter
- Recapping of needles should be discouraged. Sharps should not be carelessly put at place of work.

After this treatment the residual waste could be sent to a landfill for disposal.

Microbiology waste : This is disposed by autoclave, hydroclave, microwave or incineration. The residue could be used in specialised landfills.

Infectious solid waste : This is treated by an appropriate thermal technology method and disposed off as general waste.

Chemical waste : Chemical waste of non hazardous nature could be disposed off as general wastes or recycled/ reused. Hazardous waste should be treated and discharged into sewers after dilution or incineration.

Radioactive waste : These are generated in the Nuclear medicine, Radiotherapy or Radiology departments need to be disposed according to guidelines laid down by the Bhabha Atomic Research Centre, India. Checks also need to be carried out in these establishments for radiation emission, use of protective gears and maintenance of equipment. The solid wastes are disposed by concentration and storage, while liquids by dilution and dispersal.

Pressurised containers : These should be disposed off alongwith general waste, in special landfills.

Administrative issues

Effective hospital waste management is possible when all the components of an organisation are well trained, aware and actively supportive of the programme.

Waste Management Policy

All health care establishments should have a comprehensive waste care management policy. The hospital administrators, safety and infection control committees and departments such as nursing, housekeeping, laboratories and maintenance need to be more involved in the waste management activity. The general hospital waste management policy should serve as a mission statement, to inform regulatory and other agencies how the hospital's waste is managed. It should give an overview of the programme while the different departments need to prepare their specific procedures.

The hospital/health care establishment waste management policy should be in consonance with the existing guidelines on the subject by the regulating authority, i.e. the Biomedical Waste (Management and Handling) Rules, 1998 of the Ministry of Environment and Forests, Govt of India and should cover the following aspects :

- (a) A background survey and evaluation of waste generated should be conducted prior to implementation of waste management policy guidelines. Suitable places for placement of equipment should be identified and equipment, materials and supplies procured based on the requirement.
- (b) A Hospital Waste Management Committee could be created, especially in large hospitals. Its members could be Head of hospital, Infection Control committee members/ their representatives, Heads of certain Departments, Chief of nursing staff and representatives from ancillary and support services.
- (c) In smaller hospitals a nodal officer could be identified as in-charge hospital waste management. Key members from the hospital could be designated to assist the nodal officer in discharge of his/her duties.
- (d) The role and functions of each of the member of the hospital waste management committee should be clearly and lucidly defined. Periodic meetings could be held of the functionaries to ascertain the progress of implementation of policy, hear suggestions and discuss any change of plans.

- (e) The steps of waste management for the hospital/ health care establishment alongwith the actions of the various departments should be clearly described in the policy.
- (f) Training of staff on the issues related to hospital wastes and generating awareness regarding the vision and mission of the establishment are critical to the success of the programme.
- (g) Supervision of waste handlers and periodic reinforcement of training is required for efficient and safe management of hospital wastes.

Summary

Biomedical waste is defined as “any solid, fluid or liquid waste, including its container and any intermediate product, which is generated during the diagnosis, treatment or immunisation of human beings or animals, in research pertaining thereto, or in the production or testing of biologicals and the animal waste from slaughter houses or any other like establishments”. If it is not handled or disposed with proper care, it could be potentially hazardous and have significant public health consequences. Most of the wastes generated in a hospital (around 85%) are non-hazardous, while 10% are infective including sharps and pathological waste and the remaining 5% are non-infectious but hazardous such as chemical, pharmaceutical or radioactive wastes. The quantity of waste generated in a hospital in developed countries is 1 to 5 kg/bed/day with variations among countries, hospitals and specialities and in India; it is upto 1 to 2 kg/bed/day. As per the Biomedical waste (Management and Handling) rules 1998, under the Environment Protection Act of India, proper management of biomedical waste is a statutory requirement and these rules have been elaborated in the Gazette notification of the Ministry of Environment and Forests, Govt of India dated 20 Jul 1998.

As per WHO, the biomedical wastes could be classified into eight categories on the basis of the type of waste and the risk of transmission of infectious material in them. They are General waste (domestic), Pathological, radioactive, Chemical, Infectious, Pharmaceutical wastes, Sharps and pressurised containers.

The biomedical wastes generated in a health care setting could be rendered safe by following certain principles of infection control like developing policies for bio-waste management as well as rationale patient management; by taking measures such as universal safety precautions, hand washing and use

of disinfectants and most importantly by reduction and proper segregation of wastes. The important steps to be followed for management of biomedical waste are survey of wastes generated; segregation of the hospital wastes at the source itself; collection & categorisation of waste into colour coded containers; storage of wastes for short period of time till the time of transportation in proper containers and in earmarked areas, displaying the biohazard symbol; transportation of waste to the final disposal point in proper vehicles by earmarked staff with protective gear; treatment of waste before its final disposal to reduce its bulk and make it free from pathogenic organisms by chemical disinfection, thermal technology (like autoclave, microwave, UV, IR and incinerators), mechanical technology or by irradiation and final disposal of the waste by incineration or by disposing off in a secured landfill.

Study Exercises

Long Question : Describe the procedure of Biomedical waste management in a 100 bedded hospital / health care setting.

Short Notes : (1) Biomedical waste categorisation (2) Segregation of Waste (3) Final Disposal of Biomedical wastes (4) Incineration (5) Hazards of Biomedical waste

MCQs

1. The percentage of Biomedical waste generated in a hospital which is non-hazardous is (a) 85% (b) 50% (c) 25% (d) 15%
2. The quantity of waste generated in a hospital in developed countries is (in kg/bed/day) (a) 10-15 (b) 5-10 (c) 1-5 (d) >30
3. According to the categories of bio-medical waste, waste sharps come under which category? (a) 3 (b) 4 (c) 5 (d) 6
4. According to the categories of bio-medical waste liquid waste comes under which category? (a) 8 (b) 7 (c) 5 (d) 6
5. According to the categories of bio-medical waste incineration ash comes under which category? (a) 8 (b) 7 (c) 9 (d) 10
6. The recommended treatment option for disposal of bio-med wastes with colour-coding of Black is (a) Secured Landfill (b) Incineration (c) Chemical Disinfection (d) None
7. Category of bio-med wastes that is not colour-coded as Black (a) 5 (b) 8 (c) 9 (d) 10

Answers : (1)a; (2)c; (3)b; (4)a; (5)c; (6)a; (7)b.

Kunal Chatterjee

House, as per the New Oxford Dictionary, is defined as a building for human habitation, especially one that is lived in by a family or a small group of people and consists of a ground floor and one or more upper storeys. Housing is described as houses and flats considered collectively. For the purpose of public health aspects, housing would also include adjacent walks, paths, streets, open space, shops, utilities, health centres, schools and administrative services. The density of population in an area, number of persons per room and physical condition of the dwellings are also considered when the effect of housing on the health of a community is taken.

The last two centuries have seen a rapid rise in industrial economies in the World with consequent changes in the distribution of population resulting from migrations, movements, establishment of new settlements and temporary camps in different countries. The increase in number of people results in increase in demands on the local civic amenities. Public health infrastructure in cities is unable to cope with this rise alongside the natural rise in the population residing in it. Population movements thus result in overcrowding, uncontrolled settlements and poor environmental conditions in the urban areas.

Housing Conditions in the World

Developing Countries : Most of the developing countries have a problem of overcrowding and the living conditions are inadequate, forcing the urban dwellers into periurban slums. Cities in Southern and south-eastern Asia, African continent and Latin America variously have deplorable living conditions in these slums, which lack the basic housing and sanitation facilities. As a result of these conditions compounded by malnutrition, lack of education and inadequate medical and social services, communicable diseases become the predominant cause of morbidity. The plight of the vulnerable groups in these slums such as the children, elderly and women is terrible with the health care indicators grossly unsatisfactory. Infant mortality rates are high, high crime rates and other malevolent behaviour are often seen in the community and children may be abandoned by the parents due to poverty. These places are also the ideal grounds for breeding social unrest.

Developed Nations : In the recent decades the numbers of people without adequate shelter have increased even in the developed or relatively affluent countries. Rising economic costs of living, unemployment, inflation of commodity prices have created hard times for people in these countries and forced them out of their homes. The developed countries and their public health departments have to increasingly spend on the creating shelters and provide for such people. When these social safety nets are broken or wilt under pressure of increasing destitute population, the vulnerable people suffer the most and are turned homeless. These nations also have a problem of migrants or refugees pouring in from neighbouring

countries thereby affecting the already groaning public health infrastructure. As a consequence to this, a rise in mental health problems, substance abuse, alcoholism and crimes is noticed. Rising land prices and the need to provide accommodation for all its dwellers have also seen a proliferation of high-rise, high-density apartments. These create problems such as tensions attributable to living too close to neighbours, inadequate playing space for children and poor civic services in these areas.

Displaced Populations : The refugee population and the internally displaced people live in temporary settlements in developing countries. They depend on civic services of the nearby areas, which are themselves below par. Countries in Asia, Latin America and Africa are home to millions of refugees who have arrived due to displacement resulting from natural calamities, civil strife or wars. Their housing conditions are worse than periurban slums with inadequate health services, precarious supplies and poor record of safety and security of these people. The refugee population are often threatened by hostilities and suffer from various communicable diseases prevalent in poor camp living conditions. The children and vulnerable people exhibit signs of malnutrition and stress disorders due to trauma of displacement.

Housing Standards

Housing standards vary from country to country and are not confined to merely calculating the per capita space and floor space. Socio-economic characteristics such as family income, family size, composition, living standards, and cultural factors are also taken into consideration in determining housing standards. The Environmental Hygiene Committee has established minimum standards required to be maintained by building regulations in India, of which the important ones are:

Site - elevated, not subject to flooding, away from vector breeding places and nuisance, soil should be dry and safe for founding the structure. Subsoil water should be below 10 feet.

Set back - as open space around house with no obstruction to lighting and ventilation

Floor - pucca, impermeable, easily washable, smooth and free of cracks and crevices and damp-proof.

Walls - reasonably strong, low heat capacity, not easily damaged and should not harbour rats or vermin

Roof - height not less than 10 feet with low heat transmittance coefficient

Rooms - at least two with the number increasing according to family size

Floor area - should be 100 sq. ft for one person and at least 120 sq ft for more than one person

Cubic space - at least 500 c.ft per capita; optimum is 1000 c.ft.

Windows - at least 2 windows per living room if the room is not provided mechanical ventilation and artificial lighting, placed at a height of not more than 3 feet above ground, window area should be 1/5th of floor area.

Lighting - daylight factor exceeding 1% over half floor area.

Kitchen - should be separate for every dwelling, protected against dust and smoke, provided with storage space, water supply, drainage and adequately lighted.

Sanitary privy - in every house and readily accessible.

Garbage and refuse - should be removed daily and sanitarily disposed.

Bathing and washing facilities - should be exclusive to the house.

Water supply - should be safe and adequate.

Rural Housing Standards : At least two living rooms, ample verandah space, built up area should not exceed one-third total area, separate kitchen with paved sink or platform for washing utensils, sanitary latrine in the house, sanitary well or tube well within quarter mile of house, cattle sheds at least 25 feet from dwelling houses and adequate arrangement for disposal of waste water, refuse and garbage.

Housing Standards for Displaced Populations : Temporary shelter in existing buildings should be provided to people as per the following guidelines :

- People living on beds or mats should have minimum of 3.5 sq. m of floor area or 10 cu m of air space.
- Beds or mats separated by a minimum distance of 0.75 m.
- Buildings should have emergency exits and fire escapes and people educated in fire safety drills.
- One wash basin provided for every 10 people, separate benches for men and women.
- One shower head is needed for every 50 people in temperate climates and one for every 30 people in hot climates.
- Water flushed toilets may be made available in existing buildings. Outside latrines should be located within 50 m of the building, but at least 20 m away from kitchen, dining hall and water supply.
- One refuse bin of capacity 50-100 litres with tightly fitting lid should be provided for every 12-15 people.

The guidelines for those people who are housed in tents or makeshift shelters are as below :

- Site should be located above flood level and away from excessive vegetation
- Camps should not hold more than 10000-12000 people.
- Drainage ditches should be constructed to drain rain water away from shelters and storage areas. Stagnant water collections should be drained or filled up.
- Shelters should be arranged in rows of 10-12 on both sides of road, at least 2 m away from road edges. The road should be at least 10 m wide for easy access of vehicles and distance between tent pegs should be 8 m.
- Tents or prefabricated units could be used as shelters. Where plastic sheets are used, one piece 4 metres by 6-7 metres should be provided to one household.
- No one should have to walk more than 500 m to water point and there should be at least one water point for every 250 people.
- At least one toilet should be provided per 20 people with separate provisions for men and women. Requirement of children and elderly should be accordingly catered for suitably.

- Accommodation arrangements should be separately catered for children, with provision for adults to stay with them. These children may be disoriented and frightened and may have special nutritional needs, which should be adequately looked after. Feeding and nutrition rehabilitation units for special needs should be provided with up to 15-30 litres of potable water per bed per day.

Housing and the Governmental policy : In India the National Family Health Survey (NFHS) collects data on housing condition of people. The data from NFHS 3 shows that only about 26% of rural India lives in pucca houses, with only 28% having access to piped drinking water and 26% have access to toilet facilities. While housing is a state subject but the Union Govt formulates policy for housing especially pertaining to weaker sections, and the schemes are implemented at the state level. A separate Ministry of Works and Housing has been created as early as 1952 to implement the Government Housing Programmes. These programmes comprise of the public sector housing for governmental employees and social housing schemes for low and middle income groups.

States have established statutory housing boards for promoting various housing schemes. The National Housing Policy is enunciated in the national five year plans and the eighth and subsequent plans consist of creating an enabling environment for housing activity by eliminating various constraints and providing special assistance to the disadvantaged groups including the rural and the urban poor, the scheduled castes and tribes, physically handicapped, widows and single women.

Ventilation

The ability of an individual to comfortably accommodate himself in a house depends upon numerous factors in the physical environment of which an important one is the ventilation provided in his living and working area. The dictionary meaning of ventilation is 'intentional movement of air from outside a building to inside'. Adequate ventilation improves comfort levels of an inhabitant. However an excess of ventilation may result in discomfort due to cooling of the indoor air temperature, which is a not desirable, particularly in cold and dry or damp area in the country. Ventilation is one of the most important factors for maintaining acceptable indoor air quality in a building.

Ventilation does not merely mean flow of air in a room or replacement of vitiated air inside the room by fresh air being blown from the windows, doors or ventilators. It also implies control of the quality of air flowing inside the room by modifying the temperature, humidity and purity to provide an environment, which is thermally controlled and comfortable, gives a sense of well-being and reduces the risk of transmission of airborne diseases.

Ventilation air : The air used to provide acceptable indoor air quality is called as ventilation air. It removes the bad odours from inside building spaces due to presence of humans/ animals. This air is delivered either naturally or by means of mechanical ventilation and these means could increase or decrease the temperature of air or change its moisture content depending on the requirement inside the building. The rate at which outdoor air replaces indoor air is described as 'air

exchange rate'. When this rate is low, the pollutant levels in an environment increase.

Ventilation standards : These standards have largely been fixed on the area and amount of ventilation air required to achieve a sense of freshness in a room and remove body odours. These standards are described as :

(a) Floor space : This describes the product of the length and breadth of the room and is considered an important parameter for ventilation. The optimum floor space requirements per person vary from 50 to 100 feet.

(b) Cubic space of area : This has been used in the past and earlier prescriptions were of a fresh air supply of 3000 cu feet of air per person per hour. Since the products of respiration tend to accumulate in the lower levels, hence higher heights of rooms, beyond 12 feet, are ineffective from the point of view of ventilation and are not taken into account for establishing these standards. Current standards consider 1000 to 1200 cu feet per person per hour to be sufficient for generating comfort.

(c) Air change : It is a better standard for ventilation than cubic space requirement. If the cooling power of air arising out of adequate air changes is satisfactory, then even with a dip in the oxygen content of air upto 18 percent no deleterious effects would occur on human physiology. The recommended number of air changes in living room should be 2 to 3 in an hour, while in work rooms and assemblies the air changes could be 4 to 6 per hour. Higher changes could result in creation of air drought, which could reduce the comfort levels and hence should be avoided.

Types of ventilation

Infiltration : In infiltration the outdoor air flows into the house through openings, joints and cracks in walls, floors, ceilings and around windows and doors. Commercial buildings and sometimes residential areas are kept under slightly positive pressure relative to the outdoors to reduce infiltration. This helps in moisture management and humidity control inside the rooms.

Natural ventilation : This occurs when the air in a space is changed with outdoor air without the use of mechanical systems such as fans or circulators. Natural ventilation is mostly achieved through operable windows but could also be achieved through temperature and pressure difference between spaces. In this method of ventilation reliance is placed on the forces of nature such as wind, ambient temperature and air pressure. These are best utilised by proper location of windows, doors, ventilators and skylights. There are two types of natural ventilation occurring in buildings as described below :

(a) Wind driven ventilation : Pressures generated by wind are usually high and majority of the buildings rely mostly on this method. When wind blows through a room it is termed as 'perflation' and on its tail end it generates a suction effect known as 'aspiration'. These phenomena are seen when the doors and windows face each other and provide cross ventilation. The air has a capability to diffuse through narrow openings and spaces and thus may ventilate the rooms in addition to passage through the doors and windows.

The impact of wind on a building affects ventilation and

infiltration rates through it and the associated heat losses and gains. It creates areas of positive pressure on the windward side of the building and negative pressure on the leeward side and the sides of the building. Thus the shape of the building is crucial in creating wind pressures that will drive air flow through its apertures. Simple building shapes improve the ventilation while complex shapes create more turbulent air flows.

Wind driven ventilation has several benefits. Being a naturally occurring force it is readily available, economic to implement, could be controlled by users and achieves great magnitude and effectiveness. However it is limited by its unpredictability in speed and directions, which vary constantly; the air quality is not controlled and could introduce pollutants inside a room and may create draughts and discomfort.

(b) Stack driven ventilation : When there is temperature difference between two adjoining volumes of air, the warmer air will have lower density and be more buoyant and thus will rise above the cold air, creating an upward stream. In a house, such kind of effect, known as 'stack effect' happens in a fire place in a forced/active manner, while it occurs passively in spaces without direct access to outdoors. To have optimum ventilation due to stack effect in a building, the inside and outside air temperatures must be different, such that the warmer indoor air rises and escapes the building through the higher apertures, while colder, denser air from the exterior enters the buildings through lower level openings. The greater this temperature difference the greater the stack effect.

This kind of ventilation does not rely on wind but can take place in hot, summer days also; the air flow is relatively stable with a greater control in choosing the areas of air intake. However it is limited due to lower magnitude of ventilation, reliance on temperature differences, restrictions to the ventilation due to building designs and possibility of introducing polluted external air inside the room. Such type of ventilation is generally used in mills, boiler rooms, warehouses and industrial plants.

Natural ventilation can be an effective means when both the wind driven and stack ventilation can be used to augment each other's effect in an optimal manner. However its chief drawback is that it is not possible to regulate the velocity of incoming air or adjust its temperature and humidity.

Mechanical ventilation : This kind of ventilation is used where natural ventilation does not improve the indoor air quality or increases the chance of bringing contaminants inside the building. Such ventilation systems are usually established in places with high humidity to remove the excess moisture from ventilation air. Commonest forms of mechanical ventilation are:

(a) Ceiling fans, table or floor fans : These are used to circulate air within a room for the purpose of reducing the perceived temperature, because of evaporation of perspiration from the skin of occupants. These fans do not introduce outside air inside the room, hence do not provide ventilation in the strictest sense. Air-coolers are used in hot & dry conditions in the developing countries and are quite popular in India. They comprise of a chamber whose walls are made of straw, which is kept cool by pouring water on to the walls and evaporation

of water due to the warm air outside. A cool environment is thus created inside the chamber and a fan kept in this chamber blows cool air inside the room.

(b) Use of exhausts : Here the indoor air is extracted out with the help of mechanically driven fans. These are used in combination with the doors and windows since exhaustion of air outside the room creates a vacuum and this needs to be replaced by fresh air, which enters the room through windows, doors and other inlets. Exhausts are useful in industries especially where excess heat is generated. In residential areas they are placed in kitchens and bathrooms for extricating smoke or odours. Usually exhausts are placed near the roof to extricate hot air, which rises up in a room. The exhaust blades should be cleaned & well maintained to ensure their long life.

(c) Plenum ventilation : This is a process where air is blown inside a room by the use of fans and it enters through ducts. This kind of ventilation creates a positive air pressure inside the room. When this mechanism is combined with exhaust mechanism it creates 'balanced ventilation'. Such kind of plenum ventilation is also being used, alongwith air-conditioners, to supply air inside the building such that fresh air is circulated to leave out the odours and pollutants.

(d) Air conditioning : It is a system, which provides a combination of cooling, ventilation and control of humidity for a building where it is installed. The system has a refrigerant providing cooling through a 'refrigeration cycle'. This cycle comprises of four elements to provide the cooling effect. A *compressor* provides compression for the system. This causes the cooling refrigerant vapour to heat up. Next a condenser cools the vapour by exchanging its heat with outside air and the vapour condenses into a fluid. The condensed fluid enters the next element called as *evaporator-dehumidifier* where in the pressure drops and fluid evaporates and in the process draws heat from the surroundings, thus cooling it. The vapour is then returned to the compressor and pushed inside the room by a fan. Since the evaporator operates at a temperature below dew-point, moisture is collected at this end, which falls into a pan and is removed by a pipe outside.

Air conditioners are installed inside the residential areas or commercial complexes as either stand-alone systems or a part of central air-conditioning systems. Central air-conditioning system should be installed at the time of construction, since they are difficult to retrofit or install in a building, which was not designed to receive it, due to the large ducts needed to carry the air to the specific areas. These ducts must be carefully maintained to prevent growth of pathogenic bacteria in them. Another system of air-conditioning gaining popularity in residential areas and smaller commercial buildings is the split air-conditioning where the fan coils are connected to remoter condenser unit using piping instead of ducts.

Demand controlled ventilation : This is another technique of ventilation, which reduces the energy consumption in a building, while maintaining adequate air quality. Here, instead of a fixed air replacement rate, carbon-dioxide sensors dispersed inside the building areas are used to control the ventilation rate dynamically, based on emissions of actual building occupants.

HVAC : HVAC stands for 'Heating, Ventilation and Air-Conditioning'. This system is important in those places where humidity and temperature must be closely regulated while maintaining healthy and safe conditions inside buildings. These three terms are used in combination to ensure thermal comfort, accessible indoor quality and reasonable installation, operation and maintenance costs. HVAC systems determine the room air distribution i.e. how air is delivered to and removed from room spaces.

Ventilation requirements in different areas : Ventilation is used to remove unpleasant smells and excessive moisture, introduce outside air and to keep interior of a building air circulating to prevent stagnation of the interior air. Ventilation requirements vary from urban areas to rural areas and also post disaster situations. In urban areas the requirements differ between bungalows, high-rise buildings, slums and shanty settlements. The factors which determine the difference in ventilation are :

- Type of buildings, bungalows, high rise buildings, temporary shelters, tents, camps, hutments
- Size of the buildings and the floor areas.
- Type of roof inside the buildings such as cement-concrete, thatch, mud, tins or indigenous material, presence of false ceilings etc.
- Locally prevalent wind directions
- Number of persons occupying the room
- Proximity to commercial or industrial areas
- Sanitation of the surrounding area
- Nature of work being carried out inside the buildings
- Geographical locations such as closeness to sea, large water bodies, hilly areas

In urban areas, due to rise in ambient temperatures in the day and obstruction to wind movement due to building constructions, the residents use mechanical cooling devices and air-conditioning systems. Similarly in commercial and industrial establishments a combination of natural and mechanical ventilations is being used. Energy efficient systems are utilised in large buildings and storage areas. Urban slums are overcrowded and do not have free air circulation in most places. The houses are constructed close by each other and numerous small scale industries develop within these settlements. Most of the slum dwellings have erratic power supply in the developing countries and hence the dwellers largely rely on natural ventilation or the use of fans, circulators or air-coolers.

In rural areas the houses are mostly single storied and well spread out and thus air circulation around houses is not obstructed. Overcrowding does not usually exist and there is natural ventilation in plenty and hence the dwellers rarely use fans or air-coolers. Natural ventilation is however not able to prevent the odours arising out of animals residing nearby houses and improper disposal of garbage and solid wastes.

In post-disaster situations, the displaced persons need to be accommodated in shelters and camps constructed or occupied temporarily. These places are usually overcrowded and require proper sleeping arrangements and disposal of wastes of the dwellers. The odours and insanitation generated due to this

situation is compounded by the devastation caused by the calamity in the surroundings. There is usually a breakdown of power supply in the early days following the disaster. In such temporary shelters, arrangements should be made to ensure plenty of natural ventilation from the doors and windows and augmented by mechanical fans and coolers. However care must be taken to ensure that the air infiltration does not create a draught, especially in coastal areas and hills during cold or rainy weather conditions.

Summary

Housing is described as houses and flats considered collectively. For the purpose of public health aspects, housing would also include adjacent walks, paths, streets, open space, shops, utilities, health centres, schools and administrative services. The effect of housing conditions on the health of human beings varies with the type of community and the prevalent socio-political conditions in the country. It has been shown that the people who live in bad housing and poor environmental conditions in any area experience higher mortality rates and are generally less healthy than those who live in districts where housing is good. People living in houses with poor water supply and inadequate means of excreta disposal and fly control report higher incidence of diarrhoeal diseases. Poor domestic surroundings could result in breeding of disease vectors.

Rural housing has few characteristics like inadequate drainage of standing water around dwellings, littering with artificial containers and water stagnation in fields, improper solid waste disposal and the cohabitation of cattle and pet animals creating ideal grounds for transmission of communicable diseases among the rural inhabitants. The settlements, which house people undergoing a social and economic change, often from a rural to urban way of life, to integrate with the urban society, are termed as transitional housings. The transitional house dwellers are affected by rapid urbanisation in the towns and cities and their houses are converted into substandard dwelling units. These shanty towns need to be either replaced with good housing, which provide complete services or the current dwellers could be provided with alternate land areas at low costs to construct their own homes. This could generate a sense of integration among the dwellers with the urban areas and decrease the public health impact of their temporary settlements. During natural and civil disasters, governments and international agencies need to provide comprehensive services to cover the provision of shelter, sanitation, food, epidemiological surveillance and medical care for displaced populations.

Housing standards vary from country to country and are not confined to merely calculating the per capita space and floor space. Socio-economic characteristics such as family income, family size, composition, living standards and cultural factors are also taken into consideration in determining housing standards. The Environmental Hygiene Committee has established minimum standards required to be maintained by building regulations in India.

The data from NFHS 3 shows that only about 26% of rural India lives in pucca houses, with only 28% having access to piped drinking water and 26% have access to toilet facilities.

While housing is a state subject but the Union Govt formulates policy for housing especially pertaining to weaker sections, and the schemes are implemented at the state level. States have established statutory housing boards for promoting various housing schemes. The National Housing Policy is enunciated in the national five year plans and the eighth and subsequent plans consist of creating an enabling environment for housing activity by eliminating various constraints and providing special assistance to the disadvantaged groups including the rural and the urban poor, the scheduled castes and tribes, physically handicapped, widows and single women.

Ventilation does not merely mean flow of air in a room or replacement of vitiated air inside the room by fresh air being blown from the windows, doors or ventilators. It also implies control of the quality of air flowing inside the room by modifying the temperature, humidity and purity to provide an environment, which is thermally controlled and comfortable, giving a sense of well-being and reducing the risk of transmission of airborne diseases. Ventilation standards have largely been fixed on the area and amount of ventilation air required to achieve a sense of freshness in a room and remove body odours. The optimum floor space requirements per person vary from 50 to 100 feet and cubic space of 1000 to 1200 cu feet per person per hour. The recommended number of air changes in living room should be 2 to 3 in an hour, while in work rooms and assemblies the air changes could be 4 to 6 per hour. HVAC (Heating, ventilation and air-conditioning) is important in those places where humidity and temperature must be closely regulated while maintaining healthy and safe conditions inside buildings.

Study Exercises

Long Question : Enumerate the effects of improper Housing conditions on Health. Discuss the standards laid down for Housing.

Short Notes : (1) Criteria for Healthful Housing (2) Public Health aspects of Rural Housing (3) Steps to be taken by Public Health authorities to provide Housing for displaced during disasters (4) Overcrowding (5) Transitional housing (6) Housing policy in India (7) Ventilation standards (8) HVAC

MCQs

1. As per the Housing standards recommended by The Environmental Hygiene Committee, Subsoil water should be below (in feet) (a) 2 (b) 5 (c) 10 (d) 20
2. As per the Housing standards recommended by The Environmental Hygiene Committee, height of the roof should not be less than (in feet) (a) 2 (b) 5 (c) 10 (d) 20
3. The minimum Floor area in a house required for one person should be (a) 100 sq. ft (b) 200 (c) 250 (d) 50
4. The minimum Cubic space in a house required for one person should be (in Cu ft) (a) 100 (b) 200 (c) 250 (d) 500
5. In a House, window area should be _____ of floor area (a) $1/5^{\text{th}}$ (b) $2/5^{\text{th}}$ (c) $1/3^{\text{rd}}$ (d) $1/2$
6. The recommended number of air changes in living room should be _____ (per Hour) (a) 1-2 (b) 2-3 (c) 3-4 (d) 4-5

Answers : (1) c; (2) c; (3) a; (4) d; (5) a; (6) b.

Air Pollution

Clean air is considered to be a basic requirement of human health and well-being. However, air pollution continues to pose a significant threat to health worldwide. According to a WHO assessment of the burden of disease due to air pollution, more than 2 million premature deaths each year can be attributed to the effects of urban outdoor air pollution and indoor air pollution (caused by the burning of solid fuels). More than half of this disease burden is borne by the populations of developing countries. Source of major air pollutants and their effects on man are as mentioned in the Table - 1 and 2.

Indicators of air pollution

The WHO Air quality guidelines are designed to offer global guidance on reducing the health impacts of air pollution. They recommend measurement of selected air pollutants, viz., particulate matter (PM), ozone (O₃), nitrogen dioxide (NO₂) and sulfur dioxide (SO₂), applicable across all WHO regions. In addition, "smoke (soiling) index" and "coefficient of haze" are also commonly used indicators. In India, the Central Pollution Control Board through its National Air Quality Monitoring Programme monitors air quality in all major cities.

Particulate Matter : PM affects more people than any other pollutant. It consists of a complex mixture of solid and liquid particles of organic and inorganic substances suspended in the air. The particles are identified according to their aerodynamic diameter, as either PM₁₀ (particles with an aerodynamic diameter smaller than 10 μm) or PM_{2.5} (aerodynamic diameter smaller than 2.5 μm). The latter are more dangerous since, when inhaled, they may reach the peripheral regions of the bronchioles, and interfere with gas exchange inside the lungs.

Table - 1 : Major Air Pollutants and their Health Hazards

Pollutant	Source	Pathological effects on man
Sulphur dioxide	Colourless gas produced by coal and oil combustion and certain industrial sources	Respiratory irritant, aggravates asthma and other lung and heart diseases, reduces lung function.
Nitrogen oxides	Brownish orange gas produced by motor vehicles and combustion at major industrial sources	Inhibits cilia action so that soot and dust penetrate far into the lungs.
Hydrogen sulphide	Refineries, chemical industries and bituminous fuels	Causes nausea, irritates eyes and throat.
Carbon monoxide	Burning of coal, gasoline, motor exhausts	Reduces oxygen carrying capacity of blood.
Hydrogen cyanide	Blast furnace, fumigation, chemical manufacturing, metal plating, etc.	Interferes with nerve cells, produces dry throat, indistinct vision, headache, etc.
Ammonia	Explosives, dye making, fertilizer plants and lacquers	Inflames upper respiratory passages.
Phosgene or carbonyl chloride	Chemical and dye making	Induces coughing, irritation and fatal pulmonary edema.
Aldehydes	Thermal decomposition of oils, fats, or glycerols	Irritate nasal and respiratory tracts
Arsines	Processes involving metal or acids containing arsenic soldering	Damage red cells in blood, kidneys and cause jaundice
Suspended particles (ash, soot, smoke, etc.)	Solid or liquid particles produced by combustion and other processes at major industrial sources (e.g. steel mills, power plants, chemical plants, incinerators and almost every manufacturing process)	Respiratory irritants aggravate asthma and other lung and heart diseases (especially in combination with sulphur dioxide); many are known as carcinogens. Toxic gases and heavy metals absorb onto these particulates and are commonly carried deep into the lungs. Cause emphysema, eye irritation and possibly cancer
Lead	Very small particles emitted from motor vehicles and smelters	Toxic to nervous and blood-forming systems, in high concentrations can cause brain organ damage.
Ozone	A colourless gas formed from reactions between motor vehicle emissions and sunlight. It is the major component of smog	Respiratory irritant, aggravates asthma and other lung and heart diseases, impairs lung functions. Ozone is toxic to plants and corrodes materials.

Contaminant	Man-made sources	Natural sources
SO ₂	Fossil fuel combustion	Volcanoes, reactions of biological emissions
H ₂ S and organic sulphides, CO	Chemical processes, sewage Auto exhaust, general combustion	Volcanoes, biological processes in soil and water, forest fires, photochemical reactions
NO, NO ₂	Combustion	Biological processing in soil, lightning
NH ₃	Waste treatment, combustion	Biological processes in soil
N ₂ O	Small amounts from combustion	Biological processes in soil
CH ₄	Combustion, natural gas	Biological process in soil and water.
Isoprene and terpenes	None	Biological plant Emission
Total non CH ₃ hydrocarbons	Combustion	Biological process in soil and vegetation
CO ₂	Combustion	Biological processes
CH ₃ Cl	Combustion	Oceanic biological processes
HCl, Cl ₂	Combustion, Cl manufacturing	Atmospheric reactions of NaCl volcanoes

The guideline values (upper acceptable limits) are:

- PM_{2.5} 10 µg/m³ annual mean; 25 µg/m³ 24-hour mean
- PM₁₀ 20 µg/m³ annual mean; 50 µg/m³ 24-hour mean

The major components of PM are sulfate, nitrates, ammonia, sodium chloride, carbon, mineral dust and water. Particles may be classified as primary or secondary, depending on how they are formed. *Primary particles* are emitted into the atmosphere through man-made (anthropogenic) and natural processes including combustion of fuels in vehicle engines or in households; industrial activities; erosion of road surfaces by road traffic and abrasion of brakes and tyres; and work in caves and mines. *Secondary particles* are also emitted largely from anthropogenic sources, but they are formed in the air, usually by chemical reactions between gaseous pollutants. Particles produced by outdoor sources (industry and traffic) penetrate easily into indoor spaces and add to the burden of PM emitted indoors.

Chronic exposure to particles contributes to the risk of developing cardiovascular and respiratory diseases, as well as of lung cancer. In developing countries, exposure to pollutants from indoor combustion of solid fuels on open fires or traditional stoves increases the risk of acute lower respiratory infections and associated mortality among young children; indoor air pollution from solid fuel use is also a major risk factor for chronic obstructive pulmonary disease and lung cancer among adults.

Ozone (O₃) : Ozone at ground level - not to be confused with the ozone layer in the upper atmosphere - is one of the major constituents of photochemical smog. It is formed by the reaction with sunlight (photochemical reaction) of pollutants such as nitrogen oxides (NO_x) from vehicle and industry emissions and volatile organic compounds (VOCs) emitted by vehicles, solvents and industry. The highest levels of ozone pollution occur during periods of sunny weather. Excessive ozone in the air can have a marked effect on human health. It can cause breathing problems, trigger asthma, reduce lung function and cause lung diseases. Guidelines values for upper limits are: 100 µg/m³ (8-hour mean)

Nitrogen dioxide (NO₂) : As an air pollutant, NO₂ has several correlated activities: -

- At short-term concentrations exceeding 200 µg/m³, it is a toxic gas which causes significant inflammation of the airways.
- NO₂ is the main source of nitrate aerosols, which form an important fraction of PM_{2.5} and, in the presence of ultraviolet light, of ozone.

The major sources of anthropogenic emissions of NO₂ are combustion processes (heating, power generation, and engines in vehicles and ships). Epidemiological studies have shown that symptoms of bronchitis in asthmatic children increase in association with long-term exposure to NO₂. Reduced lung function growth is also linked to NO₂. The upper limits of guideline values are: 40 µg/m³ (annual mean) and 200 µg/m³ (1-hour mean).

Sulfur dioxide (SO₂) : SO₂ is a colourless gas with a sharp odour. It is produced from the burning of fossil fuels (coal and oil) and the smelting of mineral ores that contain sulfur. The main anthropogenic source of SO₂ is the burning of sulfur-containing fossil fuels for domestic heating, power generation and motor vehicles. The use of tall chimneys at power stations has caused widespread dispersion of SO₂ affecting populations located far away from the sources. In many developing countries, the usage of coal high in sulfur is increasing. SO₂ can affect the respiratory system and the functions of the lungs, and causes irritation of the eyes. Inflammation of the respiratory tract causes coughing, mucus secretion, aggravation of asthma and chronic bronchitis and makes people more prone to infections of the respiratory tract. Hospital admissions for cardiac disease and mortality increase on days with higher SO₂ levels. When SO₂ combines with water, it forms sulfuric acid; this is the main component of acid rain which is a cause of deforestation. The upper limit of acceptable values are 20 µg/m³ (24-hour mean) and 500 µg/m³ (10-minute mean).

Prevention

Public health recognizes air pollution as an important determinant of health, especially in developing countries. There

is significant inequality in the exposure to air pollution and related health risk; air pollution combines with other aspects of the social and physical environment to create a disproportional disease burden in less affluent parts of society. Exposure to air pollutants is largely beyond the control of individuals and requires action by public authorities at the national, regional and even international levels. The health sector can play a central role in leading a multisectoral approach to prevention of exposure to air pollution with support of other relevant sectors (transport, housing, energy production and industry). The major modes of prevention are:

(a) Containment : This prevents pollutants from entering the atmosphere. This can be carried out by engineering methods like enclosure, ventilation or air scrubbing & arresting of pollutants. The following dust control devices are generally used in industry :

(i) Dust collection systems : These are designed to handle heavy dust loads; a dust collector consists of a blower, dust filter, a filter-cleaning system, and a dust receptacle or dust removal system, such as Cyclones, Electrostatic precipitators, and, Baghouses.

(ii) Scrubber systems : These are a diverse group of air pollution control devices that can be used to remove particulates and/or gases from industrial exhaust streams, such as Baffle spray scrubber, Cyclonic spray scrubber, Ejector venturi scrubber, Mechanically aided scrubber, Spray tower, and, Wet scrubber.

(b) Replacement or modernisation of equipment/process: This can result in decrease in pollution. e.g. Use of unleaded petrol.

(c) Zoning : During the planning process itself polluting industries are kept away from habitable locations.

(d) Regulatory Measures : The Air (Prevention and Control of Pollution) Act, 1981.

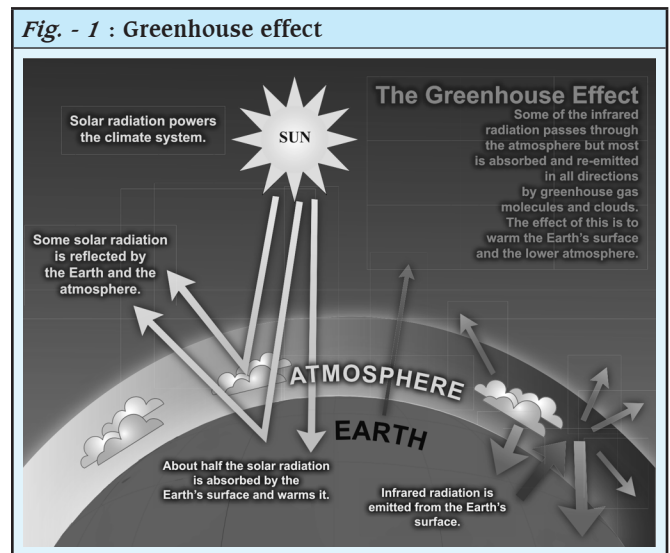

The objective of the Air (Prevention and Control of Pollution) Act, 1981 is to provide for the prevention, control and abatement of air pollution in India by the establishment of pollution control Boards at the Centre as well as State levels, and by conferring and assigning such Boards, powers and functions, with a view to implementing air pollution control measures. Details are discussed in the chapter on health legislations.

Greenhouse Gases and Society

Greenhouse gases naturally blanket the Earth and keep it about 33°C warmer than it would be without these gases in the atmosphere. This is called the Greenhouse Effect. Over the past century, the Earth has increased in temperature by about 0.5°C and many scientists believe this is because of an increase in concentration of the main greenhouse gases: carbon dioxide (76%), methane (13%), nitrous oxide (6%), and fluorocarbons (5%). People are now calling this climate change over the past century the beginning of Global Warming. Fears are that if people keep producing such gases at increasing rates, the results will be negative in nature, such as more severe floods and droughts, increasing prevalence of insects, sea levels rising, and Earth's precipitation may be redistributed. These changes to the environment will most likely cause negative effects on society, such as lower health and decreasing economic

development. However, some scientists argue that the global warming we are experiencing now is a natural phenomenon, and is part of Earth's natural cycle. Presently, nobody can prove if either theory is correct, but one thing is certain; the world has been emitting greenhouse gases at extremely high rates and has shown only small signs of reducing emissions until the last few years. After the 1997 Kyoto Protocol, the world has finally taken the first step in reducing emissions.

The "greenhouse effect" is the heating of the Earth due to the presence of greenhouse gases. It is named this way because of a similar effect produced by the glass panes of a greenhouse. Shorter-wavelength solar radiation from the sun passes through Earth's atmosphere, and then is absorbed by the surface of the Earth, causing it to warm. Part of the absorbed energy is then re-radiated back to the atmosphere as long-wave infrared radiation. Little of this long-wave radiation escapes back into space; the radiation cannot pass through the greenhouse gases in the atmosphere. The greenhouse gases selectively transmit the infrared waves, trapping some and allowing some to pass through into space. The greenhouse gases absorb these waves and re-emits the waves downward, causing the lower atmosphere to warm. The diagram below explains the process of global warming and how greenhouse gases create the "greenhouse effect" (Fig. - 1).

Greenhouse Gases

Carbon-dioxide : It is a colorless, odorless non-flammable gas and is the most prominent Greenhouse gas in Earth's atmosphere. It is recycled through the atmosphere by the process photosynthesis, which makes human life possible. Carbon-dioxide is emitted into the air as humans exhale, burn fossil fuels for energy, and deforest the planet. Every year humans add over 30 billion tons of carbon dioxide in the atmosphere by these processes. We use "fossil fuels" as coal, oil and natural gas to generate electricity, heat our homes, power our factories and run our cars. These fossil fuels contain carbon, and when they are burned, they combine with oxygen, forming carbon dioxide. Deforestation is another main producer of carbon dioxide. The causes of deforestation are logging for lumber,

pulpwood, and fuel wood. Also contributing to deforestation is clearing new land for farming and pastures used for animals such as cows. Forests and wooded areas are natural carbon sinks. This means that as trees absorb carbon dioxide, and release oxygen, carbon is being put into trees. This process occurs naturally by photosynthesis, which occurs less and less as we cut and burn down trees. As the abundance of trees declines, less carbon dioxide can be recycled. As we burn them down, carbon is released into the air and the carbon bonds with oxygen to form carbon dioxide, adding to the greenhouse effect.

Methane : Methane is a colorless, odorless, flammable gas. It is formed when plants decay and where there is very little air. It is often called swamp gas because it is abundant around water and swamps. Bacteria that breakdown organic matter in wetlands and bacteria that are found in cows, sheep, goats, buffalo, termites, and camels produce methane naturally. Since 1750, methane has doubled, and could double again by 2050. Each year we add 350-500 million tons of methane to the air by raising livestock, coal mining, drilling for oil and natural gas, rice cultivation, and garbage sitting in landfills. It stays in the atmosphere for only 10 years, but traps 20 times more heat than carbon dioxide.

Nitrous Oxide: Nitrous oxide is another colorless greenhouse gas; however, it has a sweet odour. It is primarily used as an anesthetic because it deadens pain and for this characteristic is called laughing gas. This gas is released naturally from oceans and by bacteria in soils. Nitrous oxide gas risen by more than 15% since 1750. Each year we add 7-13 million tons into the atmosphere by using nitrogen based fertilizers, disposing of human and animal waste in sewage treatment plants, automobile exhaust, and other sources not yet identified. It is important to reduce emissions because the nitrous oxide we release today will still be trapped in the atmosphere 100 years from now. Nitrogen based fertilizer use has doubled in the past 15 years. These fertilizers provide nutrients for crops; however, when they breakdown in the soil, nitrous oxide is released into the atmosphere. In automobiles, nitrous oxide is released at a much lower rate than carbon dioxide, because there is more carbon in gasoline than nitrogen.

Fluorocarbons: Fluorocarbons are a general term for any group of synthetic organic compounds that contain fluorine and carbon. Many of these compounds, such as chlorofluorocarbons (CFCs), can be easily converted from gas to liquid or liquid to gas. Because of these properties, CFCs can be used in aerosol cans, refrigerators, and air conditioners. Studies showed that when CFCs are emitted into the atmosphere, they break down molecules in the Earth's ozone layer. Since then, the use of CFCs has significantly decreased and they are banned from production in the United States. The substitutes for CFCs are hydrofluorocarbons (HFCs). HFCs do not harm or breakdown the ozone molecule, but they do trap heat in the atmosphere, making it a greenhouse gas, aiding in global warming. HFC's are used in air conditioners and refrigerators. The way to reduce emissions of this gas is to be sure that in both devices the coolant is recycled and all leaks are properly fixed

There are many environmental problems coming from the

increase concentration of greenhouse gases in Earth's atmosphere. Several signs indicate that we've begun changing Earth's climate: increased water vapor in the atmosphere, glaciers and polar ice caps appear to be melting, floods and droughts are becoming more severe, and sea levels have risen, on average, between 4 and 10 inches since 1990. We are already beginning to see this (global warming) taking place - a lot more flooding, a lot more droughts. By 2100, we might get a 2 foot sea level rise, but the catch is levels might continue to rise 2 or 3 feet per century, for 1000 years. These rises in sea level can increase the salinity of freshwater throughout the world, and cause coastal lands to be washed under the ocean. Warmer water and increased humidity may encourage tropical cyclones, and changing wave patterns could produce more tidal waves and strong beach erosion on the coasts.

Increasing amounts of greenhouse gases in the atmosphere and global warming could also lead to more health concerns. A statement released from the Intergovernmental Panel on Climate Change (IPCC) said, "Climate change is likely to have wide-ranging and mostly adverse impacts on human health, with significant loss of life." As temperatures increase towards the poles, similar to farmland, insects and other pests migrate towards Earth's poles. This could lead to 50 to 80 million additional cases of Malaria annually, a 10-15% increase. Climate change is already a factor in terms of the distributions of malaria, dengue fever, and cholera.

The most obvious health effect is directly from the heat itself. With an increase in heat waves, there will be more people who will suffer from heatstroke, heart attacks and other ailments aggravated by the heat. Hot conditions could also cause smoke particles and noxious gases to linger in the air and accelerate chemical reactions that generate other pollutants. This leads to an increase in risk of respiratory diseases like bronchitis and asthma.

Energy and Greenhouse gases : The present ways of producing Energy i.e. fossil fuels, chiefly coal, oil and natural gas, now supply most of the world's energy. Only a small amount comes from renewable sources, which do not release gases that trap heat in the atmosphere. If we could get more of our energy from renewable sources, we could reduce the amount of fossil fuels we burn. By the year 2050, renewable sources could provide forty percent of the energy needed in the world. Use of renewable energy can help both to slow global warming and to reduce air pollution. Hydro power, currently supplying only six percent of the world's energy, is a renewable energy source. Energy is produced by hydraulic turbines that rotate with the force of rushing water (higher to lower elevation). It is one of the most clean and cheapest ways of producing energy, but it can also change the flow of rivers and increase sediment which kills fish. It is a large investment for developing countries. Denmark is currently the world leader in wind power.

These fossil fuels, coal, oil, and natural gas also emit greenhouse gases when burned. Coal emits high amounts of greenhouse gases, and the world may be supplied with enough of it to last over 100 years. Oil emits high amounts of greenhouse gases and also other types of air pollution harmful to the environment. The world's oil supply is also estimated to

last over 100 years. Natural Gas is the lowest of all fossil fuels in greenhouse gas emissions; supplies are projected to last over 100 years.

Kyoto Protocol : The Kyoto Protocol is an international agreement linked to the United Nations Framework Convention on Climate Change. The major feature of the Kyoto Protocol is that it sets binding targets for 37 industrialized countries and the European community for reducing greenhouse gas (GHG) emissions. These amount to an average of five per cent against 1990 levels over the five-year period 2008-2012. The major distinction between the Protocol and the Convention is that while the Convention encouraged industrialised countries to stabilize GHG emissions, the Protocol commits them to do so.

Recognizing that developed countries are principally responsible for the current high levels of GHG emissions in the atmosphere as a result of more than 150 years of industrial activity, the Protocol places a heavier burden on developed nations under the principle of “common but differentiated responsibilities.” The Kyoto Protocol was adopted in Kyoto, Japan, on 11 December 1997 and entered into force on 16 February 2005. 182 Parties of the Convention have ratified its Protocol to date. The detailed rules for the implementation of the Protocol were adopted at COP 7 in Marrakesh in 2001, and are called the “Marrakesh Accords.” Under the Treaty, countries must meet their targets primarily through national measures. However, the Kyoto Protocol offers them an additional means of meeting their targets by way of three market-based mechanisms.

Parties with commitments under the Kyoto Protocol have accepted targets for limiting or reducing emissions. These targets are expressed as levels of allowed emissions, or “assigned amounts”, over the 2008-2012 commitment period. Since carbon dioxide is the principal greenhouse gas, people speak simply of trading in carbon. Carbon is now tracked and traded like any other commodity. This is known as the “carbon market”.

The Kyoto Protocol is generally seen as an important first step towards a truly global emission reduction regime that will stabilize GHG emissions, and provides the essential architecture for any future international agreement on climate change. By the end of the first commitment period of the Kyoto Protocol in 2012, a new international framework needs to have been negotiated and ratified that can deliver the stringent emission reductions the Intergovernmental Panel on Climate Change (IPCC) has clearly indicated are needed.

Ozone Hole : For nearly a billion years, ozone molecules in the atmosphere have protected life on Earth from the effects of ultraviolet rays. The ozone layer resides in the stratosphere and surrounds the entire Earth. UV-B radiation (280- to 315-nanometer (nm) wavelength) from the Sun is partially absorbed in this layer. As a result, the amount of UV-B reaching Earth’s surface is greatly reduced. UV-A (315- to 400-nm wavelength) and other solar radiation are not strongly absorbed by the ozone layer. Human exposure to UV-B increases the risk of skin cancer, cataracts, and a suppressed immune system. UV-B exposure can also damage terrestrial plant life, single cell organisms, and aquatic ecosystems.

In the past 60 years or so human activity has contributed to the deterioration of the ozone layer. Only 10 or less of every million molecules of air are ozone. The majority of these ozone molecules reside in a layer between 10 and 40 kilometers (6 and 25 miles) above the Earth’s surface in the stratosphere. Each spring in the stratosphere over Antarctica (Spring in the southern hemisphere is from September through November); atmospheric ozone is rapidly destroyed by chemical processes. As winter arrives, a vortex of winds develops around the pole and isolates the polar stratosphere. When temperatures drop below -78°C (-109°F), thin clouds form of ice, nitric acid, and sulphuric acid mixtures. Chemical reactions on the surfaces of ice crystals in the clouds release active forms of CFCs. Ozone depletion begins, and the ozone “hole” appears. In spring, temperatures begin to rise, the ice evaporates, and the ozone layer starts to recover. The ozone “hole” is really a reduction in concentrations of ozone high above the earth in the stratosphere. The ozone hole has steadily grown in size (up to 27 million sq. km.) and length of existence (from August through early December) over the past two decades. After a series of rigorous meetings and negotiations, the Montreal Protocol on Substances that Deplete the Ozone Layer was finally agreed upon on 16 September 1987 at the Headquarters of the International Civil Aviation Organization in Montreal.

The *Montreal Protocol* stipulates that the production and consumption of compounds that deplete ozone in the stratosphere such as chlorofluorocarbons (CFCs), halons, carbon tetrachloride, and methyl chloroform are to be phased out. Scientific theory and evidence suggest that, once emitted to the atmosphere, these compounds could significantly deplete the stratospheric ozone layer that shields the planet from damaging UV-B radiation. Man-made chlorines, primarily chlorofluorocarbons (CFCs), contribute to the thinning of the ozone layer and allow larger quantities of harmful ultraviolet rays to reach the earth. The Govt of India has come up *Ozone Depleting Substances (Regulation) Rules 2000* under the Environmental Protection Act 1986 so as to control the production, emission and consumption of Ozone depleting substances.

The Bhopal Disaster : The Bhopal Gas Tragedy is a catastrophe that has no parallel in industrial history. In the early morning of December 3, 1984 a Union Carbide pesticide producing plant

leaked a highly toxic cloud of methyl isocyanine onto the densely populated region of Bhopal, central India. The cause was the contamination of Methyl Isocyanine (MIC) storage tank No. 610 with water carrying catalytic material. Of the 800,000 people living in Bhopal at the time, 2,000 died immediately, 300,000 were diseased and as many as 8,000 have died since. The leak was caused by a series of mechanical and human errors. A series of studies made five years later showed that many of the survivors were still suffering from one or several of the following ailments: partial or complete blindness, gastrointestinal disorders, impaired immune systems, post traumatic stress disorders, and menstrual problems in women. A rise in spontaneous abortions, stillbirths, and offspring's with genetic defects was also noted. Although Union Carbide denied liability, in 1989 the Indian Supreme court agreed to a settlement payment of \$470 million by Union Carbide to the survivors of the disaster.

Noise Pollution

The word noise is derived from the Latin term *nausea*. It has been defined as unwanted sound. Noise can be described as sound without agreeable musical quality or as an unwanted or undesired sound. Thus noise can be taken as a group of loud, non harmonious sounds or vibrations that are unpleasant and irritating to ear. Sound, which pleases the listeners, is music and that which causes pain and annoyance is noise. Section 2 (a) of the Air (Prevention and Control of Pollution) Act, 1981 includes noise in the definition of 'air pollutant'. Section 2(a) air pollution means any solid, liquid or gaseous substance including noise present in the atmosphere in such concentration as may be injurious to human beings or other living creatures or plants or property or environment.

Measurement : Loudness/intensity depends on amplitude of noise which is measured in decibels. The zero on a decibel scale is at the threshold of hearing, the lowest sound pressure that can be heard. 20 db is whisper, 40 db the noise in a quiet office. 60 db is normal conversation, 80 db is the level at which sound becomes physically painful. The human ear responds to perceived intensity of sound which is expressed in dB (A). Frequency is measured in Hertz which represents one wave per second. The normal human ear can bear frequencies from 20-20,000 Hz.

Sources of Noise Pollution : Noise pollution like other pollutants is also a by- product of industrialization, urbanizations and modern civilization. Broadly speaking, the noise pollution has two sources, i.e. industrial and non- industrial. The industrial source includes the noise from various industries and big machines working at a very high speed and high noise intensity. Non- industrial source of noise includes the noise created by transport/vehicular traffic and the neighborhood noise generated by various noise pollution can also be divided in the categories, namely, natural and manmade. Most leading noise sources will fall into the following categories: roads traffic, aircraft, railroads, construction, industry, noise in buildings (as furniture and plumbing), and consumer products (as household commodities as mixies, vacuum cleaners, etc.) and "recreational" (as loud music, discos, religious and social assemblages, etc.).

Harmful Effects : Noise exposure can cause two kinds of health effects on humans. These effects are non-auditory effects and auditory effects.

Non-auditory effects : These include stress, related physiological and behavioural effects, and safety concerns. It decreases the efficiency of a man Noise causes lack of concentration in people. Thus they have to give more time for completing a job. Noise Pollution has been considered to be a cause of elevated blood pressure, sleep disturbance, and decreased school performance. Noise exposure has also been known to induce tinnitus, hypertension, vasoconstriction and other cardiovascular impacts. Beyond these effects, elevated noise levels can create stress, increase workplace accident rates, and stimulate aggression and other anti-social behaviors.

Auditory Effects

(a) Acoustic trauma : Sudden hearing damage caused by short burst of extremely loud noise such as a gun shot or blasts.

(b) Tinnitus : Ringing or buzzing in the ear.

(c) Temporary hearing loss : Also known as temporary threshold shift (TTS) which occurs immediately after exposure to a high level of noise. There is gradual recovery when the affected person spends time in a quiet place. Complete recovery may take several hours.

(d) Permanent hearing loss : Permanent hearing loss, also known as permanent threshold shift (PTS), progresses constantly as noise exposure continues month after month and year after year. The hearing impairment is noticeable only when it is substantial enough to interfere with routine activities. At this stage, a permanent and irreversible hearing damage has occurred. Noise-induced hearing damage cannot be cured by medical treatment and worsens as noise exposure continues. When noise exposure stops, the person does not regain the lost hearing sensitivity. As the employee ages, hearing may worsen as age-related hearing loss or presbycusis adds to the existing noise-induced hearing loss.

Noise-induced hearing loss is a cumulative process, both level of noise and exposure time over a worker's work history are important factors. At a given level, low-frequency noise (below 100 Hz) is less damaging compared to noise in the mid-frequencies (1000 - 3000 Hz). Noise-induced hearing loss occurs randomly in exposed persons. Some individuals are more susceptible to noise-induced hearing loss than others. In the initial stages, noise-induced hearing loss is most pronounced at 4000 Hz but it spreads over other frequencies as noise level and/or exposure time increases.

Noise affects the cochlea in the inner ear. That is why noise-induced hearing loss is sensory-neural type of hearing loss. Certain medications and diseases may also cause damage to the inner ear resulting in hearing loss as well. Generally, it is not possible to distinguish sensory-neural hearing loss caused by exposure to noise from sensory-neural hearing loss due to other causes. Medical judgment, in such cases, is based on the noise exposure history. Workers in noisy environments who are also exposed to vibration (e.g. from a jack hammer) may experience greater hearing loss than those exposed to the same level of noise but not to vibration. Noise-exposed workers who are also exposed to ototoxic chemicals (e.g. toluene, carbon

disulfide) may suffer from more hearing impairment than those who have the same amount of noise exposure without any exposure to ototoxic chemicals.

Hearing loss is measured as threshold shift in dB units using an audiometer. The 0 dB threshold shift reading of the audiometer represents the average hearing threshold level of an average young adult with disease-free ears. The PTS (permanent threshold shift), as measured by audiometry, is dB level of sounds of different frequencies that are just barely audible to that individual.

Effect on animals : Noise can have a detrimental effect on animals by causing stress, increasing risk of mortality by changing the delicate balance in predator/prey detection and avoidance, and by interfering with their use of sounds in communication especially in relation to reproduction and in navigation.

Noise mitigation

This is a set of strategies to reduce noise pollution. The main areas of noise mitigation or abatement are transportation noise control, architectural design, and occupational noise control. Roadway noise and aircraft noise are the most pervasive sources of environmental noise worldwide, and remarkably little change has been effected in source control in these areas since the start of the problem, a possible exception being the development of the hybrid vehicle.

(a) Buildings : Multiple techniques have been developed to address interior sound levels, many of which are encouraged by local building codes; in the best case of project designs, planners are encouraged to work with design engineers to examine tradeoffs of roadway design and architectural design. These techniques include design of exterior walls, internal walls and floor/ceiling assemblies; moreover, there are a host of specialized means for dampening reverberation from special purpose rooms such as auditoriums, concert halls, dining areas and meeting rooms. Many of these techniques rely upon materials science applications of constructing sound baffles or using sound absorbing liners for interior spaces.

(b) Roadway noise : The most fertile area for roadway noise mitigation is in urban planning decisions, roadway design, noise barrier design, speed control, surface pavement selection and truck restrictions. Speed control is effective since the lowest sound emissions arise from vehicles moving smoothly at 30 to 60 km per hour. Noise barriers can be applicable for existing or planned surface transportation projects. They are probably the single most effective weapon in retrofitting an existing roadway, and commonly can reduce adjacent land use sound levels by ten decibels

(c) Aircrafts : The most promising forms of aircraft noise abatement is through land planning, flight operations restrictions and residential soundproofing. Flight restrictions can take the form of preferred runway use; departure flight path and slope; and time of day restrictions

(d) Industries : Industrial noise control is really a subset of interior architectural control of noise, with emphasis upon specific methods of sound isolation from industrial machinery and for protection of workers at their task stations. In the case of industrial equipment, the most common techniques for

noise protection of workers consist of shock mounting source equipment, creation of acrylic glass or other solid barriers, and provision of ear protection equipment. In certain cases the machinery itself can be re-designed to operate in a manner less prone to produce grating, grinding, frictional or other motions that induce sound emissions.

(e) Legal Control : Under Cr PC Section 133 the magisterial court have been empowered to issue order to remove or abate nuisance caused by noise pollution. Noise pollution can be penalized under I.P.C. Public Nuisance 268-295 relating to public health, safety, decency, morals. Action can also be taken under the Law of Torts as Noise pollution is considered a civil wrong. The Factories Act does not contain any specific provision for noise control. However, under the Third Schedule Sections 89 and 90 of the Act, noise induced hearing loss, is mentioned as notifiable disease. Similarly, under the Modal Rules, limits for noise exposure for work zone area have been prescribed. In Motor vehicle Act rules regarding use horns and any modification in engine are made.

Noise Pollution Control Rule 2000 under Environment Protection Act 1996

Under this Act State governments shall take measures for abatement of noise including noise emanating from vehicular movement and ensure that the existing noise levels do not exceed the standards specified. An area not less than 100 m around hospitals, education institutions and courts may be declared as '*silence area*' for the purpose of these rules. A loud speaker or a public address system shall not be used except after obtaining written permission from the authority and the same shall not be used at night, between 10 pm to 6 am.

Personal Protection

Ear plugs and ear muffs are important appliances, particularly used in the industries, which can effectively reduce the level of noise by 15 to 30 decibels and their use must be encouraged wherever possible.

Soil Pollution

Soil pollution comprises the pollution of soils with materials, mostly chemicals that are out of place or are present at concentrations higher than normal which may have adverse effects on humans or other organisms. It is difficult to define soil pollution exactly because different opinions exist on how to characterize a pollutant; while some consider the use of pesticides acceptable if their effect does not exceed the intended result, others do not consider any use of pesticides or even chemical fertilizers acceptable. However, soil pollution is also caused by means other than the direct addition of xenobiotic (man-made) chemicals such as agricultural runoff waters, industrial waste materials, acidic precipitates and radioactive fallout. Consequently, the atmosphere, bodies of water, and many soil environments have become polluted by a large variety of toxic compounds. Many of these compounds at high concentrations or following prolonged exposure have the potential to produce adverse effects in humans and other organisms: These include the danger of acute toxicity, mutagenesis (genetic changes), carcinogenesis, and teratogenesis (birth defects) for humans and other organisms.

Some of these man-made toxic compounds are also resistant to physical, chemical, or biological degradation and thus represent an environmental burden of considerable magnitude.

Industrial Wastes : Industries are known to dispose of their pollution in pits, ponds or lagoons with little or no prior treatment. Leaking underground storage tanks compound the pollution of the soil. The most prominent chemical groups of organic contaminants are fuel hydrocarbons, polynuclear aromatic hydrocarbons (PAHs), polychlorinated biphenyls (PCBs), chlorinated aromatic compounds, detergents and pesticides. Inorganic species include nitrates, phosphates and heavy metals such as cadmium, chromium and lead; inorganic acids; and radionuclides (radioactive substances). Among the sources of these contaminants are agricultural runoffs, acidic precipitates, and industrial waste materials.

Agricultural Wastes : Fertilizers, pesticides and other chemical like soil conditioners and fumigants used in agriculture may remain for long in the soil. Some of these may enter the food chain and cause health problems in the population. On the other hand, Cattle and poultry produce and wastes are biodegradable. However when these are not properly disposed it may cause a nuisance of smell and sight and facilitate breeding of flies.

Urban Community Wastes : Refuse and other solids wastes when not disposed of properly can result in pollution of the soil. Even practices like sanitary landfill if not carried out in a systemized manner may result in contamination of the soil. Defecation in the open in farms etc. result in contamination of the soil with various biological contaminants harbored by the host.

Radiological Wastes : Occur from atmospheric fallout of a nuclear explosion, which may travel distances due to air currents. Disposal of radioactive wastes if not carried out as per laid out norms is another source of pollution.

Control measures

(a) Natural : Nature has an effective mode of controlling pollution. Most bacteria and viruses do not survive on the surface of the soil after exposure to sunlight. Rainwater also carries contaminants away from the source. Biological products which are below the upper surface of the soil are catabolised by the "Nitrogen Cycle".

(b) Bioremediation : In-situ biodegradation involves the enhancement of naturally occurring microorganisms by artificially stimulating their numbers and activity. The microorganisms then assist in degrading the soil contaminants. A number of environmental, chemical and management factors affect the biodegradation of soil pollutants, including moisture content, pH, temperature, the microbial community that is present, and the availability of nutrients. These physical parameters can be influenced, thereby promoting the microorganisms' ability to degrade chemical contaminants. Of all the decontamination methods bioremediation appears to be the least damaging and most environmentally acceptable technique.

(c) Soil Washing : For the removal and recovery of heavy metals various soil washing techniques have been developed including physical methods, such as attrition scrubbing and wet-screening, and chemical methods consisting of treatments

with organic and inorganic acids, bases, salts and chelating agents. The problem with these methods, however, is again that they generate secondary waste products that may require additional hazardous waste treatments.

(d) Engineering measures : Proper disposal of community wastes through composting, disposal in pits, sanitary landfills goes a long way in prevention of soil pollution. Industrial wastes should be properly treated prior to disposal. Non biodegradable products should be recycled or properly disposed. Farm wastes can be properly utilized by composting or used in biogas plants. The most common decontamination method for polluted soils is to remove the soil and deposit it in landfills or to incinerate it. These methods, however, often exchange one problem for another: land-filling merely confines the polluted soil while doing little to decontaminate it, and incineration removes toxic organic chemicals from the soil, but subsequently releases them into the air, in the process causing air pollution. Health education goes a long way in change of attitude of a community on oxygen defecation of disposal of agriculture wastes.

Radioactive Pollution

Radioactive contamination is the uncontrolled distribution of radioactive material in a given environment. Radioactive contamination is typically the result of a spill or accident during the production or use of radionuclides (radioisotopes), an unstable nucleus which has excessive energy. Contamination may occur from radioactive gases, liquids or particles. For example, if a radionuclide used in nuclear medicine is accidentally spilled, the material could be spread by people as they walk around. Radioactive contamination may also be an inevitable result of certain processes, such as the release of radioactive xenon in nuclear fuel reprocessing. Nuclear fallout is the distribution of radioactive contamination by a nuclear explosion.

Ionising radiation : These are radioactive rays capable of penetrating tissues. These can be of two types;

- (a) Electromagnetic - X-rays and gamma rays
 - (b) Corpuscular radiations - Alpha, beta particles & protons
- Alpha particles are ten times more harmful than X-rays but have little penetrating force. Gamma rays & X-rays are deep penetrating in nature.

Non ionizing radiations : These are of higher wavelengths & cannot penetrate. The spectrum ranges from Ultraviolet radiation, visible light, infrared radiation, microwave & radio frequency.

Activity of radioactive material is measured in Becquerel which is 1 disintegration per second. This was earlier measured as Curies. Potency of radiation is measured with -

(a) Exposure : Number of ions exposed in a ml of air is called Roentgen. Current exposure SI unit is Coulomb/kg.

(b) Absorption : Amount of radioactive energy absorbed by a gram of tissue/material is called Rad. The SI unit currently used is Gray (1Gy = 100 rads).

(c) Dose equivalent : The degree of potential danger to health is measured in Rem which is a product of Rad and a modifying factor. The newer unit is the Sievert (1 Sievert=100 Rems).

Hazards

In practice there is no such thing as zero radioactivity. Not only is the entire world constantly bombarded by cosmic rays, but every living creature on earth contains significant quantities of carbon-14 and most (including humans) contains significant quantities of potassium-40. These tiny levels of radiation are not any more harmful than sunlight, but just as excessive quantities of sunlight can be dangerous, so too can excessive levels of radiation.

Low level contamination : The hazards to people and the environment from radioactive contamination depend on the nature of the radioactive contaminant, the level of contamination, and the extent of the spread of contamination. Low levels of radioactive contamination pose little risk, but can still be detected by radiation instrumentation. In the case of low-level contamination by isotopes with a short half-life, the best course of action may be to simply allow the material to naturally decay. Longer-lived isotopes should be cleaned up and properly disposed of, because even a very low level of radiation can be life-threatening, on long exposure. Therefore, whenever there's any radiation in an area, many people take extreme caution when approaching such areas.

High level contamination : High levels of contamination may pose major risks to people and the environment. People can be exposed to potentially lethal radiation levels, both externally and internally, from the spread of contamination following an accident (or a deliberate initiation) involving large quantities of radioactive material. The biological effects of external exposure to radioactive contamination are generally the same as those from an external radiation source not involving radioactive materials, such as x-ray machines, and are dependent on the absorbed dose.

Biological effects : The biological effects of internally deposited radionuclides depend greatly on the activity and the bio-distribution and removal rates of the radionuclide, which in turn depends on its chemical form. The biological effects may also depend on the chemical toxicity of the deposited material, independent of its radioactivity. Some radionuclides may be generally distributed throughout the body and rapidly removed, as is the case with tritiated water. Some radionuclides may target specific organs and have much lower removal rates. For instance, the thyroid gland takes up a large percentage of any iodine that enters the body. If large quantities of radioactive iodine are inhaled or ingested, the thyroid may be impaired or destroyed, while other tissues are affected to a lesser extent. Radioactive iodine is a common fission product; it was a major component of the radiation released from the Chernobyl disaster, leading to many cases of pediatric thyroid cancer and hypothyroidism. On the other hand, radioactive iodine is used in the diagnosis and treatment of many diseases of the thyroid precisely because of the thyroid's selective uptake of iodine.

In general, the adverse effects on the human body may be acute or chronic (long term). Acute effects include acute radiation sickness. Chronic effects may manifest either as somatic effects or chromosomal effects which result in genetic abnormalities. The most important somatic effect is on haemopoietic system (leukaemias), cancers, particularly thyroid, and foetal

developmental abnormalities if mother is exposed during ante-natal period.

Means of contamination : Radioactive contamination can enter the body through ingestion, inhalation, absorption, or injection. For this reason, it is important to use personal protective equipment when working with radioactive materials. Radioactive contamination may also be ingested as the result of eating contaminated plants and animals or drinking contaminated water or milk from exposed animals. Following a major contamination incident, all potential pathways of internal exposure should be considered.

Effective protection : Effective protection can be given to workers in hazardous industries by provision of lead shields & lead rubber aprons. Exposed workers should wear TLD badge or dosimeters which show accumulated exposure to radiation. Periodic medical exam should also be carried out to monitor health of workers. Exposure to investigative radiology should be kept to the minimum, especially during pregnancy.

The Chernobyl disaster was a nuclear reactor accident in the Chernobyl Nuclear Power Plant in the Soviet Union on 26 April 1986. It was the worst nuclear power plant accident in history and the only instance so far of level 7 on the International Nuclear Event Scale, resulting in a severe release of radioactivity into the environment following a massive power excursion which destroyed the reactor. Two people died in the initial steam explosion, but most deaths from the accident were attributed to fallout. The plume drifted over extensive parts of the western Soviet Union, Eastern Europe, Western Europe, Northern Europe, and eastern North America. Large areas in Ukraine, Belarus, and Russia were badly contaminated, resulting in the evacuation and resettlement of over 336,000 people. According to official post-Soviet data, about 60% of the radioactive fallout landed in Belarus. The 2005 report prepared by the Chernobyl Forum, led by the International Atomic Energy Agency (IAEA) and World Health Organization (WHO), attributed 56 direct deaths (47 accident workers, and nine children with thyroid cancer), and estimated that there may be 4,000 extra cancer cases among the approximately 6,00,000 most highly exposed and 5,000 among the 6 million living nearby. Although the Chernobyl Exclusion Zone and certain limited areas will remain off limits, the majority of affected areas are now considered safe for settlement and economic activity.

Radioactive wastes are waste types containing radioactive chemical elements that do not have a practical purpose. They are sometimes the products of nuclear processes, such as nuclear fission. However, industries not directly connected to the nuclear industry can produce large quantities of radioactive waste. It has been estimated, for instance, that the past 20 years the oil-producing endeavors of the United States have accumulated eight million tons of radioactive wastes. The majority of radioactive waste is "low-level waste", meaning it contains low levels of radioactivity per mass or volume. This type of waste often consists of used protective clothing, which is only slightly contaminated but still dangerous in case of radioactive contamination of a human body through ingestion, inhalation, absorption, or injection. The United States currently has at least 108 sites it currently designates as areas that are

contaminated and unusable, sometimes many thousands of acres.

The issue of disposal methods for nuclear waste was one of the most pressing current problems the international nuclear industry faced when trying to establish a long term energy production plan.

Nuclear waste requires sophisticated treatment and management in order to successfully isolate it from interacting with the biosphere. This usually necessitates treatment, followed by a long-term management strategy involving storage, disposal or transformation of the waste into a non-toxic form.

Long-term storage of radioactive waste requires the stabilization of the waste into a form which will not react, nor degrade, for extended periods of time. One way to do this is through vitrification. It is also common for medium active wastes in the nuclear industry to be treated with ion exchange or other means to concentrate the radioactivity into a small volume. The much less radioactive bulk (after treatment) is often then discharged. For instance, it is possible to use a ferric hydroxide floc to remove radioactive metals from aqueous mixtures. After the radioisotopes are absorbed onto the ferric hydroxide, the resulting sludge can be placed in a metal drum before being mixed with cement to form a solid waste form.

High-level radioactive waste is stored temporarily in spent fuel pools and in dry cask storage facilities. This allows the shorter-lived isotopes to decay before further handling.

The process of selecting appropriate deep final repositories for high level waste and spent fuel is now under way in several countries with the first expected to be commissioned some time after 2010.

Storing high level nuclear waste above ground for a century or so is considered appropriate by many scientists. This allows for the material to be more easily observed and any problems detected and managed, while the decay over this time period significantly reduces the level of radioactivity and the associated harmful effects to the container material. Sea-based options for disposal of radioactive waste include burial beneath a stable abyssal plain, burial in a subduction zone that would slowly carry the waste downward into the Earth's mantle, and burial beneath a remote natural or human-made island. Another option is to find applications of the isotopes in nuclear waste so as to re-use them. Already, caesium-137, strontium-90 and a few other isotopes are extracted for certain industrial applications such as food irradiation and radioisotope thermoelectric generators. While re-use does not eliminate the need to manage radioisotopes, it may reduce the quantity of waste produced.

Summary

Air Pollution : According to a WHO assessment of the burden of disease due to air pollution, more than 2 million premature deaths each year can be attributed to the effects of urban outdoor air pollution and indoor air pollution. Important pollutants are Sulphurdioxide, Nitrogen oxides, Hydrogen sulphide, Carbon monoxide, Hydrogen cyanide, Ammonia, Lead, Ozone etc and their main sources are mainly industries, motor vehicles, coal and oil combustion, Explosives, dye making, fertilizer plants

etc. The pathological effects on man are aggravation of asthma and other lung and heart diseases, reduction of oxygen carrying capacity of blood, damage kidneys, cause jaundice and also toxic to nervous system.

The WHO Air quality guidelines are designed to offer global guidance on reducing the health impacts of air pollution. They recommend measurement of selected air pollutants, viz. Particulate Matter (PM), Ozone (O₃), Nitrogen dioxide (NO₂) and Sulfur dioxide (SO₂) applicable across all WHO regions. In addition, "smoke (soiling) index" and "coefficient of haze" are also commonly used indicators. In India the Central Pollution Control Board through its National Air Quality Monitoring Programme monitors air quality in all major cities.

Exposure to air pollutants is largely beyond the control of individuals and requires action by public authorities at the national, regional and even international levels. Intersectoral coordination is required with the health sector playing a central role. The major modes of prevention are Containment, dust control devices like Data collection systems, crubber systems, replacement or modernisation of equipment/process and Zoning. The objective of The Air (Prevention and Control of Pollution) Act, 1981 is to provide for the prevention, control and abatement of air pollution in India by the establishment of pollution control Boards at the Centre as well as State levels, and by conferring and assigning such Boards, powers and functions, with a view to implementing air pollution control measures.

Over the past century, the Earth has increased in temperature by about 0.5°C and many scientists believe this is because of an increase in concentration of the main greenhouse gases: carbon dioxide (76%), methane (13%), nitrous oxide (6%), and fluorocarbons (5%). This climate change might be the beginning of Global Warming. The "greenhouse effect" is the heating of the Earth due to the presence of greenhouse gases. The Kyoto Protocol, an international agreement linked to the United Nations Framework Convention on Climate Change sets binding targets for 37 industrialized countries and the European community for reducing Greenhouse Gas (GHG) emissions. In the past 60 years or so human activity has contributed to the deterioration of the ozone layer. When temperatures drop below -78°C (-109°F), thin clouds form of ice, nitric acid, and sulphuric acid mixtures and Chemical reactions on the surfaces of ice crystals in the clouds release active forms of CFCs. Ozone depletion begins, and the ozone "hole" appears. The Montreal Protocol stipulates that the production and consumption of compounds that deplete ozone in the stratosphere such as Chlorofluorocarbons (CFCs), halons, carbon tetrachloride and methyl chloroform are to be phased out. The Govt. of India has come up with Ozone Depleting Substances (Regulation) Rules 2000 under the Environmental Protection Act 1986 so as to control the production, emission and consumption of Ozone depleting substances. In the early morning of December 3, 1984 a Union Carbide pesticide producing plant leaked a highly toxic cloud of methyl isocyanate onto the densely populated region of Bhopal, leading to Bhopal Tragedy with 2,000 immediate deaths, 8000 subsequent deaths and 300,000 diseased.

Noise Pollution : Noise can be described as sound without agreeable musical quality or as an unwanted or undesired

sound. Section 2 (a) of the Air (Prevention and Control of Pollution) Act, 1981 defines air pollution as any solid, liquid or gaseous substance including noise present in the atmosphere in such concentration as may be injurious to human beings or other living creatures or plants or property or environment. 60 db is normal conversation and 80 db is the level at which sound becomes physically painful. The normal human ear can bear frequencies from 20-20,000 Hz.

Broadly, the noise pollution has two sources, i.e. industrial and non- industrial. The industrial source includes the noise from various industries and Non- industrial source of noise includes the noise created by transport/vehicular traffic and the neighborhood noise. Noise exposure can cause non-auditory effects and auditory effects. Non-auditory effects include stress, related physiological and behavioural effects, and safety concerns. It decreases the efficiency of a man. Noise causes lack of concentration in people, elevates blood pressure, sleep disturbance, and decreased school performance. Noise exposure has also been known to induce tinnitus, hypertension, vasoconstriction and other cardiovascular impacts. Beyond these effects, elevated noise levels can create stress, increase workplace accident rates, and stimulate aggression and other anti-social behaviors. Auditory effects include: Acoustic trauma, Tinnitus, Temporary hearing loss, Permanent hearing loss.

Noise mitigation is a set of strategies to reduce noise pollution, which include transportation noise control; architectural design of Buildings, roads, aircrafts and industries; and occupational noise control. Noise pollution can be penalized under I.P.C. Public Nuisance 268-295 relating to public health, safety, decency, morals. Under Noise Pollution Control Rule 2000 under Environment Protection Act 1996 State governments shall take measures for abatement of noise including noise emanating from vehicular movement and ensure that the existing noise levels do not exceed the standards specified. Personal Protection by using Ear plugs and ear muffs is also important.

Soil Pollution : Soil pollution comprises the pollution of soils with materials, mostly chemicals that are out of place or are present at concentrations higher than normal which may have adverse effects on humans or other organisms. It is caused by agricultural runoff waters, industrial waste materials, acidic precipitates, and radioactive fallout. It leads to acute toxicity, mutagenesis (genetic changes), carcinogenesis and teratogenesis (birth defects) for humans and other organisms. Control measures include Bioremediation, Soil Washing, Engineering measures like Proper disposal of community wastes, Industrial and Agricultural wastes through composting, disposable in pits, sanitary landfills etc.

Radioactive Pollution : Radioactive contamination is the uncontrolled distribution of radioactive material in a given environment. Radioactive contamination is typically the result of a spill or accident during the production or use of radionuclides (radioisotopes). The adverse effects on the human body may be acute or chronic (long term). Acute effects include acute radiation sickness. Chronic effects may manifest either as somatic effects or chromosomal effects which result in genetic abnormalities. The most important somatic effect is on haemopoietic system (leukaemias), cancers particularly thyroid and foetal developmental abnormalities if mother is exposed during ante-natal period. Effective protection - Effective protection can be given to workers in hazardous industries by provision of lead shields & lead rubber aprons, TLD badge or dosimeters, Periodic medical exams. The Chernobyl disaster was a major nuclear reactor accident in the Chernobyl Nuclear Power Plant in the Soviet Union on 26 April 1986. Nuclear waste requires sophisticated treatment and management in order to successfully isolate it from interacting with the biosphere. This usually necessitates treatment, followed by a long-term management strategy involving storage, disposal or transformation of the waste into a non-toxic form.

Study Exercises

Long Questions : (1) Enumerate the Sources and Health Hazards of Air Pollution. Describe the measures for its prevention and control (2) Enumerate the Sources and Health Hazards of Noise Pollution. Describe the measures for its prevention and control

Short Notes : (1) Chernobyl disaster (2) Bhopal gas tragedy (3) Radioactive pollution (4) Soil pollution (5) Air pollution Indices (6) Global warming (7) Ozone Hole (8) Auditory effects of Noise pollution

MCQs

1. The main greenhouse gas which is largely contributing to Global warming is (a) Carbon dioxide (b) Methane (c) Nitrous oxide (d) Fluorocarbons
2. Kyoto Protocol is an international agreement which deals with (a) Radioactive pollution (b) Soil pollution (c) Emission of green house gases (d) Noise pollution
3. Bhopal Tragedy of 1984 was due to a toxic chemical called (a) Methyl cyanide (b) Methyl isocyanate (c) Methyl isochloride (d) none of the above
4. Soiling index is an index to measure (a) Radioactive pollution (b) Soil pollution (c) Air pollution (d) water pollution
5. The Chernobyl disaster was a major nuclear reactor accident in the Chernobyl Nuclear Power Plant in the Soviet Union occurred in the year (a) 1982 (b) 1986 (c) 1989 (d) 1990

Answers : (1) a; (2) c; (3) b; (4) c; (5) b.

Rajul K Gupta

The term 'Nutrition' is derived from a Latin word *nutritic*, meaning nourishment (1). Nutrition can be considered to be the foundation of good health and freedom from disease. '*Nutrition science*' has been comprehensively defined by Robinson as '*The science of foods, nutrients and other substances therein; their action, interaction and balance in relationship to health and disease; the processes by which the organism ingests, digests, absorbs, transports and utilizes nutrients and disposes off their end products...*' (2). Simply put the word nutrition is used to refer to the processes of the intake, digestion and assimilation of nutrients and the application of this knowledge to maintain health and combat disease. See Box - 1.

Box - 1 : Significance of nutrition

Adequate nutrition is required for growth, development and maintenance of normal functions

Under nutrition contributes to 60% deaths amongst under five children (WHO, 2002)

More than 85% children in India suffer from malnutrition (44% Mild malnutrition, 38% moderate malnutrition and 4.6% severe malnutrition) (Gomez classification, NNMB 2007)

About 55% men and 75% non pregnant non lactating women are anaemic

Epidemiological data shows strong association between under nutrition and morbidity / mortality

Chronic degenerative disorders such as coronary artery disease, hypertension, type 2 diabetes, certain cancers, etc are related to diet and nutritional status

Obesity is associated with higher risk of developing cancer breast, colon, endometrium, gallbladder, esophagus, pancreas, etc.

Consumption of foods rich in dietary fibre and antioxidants is associated with reduced risk of certain cancers

Under nutrition during foetal and early childhood is known to be associated with chronic degenerative disorders in later life

Good nutrition is a fundamental requirement for positive health, functional efficiency and productivity. Nutritional status is internationally recognized as an indicator of national development. Nutrition is both an input into and an output of, the developmental process (3).

Nutrition is an extremely dynamic subject that changes every day. Continuous research and a constant study into nutrition therefore remains a subject of contemporary interest.

History

It is believed that *Hippocrates*, the Father of Medicine, paid strict attention to the diet of his patients as a feature of his

therapeutic regimens. For instance, his dietetic prescriptions reveal a close relationship of effects of individual foods on both sick and the well. Pulses, he said, should be eaten with cereals. The obese should be advised to labour much, drink little.... Remedial foods have been suggested for fever, 'hot intestines', dysentery, melancholic disorders etc. (4, 5). Ancient Indian texts give adequate indication of the importance that diet and nutrition were accorded during ancient times (Box - 2).

Box - 2 : Aahara, Vichara, Yoga and Ayurveda : The Ancient Indian wisdom

Aahara or the dietary philosophy has been central to the concept of ancient Indian system of medicine, Ayurveda. Prudent food with a strict dietary discipline was the hallmark of ancient Indian lifestyle and one of the secrets of a long and healthy life which the Indians enjoyed in the Vedic times. As per the principles of Ayurveda, the diet is supposed to change with the time of the day and seasons. 'Hot' and 'cold' temperaments of the food are supposed to be balanced with the weather, seasons and climate. These dictums were ingrained in the lifestyle along with good and noble thoughts (vichara) and the discipline of life (Yoga) for a long lasting good health and the ultimate union with the supreme power. Can we learn something from this traditional Indian wisdom!

The phrase '*science of nutrition*' was first used probably by Count Rumond in an essay on feeding poor people in 1795 (6). During the same period Lavoisier who was working on combustion and respiratory metabolism, is said to have established nutrition as a science (7). In 1753 James Lind published the first edition of *A Treatise on the Scurvy* which elaborated how 110 men were disabled by scurvy and were miraculously cured by an Indian remedy (the infusion of the needles of an evergreen tree). Lind was also the first one to study experimentally the value of different substances in the treatment of scurvy, and proved that dietary lemons and oranges cured scurvy (5).

In 1839, a Dutch physician Gerrit Mulder claimed that complex nitrogen compounds like egg albumin, serum albumin, fibrin and wheat gluten all contained a common radical, 'protein' (8). Marasmus was described in the year 1877 by Jules Poirot from France under the term "athrepsie".

The science of nutrition bloomed during the 20th century. Vitamins and amino acids were discovered, human nutritional requirements were established and the relationship between diet, nutrition and the human body in health and disease were recognized. These scientific advances evolved through several phases. Lafayette B. Mender (USA) identified the nutritive value of proteins during 1909-1928. In due course, various experiments and observations by different workers pointed towards some unknown food factors that were vital for the very sustenance of life. JBA Dumas (1871) was the earliest man of science to question the adequacy of diet composed only of proteins, carbohydrates, fats and salts. He had published his observations on the health of infants of Paris made during the siege by the Germans. Pekelharing demonstrated in 1905 the existence of unidentified nutrients in milk and why they were absolutely essential for survival of mice in minute quantities.

In 1912 Casimir Funk (Poland) propounded the theory that beriberi, scurvy, pellagra and possibly rickets were caused by deficiency of “special substances which are of the nature of organic bases” and coined the term ‘vitamine’. Thus the new concept of dietary deficiency diseases was born. In 1926 Goldberger and Lillie described malnutrition in rats also featuring growth arrest, ‘ophthalmia’, hair loss on ears, neck, chest and forearms etc. Fur became matted and fell exposing denuded pale pink skin. Oral and lingual ulcers and fissuring were also noticed. Diarrhoea was also seen in some rats. The condition was diagnosed as rat pellagra. Lean meat and yeast cured it. The curative agent was designated by Goldberger and Lillie as pellagra-preventive (P-P) factor. However, later it was found that this condition (in rats) was not analogous to human pellagra, but was caused due to the deficiency of riboflavin.

The dangerous disease Pellagra was earlier described in Northern Spain in 1735 by Casal. However, scientific world had to wait till Goldberger undertook a study in 1915. He studied the diets of patients and medical staff in State Asylums in South Carolina, Georgia and Mississippi. This study proved that the disease was caused by a deficiency rather than a poison or infection. The search for the pellagra preventing factor travelled through high proteins, yeast and liver and ended with the isolation of nicotinic acid from rice polishings by Funk in 1912. Many other workers also isolated this chemical from other food stuffs (5).

Verner McCollum (USA) discovered a fat soluble soluble factor that was essential for growth (Vitamin A) in 1916 (6). Chick, Windaus and Hess worked on Vitamin D, Evans and Bishop on Vitamin E, King and Gyorgy on Vitamin C, Dam on Vitamin K, Mitchell, Snell and Williams on folic acid and Hodjkin on Vitamin B.

McCance, Mac Kay, Widdowson, McLaren and Woodruff did pioneering work on iron deficiency. Ciceley Williams (England) described Kwashiorkor in 1933. Kerpel Fronuis, Gomez and Cravioto also worked on protein calorie deficiency.

Great debate started in the sixties and seventies on the causation and relationship between marasmus and kwashiorkor where eminent nutritional scientists, Waterlow, Gopalan, Scrimshaw, McLaren and others participated. Various studies on protein and energy requirements, the role of infection, metabolic and endocrine changes, and adaptation were carried out. Derrick Jelliffe, a pioneer in nutrition introduced the term ‘protein-calorie’ malnutrition, which was later modified to protein energy malnutrition and adopted by the FAO/WHO committee in 1971 to describe both kwashiorkor and marasmus.

Into the 21st century : The era of interdisciplinary coordination

Agriculture cannot be kept away from nutrition. Great advances in agriculture were achieved with the green revolution in India. The introduction of genetically engineered food during the last decades of the twentieth century was followed by an ongoing international scientific debate. Parallel advances were achieved in animal nutrition and veterinary medicine, which increased animal food production. The relationship between mad cow disease and animal food as well as its relationship to Cruetzfeld Jacob disease in the humans is stimulating further

research on animal nutrition, communicable disease and food safety. The bird flu endemic has once again opened the Pandora’s Box : ‘*Are the non-vegetarian foods safe enough?*’ (9). Fierce research is on, to answer these questions through the integrated effort of multidisciplinary forces... medicine, virology, veterinary medicine, nutrition, food technology, public health, epidemiology, genetics, biotechnology, mathematical modelling, information technology.... These and many other advances in nutritional sciences represent the ceaseless effort, genuine initiative and devotion of many pioneer scientists all over the world through out the ages.

Food and Nutrients : Major Categories of Foods and Nutrients

Food : Food is a substance eaten or drunk to maintain life and growth. The foods are generally classified into cereals (wheat, rice, maize etc.), legumes (pulses and peas), nuts and oilseeds, vegetables, fruits, milk and milk products and flesh foods (fish, meat and chicken and egg). Diet, on the other hand is what a person habitually eats and drinks.

Nutrients : The nutrients are chemical substances that are present in the food we eat. The important nutrients are proteins, fats, carbohydrates, vitamins and minerals. Foods contain various nutrients in different proportions. Depending on the relative concentration of various nutrients foods can be classified into protein, carbohydrate or fat rich foods.

Why do we eat food? - Functions of food : We eat to satisfy hunger (satiety) and to get energy for our day to day functioning. Food serves many functions in the body :

a) Food builds body tissues : The structural materials of food, proteins, minerals, vitamins and water are needed for growth and development. The food is also needed for the maintenance of the cells and tissues.

b) Food regulates body processes : Many a body processes are regulated by the ‘fuel’ supplied through food e.g. temperature control of the body (calories), control of osmotic pressure (proteins and electrolytes), maintenance of hydrogen ion concentration (pH through electrolytes), solvent power of fluids (proteins and water), nerve conduction (minerals), muscle elasticity (minerals), innumerable metabolic processes (vitamins and minerals).

c) Food supplies energy : The macronutrients (carbohydrates, proteins and fats) supply energy. These provide constant source of fuel to the body. It is measured in terms of a kilo calorie.

d) Food gives us enjoyment : We want to enjoy food and entertain our guests with tasty food.

These requirements may be met by various combinations of the three major food constituents : carbohydrates, proteins & fats, taken in different proportions. Although the actual distribution of each one of these nutrients in our daily diet is vital for good health, one hardly considers their proportion, as long as he enjoys the food. It must be appreciated that our lifestyle governs all facets of our life including our eating habits.

The community faces major nutritional problems from the consumption of inadequate or imbalanced diet. This is true for both healthy and sick. Economic prosperity and affluence, at least in a section of the society, are now threatening the

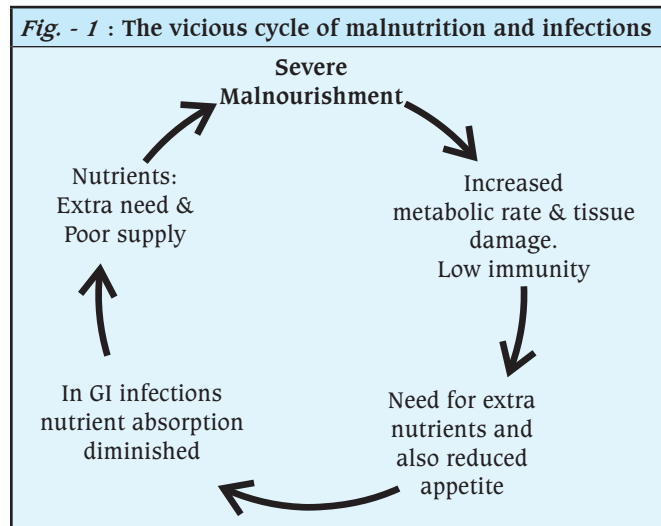

community through over nutrition and its related hazards.

From Under-Nutrition to Over-Nutrition

Within the past few decades, there has been a significant reduction in cases of nutritional deficiencies. Classical nutritional deficiency syndromes of florid pellagra, beriberi, scurvy or kwashiorkor have almost disappeared. We do not come across the famines any more. This improved scenario is a result of multiple inputs namely, smaller families, better food security, economic development, improved health systems, conquest of infections, better health awareness and accountable governance. It is seen that malnutrition among preschoolers has reduced appreciably and nutritional status of adults too has improved significantly. There is not only a major reduction in malnutrition, but over the past decade or so we have stepped into the realm of over nutrition. The number of overweight and obese is steadily and alarmingly rising in India. This is owing to the rapid lifestyle changes that have swept India. Mechanization, motorization, static entertainment (television and computers), sedentary life, low physical activity and the fast food culture has taken its toll. The situation is so alarming that there is a recommendation to redrawn BMI standards with a more stringent 'pen', in a hope to stall the rapid progression of lifestyle diseases - diabetes, hypertension and the coronary artery disease.

The Interplay between Malnutrition and Infection

There has been a close association between malnutrition and infections (Fig. - 1). It is a vicious cycle that is difficult to break in the setting of poverty, ignorance and lack of health services.

Let's take fever as an example. The raised temperature escalates the metabolic rate and thus increases the nutritional demand; it also increases the tissue breakdown further putting an extra nutritional load on the system. In almost all infections the appetite goes down and the absorption and assimilation is also hampered. The requirement of nutrients is increased and to make matters worse, the supply is diminished and the absorption is reduced. The body can cope up with this situation for few days but subsequently acute severe malnutrition develops. Repeated

attacks of acute respiratory or acute diarrhoeal infections are notorious to lead to a malnourished state. Measles is another dangerous condition that has a lasting negative effect on the system through compromised immunity, micronutrient deficiency and severe malnutrition.

Malnutrition in childhood diminishes the proper development of the immune response mechanism. The cellular immune responses are markedly impaired leading to a higher mortality from the seemingly common infections.

Variability in Nutritional Requirements

Even though there is a concept of *standard requirements and intakes*, it must not be forgotten that each person has unique nutritional requirements. This is because each one of us has a unique genetic make up and body biochemistry. A nutrient intake sufficient for one person may be inadequate for other. There are many references in literature where it is quoted that where 2 mg Vitamin B₆ is normally adequate for most but there are individuals with inherited defects in B₆ metabolism and need 30 to 100 times that amount. Similarly the absorption and daily requirements of Calcium varies 3 to 5 folds in various normal individuals. The same can be said for Vitamin D and Iron where metabolic differences in handling these nutrients alter their requirement.

Besides these genetic differences, many other factors can also alter daily requirements, including age, environment and life style choices. Factors as diverse as pregnancy, lactation, sports training, smoking and pollutants can cause nutritional needs to vary. Some of these factors are summarized in the Box - 3.

Box - 3 : Factors altering the daily requirement of nutrients

Biochemical individuality	Genetic differences
Gender	Pregnancy
Lactation	Growth
Infections	Other diseases
Surgery	Drug-Nutrient interaction
Smoking	Alcohol
Caffeine	Environmental pollutants
Activity	Exercise level
Diet factors e.g. intake of : Carbohydrates; Fat; Fibre; Proteins	

Dietary Standards : Concept of Recommended Dietary Allowance (RDA)

It is extremely important to plan the rations and food supplies for various groups, may it be the general community or a specialized group like the armed forces, a school or a prison.

For such a planning we must have a set of standard allowances that are universally acceptable and followed. The first such example (for cereals) can be traced back to ancient Rome (see Box - 4). The concept of various macro-nutrients first evolved in the nineteenth century. At that time the dietary requirements were stated in terms of nutrients rather than foods. In the early twentieth century vitamins came on the landscape and their requirements were also worked out and stated (10).

Box - 4 : The Roman Pound of Wheat

The concept of recommended allowance for the day probably came from the Romans. The Romans gave their legionaries a ration of one 'librum' of wheat per day and that was supposed to meet their caloric requirement for the day. The 'librum' became the British Pound (abbreviated to and still used as 'lb'). One pound of cereal is now known to be good enough to provide energy needed for an adult man for resting metabolism.

Recommended Dietary Allowances or Intakes (RDA or RDI)

The RDA of a nutrient is the amount (of that nutrient) sufficient for the maintenance of health in nearly all people (11). In other words these are the estimates of nutrient intakes which individuals in a population group need to consume to ensure that the physiological needs of all subjects in that population are met. It is an estimate that corresponds to mean intake of the given nutrient + 2 Standard Deviation (that is about 25% of the mean has been added). It covers the requirement of 97.5% of the population. This is the safe level of intake and the chances of this level being inadequate is not more than 2.5%. This 'safe level' approach is however not used for defining the energy requirement, as any excess of energy intake is as undesirable as its inadequate intake. Hence for defining the RDA of energy only the average requirement is considered. The recommended dietary allowances for Indians are summarized in Table - 1 in 'Chapter on Nutritional Tables'.

Can the RDA be Applied to Individuals?

It must be appreciated that the RDA is the mean requirement figure for a nutrient (except energy), to which an allowance corresponding to 2 SD has been added. There are several individuals in a population whose requirement is actually well below or above the RDA. If all the students in a class of 100 were to eat food exactly as per their RDA about half would lose and the other half would gain weight, to the extent of being seriously undernourished or obese after a year! It is because the RDA for energy is a catering average; individuals however consume as per their appetite, which follows their energy expenditure. The RDA can therefore, not be used as standard to determine whether or not a given individual's requirement of a nutrient has been met. It is therefore important to keep the principles of probability in mind and be cautious, when applying RDA at an individual level (10).

RDAs provide a standard against which the nutrients in the food eaten by a section of the community /country can be assessed. It is thus possible to find out a group with a low intake of a particular nutrient. Further nutritional investigations are then mounted to go into the details and suitable measures can be recommended. As discussed earlier, RDAs should not be used to assess the diet of an individual patient as they are designed to be on the higher side than the average individual requirement. Whenever diets are required to be planned for a group like the armed forces, a school, hostel etc., the diet should meet the RDA. Similarly, RDAs are the starting point for the food and economic planning for the agricultural, economic and food sectors. The national level food balance sheets are prepared

keeping the RDAs in mind.

Reference Man and Woman

The final goal of all nutritional policies and recommendations at a national level is to provide adequate nutrition to its population in order to attain their full genetic potential of growth and development. It is important that the ideal/desirable weights and heights are considered to recommend nutrient intakes. For this purpose the ICMR expert committee recommended reference weights for adult men and women to be 60 Kg and 50 Kg respectively.

Reference Indian Adult Man : Reference Indian adult man is between 20-39 years of age and weighs 60 Kg. He is free from disease and physically fit for work. On each working day he is employed for 8 hours in occupation that usually involves moderate activity. While not at work he spends 8 hours in bed, 4-6 hours sitting and moving about and 2 hours in walking and in active recreation or household duties.

Reference Indian Adult Woman : Reference Indian adult woman is between 20-39 years of age and healthy; she weighs 50 Kg. She may be engaged in general household work, in light industry or in any other moderately active work for 8 hours. While not at work she spends 8 hours in bed, 4-6 hours sitting and moving about in light activity and 2 hours in walking or active household chores.

Energy requirements for sedentary, moderate and hard work (12) : Energy requirements of an individual vary over a wide range depending upon the sex, age, body size, BMR and degree of physical activity. As it has been discussed earlier, energy requirements are given in terms of a Reference man/woman. Energy requirements for other individuals with different weights and age have to be calculated.

The classification of physical activity as sedentary, moderate and heavy is essentially based on the occupational activity. Some more examples are given in the Box - 5. The energy requirements for these three categories are summarized in Table 1.

Box - 5 : Some examples : Sedentary, moderate and hard workers

Sedentary worker : Teacher, tailor, barber, priest, executive, peon, retired personnel, shoe maker, housewife, maid, nurse, doctor, clerk, shopkeeper, manager, goldsmith etc.

Moderate worker : Potter, basket maker, carpenter, mason, electrician, fitter, turner, driver, welder, fisherman, coolie, site supervisor, post man etc.

Heavy worker : Stone cutter, blacksmith, mine worker, wood cutter, farm labourer, army soldier etc.

Table - 1 : Energy Requirements of Reference Indian Man and Woman

Sex	Body weight (Kg)	Activity levels		
		<i>Sedentary</i>	<i>Moderate</i>	<i>Heavy</i>
Male	60	2425	2875	3800
Female	50	1875	2225	2925

Prevention of Nutritional Disease and Upkeep of Nutrition in the Community - Role of Individuals, Family, Communities and Governments

It can be well appreciated that it is not merely the 'nutritional' factors that are responsible for nutritional disease. These conditions are truly multi-factorial in origin and progression. The scarcity of food, its nutritional value, distribution, balance in diet, cultural, local and religious factors and beliefs, other social factors like ignorance, poverty, taboos, fads, peer pressure, education, hygiene and sanitation practices, infections, availability of health services, level of immunization services, political will, corporate interests, national commitment, international influences like trade laws and treaties, export-import dynamics and compulsions, inter country relations, the state of global warming - each one of these have a bearing on the nutritional status of a society. When the etiology is so diverse, the prevention too has to be so much broad based and multifaceted. The issue can be tackled at the levels of the individual, family, community and governments.

Individual level : Health begins with the individual. The individual has to take care of himself. Selecting the correct kind of food is vital, based on his age, physiological state, taste and tradition. Besides good diet, physical activity, adequate sleep, mental peace and appropriate meditative or religious activities go a long way in keeping an individual healthy. Knowing the nearest health centre, services available there and warning signs of common illnesses is also important.

Family level : Most of the foods are 'handed over' to us through traditions, and it is not easy to break out of those. Within that framework, it might be decided by the head of the family as to what food stuff is to be brought, cooked or eaten. The family needs to be aware and educated on the issues of nutrition to select the correct foods in different situations of infancy, childhood, pregnancy or lactation. This can happen only when they have risen above the myths, taboos, fads and misconceptions encompassing foods. Misleading advertisements must be put in the right perspective. Children must be explained the hazards of junk food and food additives. Traditional values with respect to food must be highlighted. The family foods used during pregnancy, lactation and weaning must be acknowledged. Locally available foods that are easily available, cheap, fresh and suitable to a particular season are ideal and must be consumed in preference to 'imported' foods. A small kitchen garden will go a long way not only in appreciating good and wholesome food but also in fulfilling the nutritional needs of the family in the most inexpensive and enjoyable manner. The most crucial nutritional decisions are taken at the family level, so the family must be empowered through correct knowledge.

Community level : There might be a number of bottlenecks that exist at a local level which prevent the national programmes reach the grassroot. It is up to the community to meet this challenge of making these programmes actually beneficial to the people. For example the *Gram Sabha*, the local ICDS unit (*Anganwadi*) etc. must be aware of their rights and duties, and whom to approach in case of neglect. The community must be organized and 'live' up to these needs, otherwise they will have to be satisfied with whatever is 'served' to them!

Government level : The responsibility of maintaining the health of individuals lies with the state. The government endeavors to provide all the health services possible. Various nutritional programmes are being implemented as direct intervention to improve the nutritional status of the community. Noteworthy of these are the ICDS Programme, Balwadi nutrition programme and the Special Nutrition programme under the Ministry of Social welfare. Ministry of Health and Family Welfare runs the Nutritional anaemia prophylaxis programme, Iodine deficiency disorders control programme and the Vitamin A prophylaxis programme. The Mid Day Meal programme (for primary children) is being run by the Ministry of Education.

Besides these various indirect measures are being taken by the government for rural development, increasing agricultural production, population stabilization and improving the public distribution system. Research in the field of nutrition is being carried out at premier institutions like the National Institute of Nutrition at Hyderabad that has contributed to offering solutions to nutritional problems.

Summary

The science of foods and nutrients and their action, interaction and balance in relationship to health and disease; the processes by which the organism ingests, digests, absorbs, transports and utilizes nutrients and disposes off their end products is termed as nutrition. Good nutrition is a fundamental requirement for positive health, functional efficiency and productivity. There has been a close association between malnutrition and infections. It is a vicious cycle that perpetuates in the setting of poverty, ignorance and lack of health services.

The variation in the daily requirements of nutrients depends on the genetic differences, age, environment and life style choices. Factors as diverse as pregnancy, lactation, sports training, smoking and pollutants can also cause nutritional needs to vary. However a set of universally acceptable standard nutrient allowances have been devised that are useful to plan the rations and food supplies for diverse groups. The RDA of a nutrient is the amount (of that nutrient) sufficient for the maintenance of health in nearly all people. The RDA is based on the concept of Reference Indian man and woman.

Study Exercises

Long Question : Discuss the role of individual, family, community and government in the prevention of nutrition related diseases.

Short Notes : (1) Indian reference man (2) Nutritional requirement of sedentary man (3) Malnutrition-infection cycle

MCQs

1. Who coined the term 'vitamin' : (a) McCollum (b) Funk (c) Hopkins (d) James Lind
2. A teacher will be classified as a (a) Sedentary worker (b) Moderate worker (c) Heavy worker (d) Average worker
3. A 'safety margin' of + 2 SD is not incorporated for the RDA of (a) Energy (b) Fats (c) Water soluble vitamins (d) Fat soluble vitamins
4. Which of the following diseases is most notorious to prove fatal in combination with malnutrition : (a) Tetanus (b) Anaemia (c) Measles (d) Diarrhoea

5. Choosing what type of food to eat in a household is the function of the (a) Family (b) Government (c) Community (d) Any of the above

Answers : (1) b ; (2) a ; (3) a ; (4) c ; (5) a.

The Proximate Principles and Energy

Rajul K Gupta

The human body requires various nutrients for survival, maintenance of health and to prevent disease. Proteins, fats, carbohydrates, vitamins, minerals and antioxidants are the most important of these. Proteins, fats and carbohydrates are the ones which form the backbone of the nutrients in terms of quantity and these are termed as the proximate principles of food. In order to appreciate the influence of food on health and the factors which affect food requirements, it is necessary to know the chemical composition of food and its metabolism in man. The most primary function of food is to be broken down in the body to generate energy, which is vital for the very survival of the body.

Energy for basal functions, work metabolism and heat for maintenance of body temperature is produced by the oxidation of carbohydrates, fats and proteins. The intake of food is normally balanced by hunger which thus, indirectly balances energy expenditure. Hunger may, however, not indicate this in various pathological states, notably in certain forms of malnutrition. Moreover, hunger can be modified not only by enough intake of food but also by doing less muscular work. Absence of hunger is not, therefore, necessarily an index of an adequate food intake. Before going into the biochemical and physiological qualities of food let us dwell on the basics of energy.

Energy

Energy is required for maintaining the body temperature and vital activity of organs, for mechanical work and for growth. Even when an individual is at complete rest and no physical work is being carried out, energy is required for the activity

of internal organs and to maintain the body temperature. This energy is required for maintaining the basal or resting metabolism. Age, sex, height, weight and state of nutrition of the individual are some of the factors that influence it. The Basal Metabolic Rate (BMR) is determined experimentally when the subject is lying down at complete physical and mental rest, wearing light clothing in a thermo-neutral environment and in the post absorptive state (at least 12 hours after the last meal). The BMR is related more closely to lean body mass (fat free body) rather than to the surface area. The reported value of BMR for Indians is 1 Kcal / Kg/ hr.

Units of Energy

Calorie is the basic unit of energy. Kilo calorie is defined as the heat required to raise the temperature of 1 Kg of water by 1°C from 14.5°C to 15.5°C. The Joule (J) is the SI unit of energy. It is defined as the energy expended when a mass of one kilogram is moved one meter by a force of one Newton (N). Since Joule is too small a unit to describe the energy value of diet, kilo Joule (KJ) and mega Joule (MJ) are of more practical use. One KJ is equal to 1000 J and one MJ is equal to 1000 KJ. However, the old unit of energy, namely, kilocalorie (Kcal) has been in use in nutrition for a long time and is still being used (1, 2). For conversion, 1 Kcal = 4.184 KJ and 1 KJ = 0.239 Kcal. Energy contents of common food items are shown in Table -1 & 2 :

Proteins

Proteins are large molecules made up of nitrogen containing amino acids that are united together by peptide linkages. In adults approximately 16% of body weight is attributable to proteins. Next to water, protein is the major component of body tissues. Proteins are indispensable constituents of living protoplasm as they participate in all vital processes. Proteins are macromolecules consisting of amino acid chains. The human body has a limited capacity of converting one amino acid into another (1, 4). A total of 22 amino acids are now known to be physiologically important for the human body. Under proper conditions, the body is capable of synthesizing some of

Table 1 : Major contributors of energy to our diet - (Some raw foods and their energy content per 100g) (1)

Food stuff	Energy (Kcal)	Food stuff	Energy (Kcal)
Cereals & Millets		Non vegetarian foods	
Wheat flour	341	Egg (hen)	173
Rice polished	345	Fish (Hilsa)	273
Bajra	361	Chicken	109
Maize dry	342	Mutton (lean)	118
Ragi	328	Pork (muscle)	114
Pulses & Legumes		Milk & milk products	
Bengal gram	360	Milk, cow	67
Soya bean	432	Milk, buffalo	117
Rajmah	346	Milk, human	65
Redgram (Arhar)	335	Butter	729
Greengram (Moong)	334	Ghee	900
Lentil (Masoor)	343	Cheese	348
Pea dry	315	Curd	60
Fruits & Vegetables		Nuts	
Banana	116	Groundnut	567
Apple	59	Cashew nut	596
Grapes, pale green	71	Coconut, fresh	444
Custard apple	104	Miscellaneous	
Jack fruit	88	Jaggery	383
Raisins	308	Sugar	398
Potato	97	Veg oils	900

Table 2 : Energy content of selected Indian food items (per serving) (3)

Food item	Kcal	Food item	Kcal
Samosa (1 no.)	256	Dalia (1 plate)	80
Masala dosa (1 no.)	360	Khichri (1 plate)	160
Kachori (2 nos.)	500	Biscuits (4 nos.)	150
Omlette (1 egg)	236	Poha (1 plate)	120
Puri (4 nos. x 25 g each)	320	Bread (2 slices)	125
Chapati with ghee (4 nos.)	360	Chapati (2 nos. x 35 g each)	160
Cake (1 small piece)	250	Kheer (1 katori)	120
Butter chicken (1 katori)	400	Cornflakes (1 bowl)	190
Chicken biryani (200 g)	400	Veg salad	50
Malai paneer (1 katori)	270	Butter milk (1 glass)	90
Paratha (2 nos. x 50 g each)	360	Jam (1 table spoon)	40
Ice cream (100 ml)	250	Dhokla (2 pcs)	100
Pastry (1 no.)	290	Green leafy veg (1 katori)	130
Milk cake (1 piece)	300	Idli (2 nos. x 55 g each)	155
Butter (2 table spoon)	180	Dosa (2 nos. x 45 g each)	250
Fried Cashew (50 g)	375	Tinned cheese (2 tbsps)	105

these amino acids, provided the supply of nitrogen is adequate. These amino acids are known as nonessential amino acids. Others cannot be synthesized by the body and must therefore be supplied in diet. These are the eight essential amino acids viz. leucine, isoleucine, lysine, valine, methionine, threonine, tryptophan and phenylalanine. To these may be added histidine which appears to be essential for the growth of infants (5, 6).

Sources of proteins : There are two main dietary sources of proteins :

- (a) **Animal Sources** : These include eggs, milk, meat and fish
- (b) **Vegetable Sources** : Pulses, nuts, cereals, beans and

oilseed cakes

The major sources of proteins are depicted in Table - 3.

Role in health and disease : The important functions of proteins are summarized in the Box- 1.

Quality of Proteins

The nutritive value of a protein depends upon its amino acid composition. A biologically complete protein is one which contains all the essential amino acids in adequate amounts to meet human requirements. Proteins from foodstuffs of animal origin, such as milk, meat and eggs are biologically superior to proteins of vegetable origin as animal proteins have all the

Box - 1: Functions of Proteins
(a) Proteins are important for body building, growth, repair and maintenance of body tissues
(b) Proteins are required for the synthesis of plasma proteins, haemoglobin, enzymes and hormones
(c) Proteins like collagen, actin and myosin form the structural tissues - skin and muscles
(d) Proteins act as transport carriers for many molecules like iron, haemoglobin, lipids etc.
(e) Antibodies are also proteins. Proteins are involved in the acute phase of inflammation as well
(f) Albumin, a protein, acts as a buffer in the maintenance of blood pH (7)

Table 3 : Major sources including their protein content (g per 100g)

Food Item (Source)	Protein content (g)	Food Item (Source)	Protein content (g)
Eggs	13.3	Milk (Cow)	3.2
Meat (goat, lean)	21.4	Fish (<i>Hilsa</i>)	21.8
Pulses (red gram)	22.3	Soya bean	43.2
Groundnuts	25.3	Wheat flour	12.1
Rice (raw, milled)	6.8	French Beans	1.7

essential amino acids present in them. Most of the vegetable proteins lack one or more amino acid and are thus classified as biologically incomplete proteins.

The essential amino acid that is in shortest supply in a given food item is known as the *limiting amino acid*, for example the limiting amino acid in wheat is lysine and in pulses it is methionine. The quality of vegetable proteins in a vegetarian diet can be improved by providing a suitable combination of vegetable proteins. A relative lack of a particular amino acid in one protein can be compensated by simultaneous consumption of another protein, which contains that limiting amino acid. This is known as *supplementary action*. Thus a diet combining wheat products such as bread (*chapati*) with pulses (*dal*) will compensate for these deficiencies (of lysine and methionine) and provide all the essential amino acids. Other similar examples from Indian diet are *Idli-Sambhar*, *Wada-Pav*, *Rice-Dal*, *Khichri* etc.

Quantitatively the quality of a protein is worked out in terms of biological value, digestibility co-efficient, net protein utilization and protein efficiency ratio. The working formulae for each of these parameters are shown in the Box- 2. The net protein utilization (NPU) is the most commonly used parameter. A protein with an NPU of more than 65 is considered as of optimum quality. Egg protein is considered to have an NPU of 100 and is considered as ideal or reference protein against which other proteins are compared with.

Box- 2 : Quality of Proteins

The quality of a protein depends upon its amino acid composition. A protein containing all amino acids is considered as 'ideal'. Egg protein is taken as the reference protein.	
Biological value (BV) =	$\frac{\text{Nitrogen retained} \times 100}{\text{Nitrogen absorbed}}$
Digestibility co-efficient =	$\frac{\text{Nitrogen absorbed} \times 100}{\text{Nitrogen intake}}$
Net Protein Utilization (NPU) =	$\frac{\text{Retained Nitrogen} \times 100}{\text{Intake of Nitrogen}}$
Protein Efficiency Ratio (PER) =	$\frac{\text{Weight gain in g}}{\text{Protein intake in g}}$

Recommended Dietary Allowance (RDA) for Proteins :

The requirement of proteins is generally accepted to be 1g/Kg/day for adults. So the recommended dietary allowance for a reference adult male works out to 60g/day and for a reference adult female it is 50g/day. An additional allowance of 15g/day is recommended for pregnancy. During lactation an extra allowance of 25g in the first 6 months and 18g in the subsequent 6 months is recommended. Children have a higher protein requirement as elaborated in Table - 4 (1). A detailed account of the requirements of proteins for pregnant and lactating women, infants and children is discussed in the chapter on "*Physiological requirements of nutrients*". An attempt is also made to elaborate as to how this requirement could be met in the typical Indian conditions. Some tips on improving the consumption of proteins is given in the Box- 3.

Deficiency can occur when the diet does not provide enough protein in relation to the requirement which may be high as in the case of young growing children. Secondly, if energy intake is insufficient proteins will be diverted to produce energy and thus causing a deficiency of proteins. Childhood infections (esp. measles) also play an important role in triggering and sustaining a long term protein deficiency. Protein Energy Malnutrition (PEM) is a major cause of concern for children in our country. PEM is discussed in greater details in Chapter on 'Nutritional Deficiency Diseases'.

Table - 4 : Recommended Dietary Allowance (RDA) for Proteins

Group	Activity	Body weight	Requirement g/day
Man	Sedentary work		
	Moderate work	60	60
	Heavy work		
Woman	Sedentary work		
	Moderate work	50	50
	Heavy work		
	Pregnant woman	50	+15
	Lactation		
	0-6 months	50	+25
	6-12 months		+18
Infants	0-6 months	5.4	2.05/ Kg
	6-12 months	8.6	1.65/ Kg
Children	1-3 years	12.2	22
	4-6 years	19.0	30
	7-9 years	26.9	41
Boys	10-12 years	35.4	54
Girls	10-12 years	31.5	57
Boys	13-15 years	47.8	70
Girls	13-15 years	46.7	65
Boys	16-18 years	57.1	78
Girls	16-18 years	49.9	63

Box - 3 : Recommendations on Diet for Proteins
Eat nutritionally balanced diet to get adequate protein
Meat and fish are good sources
Vegetarians must eat proper combination of plant proteins from both cereal and pulses groups
Include Soyabean in your diet
Two to three servings of protein-rich food must be ensured every day
One serving may be equivalent to : <ul style="list-style-type: none"> - One to two cups of cooked meat, poultry, fish - Half cup of cooked dry beans/ lentils/ legumes - One egg - Handful of fried/roasted- salted groundnuts - Handful of roasted Bengal grams

Table-5 : Major sources including their fat content (g/100g)	
Food Item (source)	Fat content (g/100g)
Eggs (hen)	13.3
Milk, cow	4.1
Meat (Goat lean)	3.6
Fish (Hilsa)	19.4
Ghee	100
Butter	81.0
Groundnut	40.1
Mustard seeds	39.7
Coconut, fresh	41.6
Sunflower seeds	52.1

Fats

Fats are organic compounds, which are insoluble in polar solvents (water) but soluble in organic solvents such as ether, chloroform and benzene. These are actual or potential esters of fatty acids. Fats are only distinguished from oils by their different melting points; fats are solid and oils liquid at room temperature. 'Fats' and 'oils' are the ones which the housewife buys and 'lipid' (Greek, *lipos* meaning fat) is the term used by biochemists. However, the general term fat is commonly used to refer to the whole group and is used interchangeably with lipids.

Sources of fats : Dietary fats are derived from two main sources:

(a) Animal Sources : They are milk and milk products (ghee, butter), lard, egg and fish oils. Animal fats in general are poor sources of essential fatty acids with the exception of certain marine fish oils such as cod liver oil and sardine oil, but they are good sources of retinol and cholecalciferol.

(b) Vegetable Sources : They include various edible oils such as groundnut, gingely, mustard, cottonseed, safflower, rapeseed, palm and coconut oil. Vegetable oils with the exception of coconut oil are all rich sources of essential fatty acids, but they lack retinol and cholecalciferol except red palm oil which is rich in carotenoids. Major sources including their fat content are given in Table - 5.

Visible and invisible fats : The visible fats are generally derived from animal fats e.g. butter or ghee or from plant (vegetable) oils like groundnut, mustard, coconut, sunflower or safflower seeds. Hydrogenated oils and margarine would also be classified as visible oils. The visible fat is added to food for cooking, flavouring or shortening. These are the major sources of fats in our diet. Chemically they are triglycerides of fatty acids and could be saturated or unsaturated. It is now believed that the bare minimal requirement of visible fats to meet the essential fatty acid requirements is 15 to 25 g per day. The upper limit is fixed at 30% of the total energy intake or less

than 80 g / day.

Some amount of fat is present in all food stuffs. From the nutritional standpoint, important of them are cereals, pulses, oilseeds, nuts, milk, eggs and meat. Contrary to general awareness, this invisible fat contributes substantially to the total fat consumption and essential fatty acid intake of our diet. Cereals and pulses which are otherwise perceived to be poor in fats contribute significantly towards fat intake of a Indian diet. This is because most Indians depend on the 'staple' of cereals, consumed in a large quantity. The invisible fats may account for 20 to 50% of all fats consumed, depending on the type of diet. It should however contribute to not less than 6% of total energy or about 15g of invisible fats per day.

Types of Fatty Acids

Fatty acids are composed of a straight hydrocarbon chain with one methyl group ($-\text{CH}_3$) and terminating with a carboxylic acid group ($-\text{COOH}$). Hydrogen atoms are attached to the carbon chain; the number of hydrogen atoms determines the degree of saturation (with hydrogen atoms) of the fatty acid. A fatty acid with hydrogen atoms on every arm is said to be 'saturated'. Unsaturated fatty acids contain double carbon bonds where there is no hydrogen. If there is only one double bond, the fatty acid is termed as monounsaturated and when more than one double bond is present, the fatty acid will be polyunsaturated.

Saturated Fatty Acids (SFA) : *Saturate* (Latin, *to fill*, in this case with hydrogen). Saturated Fatty acids have a relatively high melting point and tend to be solid at room temperature. These are obtained from animal storage fats and their products e.g. meat fat, lard, milk, butter, cheese and cream. Fats from plant origin tend to be unsaturated with the exception of coconut oil and palm oil. A high intake of SFA is associated with an increase in LDL and total cholesterol and thus increases the risk of atherogenesis and cardiovascular disease. Some examples of SFAs are Myristic acid, Palmitic acid and Stearic acid.

Monounsaturated Fatty Acids (MUFA) : MUFA contain only one double bond and are usually liquid (oil) at room temperature. Olive oil and rapeseed oil are good dietary sources

of MUFA. MUFA are also present in meat fat and lard. Dietary MUFA does not raise plasma cholesterol. They lower LDL cholesterol without affecting the HDL. Oleic acid is an example of MUFA.

Polyunsaturated Fatty Acids (PUFA) : PUFA contain two or more double bonds and they too are liquid at room temperature. They are easily oxidized in food and in the body. PUFA have a vital role in immune response, blood clotting and inflammation. PUFA are divided into omega-3 ($\omega 3$) or omega 6 ($\omega 6$) groups of PUFA. Omega-3 (ω) polyunsaturated fatty acids PUFA are found in fish and fish oils. The health benefits of these include reducing the cardiovascular risk factors (see Box - 4). Research also indicates their beneficial role in cognitive function of brain. Some common omega-3 fatty acids are α -linolenic acid (linseed, soyabean, rapeseed, leafy vegetables), eicosapentaenoic acid (marine algae, fish oils) and docosahexenoic acid (fish oils).

Box-4 : Omega-3 ($\omega 3$) Fatty Acids in Prevention and Therapy

Coronary artery Disease (CAD) : Omega-3 ($\omega 3$) Fatty Acids reduce the tendency of platelet aggregation, blot clot formation and thus atherosclerosis. Chances of cardiac arrhythmias also go down, thus benefiting in CAD.

Hypertension : They lower the high blood pressure in hypertensives.

Hyperlipidaemia : They lower the high blood lipids (triglycerides and total cholesterol), while increasing HDL-c.

Bronchial asthma : $\omega 3$ Fatty Acids reduce inflammation, frequency and severity of asthma.

Diabetes : They lower the high blood triglycerides blood pressure and reduce leakage of proteins from small vessels, thus improving the overall metabolism and the diabetic state.

Autoimmune disorders : Omega 3-Fatty Acids are known to reduce pain, inflammation and joint stiffness in rheumatoid arthritis. Other autoimmune disorders also improve with their supplementation.

Miscellaneous : They are found to be useful in conditions like migraine, inflammatory skin disorders and osteoarthritis.

Trans Fatty Acids (t-FA)

Trans fatty acids rarely occur in nature. These are produced during the partial hydrogenation of PUFA. In Indian homes this process takes place commonly when oil is heated over and over again as it happens during the process of frying *puri*, *pakori* or *samosa*, esp. when the same oil is boiled repeatedly. Trans fatty acids have been associated with adverse effects on lipoprotein status by elevating LDL and depressing HDL.

Essential Fatty Acids (EFA)

If fats are entirely excluded from the diet, retarded growth, dermatitis, kidney lesions and an early death might result. Studies have shown that feeding of certain unsaturated fatty acids e.g. linoleic and linolenic acid is effective in curing the condition. It is therefore evident that certain unsaturated fatty acids cannot be synthesized in the body and must be acquired from diet. These are essential fatty acids. EFA are commonly found in plant and fish oils (8). The EFA requirement is 3-6% of the total energy intake depending on the age and physiological status of the individual. Fatty acid content of different fats is given in Table - 6.

Why fats in diet? : If the contemporary literature is to be believed, one tends to agree that fats are well known for their role in causation of many chronic diseases rather than any worthwhile virtue! Then why should fat be consumed at all and how much? The main functions of fat are elaborated in the Box - 5.

Unlike proteins where the precise intake, assimilation, excretion and thus requirement can be worked out, the quantity of fats that should be included in a well balanced diet is a matter of conjecture. The following aspects however are important in considering the recommendation for fat intake :

- a) The quantity of fat intake should be good enough so that requirement of essential fatty acids (which are a component of fats) is met.
- b) Absorption of fat soluble vitamins should not be compromised.
- c) Fat intake should be sufficient enough to make diet palatable.
- d) Some stores must be maintained in the body to tide over a lean period.
- e) It should not be so much in quantity that it causes undesirable effects on health.

Cholesterol
Cholesterol is always talked as if it is the hazardous abnormal fat. It is considered by many as a type of a saturated fat. In fact it is only a fat related compound. Chemically it falls under the group of sterols. It is named after the body material where it was first identified, the gallstones (Greek, <i>chole</i> , bile; <i>steros</i> , solid)
Synthesis : It is synthesized only in the animal body. All plant products are free of cholesterol. The human body synthesizes indigenous cholesterol primarily in liver (but also in adrenal cortex, skin, intestines, testis and ovaries), for sustaining life. It is a normal constituent of bile and a principal part of the gall stones
Sources : The important dietary sources are egg yolk, meat (liver and kidney). There are no plant sources of cholesterol
RDA : Since it is synthesized indigenously in the body, there is no dietary requirement of cholesterol. However, the upper limit of cholesterol consumption has been put at 300mg per day
Functions : It is vital as a precursor to various steroid hormones e.g. sex hormones and adrenal corticoid hormones.
Hazards : In dysfunctional lipid metabolism, it is considered the major factor for atherosclerosis. Epidemiological studies have linked high cholesterol intake to the increased risk of coronary heart disease

Table - 6 : Approximate fatty acid composition of common fats and oils (g/100g) (8)

Oil/Fat	Saturated	MUFA	Linoleic acid	α -linolenic acid	Predominant FA
Coconut	90	7	2	<0.5	SFA
Palm kernel	82	15	2	<0.5	SFA
Ghee	65	32	2	< 1.0	SFA
Vanaspati	24	19	3	<0.5	SFA (t-FA)
Red palm oil	50	40	9	<0.5	SFA + MUFA
Palm oil	45	44	10	<0.5	SFA + MUFA
Olive	13	76	10	<0.5	MUFA
Groundnut	24	50	25	<0.5	MUFA
Rape/ Mustard	8	70	12	10	MUFA
Sesame	15	42	42	1.0	MUFA + PUFA
Rice bran	22	41	35	1.5	MUFA + PUFA
Cotton seed	22	25	52	1.0	PUFA
Corn	12	32	55	1.0	PUFA
Sunflower	13	27	60	<0.5	PUFA
Safflower	13	17	70	<0.5	PUFA
Soyabean	15	27	53	5.0	PUFA

Table - 7 : RDA of Fats for Indians

Group	Particulars	Body wt (Kg)	RDA Fat (g/d)
Man	Sedentary work	60	20
	Moderate work		
	Heavy work		
Woman	Sedentary work	50	20
	Moderate work		
	Heavy work		
	Pregnant woman	50	30
	Lactation		
	0-6 months	50	45
6-12 months			
Infants	0-6 months	5.4	
	6-12 months	8.6	
Children	1-3 years	12.2	25
	4-6 years	19.0	
	7-9 years	26.9	
Boys	10-12 years	35.4	22
Girls	10-12 years	31.5	
Boys	13-15 years	47.8	22
		46.7	
Boys	16-18 years	57.1	22
		49.9	

Based on these aspects, the ICMR has recommended levels of fat intake for Indians (RDA) that are summarised in Table - 7.

Recommended Dietary Allowance : The RDA for adults is 20g of visible fat per day. For pregnant and lactating women it is 30 and 45 g respectively. The RDAs for various groups are given in Table - 7 (1). Fat content of diet should not exceed 20 to 30% of the total calories consumed. The dietary cholesterol should be limited to 300 mg/day.

Hazards of Excess Fat in Diet : Excess fat is dangerous on two accounts. First, in case it is consumed in a higher quantity and secondly if the wrong quality of fat is consumed.

Quantity of Fat : With an improving economy and a richer lifestyle we tend to consume a higher calories especially from the fat source. Higher calories lead to obesity and many other lifestyle diseases. A high level of fat in diet is notorious in the causation of atherosclerosis and so is a major risk factor for Cardiovascular Diseases (CVD) including coronary artery disease and strokes. Any amount that contributes to more than 30% of total calorie intake is considered as high. Low physical activity and sedentary lifestyle further augment the risk.

Quality of Fat : High levels of saturated fatty acids are more dangerous. A proportionately higher content of polyunsaturated

Box - 5 : Functions of Fats

They are concentrated sources of energy providing about 37.7 KJ/g or 9 Kcal /g.

Fats serve as vehicle for fat soluble vitamins (A,D, E and K).

Fats are structural components of cell and cell membrane.

They are the sources of essential fatty acids. Linoleic acid and arachidonic acid are precursors of prostaglandins which are required for a wide variety of metabolic functions.

Apart from their nutritional significance, fats improve the palatability of diet, delay gastric emptying & raise the caloric density.

Some fats can be converted to biologically active compounds such as steroid hormones, interleukins, thromboxanes and prostaglandins and bile acids (from cholesterol).

fatty acids is found to be protective for CVD. Unfavourable levels of certain lipoproteins have adverse effects on health. High levels of LDL are associated with higher atherosclerotic risk so LDL is colloquially known as '*bad cholesterol*'. A high level of HDL has favourable effect on the cardiovascular system and is termed as '*good cholesterol*'.

Tips on fat intake	
Food preparation	Use minimal oil for preparation
	Rotate the types of oil used
	Use only lean cuts of meat
Meat	Prefer fish to poultry
	Prefer poultry to mutton/beef/pork
	Limit added oils in meat preparations
Eggs	Avoid more than one egg a day
	Avoid adding oil to egg preparations
	Use egg whites freely
Milk	Prefer low fat milk

Carbohydrates

Carbohydrates are the basic source of fuel to run life on earth. It is these carbohydrates into which the energy from sun is converted through the process of photosynthesis by plants. In fact this is the energy that is used by all living organisms. Thus carbohydrates can be considered as the very 'basis' of life. Chemically carbohydrates are polyhydroxy aldehydes or ketones, or substances that produce such compounds when hydrolyzed. They contain carbon, oxygen and hydrogen in proportion approximating that of a 'hydrate of carbon' (CH₂O), hence the term carbohydrate.

Classification : From the nutritional or functional point of view, carbohydrates can be divided into two categories.

(a) **Available carbohydrates** : These are the carbohydrates which can be digested in the upper gastrointestinal tract, absorbed and utilized. These are further sub-classified as polysaccharides, disaccharides, monosaccharides.

(i) *Polysaccharides* such as starch, dextrin and glycogen

(ii) *Disaccharides* such as lactose, sucrose and maltose

(iii) *Monosaccharides* such as glucose, fructose and galactose.

(b) **Dietary Fibre** : The second category comprises of unavailable carbohydrates or dietary fibre, which are difficult to digest. These are cellulose, hemicellulose, gums, pectins etc. A detailed account of these is given later in this chapter.

Sources of Carbohydrates : The major source of dietary carbohydrates in an Indian set up is starch from cereal grains, millets, legumes, roots and tubers (Table - 8).

With increasing prosperity as in industrial societies, sugar has replaced complex carbohydrates as the main source. The presence of monosaccharides (free glucose or fructose) is limited to fruits and vegetables, otherwise they are not abundant in natural foods. Fructose is found in honey, fruits and vegetables. Sucrose and Lactose are the commonest disaccharides. Sucrose is extracted from sugar cane. Table sugar is 99% sucrose. Sucrose gets hydrolysed into glucose and

Food stuff	Carbo- hydrates (g)	Food stuff	Carbo- hydrates (g)
<i>Cereals & Millets</i>		<i>Pulses & Legumes</i>	
Wheat flour	69.4	Bengal gram	60.9
Rice polished	78.2	Soya bean	20.9
Bajra	67.5	Rajmah	60.6
Maize dry	66.2	Redgram (Arhar)	57.6
Ragi	72.0	Pea dry	56.5
<i>Fruits & Vegetables</i>		<i>Miscellaneous</i>	
Banana	27.2	Milk, cow	4.4
Apple	13.4	Groundnut	26.1
Mango	16.9	Cashew nut	22.3
Raisins	74.6	Coconut, fresh	13
Tapioca	38.1	Jaggery	95
Sweet potato	28.2	Sugar	99.4
Potato	22.6	Honey	79.5

fructose. Lactose is found in milk. It is hydrolysed to glucose and galactose. Maltose is present in malted wheat and barley. Other sources are nuts and seeds.

Functions of Carbohydrates : Carbohydrates are the most significant and cheapest source of energy in the diet. One gram of carbohydrates provides 4 Kcal energy. Carbohydrates provide 60 to 85% of energy in our Indian diet. Various kinds of sugars (glucose, fructose, sucrose etc.), most literally, impart the sweet taste to life! Carbohydrates play an important role wherein glycogen resources in the muscles and liver are in a state of dynamic exchange with the energy balance (of intake and expenditure) through the liver. A constant supply of carbohydrates has a protein sparing action and proteins are not required to be broken down for energy. Similarly fats are also spared to be used up if enough carbohydrate supply is maintained. The brain exclusively uses glucose and is dependent on its constant supply for its functioning.

Fibre, which is a type of carbohydrate, has the important function of increasing faecal bulk, stimulating peristalsis and blocking cholesterol synthesis in the liver.

Requirement of Carbohydrates : In a prudent diet carbohydrates should contribute to 60 to 70% of total energy (1). This translates to about 360 to 400g carbohydrates for a 2400 Kcal diet. Details about role and requirements of dietary fibre are discussed in forthcoming paragraphs.

Problems Due to Deficiency and Excess : Whenever there is a deficiency of carbohydrates in diet not compensated by other nutrients, a situation of energy deficiency sets in. This is typically seen in infants and children wherein protein calorie malnutrition is not uncommon. A similar situation of energy deficiency may result in food deprived people in cases of starvation as encountered in famines and droughts. Anorexia nervosa is a condition with a major psychological component,

wherein the patient doesn't eat food and ends up being cachexic. A very low carbohydrate diet results in utilization of other macronutrients (lipids and proteins) for energy and result in production of ketone bodies (ketosis). Eventually bone mineral loss, hypercholesterolaemia and increased risk of urolithiasis may result.

Consumption of an excess of carbohydrates seems to be a bigger problem in the present day scenario of progressive economies. If the intake is large enough to provide excessive calories such an individual ends up being obese and might fall prey to a host of lifestyle diseases (discussed in another chapter). It is interesting to note that excess of even few calories per day (100-200 Kcal) over a couple of months accumulates enough calories to cause obesity.

Dietary Fibre

Denis Burkitt (a surgeon) and Hugh Trowell (a physician), served for 30 years, after the World War II, in Makerere University, Kampala, Uganda, before returning to Britain. They were struck by the great difference in the pattern and nature of disease affecting the affluent West as opposed to more primitive communities. They concluded that the large amount of dietary fibre was not only responsible for the faecal bulk but was also directly or indirectly related to the difference in the pattern of disease. A 'fibre hypothesis' was thus formulated which suggested that unrefined complex carbohydrates protected against the 'western ailments': colonic cancer, diverticular disease, appendicitis, constipation, hemorrhoids, hiatus hernia, varicose veins, diabetes, heart disease, gall stones, obesity etc.

Dietary fibres are the remnants of the plant cell resistant to hydrolysis by alimentary enzymes and do not provide significant nourishment. They remain in the ileum but are partially hydrolyzed by the colonic bacteria. The term 'dietary fibre' is a broad term which includes Non Starch Polysaccharide (NSP) and related material such as resistant starch, resistant oligosaccharides, lignin and complex assemblies of plant tissue where polysaccharides occur in close association with other molecules (9).

Classification : Fibres can be *Carbohydrate fibres* and *non-carbohydrate fibres*. The carbohydrate fibres include Non Starch Polysaccharides (NSP) which are normally present in cell wall, cement, plant gums, mucilages and algal polysaccharides; and the Resistant Oligosaccharides (ROS) which are found in leguminous seeds e.g. Rajma, soy beans and gram (10). The *Non Carbohydrate fibres* include Lignin which is a large compound forming the woody part of some plants. It strengthens the plant cell walls.

Fibre can also be classified according to solubility in water, as soluble or insoluble. Insoluble fibre consists mainly of cellulose, hemicellulose and lignin. Since they remain undigested in the gut they form bulk and help in movement of the food and peristalsis. Thus they help in elimination of waste products as well. After absorption of water the fibre swells up and facilitates the gut movement further.

On the other hand the natural gel forming fibres like pectins, gums and mucilages are soluble.

Sources and Losses : Cereals, fruits and vegetables are the chief sources of fibres. The important sources of soluble and insoluble fibre are summarised in Table - 9.

Table - 9 : Major food sources of fibre	
Insoluble fibres	
<i>Vegetables</i> : Peas, beans, amaranth leaves	
<i>Cereals</i> : Rye, bran flakes, brown rice, Corn, whole wheat	
<i>Whole meal cereals</i> : <i>Dalia</i> , whole meal flour, <i>Ragi</i> porridge	
<i>Breads</i> : Granary bread, brown bread	
<i>Legumes</i> : Bengal gram (whole), Lentils pulses and <i>dals</i>	
<i>Sprouts</i> : Sprouted grains, legumes	
<i>Fruits</i> : Fruits with edible seeds	
Soluble fibre	
<i>Citrus fruits</i> : Orange, lime	
<i>Berries</i> : Straw berry, rasp berry	
<i>Other Fruits</i> : Pomegranate, Figs, grapes, guava, Sapota, Custard apple	

Functions : Dietary fibre stimulates chewing, improves flow of gastric juice and provides a sense of satiety. Insoluble fibre binds to water in the colon and swells. Hence, it forms substrate for colonic bacterial fermentation. This stimulates peristalsis which increases transit time in the colon thereby reducing the risk of constipation and possibly that of colon cancer. Some fibres like lignin helps in prevention of absorption of bile acids by binding to them. On the other hand soluble fibres prevent the micelle formation by binding with bile acids & other lipids (11).

Recommended Dietary Allowance : The diet should contain 35-40 grams of dietary fibre per day (15g per 100Kcal) (1). Fibre content of selected food stuffs are given in Table - 10.

Table - 10 : Dietary fibre content of common foods (g/100g)			
Foodstuff	Fibre content (g per 100g)	Foodstuff	Fibre content (g per 100g)
<i>Cereals & Legumes</i>		<i>Fruits</i>	
Rice, raw, milled	0.2	Guava	5.2
Wheat flour, whole	1.9	Mango, papaya	0.7
Bengal gram, whole	3.9	Pomegranate	5.1
Red gram (<i>Dal arhar</i>)	1.5	Peach, pears, apple	1.0-1.2
Peas dry, <i>Rajmah</i>	4.5	Figs, Sapota	2.2-2.6
<i>Green vegetables</i>		<i>Nuts</i>	
Cabbage, cauliflower, Fenugreek (<i>maithi</i>)	1.0 -1.2	Areca nut	11.2
Amaranth	1 to 6.1	Coconut fresh	3.6
Spinach, radish leaves	0.6	Groundnut	3.1

Dietary Fibre in Health and Disease : Fibre helps in achieving prevention of cardiovascular disease through various mechanisms

- Soluble fibre binds with bile acids and alters the quantity of cholesterol or fatty acids absorbed.
- The re-absorption of bile acids is slowed by soluble fibre to increase cholesterol losses in faeces.
- Intestinal bacteria reduce soluble fibre to short chain fatty acids which block cholesterol synthesis in the liver.

Fibres also help in the maintenance of weight and prevention of obesity. Soluble fibre blunts the response of blood glucose through prevention of direct glucose absorption in the gut. This helps in the control of hyperglycaemia. Soluble and viscous fibres (pectin and gums) have the greatest hypoglycemic effect (12).

Fibre is also considered to be an important contributory factor to the prevention of colonic cancer (13).

In addition, fibre increases faecal bulk and relieves constipation. This reduces the incidence of colonic cancers, diverticulitis and appendicitis. The alteration in cholesterol production and further metabolism reduces the formation of gallstones as most of them are of cholesterol origin.

Study Exercises

Short Notes : (1) Dietary fibre in prevention of lifestyle diseases (2) Hazards of excess fats in diet (3) Invisible fats (4) Dietary importance of egg (5) Supplementary action of proteins

MCQs

- Which is true for cholesterol (a) It is a type of saturated fatty acid (b) It is present in egg yolk, ghee and coconut oil (c) The dietary requirement of cholesterol is zero (d) Everyone with high cholesterol gets IHD
- Which of the following is not a source of dietary fibres (a) Vegetable fibres (b) Muscle fibres (c) Bran (d) Fruits

- The limiting amino acid in wheat is ___ and in pulses it is ___ (a) Lysine, methionine (b) Methionine, lysine (c) Cysteine, lysine (d) Lysine, cysteine
- Which lipoprotein is termed as 'good' cholesterol : (a) LDL (b) HDL (c) VLDL (d) Chylomicrons
- Which of these will provide energy the quickest : (a) Milk (b) Chapati (c) Butter chicken (d) Fruit juice

Answers : (1) b; (2) b; (3) a; (4) b; (5) d.

Rajul K Gupta

"Milk and leaves occupy a unique position, as they correct the defects of cereals, tuber, roots and meats. Thus...they be distinguished by the term 'Protective foods'."

~ EV McCollum (1)

By and large vitamins were discovered during the search for cures of classic deficiency diseases. In 1753 when James Lind, a British naval surgeon, observed that fresh lemons, limes and oranges, prevented/cured scurvy, the British sailors always carried lemons with them on long voyages and were nicknamed

as 'limeys'.

Many subsequent observations and experiments in 1896 by C Eijkman on rice polishings and beriberi, Frederick Hopkins of Cambridge University on milk in 1906, Verner McCollum (USA) on the fat soluble factor (Vitamin A) in 1916 just to name a few, established them to be vital for life that paved the way for the vitamins to be named so (from the words *vital amine*) by Casimer Funk, a Polish scientist in 1912.

Definition : Vitamins are organic compounds required in very small but definite quantities for normal growth and maintenance of a healthy life. They are not synthesised in the body and have to be supplied in the diet. They do not furnish energy and play no part in the constitution of the structure of tissues, but are essential for the transformation of energy

and regulation of tissue metabolism. They are necessary for the efficient functioning of the organism as a whole, each in a specific manner. Deficiency of vitamins causes profound changes in structural and functional wellbeing, the picture of each deficiency being specific.

Dietary sources : Vitamins are widely distributed in diet. Fresh milk, meat, eggs, fresh vegetables and fruits are rich sources. Cereals (esp. whole unrefined cereals) which form the bulk of our diet are also important sources. Storage, processing and cooking of food may cause considerable vitamin loss, so that the maintenance of an adequate intake is more difficult when fresh food is scarce. The pharmaceutical use of vitamins should be restricted to rectify or supplement the envisaged or existing deficiency in the diet or to meet the increased physiological demands (e.g. in pregnancy). No physiological benefit, however, can be expected from a large dose of vitamins under normal circumstances.

Classes of vitamins : Vitamins have long been classified into two groups; water soluble and fat soluble. The water soluble group comprises of vitamins B and C; the fat soluble vitamins are A, D, E and K. This division is still useful, since it helps to understand the distribution of vitamins in foods and their absorption and metabolism in the body.

Storage and excretion : There is an important distinction in the handling of the two classes of vitamins by the body. An excess intake of water soluble vitamins is excreted in the urine. Thus, there is virtually no danger in giving an excess of these vitamins. On the other hand, the fat soluble vitamins cannot be excreted in this way. Any excess of these vitamins, beyond the immediate requirement is stored in the liver. The storage capacity of the human liver is large and it normally holds a reserve of vitamins sufficient for many months; this is a useful provision for times when the dietary supply may temporarily be cut off. However the amount that can be stored is not unlimited (2).

Functions : As mentioned earlier they do not furnish energy and play no part in the constitution of the structure of tissues directly, but are essential for control of cell metabolism, transformation of energy, and prevention of specific nutritional deficiencies.

Many vitamins are now known to have antioxidant properties. This has rejuvenated the interest of scientist in exploring further the hidden potential of these vitamins in maintaining health and also curing disease. The scope of vitamins has now widened from their earlier role of curing specific deficiencies to preventing cancers and even aging! A summary of the traditional functions of major vitamins are given in tables at the end of this chapter.

Water Soluble Vitamins

Thiamine (Vitamin B₁)

Thiamine hydrochloride is a crystalline substance which is readily soluble in water. It is rapidly destroyed by heat in neutral or alkaline solutions. In acid solutions however, it is resistant to heat up to 120°C. It is mainly excreted in urine. Thiamine is present in the body mostly as thiamine pyrophosphate (TPP) but about 10 percent as thiamine triphosphate. TPP is the

active form of thiamine in the body.

Sources : The important stores are seeds of plants. The germ of cereals, nuts, pea, beans and other pulses and in addition yeast is a rich source. In cereal grains, thiamine is found in highest concentration in the germ or embryo, less in bran and least in endosperm. All green vegetables, roots, fruits, nuts, flesh foods and dairy produce contain significant amounts of the vitamin. Pork has a higher content of thiamine than beef or mutton. Highly processed foodstuffs like white bread, polished rice and refined sugar are deficient in thiamine (See Table-1).

Table 1: Thiamine content of selected food items (per 100g) (4)

Food stuff	Thiamine (mg)	Food stuff	Thiamine (mg)
<i>Cereals</i>		<i>Vegetables</i>	
Wheat flour	0.49	Beans	0.10
Rice polished	0.06	Spinach	0.03
<i>Bajra</i>	0.33	Carrot	0.04
Maize dry/ <i>Ragi</i>	0.42	Capsicum	0.55
<i>Pulses & Legumes</i>		<i>Fruits</i>	
Bengal gram	0.30	Pineapple	0.2
Soya bean	0.73	Guava	0.03
Green gram	0.47	<i>Amla</i>	0.03
Red Gram	0.45	Tomato	0.12
Peas dry	0.47	Mango	0.08
<i>Non vegetarian foods</i>		<i>Nuts</i>	
Egg	0.10	Groundnut	0.90
Liver sheep	0.36	Cashew nuts	0.63
Milk cow	0.05	Almond	0.24
Fish, <i>Rohu</i>	0.05	Coconut, fresh	0.05
Mutton	0.18	Coconut, dry	0.08

Losses : Milling of cereals below an extraction rate of 75 percent reduces the content of thiamine to a great extent. As thiamine is readily soluble in water, considerable amounts may be lost when foodstuffs are cooked in an excess of water which is afterwards discarded. It is relatively stable to heat up to boiling point, provided that medium is slightly acidic, as in baking with yeast. But if baking powder is used, or if soda is added in the cooking of foodstuffs, almost all the vitamin may be destroyed.

Functions : Thiamine is one of the most important water soluble vitamins and acts as a coenzyme in many metabolic reactions. The important ones being the oxidative decarboxylation of pyruvic acid and transketolase reaction in HMP shunt. The vitamin is essential for the health of the nerve tissue and for normal cardiac and gastro-intestinal functions (5,6).

Requirements : Since thiamine plays an important role in carbohydrate metabolism, its dietary allowance is related to energy intake. It is 0.5mg per 1000 Kcal (4).

Deficiency : Thiamine deficiency causes beriberi and Wernicke-Korsakoff psychosis. Three forms of Beriberi are known: Wet Beriberi (cardiac), Dry Beriberi (neurological) and Infantile Beriberi. The early symptoms and signs are common in both dry and wet Beriberi. The onset is usually insidious, though sometimes precipitated by unwanted exertion or a minor febrile illness (5).

Beriberi
(<i>Singhalese</i> , meaning "I can't, I can't"). The disease caused by the deficiency of thiamine, characterized by oedema resulting from cardiac failure (Wet beriberi) or peripheral neuritis, pain in limbs and paralysis (Dry beriberi).

(a) *Wet beriberi* is the acute form. It is characterized by high output cardiac failure, bounding pulse, warm extremities, peripheral oedema and cardiac dilatation.

(b) *Dry beriberi* is the chronic form of disease and is characterized by progressive peripheral neuropathy. The tendon jerks are sluggish and anaesthesia of the skin (especially over tibia) is common. The muscles become progressively wasted and weak and walking becomes increasingly difficult. The thin, even emaciated individual needs at first one stick, then two and may finally become bedridden.

(c) *Infantile beriberi* occurs in the first few months of life (of an infant), if the diet of mother is deficient in thiamine. The infant remains constipated and appears plump due to water retention. The heart is enlarged and the heart sounds are muffled. The infant may die of a heart failure if untreated (7)

(d) *Wernicke-Korsakoff psychosis* is seen in chronic alcoholics with poor diet. It is characterised by confusion, low levels of consciousness and poor coordination (encephalopathy). Memory loss often follows the encephalopathy.

Riboflavin

Riboflavin, the word comes from a Latin word *flavous*, yellow, containing a sugar named ribose). As is clear from the name it is a yellow green fluorescent compound, soluble in water but not in fats. Though stable in acid solution, in alkaline solution it is readily destroyed by heat. It is also destroyed by short visible and ultraviolet rays.

Sources & Losses : The best sources of riboflavin are liver, milk, eggs and green vegetables (See Table-2). Cereals and yeast extracts also contain the vitamin. Cooking does not destroy the vitamin apart from losses that occur when the water in which green vegetables have been boiled is discarded. If food, especially milk, is left exposed to sunshine, large losses may occur.

Functions : Riboflavin is involved in oxidation-reduction reactions within the cells in many metabolic pathways. The important functions of riboflavin include:

- Promotion of normal growth
- Assisting synthesis of steroids, RBC and glycogen
- Maintenance of mucous membranes, eyes and the nervous system
- Aiding iron absorption (5)

Table 2 : Riboflavin content of selected food items (per 100g) (4)

Food stuff	Riboflavin (mg)	Food stuff	Riboflavin (mg)
<i>Cereals</i>		<i>Vegetables</i>	
Wheat flour	0.17	Beans	0.06
Rice polished	0.06	Spinach	0.26
<i>Bajra</i>	0.25	Carrot	0.02
Maize dry	0.1	Amaranth	0.30
<i>Pulses & Legumes</i>		<i>Fruits</i>	
Bengal gram	0.15	Pineapple	0.12
Soya bean	0.39	Guava	0.03
Green gram	0.47	Raisins	0.19
Red Gram	0.45	Tomato	0.06
Peas dry	0.47	Mango	0.09
<i>Non vegetarian foods</i>		<i>Nuts</i>	
Egg	0.40	Groundnut	0.13
Liver sheep	1.7	Cashew nuts	0.19
Milk cow	0.19	Almond	0.57
Fish, <i>Rohu</i>	0.07	Coconut, fresh	0.10
Mutton	0.14	Coconut, dry	0.01

Requirements : The requirement of this vitamin is also related to energy intake. It is about 0.6 mg per 1000 Kcal. The daily safe requirement ranges from 0.7 to 2.2 mg/day (4).

Deficiency

Certain conditions are known to be at high risk of Riboflavin deficiency (Box - 1).

Box - 1 : Increased Risk of Riboflavin Deficiency
Growth : childhood, adolescents
Pregnancy, lactation
Malabsorption : Tropical sprue; Celiac disease; Chronic diarrhoea; Irritable bowel syndrome
Drugs impairing absorption : Thyroid hormones; Oral contraceptives; Phenothiazines; Barbiturates
Alcoholism

(1) The clinical signs suggestive of riboflavin deficiency are cheilosis, angular stomatitis, glossitis, magenta tongue, nasolabial seborrhoea and genital (scrotal or vulval) dermatosis. Corneal vascularisation is also seen but is not a specific sign of riboflavin deficiency.

(2) Severe deficiency is rarely seen, however the elderly, people suffering from anorexia nervosa and chronic dieters are at a higher risk.

(3) Secondary nutrient deficiencies may be seen in riboflavin deficient people like: Hypochromic anaemia, Vitamin B₆ deficiency and Pellagra (6).

Niacin (Nicotinic Acid & Nicotinamide)

Niacin is the generic term for a group of compounds that prevent pellagra. It is a white crystalline substance readily soluble in water and is resistant to heat, in solution or in a dry state. Although related chemically to nicotine it possesses very different physiological properties. It occurs naturally in the body in the form of an amide - nicotinamide.

Sources : Nicotinic acid is widely distributed in plant and animal foods. Meat (especially the organs), fish, chicken, eggs, milk, whole meal cereals, groundnuts and pulses are good sources (See Table-3). In some cereals, especially maize, the greater part of the vitamin may be in a bound unabsorbable form. The human body is not entirely dependent on dietary sources of nicotinic acid as it may also be synthesized from tryptophan. On an average about 60 mg of tryptophan is needed to form 1mg niacin (4).

Food stuff	Niacin (mg)	Food stuff	Niacin (mg)
<i>Cereals</i>		<i>Vegetables</i>	
Wheat flour	4.3	Cauliflower	1.0
Rice polished	1.9	Spinach	0.5
<i>Bajra</i>	2.3	Carrot	0.6
Maize dry	1.8	Amaranth	1.2
<i>Jowar</i>	3.1	Potato	1.2
Barley	5.4	Radish	1.4
<i>Pulses & Legumes</i>		<i>Fruits</i>	
Bengal gram	2.9	Raspberry	0.8
Soya bean	3.2	Guava	0.4
Green gram	2.4	Raisins	0.7
Red Gram	2.9	Tomato	0.4
Peas dry	3.4	Mango	0.9
Lentil	2.6	Custard apple	1.3
<i>Non vegetarian foods</i>		<i>Nuts</i>	
Egg	0.1	Groundnut	19.9
Liver sheep	17.6	Cashew nuts	1.2
Milk cow	0.1	Almond	4.4
Fish, <i>Rohu</i>	2.8	Coconut, fresh	0.8
Mutton		Coconut, dry	3.0

Functions : Nicotinamide is incorporated into the pyridine nucleotide coenzyme, and various other coenzymes, which are involved in numerous oxidoreductase reactions including glycolysis, fatty acid metabolism, tissue respiration and detoxification.

Requirement and Intake : Since this vitamin takes part in many reactions of energy metabolism, its requirement is also related to energy requirement. Its safe level is estimated to be 6.6mg niacin equivalents per 1000 Kcal. The daily requirement varies from 8 to 26 mg (4).

Deficiency : Pellagra (Latin *pelle*, skin; Greek *agra*, seizure) results from the deficiency of niacin. This is characterized by the three 'D's (5).

(a) **Dermatitis:** (Pellagrous dermatosis) Skin exposed to sunlight gets inflamed, that progresses to pigmentation, cracking and peeling. The neck is frequently involved and the distinctive distribution of skin lesions is known as Casal's Collar.

(b) **Diarrhoea:** This is often accompanied by inflamed scarlet tongue.

(c) **Dementia :** It may present as mild confusion and disorientation to mania and psychosis.

Folic Acid (Folate or Pteroyl Glutamic Acid)

It is a yellow crystalline substance, sparingly soluble in water and a stable molecule. When heated in neutral or alkaline media it undergoes rapid destruction. Free folate is actively absorbed from the upper small intestine. It is stored mainly in the liver. Small amount is excreted in urine and faeces. Free folic acid is converted in the liver into tetrahydrofolic acid (folinic acid) which is the functionally active form in the body.

Sources and Losses : It occurs in green leaves, pulse, cereals, liver, kidney, mushroom and yeast. Canning, prolonged heating, reheating and discarding 'cooking' water causes serious losses of folic acid. Reducing agents in food tend to protect folic acid. Folic Acid content of selected food items is depicted in Table-4.

Food stuff	Folic Acid (μg)	Food stuff	Folic Acid (μg)
<i>Cereals</i>		<i>Vegetables</i>	
Wheat flour	35.8	Cabbage	23
Rice raw, milled	8.0	Spinach	45.5
<i>Bajra</i>	45.5	Carrot	123
Maize dry	20.0	Amaranth	149
<i>Jowar</i>	20.0	Ladies finger	105
<i>Ragi</i>	18.3	Spinach	123
<i>Fruits & Nuts</i>		<i>Pulses & Legumes</i>	
Tomato	30	Bengal gram	186
Guava	20	Soya bean	100
Groundnut	20	Green gram	140
Coconut, fresh	12.5	Red Gram	103
Coconut, dry	16.5	Peas dry	7.5
Lentil	36		
<i>Non vegetarian foods</i>			
Egg	78.3	Milk cow	8.5
Liver sheep	188	Mutton	5.8

Functions

(a) Folinic acid plays important role in the synthesis of purines, pyrimidines, glycine and methionine. It is essential for the synthesis of DNA.

(b) It is a potent anti anaemia factor in the treatment of megaloblastic anaemia of malnutrition, pregnancy and malabsorption. It is also effective in treatment of pernicious anaemia.

Folic Acid and Plasma Homocysteine

A high plasma homocysteine level is a risk factor for heart disease and stroke. A strong inverse correlation between folate intake and plasma homocysteine has been found. A significant dose response relationship has also been established. Folate supplementation is known to proportionately reduce the plasma homocysteine levels and thus the risk of heart disease.

Requirement and Intake: The requirement of folic acid ranges from 50 µg to 100 µg. In pregnancy it increases to 150-300 µg (4).

Measurement: Recent intake can be assessed by serum folate. Cellular status is assessed by red cell folate levels.

Uses of Folates in Prevention and Therapy

Birth Defects: Use of supplementary folates (400µg/day) during the early weeks of conception & pregnancy can reduce birth defects like neural tube defects, cleft lip and palate.

Atherosclerosis: Folates are known to reduce high homocysteine levels and thus help prevent atherosclerosis.

Nervous Disorders: Folate supplementation is beneficial in depression, irritability and impaired concentration. It is also useful as an adjunct therapy in MDP and senile dementia.

Infections: Folates augment the immune function of the body, thereby reducing infections.

Cancers: Folate also reduces the chances of cervical, colonic and lung dysplasia.

Deficiency: Dietary folate deficiency is not uncommon. Deficiency results in megaloblastic anaemia. Deficiency may be accompanied by depression, insomnia, forgetfulness, irritability and dementia. Low folate levels are also associated with neural tube defects. Lack of folic acid is known to cause accumulation of homocysteine (hyperhomocysteinaemia), which is a potential risk factor for coronary artery disease. High folate levels overcome the hyper-homocysteinaemia. Low folate levels can also cause an altered methylation of DNA, increasing the risk of cancer (5, 6).

Vitamin B₁₂ (Cyanocobalamin)

Cobalamin is a complex molecule containing 4-percent cobalt, besides phosphorous and nitrogen. Cyanocobalamin is the commercially available form. Vitamin B₁₂ is the 'extrinsic factor' originally postulated by Castle. It requires the 'intrinsic factor', secreted by the parietal cells of the stomach, to be absorbed. It is freely soluble in water and resistant to boiling in neutral solution though unstable in the presence of alkalis.

Sources: It is unique among vitamins in that it is not present in any vegetable foods. It is present in animal products - milk, milk products, meat and fish. It is also synthesized by the micro organisms in the gut and assimilated in the food chain.

Functions

- It recycles the folate coenzyme.
- Vitamin B₁₂ plays important role in the synthesis of DNA.
- It helps in maintenance of myelin in the nervous system.
- It has an important role in the treatment of pernicious anaemia.
- It also helps in conversion of homocysteine to methionine.

Measurement: Serum B₁₂ is assessed by radioligand binding or microbiological assay. Absorption is assessed by Schilling test (5).

Requirement and intake: The daily losses of this vitamin range from 0.25 µg to nearly 1 µg. An intake of 2 µg per day has been recommended by FAO/WHO. The ICMR has, however, suggested a daily intake of 1 µg of the vitamin for Indian adults (4).

Deficiency: Since the vitamin doesn't occur in vegetable foods, vegans and strict vegetarians are at a high risk of its deficiency. Malabsorption, gastric atrophy, and reduced production of 'intrinsic factor' are some other causes of deficiency. Pernicious anaemia, which is a megaloblastic anaemia, results due to deficiency of this vitamin. Neurological symptoms characterized by loss of sensation and motor power in the lower limbs (due to degeneration of myelin) may also be seen. Since it is also synthesized in the gut, many cases of vitamin B₁₂ deficiency are not seen very frequently.

Vitamin C (Ascorbic Acid)

It is a water soluble, crystalline, white substance. Ascorbic acid is very sensitive to oxidation, which is accelerated by heat, alkaline solutions, light and traces of metals, especially copper. It is present in all body tissues but is found in a high concentration in the adrenal glands, pituitary gland, and intestinal wall.

Sources and Losses: Its rich sources are citrus fruits (oranges, lemons), guavas, papayas, pineapple, mangoes, gooseberry (amla), kiwi fruit and green leafy vegetables. Root vegetables also contain vitamin C, esp. sweet potato. It is also synthesized in germinating seeds, pulses and grains (See Table-5).

Table - 5 : Vitamin C content of selected food items (per 100g) (4)

Food stuff	Vitamin C (mg)	Food stuff	Vitamin C (mg)
Fruits		Vegetables	
Tomato	31	Cabbage	124
Guava	212	Spinach	28
Straw berry	52	Drum stick	120
Amla	600	Amaranth	179
Lime	63	Chillies, green	111
Mousambi	50	Potato	17
Orange	30	Bitter gourd	96
Papaya	57	Capsicum	137

The vitamin C content of fruits and vegetables is reduced by storage and damage to plant cells by rough handling, bruising or cutting, which results in release of enzyme ascorbic acid oxidase which oxidizes ascorbic acid. Also cooking of vegetables destroys vitamin C through the enzyme action and heat and by its extraction into cooking water. High pressure steaming as well as rapid frying of green vegetables destroys the oxidase enzyme thereby causing a greater retention of vitamin C than boiling.

Functions : Ascorbic acid is a powerful reducing agent (antioxidant) and is essential for many oxidation-reduction reactions.

- It is required for the formation of collagen and is therefore necessary for the formation and maintenance of the normal structure of the intercellular ground substance (connective tissue), bone, tendons, skin, teeth and capillaries.
- It is important for hydroxylation of dopamine to nor-adrenaline.
- It enhances the absorption of iron, through the conversion of ferric (Fe^{3+}) to ferrous ions (Fe^{2+}).
- It has anti-oxidant property like vitamins A and E, which has an important role in free radical scavenging, as an anti-aging and anti-cancer factor.
- It influences the maturation of the red blood cells, synthesis of bile and metabolism of drugs and carcinogens by the liver (5)

Requirement : The requirement of vitamin C is 40 mg/day for adults. For lactating women 80 mg/day is recommended (4)

Deficiency : Vitamin C deficiency is not common now. It causes defective formation of intercellular ground substance whose characteristic gross lesions occur in gums, bones and capillaries. Reparative process especially involving connective tissues, as in wound healing, are interfered in vitamin C deficiency due to the lack of the formation of collagen. Deficiency leads to a condition called as *scurvy*. The signs and symptoms include spongy and bleeding gums, perifollicular haemorrhages in the skin, sub periosteal haematomas and poor wound healing. Fatigue and muscle weakness is also reported.

Fat Soluble Vitamins

Vitamin A (Retinol)

Hopkins conducted an experiment in young rats (1906-1912). These were fed on casien, starch, sugar, lard and inorganic salts. These rats failed to grow and died. An addition of only 3 ml milk enabled them to thrive! An '*Accessory food factor*' was thus demonstrated. Mc Callum isolated it in 1913 and was named as Vitamin A. Wald was awarded Nobel Prize for description of '*dark vision*' and its association with Vitamin A (2,8)

Vitamin A is a term for the biologically active compound retinol and its provitamin (precursor) carotenoids. Retinol is a fat soluble pale yellow compound. It is stable to heat at ordinary cooking temperatures but liable to oxidation and destruction on rancidity of fat. However, carotenoids cannot wholly be converted into retinol in the body and man absorbs and utilizes these pigments less efficiently. 6 microgram of β -carotene has the biological activity of 1 microgram retinol (RE). Other Carotenoids have even lesser vitamin A activity (4)

Sources and losses : Retinol is found in foods of animal origin. The important sources of Retinol are meat, liver, kidney, milk, fish and eggs (See Table- 6). Retinol can also be formed in the intestinal mucosa from the pigments known as carotenoids which are widely distributed in plants. Carotenoids are found in coloured fruits and vegetables. The green outer leaves of vegetables (e.g. cabbage) are good sources of carotene. One of these, β -carotene is by far the most important source of retinol (provitamin A) and is found in abundance in yellow-orange vegetables and fruits (e.g. pumpkin, papaya, mango, apricots, yellow peaches and green leafy vegetables). β -Carotene, another carotenoid, is found in carrots, lutein in dark green leafy vegetables and β -Cryptoxanthin in citrus fruits. The pigments with *no* vitamin A activity include lycopene in tomatoes and zeaxanthin in sweet corn (4)

Vitamin E protects it from oxidation. It is destroyed by exposure to sunlight. Foods which are heated for long period of time lose an appreciable amount of vitamin A. Boiling, canning or freezing of foods does not cause loss but drying and dehydration causes considerable loss.

Table - 6 : β-Carotene content of selected food items (μg) per 100g (4)			
Food stuff	β -Carotene (μg)	Food stuff	β -Carotene (μg)
Cereals		Vegetables	
Wheat flour	25	Pumpkin	1160
Rice raw, hand pound	2	Fenugreek leaves	9100
<i>Bajra</i>	132	Carrot	6460
Maize dry	90	Amaranth	8340
		Spinach	9440
Pulses & Legumes		Fruits	
Bengal gram	189	Apricot	2160
Soya bean	426	Raspberry	1248
Green gram	94	Papaya	880
Red Gram	132	Tomato	590
Peas dry	39	Mango	1990
Non veg foods		Nuts	
Egg	420	Groundnut	37
Liver sheep	6690	Cashew nuts	60
Milk cow	53	Almond	0
Mutton	9	Coconut, fresh	0

Retinol Equivalents : Vitamin A activity of a diet is usually expressed in Retinol Equivalents. As mentioned, the term vitamin A is applied to both retinol (preformed vitamin A) and pro-vitamin A (beta-carotene). One microgram retinol is considered as 1 Retinol Equivalent (1RE). It is also known that the biological activity of 6 μg beta carotene has an activity of 1 μg retinol. International Unit or IU is an old unit and is sometimes used. 1 IU is equal to 0.3 μg of Retinol (Box - 2).

Box - 2 : Vitamin A Activity

1 Retinol Equivalent (RE) equals

- 1 μg of retinol
- 1 μg retinol activity
- 6 μg β -carotene
- 3.33 IU (International Units)

OR

- 1 μg β -carotene = 0.167 μg retinol
- 1 IU Vitamin A = 0.3 μg of Retinol

Functions

- (a) It is vital for the formation of retinal pigment rhodopsin in rods of the retina. Exposure to light results in a series of changes in its configuration, which leads to the adaptation of vision in dark. Retinol deficiency leads to impairment of dark adaptation or night blindness.
- (b) Retinol is essential for integrity of cellular structure esp. epithelial tissue - respiratory, gastrointestinal, genitourinary and skin.
- (c) It has a role in the immune defence mechanism of the body.
- (d) Vitamin A has an antioxidant property of free radical scavenging (For details refer to chapter on antioxidants).

Requirements & Recommended Dietary Allowance : The recommended intake is 600 mg of retinol equivalent per day for adults (including children above 6 years and pregnant women). Lactating mothers require 950 mg. In converting the carotene figures to retinol, a conversion factor of 0.25 has been suggested by ICMR (6). For vitamin A the RDA is given in terms of retinol (vitamin A alcohol). If the diet contains vitamin A and carotene, its content can be expressed as retinol using the following formula:

$$\text{Retinol content} = \mu\text{g retinol} + \mu\text{g of } \beta\text{-carotene} \times 0.25$$

Deficiency : Deficiency of Vitamin A leads to ocular and extra ocular manifestations. The ocular manifestations are more common. The ocular manifestations resulting from vitamin A deficiency are termed as *Xerophthalmia*. Deficiency is often seen to be associated with weaning, protein energy malnutrition and a diet poor in vegetables, fruits, milk and butter. The deficiency signs / symptoms are given in the Box - 3.

Box - 3 : Signs and symptoms of Vitamin A Deficiency

Dryness, itching, redness of conjunctiva

Night blindness (inability to see in dim light)

Other signs of xerophthalmia : Bitot spots; Corneal xerosis; Keratomalacia

Dry, rough, itchy skin; rash

Dry, brittle hair and nails

Loss of acuity of senses: smell and taste

Loss of appetite

Anaemia, fatigue

Poor growth

Low immunity: Increased vulnerability to infections

Increased risk of certain cancers

Toxicity - Hypervitaminosis A : There are exotic stories of arctic explorers and fishermen who reported reddening and exfoliation of skin after feasting on polar bear liver or halibut liver. Hypervitaminosis A can be induced by a single dose of retinol greater than 200mg (200,000 RE). Chronic hypervitaminosis may result from chronic misuse of supplements which is, greater than 4000 RE (infants) to 7000 RE (adults) consumed daily. Persistent large doses of vitamin A (more than 100 times the required amount), overwhelm the liver storage capacity and produce intoxication and liver disease.

Hypervitaminosis A is characterized by skin/mucous membrane changes. Dry lips (cheilitis), dryness of nasal mucosa and eyes, erythema, scaling, peeling of skin, hair loss and nail fragility are other signs. Headache, nausea and vomiting follow. Bone abnormalities in the form of hip fractures are also reported. Retinoids can be toxic to the fetus, causing craniofacial, CNS, cardiovascular and thymic malformations. Pregnant women are therefore advised against exceeding daily intakes of 3000 RE of vitamin A.

Vitamin D (Calciferols)

The term Vitamin D refers to two molecules - ergocalciferol (Vitamin D₂) and cholecalciferol (Vitamin D₃). Cholecalciferol is the natural form of vitamin and is produced by the ultraviolet irradiation (through sunshine) of 7-dehydrocholesterol widely distributed in animal fats such as the oily secretions in mammalian skin. Dietary ergocalciferol and cholecalciferol are biologically inactive and are activated to 25-hydroxy-cholecalciferol in liver. Further conversion in the kidney results in the production of the more active form 1,25-dihydroxy-cholecalciferol (Calcitrol) (8).

How much sunshine is good enough?

Even a brief and casual sunlight exposure of the exposed parts of body (face and arms) is good enough to provide about 5 μg equivalent of vitamin D. The ultraviolet penetration depends on melanin content of the skin and is higher in light skinned people. Window panes and use of sunglasses and sun screen creams block ultraviolet penetration, thus limiting the vitamin D intake. Dark clothing, face masks and *burqa* will also block UV rays and Vitamin D availability. Therefore a person getting even a casual exposure to sun gets enough Vitamin D through the skin conversion. Conversely, those permanently indoors (as in cold countries) or keeping themselves covered from head to toe (practice of compulsory *burqa* cover) are those who might be at a risk of vitamin D deficiency.

Food sources : Cod liver oil, other oily fish, milk, margarine, eggs, liver.

Functions : Vitamin D regulates the absorption and excretion of calcium from the small intestine and also plays an essential part in the mechanism for mineralizing bone. It is considered as a hormone rather than a vitamin.

Measurement : Vitamin D status can be assessed by the measurement of plasma 25-hydroxy-cholecalciferol. In severe deficiency plasma calcium and phosphate fall and alkaline phosphatase is elevated.

Requirement and Intake : The vitamin D requirement for a child is placed at 100 to 400 IU/day (2.5-10 μg). This requirement can be obtained from exposure of the body to sunlight. ICMR expert group therefore has not recommended any dietary intake. Whenever this requirement is not met, a therapeutic supplementation may be needed (4). The food and nutrition board, USA recommends a daily dietary intake of 5 μg for adult males, females, pregnant and lactating women.

Deficiency : People who stay indoors and are fully covered (purdah system amongst women in some religious/ethnic groups) are at a higher risk of deficiency due to lack of exposure to UV radiation due to sunlight. Malabsorption also increases the risk of deficiency. Severe deficiency results in rickets in children, characterized by reduced calcification of bone epiphysis. It leads to skeletal deformities, bone pain and muscle weakness. In adults deficiency results in osteomalacia.

Vitamin E (Tocopherol)

Eight naturally occurring forms of vitamin E are synthesized in plants; four tocopherols (α, β, γ and δ tocopherols) and four tocotrienols (α, β, γ and δ tocotrienols). Alpha tocopherol which is synthesized commercially has the highest biological activity, and is used as the standard against which activity of other forms is measured. Being fat soluble, vitamin E is found in all cell membranes (5).

Sources : Vitamin E is widely distributed in foods and the richest sources are vegetable oils like groundnut, sunflower, safflower, cotton seed, corn, wheat germ, rape seed, palm and other oils. Nuts (like almonds and peanuts) are also good sources. Eggs, butter, whole meal cereals are moderately good sources. Meat, fruits, vegetables contain small amounts. Foods rich in PUFA are also rich in Vitamin E.

Tocopherol

(Greek, *tokos*, childbirth; *pherin*, to carry)

This vitamin was so named in Greek, as the work of early investigators indicated a strong relationship to reproductive function in rats, which was not found to be true in humans.

Functions

- Like vitamin A and C, it has a strong antioxidant property and protects cell membranes and lipoproteins against damage from free radicals. It also prevents the non-enzymatic destruction of polyunsaturated fatty acids by molecular oxygen.
- It maintains the cell membrane integrity.
- It has a role in the DNA and prostaglandin synthesis.

Requirement & Intake : The human requirement of vitamin E is not known with certainty (4). The US authorities have recommended a daily intake of 12mg/day.

Deficiency : Deficiency of vitamin E in animals interferes with normal reproduction and causes a form of muscular dystrophy, but the effects if any, on human beings are being studied. However, a genetically inherited disease Familial Isolated Vitamin E (FIVE) deficiency is known. Patients develop reduced tendon reflexes by age 3-4, loss of touch and pain sensation, unsteady gait, loss of coordination and impaired eye movement in adolescence. Deficiencies have also been seen in people with

severe fat malabsorption (5).

Vitamin K

It exists in nature in two forms. Vitamin K_1 (phylloquinone), originally isolated from lucerne, is the only form that occurs in plants. It is a yellow oil, soluble in fat solvents, but only slightly soluble in water. Vitamin K_2 (menaquinone) is produced by bacteria in the lumen of large intestine.

Food sources : Green leafy vegetables, vegetable oils esp. soya bean oil, eggs, meat and dairy products are good food sources of vitamin K.

Functions

- Vitamin K promotes the synthesis of γ -carboxy glutamic acid (Gla) in the liver which is essential for formation of prothrombin (or factor II) and also factors VII, IX and X. It is well known that these factors participate, in the coagulation of blood.
- Some other proteins also contain Gla and require vitamin K for their synthesis e.g. osteocalcin, a bone protein made by osteoblasts (5).

Requirement & Intake : No recommendations are given by the ICMR. The US authorities recommend an intake of 120 μg for males and 90 μg for females.

Deficiency : This is characterized by poor blood clotting and results in low prothrombin activity. Neonates are born with very low stores of vitamin K due to sterility of intestines (and absence of bacteria producing vitamin K). So neonates are given an injection of this vitamin at birth. Adults rarely manifest the deficiency, but can be seen in cases of obstructive jaundice as lack of bile leads to poor absorption of vitamin K. The anticoagulants Warfarin and Dicoumarol can cause a deficiency.

Summary

Vitamins which were historically considered as the vital amines have not lost their vitality, and are as important today as they were at the time of their discovery. They help in many metabolic reactions and are essential for control of cell metabolism, transformation of energy, and prevention of specific nutritional deficiencies. Their role as antioxidant agents has enabled scientists to refocus their attention on vitamins. A summary of the most important vitamins is tabulated at the end of chapter.

Study Exercises

Long Questions : (1) Enumerate the water soluble vitamins. What is the role of vitamin C in the human body? (2) Name the fat soluble vitamins. Discuss the dietary sources, functions and deficiency symptoms of Vitamin A.

Short Notes : (1) Hypervitaminosis A (2) Beriberi (3) Vitamins as antioxidants

MCQs

- Which of the following will help you increase the iron absorption from diet : (a) Nicotinic acid (b) Ascorbic acid (c) Pantothenic acid (d) Folic acid
- Which of the following is not a source of beta carotene (a) Green vegetable (b) Potatoe (c) Liver (d) Papaya
- Which of the following is not known to have an

- antioxidant effect (a) Vitamin A (b) L-Ascorbic acid (c) Alpha-Tocopherol (d) Phylloquinone
- Which of the following does not fall under 'xerophthalmia' (a) Conjunctival xerosis (b) Corneal xerosis (c) Retinal xerosis (d) Lachrymal xerosis
 - Which of these is available only from animal sources (a) Vitamin B₁₂ (b) Vitamin B₁ (c) Vitamin B₆ (d) Vitamin B₂

Answers : (1) b; (2) c; (3) d; (4) d; (5) a.

<i>Fat Soluble Vitamins</i>				
Vitamin	Function	RDA	Deficiency	Sources
Vitamin A (Retinol, Retinal, Carotenes, Cryptoxanthines)	Vision, Integrity of epithelium, Gene regulation, Antioxidant	600 µg/ day	Xerophthalmia, Dry skin, impaired immunity, growth and reproduction	Retinol (animal foods): liver, egg, meat, milk Provitamin A (plant foods) yellow, green vegetables
Vitamin D (Cholecalciferol, D ₃ ; Ergocalciferol, D ₂)	Calcium homeostasis, Bone metabolism	100 - 400 IU /day - (Child)	Rickets in children Osteomalacia in adults	Synthesised in skin with exposure to sunlight; Fish oils, milk
Vitamin E (Tocopherols)	Cellular membrane antioxidant	12mg / day	RBC breakdown, anaemia, nerve damage, retinopathy	Vegetable oils, green vegetables, cereal germ, nuts, seeds
Vitamin K (Phylloquinones, Menaquinones, Menadione)	Clotting of blood, Calcium metabolism	120 µg / day (Males) 90 µg / day (Females)	Bleeding tendencies	Synthesis by intestinal bacteria, green vegetables soya oil, liver, milk

<i>Water Soluble Vitamins</i>				
Vitamin	Function	RDA	Deficiency	Sources
Vitamin C (Ascorbic acid)	Reductant in hydroxylations in collagen and carnitine synthesis Metabolism of drugs	40mg /day	Scurvy: Spongy, bleeding gums, fatigue, haemearthrosis	Citrus fruits, guava, amla, green vegetables, tomatoes, strawberries
Vitamin B₁ (Thiamine)	Normal growth Coenzyme for decarboxylation of 2-keto acids and transketolation reactions	0.5mg / 1000Kcal	Beriberi - Cardiac (wet), Neuritic (dry) and Infantile	Meat, liver, legumes, wheat germ
Vitamin B₂ (Riboflavin)	Normal growth Coenzyme in redox reactions of fatty acids and TCA cycle	0.6mg / 1000Kcal	Ariboflavinosis: Magenta tongue, Cheilosis, angular stomatitis, corneal ulcer	Milk, meat, green vegetables
Niacin (Nicotinic acid, Nicotinamide)	Coenzyme for dehydrogenases	6.6mg / 1000Kcal	Pellagra, characterized by 3 Ds- dermatitis, diarrhea, dementia	Meat, groundnuts, legumes, grains
Vitamin B₆ (Pyridoxamine)	Coenzymes in amino acid metabolism	2mg / day	Anaemia, neuritis, convulsions	Grains, seeds, poultry, meat
Folic Acid	Coenzymes in single carbon metabolism	100µg / day	Megaloblastic anaemia	Liver, green vegetables yeast, fruits
Vitamin B₁₂ (Cobalamin)	Coenzymes in amino acid, propionate and single carbon fragment metabolism	1µg / day	Pernicious anaemia	Liver, lean meat fish, seafood, milk

Rajul K Gupta

Minerals are required in small quantities and constitute only a small portion of the body weight but enter into the metabolism to a much greater degree than their mere weight indicates. A large portion of the ash of the body is composed of calcium, magnesium, sodium, potassium, phosphorous, sulphur and chlorine. The main functions of the minerals include: providing rigidity and relative permanence to the bones and teeth; providing essential elements for the formation and activities of the muscular, glandular; neural, and epithelial tissues; forming components of enzyme systems; and providing dynamic characteristics to the intra and extra cellular fluids for regulation of pH, osmotic pressure and electro-neutrality and those of secretion and excretions (1).

Minerals like zinc, molybdenum, copper, manganese and magnesium are either structural parts or functionally activate many enzyme systems. Iodine is a part of hormone, thyroxine. Sodium and potassium are important in fluid dynamics and energy transfer. They along with chloride, carbonates and bicarbonates maintain the acid base balance. Some amount of minerals is excreted daily through urine, sweat, skin and intestinal exfoliations and thus has to be replaced. Growing infants, children, pregnant and lactating women require a higher quantity of some of these minerals to meet the physiological needs. Deficiency, leads to a deranged function of systems and various pathological states in extreme conditions.

Classification

Minerals can be classified into macrominerals and microminerals (See Box- 1). Macrominerals also referred to as major minerals are distinguished from the microminerals by their occurrence in the body. Taking this as criterion, various definitions of macrominerals have evolved, such as “those which constitute at least 0.01% of body weight (5g in a 60 Kg man)” ; or a more quantifiable and unambiguous definition like “mineral whose requirement is more than 100mg per day”. Calcium, phosphorous, magnesium, sodium, potassium, chloride and sulphur are the macrominerals (2).

Box - 1 : Classification of Minerals

The Macrominerals
Calcium, phosphorous, magnesium, sodium, potassium, chloride, sulphur
The Microminerals
Iron, zinc, iodine, Copper, manganese, molybdenum, selenium, chromium and fluorine, cobalt, nickel, tin, silicon, vanadium, arsenic, cadmium, boron, aluminium

As a corollary microminerals or trace elements can be defined as those comprising less than 0.01% of total body weight or more appropriately those which are needed in a concentration of less than 1ppm (3). These were initially known as trace because their concentration in tissues could not be easily

ascertained by early analytic methods (4). Classically, iron appears to be the mineral that divides the macrominerals from microminerals. Thus a trace element (or micromineral) can be defined as one that is required by the body in the concentration equal to or less than that of iron (5). Microminerals include iron, zinc, iodine, copper, manganese, molybdenum, selenium chromium and flourine. Cobalt, nickel, tin, silicon, vanadium, arsenic and boron can be classified as ultra-trace elements (2). An element is termed ‘essential’ if a dietary deficiency of that element consistently results in a suboptimal biological function that is preventable or reversible by physiological amounts of the element (6).

Calcium (Ca)

Calcium is essential for the building of bones and teeth. It is the most abundant mineral in the human body. Most is deposited as hydroxyapatite, in bones and teeth. Constant levels of calcium in the body/plasma is maintained under the influence of parathyroid hormone and calcitonin. Factors promoting absorption of calcium are vitamin D, proteins and lactose.

Sources, Absorption and Losses : Rich sources of calcium are milk and milk products, ragi, fish (if eaten whole), dried fruits such as raisins, apricots and dates, and betel leaves with lime, pulses and tofu (See Table- 1).

Foodstuff	Calcium (mg per 100g)	Foodstuff	Calcium (mg per 100g)
<i>Cereals & Legumes</i>		<i>Fruits</i>	
Rice, raw	10	Figs	187
Wheat flour, whole	48	Raisins	87
Ragi	344	Dates, dried	120
Red gram (Dal arhar)	73	Lemon	70
Bengal gram, whole	202	Apricots, dry	110
<i>Vegetables</i>		<i>Miscellaneous</i>	
Turnip greens	710	Fish, Rohu	650
Amaranth species	200-800	Coconut dry	400
Cauliflower greens	626	Gingelly seeds	1450
Onion	46.9	Almond	230
Spinach	73	Milk, cow	120
Cluster beans	130	Mutton	150

Calcium in food is not uniformly available to the body e.g. calcium in vegetables and fruits is poorly absorbed due to the presence of oxalic acid in these foods which forms insoluble calcium oxalate. Spinach is one of the foods which is very rich in oxalic acid. Phytic acid in the pericarp of cereal grains unites with calcium to form phytin, which is not absorbed. However, many cereals such as rye and wheat contain an enzyme

phytase, which splits phytic acid so that it can no longer bind with calcium and thus makes calcium available for absorption. Excess of fatty acids, particularly saturated fatty acids in the small intestine may form insoluble soaps with calcium and may carry significant amount of calcium into faeces. Calcium in milk and dairy foods is more readily absorbed (7, 8).

Foods interfering with absorption of Calcium
Protein intake >20% of calories
Phosphorus (milk, meat, colas)
Oxalates (Spinach, tomato)
Sodium (salt)
Tannins (black coffee, tea)
Alcohol

Functions

Bone formation : More than 99% of body calcium is found in the bones. Calcium is essential for providing the structural rigidity to bones and teeth.

Nerve conduction: Calcium is responsible for the maintenance of optimum excitability of the nervous and muscular tissues.

Blood Coagulation: Calcium has an important role in the coagulation of blood as factor IV.

As a cofactor : Calcium acts as a co-factor for a number of enzymes e.g. lipase (9).

Requirement and Intake : The suggested levels for calcium intake for adult men and growing children are 400 to 600mg/day. In case of pregnant and lactating women it is 1000mg/day (10).

Deficiency : Plasma calcium levels are tightly controlled and are not usually affected by dietary insufficiency in healthy adults. Reduction in the level of circulating ionised calcium produces a clinical condition known as tetany. This is characterized by twitching of muscles of face, hand and feet. Cardiac arrhythmias may also result. A long term calcium deficiency during the bone formative age can cause stunted skeletal growth and a low bone density. Vitamin D deficiency leads to rickets in children due to poor calcium absorption (9).

Osteoporosis is an abnormal thinning of bones. It is not due to a primary calcium deficiency but results from conditions leading to chronic calcium deficiency. These factors are inadequate calcium intake, poor absorption, abnormal hormone levels, upsetting the calcium homeostasis and subnormal physical activity. Osteoporotic bones are more likely to get fractured with trivial injuries (falls), as commonly seen in post-menopausal women and the elderly.

Phosphorus

The role of phosphorus in bone formation is almost as important as calcium and so it is a macromineral of extreme value. It gets deposited in bones and teeth as calcium phosphate. An adult human body contains about 400-700 g of phosphorus as phosphate mostly in bones and teeth (10).

Sources : Phosphorus is widely distributed in food stuffs and therefore, its deficiency rarely occurs. Milk, milk products,

cereals, meat, fish, nuts, fruits and vegetables are good sources. A large part of phosphorus present in vegetable foods occurs in combination with phytin (fibre) and is available to the body only to the extent of 40-60 percent.

Functions

Bone formation : It is essential for the formation of bones and teeth along with calcium as hydroxyapatite.

Energy metabolism: It also plays an important role in all metabolism for derivation of energy from the phosphate bonds in adenosine triphosphate (ATP).

Acid base balance: Phosphorus acts as an important buffer that prevents changes in the pH of body fluids.

Miscellaneous: It is an important constituent of nucleic acids, phospholipids and membranes (11).

Requirements : It is suggested that phosphorus intake should be about 1 g per day that is about twice as large as that of calcium (10).

Deficiency : Phosphorus deficiency is unlikely to occur as it is widely available in foodstuff. However hypophosphataemia may occur in pathological conditions (sepsis, liver disease, alcoholism, diabetic ketoacidosis) patients on prolonged parenteral nutrition, hypophosphataemic rickets and excessive use of aluminium-containing antacids (9).

Sodium

Sodium is one of the most abundant minerals present in the human body. An adult male has total body sodium of about 92-110 g, almost equally divided into the Extracellular Fluid (ECF) and bone. In the blood and interstitial fluid it is found to be largely combined with chloride and bicarbonate. Intracellular fluid contains about a third of the sodium content of the extracellular fluid (9).

Sources : Common salt (sodium chloride) is the cheapest, best and most widely available source of sodium; 3 g salt is roughly equivalent to 1.2 g of sodium. Indian diet is particularly rich in sodium (pickles, chutneys, etc.). It is also present in food additives like monosodium glutamate, mainly used in Chinese cuisine. Natural foods like meat, milk, eggs, vegetables and fruits all contain sodium. Salt is added to almost all processed foods, thereby increasing their sodium content.

Functions : Sodium is the main cation in the ECF of human body. It takes an important part in osmotic processes. It is important in the blood pressure regulation along with potassium. Acid-base regulation is a function of sodium. It also maintains the osmotic pressure. Sodium is also a vital component of the electrophysiological control of muscles and nerves.

Requirement : The daily intake varies from 2 to 20 gm/day. The recommended daily intake of sodium chloride is about 5 g (10).

Deficiency : Excessive sweating as in hot and humid climates and extreme exertion, diarrhoea and dehydration can lead to sodium deficiency. This may be manifested as muscle cramps and severe dehydration and hypovolemia.

Potassium

The adult human body contains about 250 g of potassium

which is twice the amount of sodium. Potassium occurs widely in foodstuffs, so there is little likelihood of its deficiency. It is the principal intracellular cation.

Sources : Most foods contain useful amounts of potassium, particularly those of vegetable origin. Fruits like melons, apricots, fruit juices, vegetables including potatoes, pulses, meat and whole grain cereals are good sources (See Table- 2).

Foodstuff	Potassium (mg per 100g)	Foodstuff	Potassium (mg per 100g)
<i>Cereals & Legumes</i>		<i>Fruits</i>	
Rice, flakes	154	Apricots	430
Wheat flour, whole	315	Peaches	453
Ragi	408	Musk melon	341
Red gram (Dal arhar)	1104	Mosambi	490
Bengal gram, whole	808	Cherries	320
<i>Vegetables</i>		<i>Miscellaneous</i>	
Spinach	206	Rohu	288
Amaranth	341	Coconut meal, deoiled	2003
Brussels sprouts	477	Mutton	270
Sweet potato	393	Milk cow	140
Brinjal	200	Drumstick	259

Functions : Potassium is the principal ion in the intracellular compartment, thus plays an important role in the water balance of the body with sodium being in the extracellular compartment. Along with sodium, potassium too is involved in acid-base regulation. Potassium along with sodium is essential for the cellular uptake of molecules through the sodium-potassium pump. Potassium is necessary for the release of insulin from the pancreatic cells in response to high blood glucose. There is an important role of the sodium to potassium ratio in the regulation of blood pressure, rather than sodium alone. This ratio should ideally be 1:1 to have a healthy blood pressure.

Requirements : The daily requirement of potassium has not been determined accurately (10). The acceptable intake appears to be about 4.7 g per day, almost the same as of sodium.

Deficiency : Dietary deficiency is not common. However deficiency could be caused by diarrhoea, vomiting, dehydration, purgatives, chronic acidosis or alkalosis, diuretics, etc. Potassium deficiency affects the electrophysiology of cell. It may cause cardiac arrhythmias and muscle weakness (9).

Magnesium

Magnesium has wide ranging body functions. All human tissues contain small amounts of magnesium. The adult

body contains about 25 g of the metal and greater part of this amount is present in bones in combination with phosphate and bicarbonate. About one fifth of the total magnesium in the body is present in the soft tissues, where it is mainly bound to protein. Inside the cells, the metal is concentrated within the mitochondria.

Sources : Most foods contain useful amounts of magnesium, particularly those of vegetable origin. Green vegetables, pulses, meat, nuts and whole grain cereals are good sources. Hard drinking water may make a significant contribution to magnesium intake.

Functions : Magnesium is an integral part of bones and teeth. Within the mitochondria it is a co-factor for co-carboxylase and co-enzyme A and is concerned with intracellular energy metabolism. It is important in the replication of DNA, synthesis of proteins and RNA. It is essential for muscle and nerve cell function.

Requirements : Estimated to be about 350 mg/day for adults (10).

Deficiency : It is unlikely that magnesium deficiency would arise in man from simple lack of food. Vitamin D appears to increase magnesium absorption from the intestine. Excessive losses of magnesium in the faeces or urine occur in many diseases e.g. renal or adrenal disease, malabsorption, use of some drugs (e.g. diuretics) and in re-feeding syndrome. Magnesium deficiency leads to apathy and muscular weakness and sometimes to tetany, convulsions, cardiac arrhythmias and cardiac arrest (9).

Iron

Iron is probably one of the most studied minerals in context of human health. It is one of the most important micronutrients and is of fundamental importance to life. The body of an adult human contains iron equal in weight to a large 'nail' (about 4 g), of which more than two thirds (about 2.4g) is present in haemoglobin. The rest of the iron in the body is present as a reserve store in liver and to a lesser extent in other organs.

Sources : The sources of iron can be divided into two main groups:

(a) **Haem Iron Sources**: These are essentially the non-vegetarian sources of iron e.g. meat, fish and eggs. Milk is considered a poor source of iron but breast milk is an efficient source for the infant.

(b) **Non-haem Iron Sources** : These are the vegetarian sources, namely cereals, dark green leafy vegetables, pulses, nuts and dry fruits. Absorption of iron from these foods is only 1 to 20 percent (See Table- 3).

Non-haem iron is poorly absorbed (1-20%) and is influenced by dietary constituents. Certain compounds like Phytic acid (in cereals, fibre), polyphenols (in plants), tannins (in tea), phosphates (in milk and eggs) present in foods of vegetable origin inhibit the absorption of iron. There are also factors in the diet that increase non-haem iron absorption, such as red meat, fish, chicken and liver. Ascorbic acid and low pH also enhance the absorption of non-haem iron. Haem-iron is absorbed directly into the mucosal cells where iron is released by haem oxidase and then bound to transferrin.

Foodstuff	Iron (mg per 100g)	Foodstuff	Iron (mg per 100g)
Cereals & Legumes		Fruits	
Rice, raw milled	0.7	Apricots	2.2
Wheat flour, whole	4.9	Pineapple	2.42
Jowar	4.1	Water melon	7.9
Lentil	7.6	Custard apple	4.31
Bengal gram, whole	5.3	Mango	1.3
Soyabean	10.4	Pomegranate	1.79
Vegetables		Miscellaneous	
Spinach	1.14	Fish, <i>Hilsa</i>	2.1
Amaranth	1.8-38.5	Milk cow	0.2
Cauliflower greens	40	Mutton, muscle	2.5
Radish leaves	18.0	Jaggery	2.64

Maximum absorption of iron takes place in duodenum and upper part of small intestine. The amount of iron absorbed from a given meal depends to a large extent on the iron status of the individual. Iron absorption increases during growth and pregnancy.

When the body needs iron it passes directly through the mucosal cells and is transported by transferrin to the bone marrow. If iron is not required it is stored in the mucosal cells as transferrin. It will be lost in faeces when the mucosal cells are exfoliated. Excess iron is stored as ferritin or haemosiderin in the liver, spleen, or bone marrow. It can be mobilized from these stores when demand is increased.

It is lost mainly during menstruation and from the gastrointestinal tract. Physiological losses from all other routes (exfoliation from alimentary, urinary and respiratory tract and by dermal and hair losses and losses in the sweat) also occur. Excretion of iron is very low (about 1mg/day in men).

Functions : Iron is a component of haemoglobin and myoglobin. Iron is an essential component of heme. It is also a constituent of important enzymes like cytochromes, catalase, peroxidase, etc. As a part of these haemocomplexes and metallo-enzymes, it serves important functions in oxygen transport and cellular respiration. It is also involved in cellular immune response for appropriate functioning of phagocytic cells (9, 11).

Requirements : The requirement of iron is quite small, in the vicinity of 1 to 3 mg/day. It changes constantly depending on the age, sex and the physiological status of the individual like pregnancy, lactation and growth. But since the absorption of iron is rather poor, the dietary intake of iron should be 10 to 25 times the requirement. Hence the RDA of iron is about 28 mg for males and 30 mg for females (38mg for pregnant females) (10).

Group	Requirement	RDA
Male	0.9 mg	28 mg
Female	2.8 mg	30 mg
Pregnancy	3.5 mg	38 mg
Lactation	2.4 mg	30 mg

Deficiency : Iron deficiency anaemia is the most common nutritional deficiency in the world. It is estimated that up to half of all women and two-thirds of all pregnant women have anaemia esp. in developing countries (9). Contrary to common belief, the prevalence of anaemia in males is also of a very high magnitude of about 40%.

Increased risk of Iron Deficiency
Women
Growing children and adolescents
Pregnancy
Heavy menstruation
Chronic bleeds <ul style="list-style-type: none"> ● Haemorrhoids ● Peptic ulcers ● Irritation from drugs/alcohol ● Acute gastritis
Iron poor diets
Strict vegetarians
Heavy tea/coffee drinkers
Reduced gastric acid secretion
Atrophic gastritis
Stomach surgery
Chronic antacid use
Reduced transport due to deficiency of <ul style="list-style-type: none"> ● Vitamin A ● Vitamin B₆ ● Copper

The details of the condition are extensively elaborated in a separate chapter on nutritional deficiencies.

Toxicity : The major cause of iron overload is hereditary haemochromatosis, another cause could be transfusion overload. The latter may be seen in cases receiving frequent transfusions as in Sickle cell anaemia and Thalassemia. Haemosiderosis is a condition seen in individuals consuming an abnormally large amount of iron.

Recent studies suggest that iron plays an active role as a pro-oxidant (opposite to the 'favourable' antioxidant activity of certain vitamins and minerals) (See Box- 2).

Iodine

Iodine has also been studied for a very long time. As early as 2800 BC Shan Nuang in China suggested sea weeds as a remedy for goiter. It was discovered as an element in 1811 by Courtois (France). It is an essential trace element because it is

Box - 2 : Pro-oxidant activity of Iron

There is no doubt in the fact that iron is an important mineral involved in various vital metabolic functions. But lately, a pro-oxidant role of iron is being studied. Excess iron promotes lipid peroxidation and tissue damage *in vitro*. There is a possibility that, via these pro-oxidant effects, disturbances in iron metabolism play a pathogenic role in many diseases. Therefore iron may be potentially harmful in some situations, esp. during preexisting inflammation and disease (12). For more details section on 'Antioxidants' can be referred to.

an integral component of the thyroid hormones: thyroxine and triiodothyroxine, both of which have important metabolic roles. Iodine deficiency is endemic in the mountainous areas with poor soil content such as the sub-Himalayan regions. This is due to iodine being washed from the soil. Its deficiency causes the widely prevalent preventable iodine deficiency disorders that affect all ages: abortions, still births, cretinism, mental retardation, deaf-mutism, dwarfism and goiter.

Sources and losses : The presence of iodine in the food is a function of the iodine content of local soil. Wherever the soil contains adequate amount of iodine, all crops growing there are rich in iodine. Among the natural foods the best sources of iodine are seafoods and vegetables grown on iodine-rich soils. Dairy products, eggs, cereal grains, legumes and green leaves (spinach) are also reasonable sources of iodine. Water contains traces of iodine which contributes to as much as 10% of our total iodine intake.

Goitrogens : Certain vegetables of Brassica group such as cabbage, cauliflower and radish contain goitrogens such as thiocyanates and cynoglycosides. Consumption of large quantities of these foods may lead to the development of goiter by making the iodine present in food unavailable to the body. Goitrogens are inactivated by heating.

Absorption : Dietary iodine absorbed from the small intestine follows two main pathways within the body. Approximately 30 percent is used up by the thyroid gland for the synthesis of thyroxine hormone; the remainder is excreted in the urine (9).

Functions : Iodine is an integral component of the thyroid hormones thyroxine (T_4) and tri-iodothyronine (T_3). In addition, the fetus and neonate normal protein metabolism in the brain and CNS requires iodine.

Requirement : The daily requirement of iodine is $150\mu\text{g}$ for an adult (10). However the requirements differ with age and physiological states. See box-3.

Box - 3 : RDA of Iodine

Infants	$50\mu\text{g}$
Children	$100\mu\text{g}$
Adults	$150\mu\text{g}$
Pregnancy	$200\mu\text{g}$

Deficiency : Endemic goiter of varying degrees is found in a large proportion of the population in India, where the soil and thus food materials are deficient in iodine. This is particularly true for the sub-Himalayan regions of India. By virtue of the slopes, iodine from the top soil constantly gets washed off by rains. Other regions located close to the hills e.g. Western and Eastern Ghats, Jharkhand, Chhatisgarh etc also face this problem. Hence, iodine deficiency of varying degree is

encountered in many districts in India. The deficiency of iodine leads to various deficiency disorders, commonly termed as *Iodine Deficiency Disorders (IDD)* that shows a wide spectrum of picture ranging from still births to goiters in adults (See Box - 4). Fortification of salt with iodine is carried out to reduce IDD. The PFA act has specified an iodine concentration of 30 and 15 ppm in salt at source and consumer ends respectively thereby providing 150 mg of iodine in 10 gm of salt.

Box - 4 : Iodine Deficiency Disorders

Adults : Iodine deficiency disorder (IDD) in adults results in hypothyroidism and raised levels of TSH, which cause hyperplasia of thyroid tissues resulting in goitre. Hypothyroidism is characterized by lethargy, poor cold tolerance, bradycardia, and myxoedema. Infertility is known to occur in IDD.

Fetus & infants: In the fetus, IDD results in cretinism. The same is manifested as mental retardation, hearing, speech defects, squint, disorders of gait, and growth retardation in infant life.

At birth : IDD is also linked to an increase in the rates of still birth, miscarriage. Neonatal hypothyroidism is a sensitive indicator of the incidence of IDD in a community.

Recent Advances : Detection of iodine in salt

It must be appreciated that mere iodination of salt does not ensure availability of iodine to the consumer. Iodine has a property to 'sublimate' and is thus constantly lost from its 'iodized vehicle (salt)' on keeping. It is therefore recommended to consume the iodized salt within a period of 6 months of iodization. There is a simple inexpensive rapid test (UNICEF) available to detect the level of iodine in salt. Test kits can be obtained by directing requests to MBI, 85 GN Chetty Road, III Floor, T Nagar, Madras 600 017 (13)

Fluorine

It is normally present in the bones and teeth and is essential for the normal mineralisation of bones and formation of dental enamel.

Sources : Fluorine is widely but unevenly distributed in nature. It is found in many foods, but seafoods, cheese and tea are rich sources. However, the main source of fluorine to man is drinking water. The fluoride content of drinking water in India is about 0.5 mg/l but in fluorosis endemic areas, the natural waters have been found to contain as much as 3 to 12 mg of fluoride/l. A concentration of 0.5 to 0.8 mg/l in water is considered a safe limit in India. In temperate climate where the intake of water, is low, the optimum level of fluorine in drinking water is accepted as 1 mg/l (14).

Deficiency : Deficiency of fluoride in water below 0.5 mg/1 is usually associated with dental caries.

Excess : Ingestion of large amounts of fluorine (>2-3ppm in water) is associated with dental and skeletal fluorosis. Skeletal fluorosis has been reported to be health problem in rural districts of Andhra Pradesh, Haryana, Karnataka, Kerala, Punjab, Rajasthan and Tamil Nadu. Scientists working at the National Institute of Nutrition Hyderabad found new form of fluorosis characterized by genu valgum and osteoporosis of the lower limbs in some districts of Andhra Pradesh and Tamilnadu.

Zinc

Zinc is present in small amounts in all tissues of the body. Total content of the body is over 2.0 g.

Sources : Zinc is widely distributed in food stuffs of both animal and vegetable origin. Good sources of zinc are meat, whole grains and legumes. Its bioavailability in vegetable foods is poor due to presence of phytates which impair its absorption.

Requirement : The daily requirement of zinc is about 15 mg in men and 12 mg in women (15).

Functions : Zinc is part of over 100 enzymes and is thus of importance in protein and carbohydrate metabolism, bone metabolism, and oxygen transport. Zinc is also important in the immune response and gene expression. It is an important structural constituent of leucocytes and has a vital role to play in the synthesis of nucleic acids (9). Lymphoid tissue too contains substantial amounts of zinc. Zinc interacts with insulin in the pancreas and serves in the efficient storage of the hormone. Zinc is a also powerful antioxidant.

Deficiency : A clinical syndrome characterized by small stature, hypogonadism, mild anaemia and low plasma zinc occurs in older children and adolescents in poor peasant communities in Iran and elsewhere in Middle East, where the staple diet is unleavened bread. The zinc intake is low and its absorption is impaired by phytate in the unleavened bread. However, the common deficiency symptoms are:

- Severe deficiency results in growth retardation, failure to thrive, delayed sexual maturation esp. in children.
- Deficiency of zinc impairs cellular immune mechanism while excess of it may depress neutrophils.
- Zinc deficiency may present as a tetrad of symptoms comprising of neuro-psychiatric changes, dermal lesions, diarrhoea and alopecia (Acro-dermatitis Enteropathica). Zinc supplementation has been found useful in these conditions (9,15).

Copper

It is an essential trace element as it is a component of many metallo-enzyme systems and iron metabolism is closely dependent on it. The amount of copper in the adult body is estimated to be 80 -100mg. Copper is widely distributed in nature and therefore primary copper deficiency in adults has never been reported in adult man. Even poor diets provide enough copper for human needs.

Sources : Meat, nuts, cereals and fruits are good sources.

Functions : Many metalloenzymes contain Copper. These enzymes have various functions which are summarized in the Box- 5 (9).

Box - 5 : Functions of some copper containing metalloenzymes	
Enzyme	Function
Caeruloplasmin (Ferrioxidase 1)	- Iron oxidation and transport
Superoxide dismutase	- Antioxidant
Cytochrome-c oxidase	- Electron transport
Dopamine hydroxylase	- Hydroxylation of Dopa in brain
Tyrosinase	- Formation of melanin
Clotting factors V and VIII	- Thrombogenesis

Requirement : Suggested daily intake is 1-2 mg (10).

Deficiency : Copper deficiency is rare. Hypocupraemia occurs in patients with nephrosis, Wilson's disease and sometimes in protein energy malnutrition. Neutropaenia is the commonest documented abnormality of copper deficiency. Infants, especially those who are premature, may develop copper deficiency which usually presents as chronic diarrhoea. Neutropaenia and later anaemia develop and they do not respond to iron. Menke's disease, a rare hereditary defect of copper absorption is invariably fatal. Copper deficiency may be a risk factor for coronary heart disease as it has been associated with raised plasma cholesterol levels and heart-related abnormalities.(9)

Selenium

There is a resurgence of interest in the mineral selenium due to its antioxidant properties. It is an essential component of glutathione peroxidase, an important enzyme. It is present in all body tissues except fat.

Sources : Meat, fish, nuts and eggs are good sources. Lacto-ova vegetarians and vegans may be at risk of deficiency.

Functions : Selenium is an integral part of over 30 selenoproteins; the most important of which are glutathione peroxidases and iodothyronine deiodinases. Glutathione peroxidase has an important role in the detoxification of peroxides and free radicals. Its antioxidant action might be protective against certain cancers especially prostate, lung, colon and non-melanoma skin cancers. It may also be helpful in delaying the aging process. It is also involved in the production of tri-iodothyronine from thyroxine. It also contributes to antibody responses, the production of eicosanoids as well as cytotoxicity of natural killer cells (9).

Requirements : Recommended daily intake is 70 µg (11).

Deficiency : Its deficiency has a wide range of symptoms, not all attributable to glutathione peroxidase. Its deficiency is associated with increased coronary artery disease. Keshan disease (endemic cardiomyopathy) in China and Kashin Beck syndrome, an osteo-arthropathy in children of 05-13 years age is seen in selenium deficient areas (9,10).

Who is likely to get Selenium Deficiency?

Poor Soil Content : Poor soil content of Selenium compromises its dietary availability through poor contents of crops and animals. It is seen in large parts of Scandinavia, China, Central Europe, Africa and New Zealand.

Increased Oxidative Stress : Strenuous exercise, physical activity, smoking, exposure to environmental chemicals, radiation and chronic illness increase oxidative stress. This escalates the turnover of glutathione peroxidase which in turn increases the requirement of Selenium and likelihood of its deficiency.

Malabsorption : As caused in pancreatic disorders, cystic fibrosis, inflammatory bowel disease also put one to the risk of Selenium deficiency.

Summary

Minerals are single inorganic elements, used by the body to activate, regulate and control metabolic activities, in structural building of cell/tissue and in neural transmission and muscle

contraction. They could be macrominerals or microminerals depending on their requirements (more than 100 mg and less than 100 mg/day respectively). Salient features are tabulated in Summary Box 1 and 2.

Summary Box - 1 : The Macrominerals

Mineral	Function	RDA	Deficiency	Sources
Calcium	Bone & teeth formation, Blood clotting, Muscle contraction, Nerve transmission	Adults: 400 mg Pregnancy & Lactation 1 g	Tetany, Rickets, Osteoporosis	Dairy products, Meat products, Leafy vegetables
Phosphorus	Bone & teeth formation, Energy metabolism, Nucleic acid synthesis, Acid base balance	1 g	Not seen often Can cause bone loss, anorexia	Dairy products, Meat products, Leafy vegetables
Sodium	Extracellular fluid component, Water balance Acid base balance Nerve transmission, Muscle action	5 g	Cramps, Acid-base imbalance, Water imbalance	Table salt
Potassium	Major Intracellular fluid component, Acid-base balance; Nerve transmission, Muscle action	5 g	Muscle weakness, Arrhythmias	Fresh fruits, meats, whole grains, vegetables
Magnesium	Coenzyme in metabolic reactions, Nerve conduction	350 mg	Tremors, spasm	Meat, cheese, eggs, nuts, legumes

Summary Box - 2 : The Microminerals

Mineral	Function	RDA	Deficiency	Sources
Iron	Haemoglobin & Myoglobin formation, Cellular oxidation reactions, Antibody formation	Male:28mg Female:30mg Pregnancy:38mg Lactation:30mg	Anaemia, fatiguability. Impaired immune function	Meat products, Liver, Green leafy vegetables
Iodine	Thyroxine synthesis	Adults 150µg Pregnancy 200µg	Goitre, cretinism, hypothyroidism, Infertility, still births	Iodized salt, Plant products grown in iodine rich soil
Zinc	Essential enzyme constituent, Protein metabolism, Immune function, Insulin storage, Sexual maturation	15mg	Retarded sexual and physical activity; Impaired wound healing	Dairy products, Meat products, Eggs, whole grains
Selenium	Antioxidant function Forms glutathione peroxidase, spares Vitamin E	70 µg	Impaired immune function, Keshan disease	Liver, meats, whole grains, sea food
Fluoride	Bone and teeth constituent	< 1mg	Dental caries	Flouridated water, toothpaste

Study Exercises

Long Question : Which are the minerals of importance to public health in India? Discuss the sources, requirement and functions of Iodine.

Short Notes : (1) Importance of selenium as an antioxidant (2) Osteoporosis (3) Trace elements.

MCQs

- Which of the following iron sources falls under the category of non heme iron (a) Jaggery (b) Meat (c) Eggs (d) Milk
- Calcium homeostasis is maintained by (a) T_3 and T_4 (b) Vitamin D and parathyroid hormone (c) Phosphorus and magnesium (d) Calcitonin and bone matrix
- Ideal sodium potassium ratio should be (a) Not specified (b) 1:1 (c) 1:2 (d) 2:1
- Which of the following does not fall under 'IDD' : (a) Cretinism (b) Mongolism (c) Deaf-mutism (d) Infertility
- Which of these is not a constituent of metallo-enzymes (a) Copper (b) Zinc (c) Iron (d) Nickel

Answers : (1) a; (2) b; (3) b; (4) b; (5) d.

Major Foods and their Nutritive Value

Rajul K Gupta

The Major Food Groups

There are innumerable food items that constitute human diet. The major foodstuffs can be broadly classified into ten major groups. These are shown in the Box-1.

Foods have different nutritional profiles. Moreover, availability of foods varies at different places and in different seasons. People from diverse cultures, religions and states tend to consume different types of food stuff. But one thing that is common for the good health of all humans is the absolute necessity of a well balanced diet. To formulate a well balanced diet for optimum health, it is extremely important to appreciate the details of these food items and their nutritive value. Therefore these facts are required to be learnt before we could proceed further in unveiling the complex relationship of food,

health, disease and its prevention. This chapter endeavors to elaborate in brief the commonly used food items.

Box - 1 : Ten major food groups
Cereals and millets
Pulses and legumes
Vegetables, roots and tubers
Fruits and nuts
Animal foods <ul style="list-style-type: none"> ● Meat/Poultry ● Milk and milk products ● Eggs
Oilseeds
Sugar, jaggery, salt
Non - Alcoholic beverages
Alcoholic beverages
Spices and condiments

Cereals and Millets

Cereals and millets form the staple food for human diet as they are cheap and have a high energy value, approximately 350 Kcal/100g. In an agricultural country like ours, rice, maize, wheat and millets (*jowar*, *bajra* and *ragi*) form the bulk of the diet which makes up for as much as three fourth of the total energy requirement of a rural Indian. Thus knowing about the nutritive quality of these staple cereals is of great importance. Cereals and millets provide almost all major nutrients, as elaborated below.

Carbohydrates : Cereals are most important sources of carbohydrates and energy in our diet. They provide 60 to 75 % of the total energy in our diet.

Proteins : Cereals are moderate sources of proteins (about 6 to 12g/100g). Cereal protein is of poor quality as it is deficient in essential amino acids. Wheat proteins are deficient in Lysine and maize in Tryptophan. Pulse proteins on the other hand, are rich in these deficient amino acids (lysine and tryptophan). A predominantly cereal diet should therefore invariably be supplemented with other sources of proteins like the pulses, especially for the vegetarians. This helps to improve the quality of protein in our diet. This is called as the supplementary action of proteins.

Cereal proteins are quantitatively an ample amount of protein in an otherwise protein deficient Indian diet. As much as 50% of the total proteins in Indian diet is contributed to by cereal proteins. Hence cereals constitute a vital source of proteins in our diet.

Micronutrients : Cereals contain minerals like iron and calcium, little carotene but no vitamin C. *Ragi* is particularly rich in calcium. The millets are also rich in phytates and tannins which interfere with the absorption of minerals. Whole (unrefined) cereals are relatively good sources of the B complex vitamins. Most of the vitamins lie in the outer layers so milling and polishing removes these vitamins to a great extent.

Fibre : The outer layers of cereals and millets contain the all important fibre in plenty (1-8g/100g). The fibre is lost depending on the level and extent of milling.

Milling : Now a days machine milling of cereals has become an integral part of the processing of grains. Milling not only does the basic processing but also makes the grain more shiny, whiter and sparkling ('refined white flour and polished white rice'). This appeals to the sense of sight and thus improves the palatability. But we have to pay the cost for it in terms of losing its nutritive value. Milling separates germ and outer layers (pericarp and testa) that are discarded as bran. Such highly milled wheat and rice is thus devoid of fibre. Since the vitamins are also concentrated in the outer layer of the whole grains, which are removed by machine milling, these refined cereals lose not only much of their fibre but also the vitamin, mineral and protein content during processing (1).

Machine milling and refining cause considerable deterioration of nutritive value of cereals that eventually affects public health. For example, beriberi is endemic in countries where polished rice is habitually eaten. Even though whole meal flour has marginally lower energy value than white flour, the protein

content of whole meal flour is relatively higher (3). Milling is undoubtedly a necessary evil. Cereals should not be 'hard' milled. Highly milled cereals should be avoided. It is advisable to consume whole wheat atta of 85 percent extraction. Not more than 5 percent bran should be permitted to be removed during milling. Parboiling of rice is also an effective solution. Parboiled rice is the only cereal which does not suffer appreciably when machine milled.

Effects of Refining on Nutrient Content of Wheat Flour (per 100 g) (2).

Nutrient	Content before refining (per 100 g)	Content after refining (per 100 g)
Thiamin	580 µg	140 µg
Vitamin B ₆	750 µg	130 µg
Niacin	2520 µg	340 µg
Folate	57 µg	6 µg
Vitamin E	1.4 mg	0.3 mg
Calcium	44 mg	23 mg
Zinc	29 ppm	8 ppm
Copper	4 ppm	1.3 ppm
Iron	35 ppm	10 ppm

Rice

Rice is staple to more than half of the world population.

Nutritive value : Rice is high in energy (about 350 Kcal/100g). The protein content is moderate, 6-9 g%. It is richer in lysine than other cereals. Rice is also fairly rich in thiamine, riboflavin and niacin. It is a poor source of vitamins A, C and D. It is poor in calcium and iron as well.

Nutritive losses : Milling and polishing cause the greatest nutritional loss. Polishing is a process where milled rice is passed through rubber rollers to make it smooth, shiny and whiter. During processing the B -complex vitamins, fibre and proteins are lost to a great extent, depending on the level of milling and polishing. Rice also loses substantial amount of water soluble vitamins and minerals during washing it in plenty of water and discarding it. Similarly draining the water in which the rice was cooked also causes loss of water soluble nutrients.

Preventing nutritive losses : The nutritive losses because of milling, polishing, other processing and cooking practices can be prevented by taking suitable and timely measures. One such widely used method is parboiling.

Parboiling : It is an old technique practiced in India for a long time at the household level. This involves steaming the rice that renders it partially cooked. The technique is now being used at a commercial level as well. The 'Hot Soaking Process' of parboiling has been recommended by the Central Food Technological Research Institute, Mysore.

The process : The paddy is soaked in hot water at 70°C for 3 to 4 hours. With this soaking the outer husk splits and becomes easier to remove. The excess water is drained. This paddy is then steamed for about 10 minutes. The paddy is dried. At a

domestic level it is home pounded and commercially, it is milled for final use. Advantages of parboiling are given in Box - 2.

Box - 2 : Advantages of parboiling
Parboiling causes the B group vitamins in the outer layers (aleurone) to diffuse in to the interior of the grain (endosperm) thus saving them from being lost during milling.
Drying the rice causes the germ to attach firmly to grain, so that the germ is not lost during milling and polishing.
The heat hardens the grain as the starch gets gelatinized. This increases the keeping quality and storage capacity of rice.
The parboiled grain also becomes more resistant to insects.

Disadvantage of parboiling : There are no disadvantages of the parboiled rice except for the fact that it imparts an off flavour to rice. The rice also attains a pale hue. The off flavour is not liked by people who are used to eating the non-parboiled rice.

Wheat

Wheat is the most widely consumed cereal in North India. It is used to make flour (atta for chapattis and puri), maida for bread, dalia and also suji, to make various savouries.

Nutritive value : The calorie content of wheat is almost the same as that of rice ie about 350 Kcal/100g. The protein content is higher than that of rice i.e. 9 to 16g %. The quality of protein is however poor as it is deficient in the essential amino acids lysine and threonine.

Nutritive losses and their prevention : Hard milling, extraction and discarding the bran causes loss of fibre, vitamins and proteins. As discussed earlier it is advisable to consume whole wheat atta and dalia. Products made up of refined flour like white bread, biscuits, cakes, noodles and burgers should be discouraged.

Maize

Maize is the staple diet in many parts of Africa and Central Asia. However, in most parts of India and many other parts of the world it is commonly eaten only as corn. It is also used to make cornflakes. Cornflour is used in confectionery and to

make custards.

Nutritive value : The calorie content of maize is about 342 Kcal/100g. The protein content is higher than that of rice i.e. 9 to 16g %. The quality of protein is poorer as it is deficient in lysine and tryptophan. It also contains excess leucine which interferes with conversion of tryptophan to niacin (60mg of tryptophan is required to produce 1mg niacin). Thus maize eaters may face the deficiency of niacin and a higher risk of pellagra. Maize is also rich in carotenoids. Nutritive values of common Cereals and Millets are given in Table - 1.

Millets

Millets are consumed without milling. The commonly used millets are *jowar* (sorghum), *bajra* (pearl millet) and *ragi*. These are traditional foods in many parts of India. *Jowar* and *Bajra* are widely used in Maharashtra and Rajasthan respectively.

Nutritive value : The calorie content of millets is about 350 Kcal/100g. The protein content is about 8 to 14g %. They are also rich in minerals. *Ragi* contains a high amount of calcium - 344 mg / 100 g.

Jowar is important millet in the western and central India (esp. Maharashtra, MP and Andhra Pradesh) and is the staple for many Indians. It is nutritious millet with a high iron content of 4.1 mg/100g. The protein content is in the range of 9 to 14%. Like other millets the protein is limited in the amino acids lysine and threonine. In some species the leucine content might be higher that interferes with the conversion of tryptophan to niacin thus sole consumption of *Jowar* could be pellagrogenic.

Bajra (Pearl millet) is grown in the arid regions of our country. It is relished in Rajasthan, Gujarat and some parts of Maharashtra as porridge. It is also used to make flour for preparing chapatis. The protein content is in the range of 10 to 14%. The iron content of *Bajra* is the highest among all cereals and millets at 8mg/100g. It is also relatively rich in calcium, carotene, riboflavin, niacin and folic acid.

Pulses and Legumes

Pulses and legumes comprise of dried peas, beans, dals and grams and are an integral part of the Indian diet. Commonly used dals are red gram (*arhar*), green gram (*moong*), lentil (*masoor*), bengal gram (*channa*) etc. They are, therefore a

Food stuff	Proteins (g)	Fat(g)	Fibre (g)	Carbohydrates (g)	Energy (Kcal)	Iron (mg)	Carotene (µg)	Thiamine (mg)	Riboflavin (mg)	Niacin (mg)	Folic acid (µg)	Vitamin C (mg)

Soya bean - The 'Queen' of pulses and legumes

Soya bean is a pulse which has very high protein (43.2g/100g) and fat content (19.5g/100g). It possesses high contents of iron as well. It is also rich in carotene, niacin and folic acid. The nutritive value of soya bean proteins is equivalent to milk proteins even though the protein quality is inferior. The rather bland taste of unprocessed soya bean can be made up by suitably cooking or processing it. It can be simply cooked as dal or can be prepared with other legumes as mixed dal. Soya bean can be processed into many foods which are enjoyed by the community. It is commonly eaten as nuggets (baris). Its flour can be mixed in wheat flour to make it more nutritious. Soya milk and curd is also popular. It can be processed to fried nuggets (kukure), which are relished by the children. In the South East Asian countries its preparations like tofu, miso and soya sauce are relished. By virtue of its high fat contents its oil is extracted and used as cooking oil. This oil is one of the very few oils rich in alpha-linolenic acid (>5%) besides its high contents of linoleic acid (53%). Soya bean is truly the 'Queen' of pulses and legumes.

Nutritional profile of Soya bean (per 100g)

Nutrient	Contents	Nutrient	Contents
Protein	43.2 g	Thiamin	0.73 mg
Fat	19.5 g	Riboflavin	0.39 mg
Iron	10.4 mg	Niacin	3.2 mg
Carotene	426 µg	Folate (total)	100µg

valuable constituent of the vegetarian diet. Pulses are cheap and easily available.

Nutritive Value : Pulses and legumes are colloquially referred to as the poor man's meat as they have high protein content of about 20-25%. Although they are poor in methionine and cysteine and the biological values of their protein is inferior to foods of animal origin (meat, fish eggs and milk), they are a substantial source of proteins for those not consuming meat. Pulse protein is rich in lysine which compensates for the low lysine content of cereal proteins. They are an important source of vitamins and minerals like calcium, iron and vitamin B. Bengal gram (*channa dal*) and to a lesser extent green gram (*moong*) contain a small amount of ascorbic acid in the dry state. The energy content is approximately the same as that of cereals i.e. about 350 Kcal/100g (1).

Germination of Pulses : The ascorbic acid content of all unsplit pulses can be increased by germinating or sprouting. Whole unsplit dal or gram is first soaked in water for 12 to 24 hours and then spread on a damp blanket in a thin layer to allow access of air and covered with another blanket kept damp by sprinkling water. In few hours small sprouts appear; when

these are 10 to 20 mm long the process is complete. The vitamin C content is maximal after about 30 hours of germination. Germination causes an increase in vitamin B also (4).

Fermentation too improves the nutritional value of pulses. The vitamin content of B group of vitamins esp. thiamin, riboflavin and niacin goes up. The digestibility of pulses also improves with germination. The nutritive value of common pulses and legumes is summarized in Table - 2.

Animal Foods

Meat and fish

Meat is a word commonly used for the flesh of cattle (beef), goat and sheep (mutton), pig (pork) or chicken. It is a good source of high quality protein (15 to 20g per 100g). Moreover this protein is qualitatively as good as that of fish, egg, milk, cheese and other dairy produce, since it contains all essential amino acids. It is also a good source of most B vitamins like nicotinic acid. Meat is rich in phosphorous but poor in calcium. Liver, a component of meat, too has not only high quality proteins but also vitamin A and vitamin B complex. Meat is also rich in minerals especially iron and zinc. The iron content

Table - 2 : Nutritive value of common pulses and legumes (per 100g)

Pulses and legumes	Proteins(g)	Fat (g)	Fibre (g)	Carbohydrates (g)	Energy (Kcal)	Iron(mg)	Carotene (µg)	Thiamine (mg)	Riboflavin (mg)	Niacin (mg)	Folic acid (µg)	Vitamin C (mg)
Peas dry	19.7	1.1	4.5	56.5	315	7.05	39	0.47	0.47	3.4	7.5	0
Green gram	24.5	1.2	0.8	59.9	348	3.9	94	0.47	0.47	2.4	140	0
Bengal gram	17.1	3	3.9	60.9	360	4.6	189	0.30	0.15	2.9	186	3
Soya bean	43.2	19.5	3.7	20.9	432	10.4	426	0.73	0.39	3.2	100	-
Rajmah	22.9	1.3	4.8	60.6	346	5.1	-	-	-	-	-	0
Redgram	22.3	1.7	1.5	57.6	335	2.7	132	0.45	0.45	2.9	103	0

of meat is of the heme variety which has high bioavailability. Meat has a high content of fat including the saturated fatty acids, which may be a risk for good health.

Fish is generally considered good for health as it is rich in unsaturated fatty acids including the omega 3 fatty acids and vitamins A and D. Fish has high quantity of proteins (15 - 25g/100g), which are of high biological value and are easily digestible. Sea fish is also rich in minerals like Iodine. With the current emphasis on higher intake of polyunsaturated fatty acids, including the omega-3 fatty acids fish is of immense value in diet.

Milk and Milk Products

Milk is the complete food on which the young one may subsist for up to six months. It is the sole food for all growing young mammals. The human milk might be poorer than cow's or buffalo's milk, but is adequate for the infant. Milk is used to prepare curd, yogurt, butter, ghee and buttermilk. These are used extensively for the preparation of many traditional Indian sweets.

Nutritive Value of Milk : All the important nutrients are well represented in milk except for iron and nicotinic acid. Newly drawn milk contains 2 mg of vitamin C per 100 ml but this readily disappears on storage, heating or processing in any other way. On the average, one liter of cow's and buffalo's milk contains 32 and 43 g of protein respectively. Human milk contains about 1.1g % proteins. Milk proteins are caseinogen (85%), lactalbumin (12%) and lactoglobulin (3%). These proteins are of high biological value and are rich in tryptophan and cysteine. Calcium caseinogenate is a complex formed with calcium in milk.

The fat content in milk varies from 3.4 (human) to 6.5 % (buffalo), depending on the source. Milk fat is an emulsion of extremely fine particles of the glycerides of butyric, palmitic and oleic acid rendering it easily digestible and this is especially so in cow's milk. Milk is also rich in linoleic acid and oleic acid. Milk is a good source of vitamin A and D as well. Milk contains more than 30 types of sugars, Lactose being the most predominant of them. A litre of milk contains as much as 50 g of lactose. Milk is also very rich in calcium (1200 mg per litre

of cow's milk) and phosphorus. One litre of cow's milk provides about 670 Kcal (2.8 Mj) of energy (1).

Curd : Curd is traditionally relished in the Indian diet. It is produced by the action of lactobacilli on lactose (in milk), which is broken down to lactic acid. The proteins are coagulated by the acid and curd is formed. Curd and whole butter milk are easily digestible. They have the same nutritive value as that of the original milk from which they were prepared, being very good sources of protein, calcium, vitamin A and riboflavin.

Cream, Butter and Ghee : Cream, butter and ghee are the various types of fats extracted from milk. Cream can be extracted by centrifugation of unboiled milk. Butter is the fat extracted from buttermilk. Ghee is the clear fat extracted after boiling butter. Cream has nutritive value in between whole milk and butter. Good butter should not contain more than 16 percent of water and not less than 80 percent of fat. 100gm butter yields about 729 Kcal (3.05 Mj). On the other hand, ghee is almost 100% fat, 100 g of ghee yielding 900 Kcal (3.76 Mj). Nutritive value of milk and milk products is summarized in Table - 3.

Skimmed and Toned Milk : The milk available in market may be pure milk from cow or buffalo. Sometimes a mixture of buffalo's and cow's milk might also be available. Some people prefer low fat or fat free milk. This is the skimmed milk from which fat has been removed. This is useful for those who have been recommended low fat in diet, due to a medical condition. Toned milk can be manufactured by adding 1 part water and 1/8 part skimmed milk to 1 part milk. This blend is then stirred, pasteurized and bottled. It becomes quite similar to cow's milk.

Tinned Milk : Powdered or tinned milk could be an alternative to whole milk when fresh milk cannot be made available. Condensed, evaporated or homogenized milk can be tinned. It could be sweetened or unsweetened. Condensed milk contains 50 percent cane sugar, which is a good preservative. Dried or powered milk is reconstituted by adding 7 volumes of boiled water just before consumption. Tinned milk should be reconstituted as per instructions.

Eggs

Eggs contain all the nutrients required for the embryo. They

Table - 3 : Nutritive value of milk and milk products (per 100ml) (1)

Food stuff	Proteins (g)	Fat (g)	Energy (Kcal)	Iron (mg)	Carotene (µg)	Thiamine (mg)	Riboflavin (mg)	Niacin (mg)	Folic acid (µg)	Vitamin C (mg)
Milk, buffalo	4.3	6.5	117	0.2	48	0.04	0.10	0.1	3.3	1
Milk, cow	3.2	4.1	67	0.2	53	0.05	0.19	0.1	5.6	2
Milk, human	1.1	3.4	65	-	41	0.02	0.02	-	1.3	3
Ghee	-	100	900	-	600	-	-	-	-	-
Butter	-	81	729	-	960	-	-	-	-	-
Cheese	24.1	25.1	348	2.1	82	-	-	-	-	-
Curd	3.1	4	60	0.2	31	0.05	0.16	0.1	3.3	1

have a high nutritive value. An egg provides about 70 Kcal. An egg contains about 6 g protein. The proteins are of a high biological value. The NPU of egg protein is 100 and is taken as the standard protein, to compare other proteins with. An egg contains about 6 g of fat. It also has a high cholesterol content of 250mg. The fat is present in the yolk. It is finely emulsified and hence easily assimilated. The minerals and vitamins exist in the yolk, which is also a valuable source of calcium, phosphorus, iron and vitamins A and D. The white of the egg is one of the best sources of riboflavin. It is however deficient in Vitamin C. Nutritive value of egg is given in Table - 4.

Vegetables

Vegetables and fruits add colour and variety to our food. It is the vegetables and fruits that impart a seasonal touch to the diet, as they change with the seasons. We have green leafy vegetables, coloured vegetables, roots and tubers.

Nutritive Value : Vegetables esp. green leafy and coloured vegetables are a store-house of vitamins, minerals, various phytochemicals and antioxidants, hence they along with fruits are termed as the *protective foods*.

a) Vitamins and Antioxidants : They contain ample amounts of carotene, ascorbic acid, folic acid, calcium, iron and riboflavin. The carotenoids, vitamin C and numerous other phytochemicals possess antioxidant properties (See Box - 1). A yellow vegetable like pumpkin is rich in carotene. However, the carotene of green vegetables like drumstick, cabbage, amaranth and methi is better utilized than of yellow vegetables. Gourds are generally of poor nutritive value; but the bitter gourd is relatively rich in ascorbic acid. The tomato has good ascorbic acid, riboflavin and antioxidant lycopene contents. Onion may not have outstanding nutritive properties, but is virtually irreplaceable because of its value as a flavouring agent and appetizer.

b) Minerals : Vegetables are good source of minerals like calcium, phosphorus, iron, zinc and many trace elements. The absorption and bioavailability of some of the minerals may not be very good due to various reasons. Iron from green leafy vegetables is not very well absorbed as it is present in the ferric state which is not conducive for absorption. In addition calcium, oxalates, phosphates and phytates present alongside (in the vegetables) inhibit the absorption of minerals further.

c) Fibre : Vegetables are rich in fibre, especially the soluble fibre. Fibre is considered extremely important for normal bowel motility, getting rid of toxins from the intestine and guarding it against the rapid absorption of glucose and lipids, thus

preventing hyperglycemia and hyperlipidaemia.

<i>The Rainbow of Phytochemicals</i>		
Colour	Fruit or vegetable	Phytochemicals
Red	Tomato	Lycopene
Yellow-green	Pumpkin, papaya	Zeaxanthin
Red-purple	Beet root,	Anthocyanins
Orange	Pumpkin, papaya, mango	Beta carotene
Orange-yellow	Apricots, apple, cherry, tomato, orange	Flavonoids
Green	Leafy vegetables, cabbage	Glucosinolates
White-green	Garlic, onion	Allyl sulphides

d) Calories : There are not many foods in our diet that could be claimed to be low in calorie and yet nutritious! Vegetables have this unique distinction. By virtue of their high moisture and fibre content the calorie content of most of the green vegetables is in the range of 20 to 60 Kcal/100g. This is a boon for those who have been advised to restrict calories.

Root and tuber vegetables are of variable nutritive value. The carrot is outstandingly rich in carotene. Most roots and tubers contain starch and moderate amounts of ascorbic acid. Potatoes and sweet potatoes having high carbohydrate content have a good energy value and contain moderate quantities of ascorbic acid. Nutritive values of common vegetables are given in Table - 5.

Fruits

Fruits hold a special place in the nutrition of man. They can be eaten any time and as much. Everyone loves them. Different fruits are available in different seasons. They are extremely nutritious. Being eaten raw and fresh, the minerals, vitamins and phytochemicals present in them, do not have to suffer the humiliation of 'mutilation' through heat and fire. Fruits can be classified into citrus, non-citrus and dry fruits.

Nutritive Value

a) Vitamins and Antioxidants : It is known since James Lind that citrus fruits like oranges, lime, lemon, mosambi, malta, etc are rich sources of vitamin C. Guava and amla too are very rich sources of vitamin C. Papaya and mango are rich in carotene and moderately rich in vitamin C. Pineapples, strawberries

Table - 4 : Nutritive value of egg (per 100g*) (1)

Food stuff	Proteins (g)	Fat (g)	Energy (Kcal)	Iron (mg)	Carotene (µg)	Thiamine (mg)	Riboflavin (mg)	Niacin (mg)	Phosphorus (mg)	Calcium (mg)

Egg, duck	13.5	13.7	181	2.5	405	0.12	0.26	0.2	260	70

* One egg weighs about 60 to 70 g

Table - 5 : Nutritive value of common vegetables (per 100g) (1)

Vegetable	Fibre (g)	Carbohydrates (g)	Energy (Kcal)	Iron (mg)	Carotene (µg)	Thiamine (mg)	Riboflavin (mg)	Niacin (mg)	Folic acid (µg)	Vitamin C (mg)
Beans	1.8	4.5	26	0.61	187	0.10	0.06	0.7	45.5	24
Spinach	0.6	2.9	26	1.14	5580	0.03	0.26	0.5	123	28
Tomato	0.8	3.6	20	0.64	351	0.12	0.06	0.4	30	27
Carrot	1.2	10.6	48	1.03	1890	0.04	0.02	0.6	15	3
Onion	0.6	11.1	50	0.6	15	0.08	0.02	0.5	-	2
Potato	0.4	22.6	97	0.48	24	0.1	0.01	1.2	7	17
Cauliflower	1.2	4	30	1.23	30	0.04	0.1	1	-	56
Cabbage	1	4.6	27	0.8	120	0.06	0.09	0.4	23	124
Pumpkin	0.7	5.8	39	-	50	0.06	0.04	0.5	13	2

and papaya are moderately rich sources of vitamin C. Yellow peaches are a good source of carotene. Banana, orange and strawberries are moderate sources of folates. Dried fruits like dry figs provide thiamin, niacin and riboflavin. Dried apricots and prunes are rich in vitamin A (See Table- 6).

b) Minerals : Watermelon is rich in iron. Custard apple is rich in phosphorus and iron. Apricots, lime, guava and figs are rich in calcium. Apricots are rich in zinc too. Banana and apples are moderately rich in potassium. Dried fruits : Raisins, figs, dates and dry apricots are rich in iron. Dried figs are also rich in phosphorus, calcium, potassium and zinc (1).

c) Energy : Banana and plantain have high energy value.

d) Fibre : Fruits are rich in fibres. Their soluble fibre is particularly useful in inhibiting the rapid absorption of glucose and lipids from the intestine. This is helpful in prevention of hyperglycemia and hyperlipidaemias

A daily recommendation of about 400g of fruits and vegetables has been made by the American Dietetic Association. It is wise to consume fresh, seasonal and locally available fruits that are less costly and more affordable than the imported fruits. Nutritive values of common fruits are given in Table - 6.

Nuts

The common nuts in use are almond, cashew nut, groundnut, coconut, pistachio, walnut, etc. Nuts are relished by the young and all primarily for their taste. Nuts have a very high nutritive value (See Table - 7).

Nuts have a high fat and protein content and hence a high energy value. They are a good source of fats, vitamins and proteins as well. They contain minerals too in good quantities. Groundnuts are a good source of proteins, fats & vitamin B complex esp. niacin. Even though the proteins are of low biological value, it is a cheap and ample source of proteins (See Box - 3). Pistachio

Table - 6 : Nutritive value of common fruits (per 100g) (1)

Fruit	Fibre (g)	Carbohydrates (g)	Energy (Kcal)	Iron (mg)	Carotene (µg)	Thiamine (mg)	Riboflavin (mg)	Niacin (mg)	Vitamin C (mg)

Box - 3 : Groundnuts - The King of Nuts

Groundnuts are the cheapest and arguably the most nutritious of all nuts. It contains almost as much oils and fats as an oilseed does (40%). Its MUFA content is one of the highest amongst all Indian oilseeds, at 50% (exceeded only by mustard and rape seed). Its protein content is very high (25.3%). Its niacin content is unmatched (about 20mg/100g), that is 5 to 20 times higher than other nuts. It is a household item in many Indian states like Maharashtra, Gujarat and Andhra Pradesh. It is relished boiled, roasted, fried or simply salted. It can be made into powder or flour. Groundnut chikki (with jaggery) is not only favourite with children, but is extremely nutritious even for the pregnant and lactating. Powdered or ground groundnuts are also used in vegetable preparations and curries. Owing to its low cost and high nutrition value, it finds favour in various national nutritional programme menus like in 'multipurpose food and balahar' as well.

Multipurpose food used in national nutritional programme is made using a mixture of 75 percent groundnut flour (from which fats have been extracted) and 25 percent roasted red gram. It is further fortified with vitamins and minerals. It is a rich source of proteins.

Its low cost, high nutritive value, immense variety of preparations and delicious taste crowns the groundnuts as the 'King of nuts'.

is rich in iron, containing 7.7 mg/100g. Almond and cashew nuts are also moderate sources of iron and proteins.

Fats and Oils

Fats and oils hold a vital place in our daily diet. They are an integral part of cooking as they not only impart good taste, but also contribute to the texture, crispness and energy to our food. They also serve as a medium for cooking as their boiling point is very high.

Fats that are liquid at room temperature are termed as oils. Fats and oils could be of either plant or animal origin. Vegetable oils such as mustard, ground nut, gingelly, coconut and safflower oils are widely used for cooking purposes. Vegetable oils (except red palm oil) are free of any vitamin A activity and contain predominantly unsaturated fatty acids. However, coconut and palm oils are the only commonly used plant oils that are rich in saturated fatty acids.

Butter and ghee are fats of animal origin. These are also used as a cooking medium. They are rich in vitamin A and D. All fats and oils provide 9 Kcal per gram. Excess consumption of these is in disrepute as they are considered to be atherogenic. Excess consumption also contributes to dyslipidaemia, a risk factor for cardiovascular diseases.

Sugar and Jaggery

It is pure sucrose & is used for its sweetening effect & energy value. Excessive consumption of such refined sugar that

provides only 'blank calories' at the expense of complex carbohydrates lowers the relative vitamin, mineral and protein intake. Jaggery is a sweet food popular in rural India. Besides being tasty, it contains an appreciable amount of carotene & iron.

Salt

Salt contains the essential mineral sodium. Even though the daily sodium requirement is very low, the average daily diet contains salt much in excess. The recommended daily salt intake is 5 g. Excess of salt and a skewed sodium potassium ratio (> 1) is known to be a causative factor of hypertension. It is the added salt that is harmful to the body rather than the moderate amounts put in food preparations.

Where does 'High' Salt Come From ?		
High salt	Very High Salt	Excessively High Salt
Bread	Cheese	Pickles
Potato chips	Processed meat	Chutneys
Cornflakes	Soups	Salted Nuts
Canned vegetables	Ketchups	Salted fish
Canned fruits	Processed butter	Chaat

Sugar substitutes

There are occasions when sugar substitutes have to be used instead of sugar. They are preferred for their very high sweetening power and negligible calorific value. These are commonly used for preparing ice creams, candies, toffees, jellies, sweets, etc. They are also used as sweetening agents in cold drinks, flavoured milk and even in tooth pastes. They are also popular amongst diabetics and people desirous of losing weight. Sugar substitutes can be classified into two groups :

(a) *Nutritive sweeteners* : Sugar alcohols (sorbitol, mannitol, xylitol) used as sugar substitutes in candies, chewing gum and beverages. These provide 4 Kcal/gm of energy.

Advantages :

- These are not absorbed as rapidly as sucrose, so can be used in those who cannot tolerate a high blood sugar level.
- The risk of dental caries is lower, as these alcohols can not be used by oral bacteria.

(b) *Non-nutritive sweeteners* : These do not supply any calories. Common examples are aspartame, sucralose, alitame and saccharin. They are several hundred times sweeter than sugar, so a small quantity is sufficient to sweeten the food.

Spices and Condiments

Spices are used to flavour food and improve its palatability. They stimulate the appetite and thus improve health. They are essential to the Indian culinary art. They are used in very small quantities as flavouring agents and for their carminative properties. Green or dry chillies have a high carotene and vitamin C content. As per the new research turmeric (*haldi*) has very high antioxidant content and has medicinal value. Tamarind (*imli*) is widely used for its preservative effect and high vitamin C content. Cloves, Black pepper, ginger, garlic and red chillies have been shown to have antioxidant properties. Spices and condiments are used to prepare pickles and chutney which are used as appetizers.

Non Alcoholic Beverages

Earlier it was thought that by themselves tea, coffee, cocoa or other non-alcoholic beverages do not provide energy or vitamins except that from the sugar and milk added to them. Tea contains alkaloids like caffeine, theophylline and theobromine which are cortical stimulants and help relieve fatigue. If used in excess they may cause insomnia, tachycardia and gastritis in some individuals. Recent studies show that they contain substantial amounts of antioxidants which have distinct health benefits. Alcoholic beverages have been discussed in another chapter.

Summary

The ten major food groups are cereals/millet, pulses/legumes, vegetables (including roots and tubers), fruits/nuts, animal foods (meat/poultry, milk and milk products, eggs), oilseeds, sugar, jaggery, salt, beverages and lastly spices/condiments. Each of these has their own vital value in our diet and for good health.

Cereals and millets contribute to up to 75% of total energy intake. They also contain substantial amount of proteins and invisible fats which contribute handsomely to an Indian diet that is otherwise considered to be poor in these nutrients. Excessive milling denudes cereals of their outer cover and with that the major portion of vitamins, minerals and proteins are lost. Coarse ground flour (atta) and parboiled rice help in reducing the nutritive losses due to milling.

Pulses are the major contributors of proteins esp. in a vegetarian diet. Cereal proteins are poor in lysine which are compensated by the pulse proteins that are rich in these amino acids but poor

in methionine. Groundnuts and soya beans are of exceptionally high nutritive quality with high content of proteins, fat and vitamins. Fats are the storehouse of energy, present in animal oils (ghee/butter) or in vegetable oils (mustard, groundnut, etc).

Fruits and vegetables are rich sources of vitamins, minerals and antioxidants. Roots and tubers also contain starch that is high in calories. Milk which is a complete food is essential for infants and children. Egg protein is one of the best quality proteins available to us and its use must be encouraged. Meat contains high quality iron and proteins. But owing to its high saturated fat content, excessive consumption of meat should be guarded against. Spices and condiments not only provide flavour to the diet but also contribute to the antioxidant content of food.

Study Exercises

Long Question : Enumerate major food groups. Describe the importance of legumes in diet.

Short Notes : (1) Importance of fruits in diet (2) Parboiling of rice (3) Nutritional importance of eggs.

MCQs

1. The highest content of niacin is present in : (a) Jaggery (b) Groundnuts (c) Pistachio (d) Milk
2. Yellow-orange fruits and vegetables are rich in (a) Carotenes (b) Vitamin D (c) B Complex vitamins (d) Zinc
3. Food item with highest protein content is (a) Groundnuts (b) Meat (c) Soyabean (d) Fish
4. Egg is a poor source of vitamin (a) A (b) B (c) C (d) D
5. Jaggery is a rich source of (a) Carotene and thiamine (b) Zinc and iron (c) Iron and carotene (d) Sugar and proteins

Answers : (1) b; (2) a; (3) a; (4) c; (5) c.

Rajul K Gupta

It is amazing as to how the same human body changes and behaves differently in different 'periods' of its lifecycle. At different stages of the organism with reference to changing age and continuously changing physiological status, the requirement of nutrients is based on activity, BMR, growth rate, etc. These factors change constantly as the organism grows over a lifetime. With these variations change the nutritional requirements. This chapter discusses the nutritional requirements over a lifecycle and how to meet that changed requirement through a typical Indian diet.

Pregnancy & Lactation

Physiological Changes During Pregnancy and Lactation

Immense physiological changes take place in the human body during pregnancy. The uterus undergoes hypertrophy and hyperplasia, there is an increased vascularity within the uterus (and placenta). The heart rate, stroke volume and cardiac output increase so do the tidal volume and oxygen consumption. The renal plasma flow and GFR also increase. Appetite changes; cravings and aversions set in for certain foods. This is augmented by certain endocrine changes. Changed peristalsis state leads to constipation. Besides these the requirement for energy and various other nutrients go up steeply to cater for the developing fetus (1). The physiological changes continue during lactation. There are hormonal changes followed by physiological changes in the mammary system, involution of uterus continues. Psychological and emotional changes too play a part. The process of lactation requires energy. The additional

energy required is based on the volume of milk secreted, its energy content and the efficiency of conversion of food energy into milk energy. Women secrete up to 850 ml milk per day at 80% efficiency of conversion of food energy into milk energy.
